Supplementary Materials and Methods

Powder X-ray Diffraction (PXRD). Diffractograms were recorded using a PANalytical Empyrean™ diffractometer equipped with a PIXcel^{3D} detector operating in scanning line detector mode with an active length of 4 utilizing 255 channels. The diffractometer is outfitted with an Empyrean Cu LFF (long fine-focus) HR (9430 033 7310x) tube operated at 40 kV and 40 mA and CuK_α radiation ($\lambda_{\alpha} = 1.540598 \text{ \AA}$) was used for diffraction experiments. Continuous scanning mode with the goniometer in the theta-theta orientation was used to collect the data. Incident beam optics included the Fixed Divergences slit with anti-scatter slit PreFIX module, with a 1/8° divergence slit and a 1/4° anti-scatter slit, as well as a 10 mm fixed incident beam mask and a Soller slit (0.04 rad). Divergent beam optics included a P7.5 anti-scatter slit, a Soller slit (0.04 rad), and a Ni-β filter. In a typical experiment, 20 mg of sample was dried, ground into a fine powder and was loaded on a zero background silicon disks. The data was collected from 5°–45° (2θ) with a step-size of 0.0131303° and a scan time of 30 seconds per step. Crude data were analyzed using the X'Pert HighScore Plus™ software V 4.1 (PANalytical, The Netherlands).

Variable Temperature Powder X-ray Diffraction (VT-PXRD). Diffractograms at different temperature were recorded using a PANalytical X'Pert Pro-MPD diffractometer equipped with a PIXcel^{3D} detector operating in scanning line detector mode with an active length of 4 utilizing 255 channels. Anton Paar TTK 450 stage coupled with the Anton Paar TCU 110 Temperature Control Unit was used to record the variable temperature diffractograms. The diffractometer is outfitted with an Empyrean Cu LFF (long fine-focus) HR (9430 033 7300x) tube operated at 40 kV and 40 mA and CuK_α radiation ($\lambda_{\alpha} = 1.54056 \text{ \AA}$) was used for diffraction experiments. Continuous scanning mode with the goniometer in the theta-theta orientation was used to collect the data. Incident beam optics included the Fixed Divergences slit, with a 1/4° divergence slit and a Soller slit (0.04 rad). Divergent beam optics included a

P7.5 anti-scatter slit, a Soller slit (0.04 rad), and a Ni- β filter. In a typical experiment, 20 mg of sample was dried, ground into a fine powder and was loaded on a zero background sample holder made for Anton Paar TTK 450 chamber. The data was collected from 5°–45° (2 θ) with a step-size of 0.0167113° and a scan time of 50 seconds per step. Crude data were analyzed using the X'Pert HighScore Plus™ software V 4.1 (PANalytical, The Netherlands).

In-situ Powder X-ray Diffraction (In-situ PXRD). *In-situ* diffractograms, 5°–40° (2 θ) were recorded using a Cryo & Humidity Chamber: CHC plus⁺ equipped with a Panalytical Emyrean with Cu tube (40kV and 40mA) in Bragg-Brentano configuration. CHC plus⁺ is a combination of the multi-purpose CHC Cryo & Humidity Chamber and an advanced humidity (RH) generator for the analysis of humidity-dependent and/or temperature-dependent structural changes in solids using powder X-ray diffraction. Incident side optics: 10 mm beam mask, 0.25° fixed divergence slit. Diffracted side optics: 0.25 fixed anti-scatter slit, Ni filter, Xcelerator detector in 1D mode. In a typical experiment, 20 mg of sample was dried, ground into a fine powder and was loaded on a zero background sample holder made for Anton Paar CHC plus⁺ chamber. The pressure for the CO₂ experiment was measured along the gas line from the chamber (at 30 °C and 1 bar). For the humidity measurement, 90 % relative humidity (RH) at 30 °C was used. Crude data were analyzed using the X'Pert HighScore Plus™ software V 4.1 (PANalytical, The Netherlands).

Thermogravimetric Analysis (TGA). Thermograms were recorded under nitrogen using TGA instrument TA Q50 V20.13 Build 39. Platinum pans and a flow rate of 60 cm³ min⁻¹ for the nitrogen gas were used for the experiments. The data was collected in the High Resolution Dynamic mode with a sensitivity of 1.0, a resolution of 4.0, and a temperature ramp of 20 °C min⁻¹ up to 500 °C. The data was evaluated using the T.A. Universal Analysis suite for Windows XP/Vista Version 4.5A.

Recyclability tests (trace CO₂ mixtures: dry and wet). Gravimetric uptakes were recorded under CO₂/N₂ mixture gases of composition: 1000, 3000, 5000, and 10,000 ppm CO₂ (each,

without and with 74 % RH) saturated with N₂, using TGA instrument TA Q50 V20.13 Build 39. Platinum pans and a flow rate of 20 cm³ min⁻¹ for the mixture gases were used for the experiments. Desorption at 348 K was performed under N₂ flow of 20 cm³ min⁻¹. The data was collected in the High Resolution Dynamic mode with a sensitivity of 1.0, a resolution of 4.0, and the weight changes during CO₂ adsorption step were monitored under isothermal condition at 303 K. The data was evaluated using the T.A. Universal Analysis suite for Windows XP/Vista Version 4.5A. All the dry and wet mixture gas compositions were set by monitoring Hiden HPR-20 QIC MS.

Particle size distribution (PSD). Number-based particle size distribution (PSD) was measured using Malvern Morphologi G3SE microscopic-image-analysis instrument. A standard operating procedure (SOP) defined to disperse the sample of particles using a sample dispersion unit (SDU-5541 mm² area) on a glass plate (180 x 110 mm) with an injection pressure of 4.0 bar, the injection time of 10 minutes and a settling time of 60 seconds. A diasopic light passed from the bottom of the glass plate with automatic light calibration intensity with a set value 80 and intensity tolerance to 0.20. A range of particle size from 0.5 μm–40 μm were analysed using 50X (Nikon TU plan ELWD) magnification optics selection. SOP also determines the image analysis parameters like background separation using an automatic estimated threshold value and watershed segmentation method to separate aggregated particles. Length of the particle, which is the longest projection of two points on the major axis of the particle 2-dimensional area, used to determine particle size distribution. Sauter mean diameter value of D32 used to determine the mean size and distribution width determined with D10, D50, and D90.

FE-SEM Measurements. Scanning electron microscopy (SEM) analysis was performed on a Hitachi SU-70 system operating between 3 and 20 kV. In order to inhibit charging of the samples, they were sputter coated with gold for 45 seconds (20 mA current was applied). The stage height was set to 15 mm.

Vacuum Dynamic Vapour Sorption (DVS) Measurements. Vacuum dynamic vapour sorption (DVS) measurements were conducted using a Surface Measurement System DVS Vacuum device (London, UK). The DVS instrument used for these studies measures the uptake and loss of vapour gravimetrically. DVS methods were used for the determination of water vapour sorption isotherms. The experiments were performed in a temperature-controlled incubator at different temperatures (298 K, 303 K, 308 K and 323 K). Activated and degassed samples were further degassed *in-situ* under high vacuum ($2 \cdot 10^{-6}$ Torr) to establish the dry mass. Stepped increases in relative humidity were controlled by equilibrated weight changes of the sample ($dm/dt = 0.006 \text{ \% min}^{-1}$) from 0 to 95 % RH (P/P_0) in 2 %, 5 % or 10 % incremental RH steps. The P/P_0 was then decreased in a similar manner to accomplish a full adsorption/desorption cycle. Vacuum pressure transducers were used with the ability to measure from $1 \cdot 10^{-6}$ Torr up to 760 Torr with a resolution of 0.01 %. Therefore, the vacuum system with its pre-heater (up to 673 K) allows a complete material degasification. Approximately 20–30 mg of sample were used for each experiment. The mass of every sample was determined by comparison with an empty reference pan and recorded by a high resolution microbalance with a mass resolution of $\pm 0.1 \text{ }\mu\text{g}$. The high mass resolution and its excellent baseline stability allow the instrument to measure the adsorption and desorption of very small amounts of water molecules. The vapour partial pressure around the sample is controlled by mixing saturated and dry carrier vapour streams using electronic mass flow controllers. The temperature is maintained constant at $\pm 0.1 \text{ K}$, by enclosing the entire system in a temperature-controlled incubator. Pure water (HPLC Gradient Grade, CAS No. 7732-18-5, Fisher Chemical) was used as the adsorbate for the studies.

Intrinsic Dynamic vapour sorption (DVS) Measurements. Water vapour adsorption–desorption experiments at atmospheric pressure were performed using a dynamic vapour sorption (DVS) intrinsic analyser (from Surface Measurement Systems, London, UK). The DVS Intrinsic is designed to accurately measure sample's mass change as it sorbs high-

precisely controlled concentrations of water vapour using air as a carrier gas. The sample (*ca.* 20–30 mg) was loaded into a stainless steel pan and suspended from an ultra-sensitive recording microbalance (with a resolution of 0.1 μg) with the help of a hang-down wire. Before the experiment started, once the sample was loaded from said hang-down wire, it was allowed to reach temperature and humidity equilibria within its chamber for a short period of time. The sample was exposed to an air flow with known % RH (from 0 % RH to 90 % RH) with increasing/decreasing steps of 10 % RH in the adsorption/desorption branches, respectively. The flow-rate used in the experiments was 200 sccm (Standard Cubic Centimetres per Minute), and the temperatures employed were 298, 300, 303, 308 and 313 K (± 0.2 K to each). Equilibria determination of the sample mass at each RH stage was performed by measuring the change rate percentage of mass over time (dm/dt). Not until said (dm/dt) reached a value of $0.002 \text{ \% min}^{-1}$, the equilibria was considered to be achieved (with an accuracy of $\pm 1.0 \text{ \% RH}$), and the device was allowed to measure the next stage of RH. Accordingly, the sample mass readings obtained from the microbalance within said equilibria revealed the vapour adsorption/desorption behaviour of the sample. Consequently, isotherm analysis and kinetics profiles of water vapour sorption and desorption were recorded.

Accelerated Stability Protocol. In a typical experiment, as followed by the pharmaceutical industries (33, 41), microcrystalline samples of **SIFSIX-18-Ni- β** were exposed to 313 K and 75 % RH for 1, 7 and 14 days (d) in a desiccator (corresponding to 4 d, 1 month and 2 months shelf-life, respectively). These conditions were achieved by using a supersaturated aqueous solution of NaCl maintained at 313 K in a closed desiccator. After 1, 7 and 14 d, sample aliquots were removed from desiccator and characterized by PXRD and N_2 (77 K) surface area measurements in order to detect signs in the sample which may have been affected by humidity. 298 K CO_2 sorption isotherms were also measured after duly activating each of the humidity exposed samples of **SIFSIX-18-Ni- β** .

Fourier-transform infrared (FT-IR) spectroscopy experiments. FT-IR spectra were obtained on a PerkinElmer Spectrum 100 FT-IR Spectrometer with a resolution setting of 2 and 16 scans per sample. Data was plotted as percent transmittance in Y-axis and analysed using the Spectrum V 6.3 software package.

Supplementary Text

Molar Selectivity (or Ideal Selectivity).

For a binary mixture, the *adsorption selectivity* (S_{ads} or α_{ij}) is defined as follows

$$S_{ads} = \frac{q_i/q_j}{p_i/p_j}$$

$q_{i,j}$ and $p_{i,j}$ denote the uptakes and partial pressures for components i and j , respectively. This is also referred to as *Ideal selectivity (IS)* or *molar selectivity*.

For 10,000 ppm CO₂/99 % O₂ mixture, $q_{CO_2} = 2.1 \text{ mmol g}^{-1}$, $q_{O_2} = 0.1 \text{ mmol g}^{-1}$, $p_{CO_2} = 0.01$, $p_{O_2} = 0.99$, the CO₂/O₂ adsorption selectivity (S_{CO}) is 2,079.

Ideal Adsorbed Solution Theory (IAST).

IAST calculations were carried out using a modified version of the program pyIAST (29). We note that the IAST calculations are limited by three assumptions:

- (a) The pure components form an ideal mixture (*i.e.* no change in area or enthalpy upon mixing of pure components);
- (b) The area accessible to both adsorbates are equal (*i.e.* the sorbent is not a molecular sieve);
- (c) The thermodynamic properties of the sorbent do not change relative to the thermodynamic properties of the sorbate (*i.e.* there is no sorbate-induced phase transition).

Isotherm Fitting. The data points of the experimental 298 K isotherms for CO₂, N₂, C₂H₂, and H₂O were interpolated *via* numerical quadrature

$$\frac{A}{RT} \pi_i(P_i^\circ) = \int_0^{P_1} \frac{n_i^\circ(P)}{P} dP + \sum_{j=1}^{k-1} \int_{P_j}^{P_{j+1}} \frac{n_i^\circ(P)}{P} dP + \int_{P_k}^{P_i^\circ} \frac{n_i^\circ(P)}{P} dP \quad \text{Equation (1)}$$

A model of each isotherm was formulated where the spreading pressure, $\frac{A}{RT} \pi_i(P_i^\circ)$, from absolute vacuum to the first data point is assumed to follow Henry's law

$$n_i^\circ(P) = K_H P \quad \text{Equation (2)}$$

Where n_i° is uptake, and P is pressure, and therefore

$$\int_0^{P_1} \frac{n_i^\circ(P)}{P} dP \approx \int_0^{P_1} K_H dP = n_i^\circ(P_1) \quad \text{Equation (3)}$$

Between the first to the last experimental data points, the function $n_i^\circ(P)$ is approximated via linear interpolation where

$$\int_{P_j}^{P_{j+1}} \frac{n_i^\circ(P)}{P} dP \approx m_j (P_{j+1} - P_j) + b_j \log\left(\frac{P_{j+1}}{P_j}\right) \quad \text{Equation (4)}$$

m_j is the slope and b_j is the intercept of the line that passes through the points $(P_j, n_i^\circ(P_j))$ and $(P_{j+1}, n_i^\circ(P_{j+1}))$. The index k defines the range $P_k \leq P_i^\circ \leq P_{k+1}$. Therefore the integral $\int_{P_k}^{P_i^\circ} \frac{n_i^\circ(P)}{P} dP$ acts in the same way as Eq. 4 but accounting for the line that passes through interpolated points.

Discussion on IAST.

As observable from comparison of the room temperature pure gas isotherms in **SIFSIX-18-Ni- β** , there is negligible adsorption of N₂ (fig. S10). Such results violate the second

assumption required for IAST calculations. Attempts at IAST calculations resulted in S_{CN} selectivity of $> 1 \times 10^7$ and increased with pressure, which suggest that this is indeed the result of partial sieving effects (*partial* since $6.27 \text{ mmol g}^{-1} \text{ N}_2$). Similar IAST sieving results were obtained for CO_2/O_2 selectivity *i.e.* S_{CO} under varying trace compositions (fig. S46).

Calculations of S_{CW} were carried out on **SIFSIX-18-Ni- β** at CO_2 concentration of 500 ppm, 5000 ppm, and 10,000 ppm at 10–95 % RH. Given the hydrophobic nature of the pore, IAST calculations were calculated based on dynamic vapour sorption experiments conducted under vacuum (where uptake is considered as all water vapour adsorbed into the pore and onto the surface of the particles), minus dynamic vapour sorption experiments conducted under ambient pressure (where uptake is considered as only water vapour adsorbed onto the surface of the particles). IAST calculations for S_{CW} at 74 % RH are shown in table S1. Given the significantly higher uptake of water vapour in **Zeolite 13X** and **Mg-MOF-74**, and the observed negative adsorption in **TIFSIX-3-Ni** and **SIFSIX-3-Ni**, S_{CW} was not calculated for these compounds.

Structural solution of SIFSIX-18-Ni.

Structure solution and refinement of **SIFSIX-18-Ni- α** was carried out in GSAS-II (fig. S55 and table S5) using an overnight scan using the PANalytical Empyrean in reflection mode. The lattice parameters were determined and structure factors obtained *via* the Le Bail method. A Monte Carlo/simulated annealing method was used for structure solution using free moving rigid bodies obtained from the Cambridge Structural Database (CSD) (CSD Refcodes: FUDQIF = SiF_6^{2-} ; KIKDOZ = 3,3',5,5'-tetramethyl-1H,1'H-4,4'-bipyrazole).

Structure solution and refinement of **SIFSIX-18-Ni- β** was carried out in GSAS-II and HighScore PlusTM (fig. S56 and table S5) using data collected at 393 K after 1 hour of annealing. The lattice parameters were determined and structure factors obtained via the Pawley method. The inorganic axis was identified from Fourier maps using the charge

flipping method. A Monte Carlo/simulated annealing method was used for further structure solution using free moving rigid bodies obtained from the Cambridge Structural Database (CSD) (CSD Refcodes: FUDQIF = SiF₆²⁻; WEWHEN = 3,3',5,5'-tetramethyl-1H,1'H-4,4'-bipyrazole). A final Rietveld refinement was carried out in HighScore PlusTM (table S5).

Isosteric Heats of Adsorption Calculations.

The Q_{st} of CO₂ for **SIFSIX-18-Ni-β** was calculated from the low pressure CO₂ adsorption isotherms collected at 273, 283 and 298 K while that for **ZIF-8** was calculated from isotherms recorded at 273 and 293 K. All other Q_{st} plots and associated parameters are included in our earlier contribution (26).

The Clausius-Clapeyron equation was used for the calculation of Q_{st} where virial-type equations were used to fit ten points in the adsorption data between 0 and 10,000 ppm at multiple temperatures (Equation (5) below). All fitting was performed using Origin Pro 8

$$\ln P = \ln N + \sum_{i=0}^m a_i N_i + \sum_{i=0}^n \binom{n}{k} b_i N_i \quad \text{Equation (5)}$$

Q_{st} was then calculated from the virial model using Equation (6)

$$-Q_{st} = -R \sum_{i=0}^m a_i N_i \quad \text{Equation (6)}$$

Ten adsorption points between 0 and 10,000 ppm (10 mbar) were used for fitting to the Virial equation where the fit for each of the compounds is shown in figs. S19, S20.

Synthesis of materials.

Zeolite 13X was obtained from Sigma-Aldrich. **SIFSIX-3-Ni**, **Mg-MOF-74**, **TIFSIX-3-Ni**, **ZIF-8** and **NbOFFIVE-1-Ni** were synthesised according to literature procedures (23, 25).

3,3',5,5'-tetramethyl-1H,1'H-4,4'-bipyrazole (18) synthesis.

3,3',5,5'-tetramethyl-1H,1'H-4,4'-bipyrazole (**18**) was synthesized following reported procedure (42).

Preparation of [Ni(3,3',5,5'-tetramethyl-1H,1'H-4,4'-bipyrazole)₂(SiF₆)_n] (SIFSIX-18-Ni).

SIFSIX-18-Ni was synthesized by hydrothermal treatment of 3 mmol of NiSiF₆.xH₂O (930 mg), and 6 mmol of ligand **18** (Me₄bpz = 3,3',5,5'-tetramethyl-4,4'-bipyrazole) in 5 mL of water over 72 hours. The resulting suspension was filtered under vacuum and dried in air to obtain the as-synthesized precursor. This precursor was washed thrice, each with *ca.* 20 mL portion of methanol on a Büchner filter. After air drying, the solid was heated at 55 °C for 24 hours to obtain **SIFSIX-18-Ni- α** . Activation of **SIFSIX-18-Ni** was achieved by degassing the methanol-exchanged sample on a SmartVacPrep™ using dynamic vacuum and heating for 4 hours (sample heated from RT to 348 K with a ramp rate of 5 K).

Heating **SIFSIX-18-Ni- α** under vacuum to 348 K induced a phase transition to **SIFSIX-18-Ni- β** , which exhibited a 13.4 % reduction in unit cell volume. All properties reported herein were conducted on this activated form of **SIFSIX-18-Ni- β** . Slow diffusion through MeOH/DCM layers yielded polycrystalline **SIFSIX-18-Ni- γ** , which was non-porous and isostructural to a previously reported structure (CSD Refcode: KIKDUF). Expectedly, **SIFSIX-18-Ni** forms a primitive cubic, **pcu**, net wherein two-dimensional (2D) nets of metal nodes cross-linked by organic linkers are pillared by inorganic anions, affording square channels lined with inorganic fluorides, organic amines and organic methyl groups. See fig. S12 for 298 K CO₂ gas sorption isotherms for each phase of **SIFSIX-18-Ni**.

Molecular modelling to locate the CO₂ binding sites in SIFSIX-18-Ni.

To determine the optimal binding site of CO₂ in **SIFSIX-18-Ni**, a screening of periodic plane-wave Density Functional Theory calculations were first performed using CP2K (43), where a single CO₂ molecule was placed in the cavity of a 1x1x1 cell of **SIFSIX-18-Ni- α** and **SIFSIX-18-Ni- β** . The revPBE XC functional was used with MOLOPT basis sets for all atoms with the DFTD3 pair potential for dispersion correction. These calculations were performed using Unrestricted Kohn-Sham DFT with a total multiplicity of 5 (corresponding to the triplet

spin state for Ni atoms). The sample locations for the sorbate CO₂ were collinear with the F–F line in the cavity (between SIFSIX groups). The distance of the CO₂ molecule's center-of-mass to the nearest F atom ranged from 2-5 Å, and different orientations were sampled by rotating the CO₂ about the C_{CO2}–F axis. A total of 224 unique configurations of CO₂ were sampled, ignoring obvious atomic overlaps. The configuration with lowest CO₂–HUM interaction energy (as calculated by $E_{\text{HUM}+\text{CO}_2} - E_{\text{HUM}} - E_{\text{CO}_2}$) was then treated in a full-atom optimization of the [HUM + CO₂] system using the same methods in CP2K with the Conjugate Gradient algorithm for minimizing the energy of the system. After convergence this resulted in the structure shown in Figure 2f.

For empirical modelling, Canonical Monte Carlo simulations were performed in a 2x2x2 box of **SIFSIX-18-Ni-β** using Monte Carlo Molecular Dynamics (MCMD), an open-source code developed by the Space group and available on GitHub (D. M. Franz, *Monte Carlo - Molecular Dynamics*, <https://github.com/khavernathy/mcmd>. (2017)). The system was filled with CO₂ molecules corresponding to the experimental loading at 298 K and 1 atm and the energy of the system was allowed to relax by random translations and rotations of the CO₂ molecules with acceptance of the moves guided by the Boltzmann factor corresponding to the energy change from the trial move. The UFF forcefield (44) was used for all atoms in the HUM, with the Lennard-Jones potential describing repulsion-dispersion interactions between all pairs of atoms. The CO₂-PHAST model (45) was used for CO₂ repulsion-dispersion and partial charges. The electrostatics of the system were computed using Ewald summation, and partial charges on the HUM atoms were determined by a RESP fit to the electrostatic surface potential computed using CP2K with the previously described methods. A total of 1x10⁷ Monte Carlo trial moves were conducted to determine the equilibrated structure, after an initial equilibration run with 1x10⁶ steps.

Table S5. Crystallographic data for SIFSIX-18-Ni.

	SIFSIX-18-Ni-α (CCDC 1888094)	SIFSIX-18-Ni-β	SIFSIX-18-Ni-β (CCDC 1888095)
Refinement Method	Le Bail	Pawley	Rietveld
Formula	$C_{20}H_{28}N_8NiSiF_6$		
Mass	581.27		
Crystal system, space group	monoclinic, $P 2_1$	monoclinic, $C 2$	
a (Å)	8.539(1)	14.197(2)	14.163(6)
b (Å)	14.965(1)	13.838(2)	13.869(5)
c (Å)	13.335(1)	7.4929(5)	7.493(1)
α (°)	90	90	90
β (°)	94.42(4)	94.60(3)	94.78(5)
γ (°)	90	90	90
Volume (Å³)	1698.91	1467.34	1466.68
ρ (g·cm⁻³)	1.08	1.31	1.32
Temp (K)	293	393	
λ (Å)	1.540598		
2θ range	$6.70 \leq 2\theta \leq 31.01$	$4.02 \leq 2\theta \leq 49.99$	
R_p	0.1288	0.0717	0.1683
wR_p	0.1812	0.1070	0.2311
R_{bragg}	-	-	0.1174
R_{exp}	0.0075	0.0157	
$R(F)$	-	0.0446	-
$R(F^2)$	-	0.0782	-
GoF	24.04	6.97	14.757
