Supplementary Information Text Supplemental Methods

Multiple Displacement Amplification

MDA conditions described here are modified from previously established protocols (1-4). Supplies and specialized reagents used for MDA reactions include phi29 DNA polymerase and 10x reaction buffer (New England BioLabs), trehalose (Sigma; T5251-10G), and Zymo-10 columns (Zymo Research; D4011). The random hexamer primer (p6N), purchased from Integrated DNA Technologies, contains phosphorothioate linkages at the ultimate and penultimate 3'-terminal positions, and is 5' phosphorylated (IDT synthesis code: /5phos/NNNN*N*N). 8x D-solution (3.2 M KOH, 80 mM EDTA), 1x N-solution (0.4 M Trizma-HCl). 0.8 M trehalose, 0.5 M KCl, and 10 mM dNTPs were prepared prior to dilution and dispensation of extracted cellular DNA into 96-well plates and stored at -20°C. 8x D-solution should be remade at least once every six months, stored in small aliquots and diluted to 1x immediately prior to use. For each MDA plate, extracted cellular DNA was diluted in 5ml Tris-HCL pH 8.0 to a concentration of 0.3 proviruses/2 μ L solution as determined by the standard SGS endpoint, and 2 μ L of this dilution transferred to each well of a 96 well plate. Genomic DNA in each sample was chemically denatured by addition of 2µL 1x D-solution followed by incubation at room temperature for 3-6 minutes. Reactions were neutralized by addition of 4μ L 1x Nsolution and immediately placed on ice to minimize partial renaturation of genomic DNA. The nucleic acid mixtures (NA-mixes) were supplemented with $2\mu L 1 \text{ nmol}/\mu L \text{ p6N}$ primer and kept on ice during preparation of the Enzyme Mixture (E mix). Sufficient Emix was prepared to permit the addition of 30 μ L to all NA-mixes, with each aliguot containing the following components: 4µL 10x phi29 DNA pol reaction buffer, 4µL 0.5 M KCl, 4μL 10 mM dNTPs, 10μL 0.8 M trehalose, 7μL water and 1 μL phi29 DNA polymerase. E-mixes were assembled and dispensed to NA-mixes on ice, and MDA reactions incubated at 30°C for 18hr in a thermal cycler utilizing a heated lid to minimize condensation. Completed reactions were incubated at 65°C for 10min to denature the polymerase and stored at -20°C, as necessary.

Integration sites assay (ISA)

Prior to ISA, MDA reactions were purified using Zymo10 DNA clean and concentration (Zymo; D4011). ISA was performed as previous described (5-8) using patient virus-specific primers to the 5' and 3' LTRs. All integration sites are reported using the 3' LTR mapped to hg19. The primer sequences are as follows:

Near-Full-Length Sanger Sequencing from MDA wells

Near-full-length (NFL) amplification was performed with 2 μ L of a 1:8 dilution of input DNA from an MDA well. PCR reactions (10 μ L) were performed using the Ranger enzyme (BIOLINE-BIO-25052). PCR1, denoted NFL1, was used to generate a 9kb amplicon from U5-5'LTR to U5-3'LTR (primers in Table S2). NFL1 product, diluted 1:5, was used as template for nested PCR to generate four 2.9-3.2kb genome-spanning amplicons, denoted F1, F2, F3, and F4 (Figure S2). Alternatively, a 9kb NFL2 amplicon was generated. Target amplicons sizes were confirmed by ethidium bromide gel visualization and sequenced by Sanger sequencing or PacBio sequencing. The resulting data were used to generate the sequence of an NFL genome.

Near-Full-Length PacBio Sequencing from MDA wells

Amplicon DNA generated from PCR was purified using PB AMPure beads (Pacific Biosciences). Quality, concentration, and size were determined using the Nanodrop 8000 Spectrophotometer (Thermo Scientific) and the BioAnalyzer 2100 (Agilent). Each set of samples was combined into an equimolar pool and subjected to library preparation following the PacBio standard 2 kb protocol, using a-tailing and overhang adapter ligation instead of blunt ligation. Each completed pool was then loaded onto a SMRT Cell for sequencing. The libraries were sequenced on either the PacBio RSII (Pacific Biosciences) using P6/C4 chemistry, a 0.15 nM MagBead loading concentration,

and 360-minute movie lengths, or on the PacBio Sequel (Pacific Biosciences) using the diffusion method, v2.0 or v2.1 chemistry, a 4 pM loading concentration, and 600 minute movie lengths, both located at the Frederick National Laboratory for Cancer Research (Frederick, MD, USA).

Quantitative Viral Outgrowth Assay on PBMC from donor R-09

Quantitative viral outgrowth assays (QVOA) were performed, as described previously (9), with the following modifications: CD4+ cells were isolated from Cryopreserved PBMC by negative selection (Stemcell Technologies), serially diluted 3-fold from 1,000,000 cells per well to 30,000 cells per well, and seeded in individual wells in 6 replicates. Cells were stimulated with PHA overnight and a 10-fold excess of allogeneic irradiated feeder cells obtained from uninfected donors was added. CD4+ lymphoblasts from HIV-1-negative donors were added, and virus co-cultures were carried out for 3 weeks. Supernatants were tested weekly to measure HIV-1 p24 antigen by ELISA (Perkin Elmer). Aliquots of the supernatants were also frozen for sequencing the recovered viruses. The frequency of HIV- 1 infected cells carrying a recoverable infectious provirus (IUPM) was determined by a maximum likelihood method, as previously described (10).

Pipeline for analysis of HIV single-genome PacBio Sequencing

Fastq files containing PacBio CCS reads were processed using the Robust Amplicon Denoising algorithm (11), which attempts to extract error-free variants from complex amplicon mixtures. These denoised variants were mapped, using USEARCH (12) to an HIV-1 reference sequence (consensus B) to retain only HIV-1 reads, which were then manually stitched together (merging overlapping ends) to construct near-full-length contigs.

Figure S1. Near-Full-Length (NFL) Amplification and Sequencing. PCR amplification strategies used to screen MDA wells and to amplify and sequence near-full-length proviruses by either amplifying as one (9kb) or four (3kb) overlapping amplicons.

Figure S2. MDA and NFL Amplification Products. (A) MDA product (lane 2) fractionated on 0.8% agarose eGel (Invitrogen) with E-Gel 1 Kb Plus Ladder, Invitrogen (lane 1). (B) AMBI-1 near-full-length PCR product (lane 2). PCR products from fragment 1 (bp 634-3528), fragment 2 (bp 1871-5267), fragment 3 (bp 4133-7349), and fragment 4 (bp 6445-9643) (lanes 3-6). PCR products from P6-PR-RT (bp 1871-3438), integrase (bp 4133-5267), and partial envelope (bp 6445-7349) (lanes 7-9).
