Supplementary Note 1

The study was carried out in a sample of communities (21 villages and one town) randomly drawn from four neighbouring municipalities in a southern Polish district in the province of Małopolska, containing a total of 34 potential study populations. All 22 of the sampled communities agreed to participate. I did not have access to a census list of names or a map of households, so within each community every third house was sampled, with every adult woman (≥ 18 years) present in the house invited to take part in the survey. This strategy was further stratified in the town, by randomly selecting streets from a list obtained from the local government and approaching every third house/apartment on that particular street. I returned to houses that were unoccupied at the time of selection on up to three occasions. All consenting adult women were interviewed. All eligible women who declined to take part were noted as non-responders, as were women ineligible to take part due to age or illness. 52.4% to 89.4% of respondents who were approached in any village agreed to an interview, and the average response rate for the entire sample was 75% ($\text{total interviews} \div [\text{total responders} + \text{non-responders}]$). My sampling strategy means that important variables such as age are approximately normally distributed in all groups. The sample should not be considered representative of the country as a whole, but of the wider rural population of this particular region.

Social Network Questionnaire

The social network questionnaire was administered as part of a broad-ranging semi-structured interviews with women. The questionnaire section for eliciting the network data (questions 30, 31 and 34 of a larger interview) is given below, first in Polish and then in English. Supplementary Table 1 below provides descriptive statistics of the networks.
