Supplementary analyses

Using a mixed procedure for repeated data (PROC MIXED, SAS 9.14, Cary, NC), we assessed the change in $\delta^{15}\text{N}$ and $\delta^{13}\text{C}$ between two consecutive segments of hair, the first and second adjacent 5 mm segments closest to the scalp. The first (proximal) segment corresponds with the more recent period, from -3 to -1 weeks before sampling. The second (distal) segment corresponds with the earlier period, from -5 to -3 weeks before sampling. Because the data presented in Figure 1 and Table 4 of the manuscript suggest that the age of children at inclusion may affect the change in $\delta^{15}\text{N}$ and $\delta^{13}\text{C}$ between the two segments, age at inclusion was included as a covariate in the model.

Our results indicate a slight but significant (-0.03) decrease in both $\delta^{15}\text{N}$ and $\delta^{13}\text{C}$ from the distal to the proximal segment, corresponding to a more recent period of 2 weeks (**Supplementary Table S5**). These results are in line with a progressive decrease in $\delta^{15}\text{N}$ and $\delta^{13}\text{C}$ observed between 6 months and 5 years, due to the weaning process.

* significantly different from the older segment, P < 0.05

We evaluated the effect of wasting and stunting on this isotopic change and did not find evidence of interaction between wasting or stunting and the changes in $\delta^{15}\text{N}$ and $\delta^{13}\text{C}$ between distal and proximal segments (**Supplementary Table S6**). This suggests that the low $\delta^{15}\text{N}$ and $\delta^{13}\text{C}$ values observed in severely stunted children are due to dietary or metabolic changes that occurred before the one-month period covered by the two consecutive hair segments.
