### Impact of isolation on hospitalised patients who are infectious: systematic review with quantitative analysis

#### Abstract

#### Objective

To systematically review the literature exploring impact of isolation on hospitalised patients who are infectious: psychological and non-psychological outcomes

#### Design

Systematic review with quantification

#### Data Sources

Embase, Medline and Psychinfo were searched from inception until December 2018. Reference lists and Google Scholar were also handsearched.

#### Results

Twenty seven papers published from database inception until December 2018 were reviewed. A wide range of psychological and non-psychological outcomes were reported. There was a marked trend for isolated patients to exhibit higher risk of depression, anxiety and worse outcomes for a range of care-related factors but with significant variation.

#### **BMJ** Open

#### Conclusion

The review indicates that isolation to contain risk of infection has negative consequences for segregated patients. Although strength of the evidence is weak, comprising primarily single centre convenience samples, consistency of the effects may strengthen this conclusion. More research needs to be undertaken to examine this relationship and develop and test interventions to reduce the negative effects of isolation.

#### Strengths and limitations of this study

- The isolation of those with infectious disease is common, and in the age of increased antimicrobial resistance may become more common and important.
- It is important to examine both psychological and non-psychological outcomes associated with isolation.
- This is a methodologically challenging area to examine, however consistency in the body of evidence might increase confidence in the findings.
- It is not known if any effects are temporary or how long they last.

#### **Funding statement**

This research received no specific grant from any funding agency in the public, commercial or not-for-profit sectors

#### A competing interests statement

#### Introduction

Isolation is an established part of any infection prevention programme. Its purpose is to prevent the transmission of antibiotic-resistant pathogens, those that are highly contagious or cause serious infection.[1] The effectiveness of isolation has been questioned however [2–5] and it can be challenging to undertake, especially if patients' lack of understanding of the need for segregation, boredom or distress result in uncooperative behaviour. [6] Although single rooms are assumed to reduce infection risk, evidence of ability to contain spread is equivocal [7,8] and a recent study conducted in an all-single-room hospital was unable to demonstrate lower infection rates than in hospitals where most care takes place in open wards. [9] This study identified advantages and disadvantages of single room accommodation, whereas isolating infectious patients is generally assumed to result in adverse outcomes.[10]

A systematic review reported eight years ago indicated higher levels of anxiety, depression, perceptions of stigmatisation and a higher incidence of falls, medication errors and other incidents that detract from patient safety among patients who were isolated compared to those who were not.[11] This review reported studies undertaken before 2010 and included patients whose experiences are unlikely to be comparable: children and adults and those isolated to reduce their own risk of infection as well as infectious patients. The review was not reported according to standards currently expected for systematic reviews [12] and presents a qualitative description of patient outcomes only. A more rigorous and up-to-date systematic review is indicated in view of increasing concern about satisfaction with health care and patient safety and

#### **BMJ** Open

increasing emphasis on infection prevention as part of the global strategy to reduce risks of antimicrobial resistance.[13]

We undertook a systematic review of the literature to establish the effects of infection related isolation on psychological and non-psychological care-related outcomes in adults. This review is therefore more focussed than that previously undertaken which also included those in protective isolation, and contains a significant body of literature published since 2010.

#### Method

The eligibility criteria for inclusion was that studies should compare psychological or non-psychological outcomes in adult patients who are in infective isolation with those not isolated. Purely symptomatic/disease progression outcomes were not included, neither were those looking at those isolated due to immunosuppression. Studies not containing comparative data were also excluded. Information sources were Embase, Medline and Psychinfo, which were searched from inception until December 2018. Reference lists and Google Scholar were also handsearched. Full details of the search and PRISMA flow-chart together with excluded papers are given in the supplementary information. No protocol was published in advance.

Where available raw data were extracted and entered into a spreadsheet, and depending upon the nature of the data either the relative risk or standardised mean difference calculated. Results were then presented as forest plots. All calculations and plots were produced using the meta package in R.[14,15] Where raw data were not provided the summary results are given in the text but not the forest plots. Due to

the variety of different settings and methods it was deemed that the methodological and clinical heterogeneity was too broad to pool results; in particular outcomes were measured in a variety of different ways.

Patient and Public Involvement

As a secondary analysis patients and public were not involved in this work

#### Results

A total of 3 879 papers were retrieved from the three databases; 39 of which were screened and 12 excluded, leaving 26 in the final analysis. Of these 13 studies provided data suitable for the calculation of relative risks, 5 giving psychological outcomes,[16–20] and 12 non-physiological;[18,21–31] and 8 provided data for the calculation of standardised mean differences, 6 giving psychological outcomes,[20,29,32–35] and 3 non-psychological.[25,28,36] A further 6 studies did not provide raw data but are included in the results; 3 each giving psychological outcomes[37–39] and non-psychological outcomes.[16,40,41]

As it had been decided not to attempt statistical pooling of study results, the data from studies are shown as forest plots but without meta-analysis. The forest plots contain results from the studies where sufficient data were given to calculate either the relative risk or standardised mean difference. A number of studies provided data on those under contact precautions, but no comparative data and so were not included.[42–45]

#### **BMJ** Open

Because of the large number of non-psychological outcomes for which RR could be calculated, it was decided that a change of 20% (i.e. a RR of 0.8 or less, or 1.2 or more) would be clinically significant, regardless of the statistical significance. Results are shown in Figures 1 to 5. Figure 5 contains results that did not meet our criteria for being clinically significant (see supplemental information).

The studies included were primarily single-centre and consisted of case-control, cross-sectional and cohort studies. Although these studies have limited generalisability, there did not appear to be significant cause for concern regarding bias within the limitation inherent in these study designs. Full details of each study is given in the supplementary information.

The data from the comparative studies suggest that although in many cases contact precautions makes little difference to psychological outcomes, where it does make a difference this is primarily negative. There were significant declines in mean scores related to control and self-esteem, and in many studies increases in the mean scores for risk of anxiety and depression. However, these findings were not consistent, and some larger studies showed little or no difference between the groups for these outcomes. These are shown in Figures 1 and 2 respectively.

#### [INSERT FIGURES 1 and 2 HERE]

Figure 1. Relative risk of psychological events in those isolated versus not isolated

# Figure 2. Standardised mean difference of psychological scores in those isolated versus those not isolated

Studies not reporting the raw data showed that contact precautions were associated with depression OR 1.4 (95% CI 1.2 to 1.5) but not anxiety OR 0.8 (95% CI 0.7 to 1.1) in a non-ICU population.[40] There was also an association with delirium OR, 1.40 (95% CI 1.24 to 1.51); although this was primarily among those who were newly diagnosed as needing isolation OR, 1.75 (95% CI 1.60 to 1.92, p<0.01) rather than those who had been under contact precautions for their entire stay OR 0.97 (95% CI 0.86 to 1.09, p=0.60).[16] Another study showed no difference in the median values for the Hospital Anxiety and Depression Scale anxiety or depression scores (HADS-A and -D), or the EuroQol Visual Analogue Scale EQ VAS scores.[41]

For non-psychological outcomes, using a difference in the risk of +/- 20% of an event as being a measure of clinical significance it appears there was a trend for less attention to be given to, and for more errors to occur in those who were isolated. However, again there was wide variation between studies. Data on these outcomes are given in Figures 3 and 4, and the non-clinically significant risks in the supplementary information (Figure 5).

#### [INSERT FIGURES 3 and 4 HERE]

Figure 3. Relative risk of non-psychological events in those isolated versus not isolated

#### **BMJ** Open

Figure 4. Standardised mean difference of non-psychological scores in those isolated versus those not isolated

A study not giving raw data which looked at the rates of falls and pressure ulcers before and after a policy change that resulted in the discontinuation of contact precautions for patients with methicillin resistant *Staphylcoccus aureus* (MRSA) or vancomycin resistant enterococci (VRE) found that falls and pressure ulcers were more common among those with MRSA or VRE both before the change (when they were in isolation) and afterwards (when they were not). Before the change the number of falls was 4.57 vs 2.04 per 1000 patient-days respectively (p< 0.0001) and pressure ulcers 4.87 vs 1.22 per 1000 patient-days (p< 0.0001). After the policy change the same numbers were falls 4.82 vs 2.10 (p<0.0001) and pressure ulcers 4.17 vs 1.19 per 1000 patient-days (p<0.0001).[38] Other studies found that staff spent less time with those on contact precautions: internal medicine interns spent less time with their isolated patients compared to non-isolated patients, the median times being 5.2 and 6.9 minutes respectively (p<0.001)[37]; while the mean number of contacts per hour with healthcare workers was 2.1 compared to 4.2 in those not isolated (p=0.03), although the duration was longer at 4.5 minutes compared to 2.8 (p=0.6).[39]

#### Discussion

Current recommendations say that contact precautions should include a single room, with personal protective equipment consisting of a gown and gloves for all patient contacts or contacts with potentially contaminated environmental areas.[1] This review has shown that there are a number of apparently negative aspects to contact

#### **BMJ** Open

precautions, in particular with regards to psychological effects and a reduction in the quality of some aspects of care. These data come from studies carried out in a variety of countries and different types of facility; although there are few data from particularly vulnerable populations such as the elderly.

Although at times there are discussions as to the necessity of contact precautions for drug resistant organisms, with some arguing that that there is mixed evidence for or against their use[46] another recent review has concluded that they are of great importance in the control of epidemic and endemic multidrug-resistant microorganisms.[47] The ethics of using contact precautions and other forms of isolation rely on a positive assessment of the balance between the risks and benefits of this to the individual concerned and that of the broader population of patients and staff.[48] However, even when this assessment is positive, it is important to ensure that any harm to the individual is minimised.

One way of balancing the various priorities is to use the GRADE Evidence to Decision Framework, which provides criteria for making recommendations at the individual, group and policy-levels, and provides a number of highly patient focussed criteria for doing this. In addition to the certainty of evidence and resource requirements, it also requires consideration of: the balance of desirable and undesirable effects; the impact upon equity; and the feasibility and acceptability of the intervention.[49] The last two of these might have very different outcomes when considered at the population and individual levels; and there is certainly evidence here that for the individual patient the balance of desirable and undesirable effects might be very different to that of the broader population.

#### **BMJ** Open

However, within the broad population of infected or potentially infected patients, some groups might have different needs. For example a study of people isolated for MERS found that while access to telephones reduced anxiety and anger; access to email, text and internet increased these.[50] This was not an area investigated in any depth in these studies. Another area where information may be lacking is that of age, as older people in particular might feel sadness and loneliness more; and gender, as women were more concerned about precautions and transmission while men were more resigned, rational and tended to cope better.[51]

In some countries, such as the United States single-rooms have become the standard for new hospitals and so one might expect fewer adverse effects if everyone is in a single room, this being the norm. However it may be that a single room is necessary but not sufficient for these findings, and that it is the combination of a single room with an infection that leads to these results. Certainly it is far from clear that the long list of advantages claimed for single rooms which include reduced stress, the ability to deliver better care, and a lower probability of dietary or medication errors apply to this group of patients.[52]

Caring for patients in single-rooms does have many challenges, but there is evidence that these can be mitigated in a general population;[9] however the expanding literature on how this can be done in a general population does not necessarily apply here due to the necessity of isolation procedures which are, by design, 'a barrier'. Therefore patients' needs for greater social interaction will need a solution quite

#### **BMJ** Open

different from that which might be used for a different patient population, and the benefit of choice about this which single rooms offer does not apply here.[53] Although this review has quantified the extent of the problem, we have not been able to find solutions in the literature. Care might be improved through increased staff attention with more resources being allocated to these patients, although the extra cost of contact precautions is already considerable, one estimate being that it was an extra \$158.90 (95% CI \$124.90 to \$192.80) per patient day.[54] Alternatively new ways of working might be developed, perhaps using technology to mitigate some of these problems. What these might be is not clear however.

#### Study strengths and limitations

This review suggests that infectious isolation has a number of negative effects on patients. Because this evidence is comprised of cohort and case-control studies, a claim for a causal relationship cannot be made on this evidence, although the strong and consistent effects across the studies may increase the confidence in this relationship. There are some qualitative data, although more in-depth mixed-methods data where those reporting negative effects are questioned about them would strengthen the evidence on this. In some cases large effect sizes were accompanied by very wide confidence intervals, suggesting that studies were underpowered, thus studies with larger sample sizes would be useful.

Although these data suggest that there is a problem, there is a clear gap both in what we know about improving the experience of isolation and what can be done in practical terms to make it more tolerable for patients and their families. In particular older people who may be most vulnerable to these negative effects were under-

 represented in these studies; and this group are likely to represent an increasingly large proportion of those isolated. Lastly the use of isolation may need to increase if the current trends of antimicrobial resistance continue.

#### **Characteristics of studies**

Reference	Study type	Isolated	Non isolated
Chittick (2016)	Cross sectional survey. Response rate 48.7%. Tertiary centre, United States January 1, 2014 to December 31, 2014	Patients in contact isolation for >48 hours Demographics not given	
Colorado (2014)	Retrospective matched case control study. Rehabilitation facility- tertiary centre United States July 2009 to December 2010	N20 Patients in contact isolation	N=20 Matched to patients not in contact isolation based on age, rehabilitation diagnosis, and type of insurance
Croft (2015)	Prospective cohort Medical or surgical inpatients admitted to non–intensive care unit hospital wards, United States. January to November 2010.	N=148 Patients on contact precautions Age: 52 (13.8) % male: 53.4	N=148 Individually matched by after an initial 3-day length of stay to patients not on contact precautions. Age 52.3 (14.6) % male: 46.6
Dashiell- Earp (2014)	Collected real-time data on the location of 15 internal medicine interns, United States. October 1, 2012 to December 31, 2012	1156 encounters	2467 encounters
Day (2011)	Patients admitted to the general acute care units, United States. June 1, 2009 to October 30, 2009	N=20 Age: 68.5 (14.7) % male: 85.0	N=83 Age: 63.9 (12.6) % male: 95.2
Day (2011)	A two-year retrospective cohort Tertiary care, United States All general inpatients over 18 years hospitalized for >24 h February 1, 2007 to January 31, 2009.	Contact precautions private room when possible, can be cohorted General N = 3138 Age: 51.2 (17.5) % male 58.9 ITU N=1694 Age: 54.9 (17.5) % male 61.0	General N = 25 426 Age: 49.6 (19.0) % male 46.3% ICU N = 5 854 Age: 56.0 (17.7) % male 59.7
Day (2012)	2-year retrospective cohort study of all non-psychiatric hospital admissions >18 years, United States. February 1, 2007 to January 31, 2009	N = 9 684 Contact precautions as above Mean age: 50.1 (18.8) % male 51.4	N = 50 458 Mean age: 52.3 (16.9) % males 59.1
Day (2013)	Longitudinal frequency-matched	N = 148	N = 148

## PRISMA 2009 Checklist

Section/topic	#	Checklist item	Reported on page #
TITLE			
Title	1	Identify the report as a systematic review, meta-analysis, or both.	1
ABSTRACT			
Structured summary	2	Provide a structured summary including, as applicable: background; objectives; data sources; study eligibility criteria, participants, and interventions; study appraisal and synthesis methods; results; limitations; conclusions and implications of key findings; systematic review registration number.	1-2
NTRODUCTION			
Rationale	3	Describe the rationale for the review in the context of what is already known.	3
Objectives	4	Provide an explicit statement of questions being addressed with reference to participants, interventions, comparisons, outcomes, and study design (PICOS).	4
METHODS			
Protocol and registration	5	Indicate if a review protocol exists, if and where it can be accessed (e.g., Web address), and, if available, provide registration information including registration number.	4
Eligibility criteria	6	Specify study characteristics (e.g., PICOS, length of follow-up) and report characteristics (e.g., years considered, language, publication status) used as criteria for eligibility, giving rationale.	4
Information sources	7	Describe all information sources (e.g., databases with dates of coverage, contact with study authors to identify additional studies) in the search and date last searched.	4
Search	8	Present full electronic search strategy for at least one database, including any limits used, such that it could be repeated.	Suppl information
Study selection	9	State the process for selecting studies (i.e., screening, eligibility, included in systematic review, and, if applicable, included in the meta-analysis).	4
Data collection process	10	Describe method of data extraction from reports (e.g., piloted forms, independently, in duplicate) and any processes for obtaining and confirming data from investigators.	5
Data items	11	List and define all variables for which data were sought (e.g., PICOS, funding sources) and any assumptions and simplifications made.	5
Risk of bias in individual studies	12	Describe methods used for assessing risk of bias of individual studies (including specification of whether this was done at the study or outcome level), and how this information is to be used in any data synthesis.	6
Summary measures	13	State the principal summary measures (e.g., risk ratio, difference in means).	5
Synthesis of results	14	Describe the methods of handling data and combining results of studies, if done, including measures of consistency (e.g., I <sup>2</sup> ) for each meta-analysis.	5
		For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

## PRISMA 2009 Checklist

4 5	Section/topic	#	Checklist item	Reported on page #	
6 7 8	Risk of bias across studies	15	Specify any assessment of risk of bias that may affect the cumulative evidence (e.g., publication bias, selective reporting within studies).	6	
9 10	Additional analyses	16	Describe methods of additional analyses (e.g., sensitivity or subgroup analyses, meta-regression), if done, indicating which were pre-specified.	None	
1 12	RESULTS				
13 14	3 Study selection 17 Give numbers of studies screened, assessed for eligibility, and included in the review, with reasons for exclusions a each stage, ideally with a flow diagram.		5		
15 16 17	Study characteristics	18	For each study, present characteristics for which data were extracted (e.g., study size, PICOS, follow-up period) and provide the citations.	Suppl information	
18 19	Risk of bias within studies	19	Present data on risk of bias of each study and, if available, any outcome level assessment (see item 12).	Suppl information	
20 21	Results of individual studies	20	For all outcomes considered (benefits or harms), present, for each study: (a) simple summary data for each intervention group (b) effect estimates and confidence intervals, ideally with a forest plot.	Figures	
23	Synthesis of results	21	Present results of each meta-analysis done, including confidence intervals and measures of consistency.	None	
24	Risk of bias across studies	22	Present results of any assessment of risk of bias across studies (see Item 15).	6	
2:	Additional analysis	23	Give results of additional analyses, if done (e.g., sensitivity or subgroup analyses, meta-regression [see Item 16]).	None	
27			·		
29 29 30		24	Summarize the main findings including the strength of evidence for each main outcome; consider their relevance to key groups (e.g., healthcare providers, users, and policy makers).	9-10	
31	Limitations	25	Discuss limitations at study and outcome level (e.g., risk of bias), and at review-level (e.g., incomplete retrieval of identified research, reporting bias).	11	
34 34	Conclusions	26	Provide a general interpretation of the results in the context of other evidence, and implications for future research.	11	
35	FUNDING	1			
37	Funding	27	Describe sources of funding for the systematic review and other support (e.g., supply of data); role of funders for the systematic review.	None

Impact of isolation on hospitalised patients who are infectious: systematic review with quantitative and meta-analysis

#### Abstract

# Objective

To systematically review the literature exploring impact of isolation on hospitalised patients who are infectious: psychological and non-psychological outcomes

#### Design

Systematic review with meta-analysis

### Data Sources

Embase, Medline and Psychinfo were searched from inception until December 2018. Reference lists and Google Scholar were also handsearched.

# Results

Twenty seven papers published from database inception until December 2018 were reviewed. A wide range of psychological and non-psychological outcomes were reported. There was a marked trend for isolated patients to exhibit higher levels of depression, the pooled standardised mean difference being 1.28 (95% CI: 0.47 to 2.09) and anxiety 1.45 (95% CI: 0.56 to 2.34), although both had high levels of heterogeneity; and worse outcomes for a range of care-related factors but with significant variation.

# Conclusion

The review indicates that isolation to contain risk of infection has negative consequences for segregated patients. Although strength of the evidence is weak, comprising primarily single centre convenience samples, consistency of the effects may strengthen this conclusion. More research needs to be undertaken to examine this relationship and develop and test interventions to reduce the negative effects of isolation.

# Strengths and limitations of this study

- This review covers a wide variety of literature from a range of different clinical areas.
- Data collected and the methods of collecting data on the impact of isolation is varied across studies.
- These data do not show if these effects are temporary, or in most cases if they are clinically significant.

# **Funding statement**

This research received no specific grant from any funding agency in the public,

commercial or not-for-profit sectors

# **Competing interests statement**

No authors have any competing interests to declare

#### Introduction

Isolation is an established part of any infection prevention programme. Its purpose is to prevent the transmission of antibiotic-resistant pathogens, those that are highly contagious or cause serious infection.[1] The effectiveness of isolation has been questioned however [2–5] and it can be challenging to undertake, especially if patients' lack of understanding of the need for segregation, boredom or distress result in uncooperative behaviour. [6] A recent survey exploring the care of patients isolated for infectious conditions suggests that in clinical practice the main issues are identifying which patients need to be isolated as quickly as possible and prioritising which patients should be segregated when isolation accommodation is in short supply. Infection preventionists were aware that isolation could have negative effects on patients such as increased risk of anxiety, depression and falls and felt that more should be done to prevent these risks.[6]

Although single rooms are assumed to reduce infection risk, evidence of ability to contain spread is equivocal [7,8] and a recent study conducted in an all-single-room hospital was unable to demonstrate lower infection rates than in hospitals where most care takes place in open wards. [9] This study identified advantages and disadvantages of single room accommodation, whereas isolating infectious patients is generally assumed to result in adverse outcomes.[10]

A systematic review reported eight years ago indicated higher levels of anxiety, depression, perceptions of stigmatisation and a higher incidence of falls, medication errors and other incidents that detract from patient safety among patients who were isolated compared to those who were not.[11] This review reported studies undertaken

#### **BMJ** Open

before 2010 and included patients whose experiences are unlikely to be comparable: children and adults and those isolated to reduce their own risk of infection as well as infectious patients. The review was not reported according to standards currently expected for systematic reviews [12] and presents a qualitative description of patient outcomes only. A more rigorously reported and up-to-date systematic review is indicated in view of increasing concern about satisfaction with health care and patient safety and increasing emphasis on infection prevention as part of the global strategy to reduce risks of antimicrobial resistance.[13]

We undertook a systematic review of the literature to establish the effects of infection related isolation on psychological and non-psychological care-related outcomes in adults. This review is therefore more focussed than that previously undertaken which also included those in protective isolation, and contains a significant body of literature ien published since 2010.

#### Method

The eligibility criteria for inclusion was that studies should compare quantitative data on psychological or non-psychological outcomes in adult patients who are in infective isolation with those not isolated. Purely symptomatic/disease progression outcomes were not included, neither were those looking at patients isolated due to immunosuppression. Studies not containing comparative data between those isolated and not isolated were also excluded. Search terms were: Patient isolation; cross infection; contact isolation; respiratory, source or contact isolation; droplet, airborne or contact precautions; cubicle; MRSA or methicillin resistant Staphylococcus aureus; patient safety or harm; depression; anxiety; adaptation; stress; patient satisfaction;

Page 7 of 57

#### **BMJ** Open

quality of life. These were searched as free-text and index terms where these existed. The information sources used were Embase, Medline and Psychinfo, which were searched from inception until December 2018. Reference lists and Google Scholar were also handsearched. Characteristics of included and excluded papers are shown in Supplementary File 1. The PRISMA flow-chart together is given in Supplementary File 2. given in with details of excluded papers are given in No protocol was published in advance.

Studies were initially screened for relevance by one author (EP), with the final stage being undertaken by two (EP, DG). Data were extracted and checked by two authors (DG, EP); where there were disagreements data were rechecked for relevance and accuracy. Where available, raw data were extracted and entered into a spreadsheet, and depending upon the nature of the data either the risk ratio or standardised mean difference calculated. Results were then presented as forest plots. Due to the variety of different settings and methods it was deemed that the methodological and clinical heterogeneity was too broad to pool results; apart from those related to anxiety and depression, for which results were pooled using the random-effects model. All calculations and plots were produced using the meta and metafor packages in R.[14–16] Where raw data were not provided the summary results are given in the text but not the forest plots. All data relevant to the study are included in the article or uploaded as Supplementary File 3.

# **Patient and Public Involvement**

No patient involved.

#### Results

A total of 3 879 papers were retrieved from the three databases; of which 34 were assessed for eligibility by reading the full text. Of these 13 studies provided data suitable for the calculation of risk ratio, 5 giving psychological outcomes,[17–21] and 12 non-psychological;[19,22–32] and 8 provided data for the calculation of standardised mean differences, 6 giving psychological outcomes,[21,30,33–36] and 2 non-psychological.[29,37] A further 6 studies did not provide raw data but are included in the results; 3 each giving psychological outcomes[38–40] and non-psychological outcomes.[17,41,42] Meta-analyses were possible on two outcomes: anxiety and depression from 8 studies using standardised mean difference. [19–21,30,33–36] Where only risk ratio data were given[20,21] conversion to standardised mean difference was undertaken using the Campbell Collaboration calculator (https://campbellcollaboration.org/research-resources/effect-size-calculator.html).[43]

Where it was not possible to pool outcome data because of methodological and clinical heterogeneity, the data from studies are shown as forest plots but without meta-analysis. The forest plots contain results from the studies where sufficient data were given to calculate either the risk ratio or standardised mean difference. A number of studies provided data on those under contact precautions, but no comparative data and so were not included.[44–47]

Because of the large number of non-psychological outcomes for which RR could be calculated, it was decided that a change of 20% (i.e. a RR of 0.8 or less, or 1.2 or more) would be clinically significant, regardless of the statistical significance. This

Page 9 of 57

#### **BMJ** Open

was a pragmatic decision, and all results are shown in Supplementary File 3. Results are shown in Figures 1 to 6. Supplementary Figure 1 contains results that did not meet our criteria for being clinically significant. Outcomes were classified into one of three categories: those to do with quality of care; satisfaction of care; and adverse events from which median values and interquartile ranges were calculated.

The studies included were primarily single-centre and consisted of case-control, cross-sectional and cohort studies. Risk of bias was assessed using the Newcastle-Ottowa scale, full details of each study and its risk of bias are in the Supplementary File 4.[48] Overall, although these studies have limited generalisability, there did not appear to be significant cause for concern regarding bias within the limitations inherent in these study designs. Most studies used established or validated tools[17–21,23–25,27,29,30,33–37] or clinical outcomes.[22,26,28,31,32]

The data from the comparative studies suggest that although in many cases infective isolation precautions make little difference to psychological outcomes, where it does make a difference this is primarily negative. There were significant declines in mean scores related to control and self-esteem, and in many studies increases in the mean scores for risk of anxiety and depression. However, these findings were not consistent, and some larger studies showed little or no difference between the groups for these outcomes. These are shown in Figures 1 and 2 respectively.

# [INSERT FIGURES 1 and 2 HERE]

# Figure 1. Risk ratio of psychological events in those isolated versus not isolated

Figure 2. Standardised mean difference of psychological scores in those isolated versus those not isolated

For the 8 studies reporting data on anxiety the pooled SMD was 1.45 (95% CI: 0.56 to 2.34); although within this there was significant heterogeneity (Q = 168.11, df = 7, p < 0.0001; I<sup>2</sup> = 95.84%). This was primarily caused by two studies [30,34] which showed lower levels of anxiety than the remaining studies. For depression the SMD was 1.28 (95% CI: 0.47 to 2.09); again with significant heterogeneity (Q = 154.5, df = 7, p < 0.0001;  $I^2 = 95.47\%$ ), in this case the studies falling into two categories, those with lower [30,34,35] and higher depression scores among those isolated.[19,20,33,36] The forest plots for these outcomes are shown in Figures 3 and eren 4 respectively.

[INSERT FIGURES 3 and 4 HERE]

Figure 3. Meta-analysis of the standardised mean difference of anxiety in those isolated versus those not isolated

Figure 4. Meta-analysis of the standardised mean difference of depression in those isolated versus those not isolated

Studies not reporting the raw data showed that contact precautions were associated with depression OR 1.4 (95% CI 1.2 to 1.5) but not anxiety OR 0.8 (95% CI 0.7 to 1.1) in a non-ICU population.[41] There was also an association with delirium OR

#### **BMJ** Open

1.40 (95% CI 1.24 to 1.51); although this was primarily among those who were newly diagnosed as needing isolation OR 1.75 (95% CI 1.60 to 1.92, p<0.01) rather than those who had been under contact precautions for their entire stay OR 0.97 (95% CI 0.86 to 1.09, p=0.60).[17] Another study showed no difference in the median values for the Hospital Anxiety and Depression Scale anxiety or depression scores (HADS-A and -D), or the EuroQol Visual Analogue Scale EQ VAS scores.[42]

For non-psychological outcomes, using a difference in the risk of +/- 20% of an event as being a measure of clinical significance it appears there was a trend for less attention to be given to, and for more errors to occur in those who were isolated. However, again there was wide variation between studies. Data on these outcomes are given in Figures 5 and 6, and the non-clinically significant risks in the Supplementary Figure 1. For those outcomes associated with quality, the median risk ratio (with positive outcomes reversed so a higher risk ratio is associated with a worse outcome) was 0.94 (IQR 0.92 to 0.98), satisfaction 0.95 (IQR 0.89 to 1.01) and adverse events was 1.27 (0.91 to 2.5). The minimum and maximum risk ratio for each category was 0.49 and 1.72; 0.3 and 8; and 0.3 and 18 respectively.

[INSERT FIGURES 5 and 6 HERE]

Figure 5. Risk ratio of non-psychological events in those isolated versus not isolated with a RR of < =0.8 or > =1.2

\* outcome was measured in rate per 100 admissions

Figure 6. Standardised mean difference of non-psychological scores in those isolated versus those not isolated

FIM – functional independence measure

A study not giving raw data which looked at the rates of falls and pressure ulcers before and after a policy change that resulted in the discontinuation of contact precautions for patients with methicillin resistant *Staphylcoccus aureus* (MRSA) or vancomycin resistant enterococci (VRE) found that falls and pressure ulcers were more common among those with MRSA or VRE both before the change (when they were in isolation) and afterwards (when they were not). Before the change the number of falls was 4.57 vs 2.04 per 1000 patient-days respectively (p< 0.0001) and pressure ulcers 4.87 vs 1.22 per 1000 patient-days (p< 0.0001). After the policy change the same numbers were falls 4.82 vs 2.10 (p<0.0001) and pressure ulcers 4.17 vs 1.19 per 1000 patient-days (p<0.0001).[39] Other studies found that staff spent less time with those on contact precautions: internal medicine interns spent less time with their isolated patients compared to non-isolated patients, the median times being 5.2 and 6.9 minutes respectively (p<0.001)[38]; while the mean number of contacts per hour with healthcare workers was 2.1 compared to 4.2 in those not isolated (p=0.03), although the duration was longer at 4.5 minutes compared to 2.8 (p=0.6).[40]

# Discussion

Current recommendations say that contact precautions should include a single room, with personal protective equipment consisting of a gown and gloves for all patient contacts or contacts with potentially contaminated environmental areas.[1] This review has shown that there are a number of apparently negative aspects to contact

#### **BMJ** Open

precautions, in particular with regards to psychological effects and a reduction in the quality of some aspects of care. These data come from studies carried out in a variety of countries and different types of facilities; although there are few data from particularly vulnerable populations such as the elderly.

Although at times there are discussions as to the necessity of contact precautions for drug resistant organisms, with some arguing that that there is mixed evidence for or against their use[49] another recent review has concluded that they are of great importance in the control of epidemic and endemic multidrug-resistant microorganisms.[50] The ethics of using contact precautions and other forms of isolation rely on a positive assessment of the balance between the risks and benefits of this to the individual concerned and that of the broader population of patients and staff.[51] However, even when this assessment is positive, it is important to ensure that any harm to the individual is minimised.

One way of balancing the various priorities is to use the GRADE Evidence to Decision Framework, which provides criteria for making recommendations at the individual, group and policy-levels, and provides a number of highly patient focussed criteria for doing this. In addition to the certainty of evidence and resource requirements, it also requires consideration of: the balance of desirable and undesirable effects; the impact upon equity; and the feasibility and acceptability of the intervention.[52] The last two of these might have very different outcomes when considered at the population and individual levels; and there is certainly evidence here that for the individual patient the balance of desirable and undesirable effects might be very different to that of the broader population.

#### **BMJ** Open

However, within the broad population of infected or potentially infected patients, some groups might have different needs. For example a study of people isolated for MERS found that while access to telephones reduced anxiety and anger; access to email, text and internet increased these.[53] This was not an area investigated in any depth in these studies. Another area where information may be lacking is that of age, as older people in particular might feel sadness and loneliness more; and gender, as qualitative data suggest that women in isolation were more concerned about precautions and transmission while men were more resigned, rational and tended to cope better.[54]

In some countries, such as the United States single-rooms have become the standard for new hospitals and so one might expect fewer adverse effects if everyone is in a single room, this being the norm. However it may be that a single room is necessary but not sufficient for these findings, and that it is the combination of a single room with an infection that leads to these results. Certainly it is far from clear that the long list of advantages claimed for single rooms which include reduced stress, the ability to deliver better care, and a lower probability of dietary or medication errors apply to this group of patients.[55]

Caring for patients in single-rooms does have many challenges, but there is evidence that these can be mitigated in a general population;[9] however the expanding literature on how this can be done in a general population does not necessarily apply here due to the necessity of isolation procedures which are, by design, 'a barrier'. Therefore patients' needs for greater social interaction will need a solution quite

#### **BMJ** Open

different from that which might be used for a different patient population, and the benefit of choice about this which single rooms offer does not apply here.[56]

Although this review has quantified the extent of the problem, we have not been able to find solutions in the literature. Care might be improved through increased staff attention with more resources being allocated to these patients, although the extra cost of contact precautions is already considerable, one estimate being that it was an extra \$158.90 (95% CI \$124.90 to \$192.80) per patient day.[57] Alternatively new ways of working might be developed, perhaps using technology to mitigate some of these problems. Technology might be particularly useful in reducing adverse events such as medication or clinical errors; although increasing satisfaction and some areas of quality are more likely to be achieved by increasing the availability of staff and other CZ.C people.

# Study strengths and limitations

This review suggests that infectious isolation has a number of negative effects on patients. Because this evidence is comprised of cohort and case-control studies, a claim for a causal relationship can not be made on this evidence, although the strong and consistent effects across the studies may increase the confidence in this relationship. There are some qualitative data, although more in-depth mixed-methods data where those reporting negative effects are questioned about them would strengthen the evidence on this. In some cases large effect sizes were accompanied by very wide confidence intervals, suggesting that studies were underpowered, thus studies with larger sample sizes would be useful. It would also be useful if there were more consistent methods of examining and reporting these data, particularly outside

of the realms of depression and anxiety where the variety of methods makes analysis of the body of evidence difficult.

Although these data suggest that there is a problem, there is a clear gap both in what we know about improving the experience of isolation and what can be done in practical terms to make it more tolerable for patients and their families. In particular older people who may be most vulnerable to these negative effects were underrepresented in these studies; and this group are likely to represent an increasingly large proportion of those isolated. Lastly the use of isolation may need to increase if the current trends of antimicrobial resistance continue.

# Contributors

EP, DG and JC conceived the review, EP conducted the search, EP and DG examined the studies and extracted data, EP undertook the quantitative analysis, EP, DG and JC undertook the qualitative analysis and wrote the discussion.

# Funding

This research received no specific grant from any funding agency in the public, commercial or not-for-profit sector.

# Figure 6. Standardised mean difference of non-psychological scores in those isolated versus those not isolated

321x127mm (300 x 300 DPI)

# Characteristics of studies

Reference	Study type	Isolated	Non isolated
Colorado (2014)	Retrospective matched case control study. Rehabilitation facility- tertiary centre United States July 2009 to December 2010	N20 Patients in contact isolation	N=20 Matched to patients not in contact isolation based on age, rehabilitation diagnosis, and type of insurance
Croft (2015)	Prospective cohort Medical or surgical inpatients admitted to non–intensive care unit hospital wards, United States. January to November 2010.	N=148 Patients on contact precautions Age: 52 (13.8) % male: 53.4	N=148 Individually matched by after an initial 3-day length of stay to patients not on contact precautions. Age 52.3 (14.6) % male: 46.6
Dashiell- Earp (2014)	Collected real-time data on the location of 15 internal medicine interns, United States. October 1, 2012 to December 31, 2012	1156 encounters	2467 encounters
Day (2011)	Patients admitted to the general acute care units, United States. June 1, 2009 to October 30, 2009	N=20 Age: 68.5 (14.7) % male: 85.0	N=83 Age: 63.9 (12.6) % male: 95.2
Day (2011)	A two-year retrospective cohort Tertiary care, United States All general inpatients over 18 years hospitalized for >24 h February 1, 2007 to January 31, 2009.	Contact precautions private room when possible, can be cohorted General N = 3138 Age: 51.2 (17.5) % male 58.9 ITU N=1694 Age: 54.9 (17.5) % male 61.0	General N = 25 426 Age: 49.6 (19.0) % male 46.3% ICU N = 5 854 Age: 56.0 (17.7) % male 59.7
Day (2012)	2-year retrospective cohort study of all non-psychiatric hospital admissions >18 years, United States. February 1, 2007 to January 31, 2009	N = 9.684 Contact precautions as above Mean age: 50.1 (18.8) % male 51.4	N = 50 458 Mean age: 52.3 (16.9) % males 59.1
Day (2013)	Longitudinal frequency-matched cohort study of patients admitted to general medical and surgical units, United States. Day 0, day 3 then weekly. January to November 2010	N = 148 Mean age: 52.0 (13.9) % male 58.1	N = 148 Mean age: 52.3 (14.6) % male 50.7

Evans (2003)	Prospective observation; survey; retrospective review, United States. Tertiary care. June and July 2001	N 48 Mean age: 47.8 (2) % male 85%	N = 48 Mean age: 58.3 (2.4) % male 75%
Findink (2012)	Non-random quasi-experiment, Turkey Age 18 to 65 Administered day 5 January 1, 2009 to December 31, 2009	N = 60 Mean age: 53.95 (18.4) % male 75%	N = 57 Mean age: 56.14 (17.1) % male 76.3%
Gammon (1998)	Quasi experiment Selected if last two numbers on their case notes even. Two large District General Hospitals and one elderly care hospital, United Kingdom	N = 20 Placed in isolation for a minimum of 7days Mean age: 61 years % male: 65	N = 20 Mean age: 52 years % male: 55
Gandra (2014)	Retrospective hospital-wide cohort study, United States. All patients admitted to medical-surgical inpatient units November 1, 2009 to October 31, 2011	Falls N=77 Mean age: 66.1 (14.3) % male: 61% Pressure ulcers N=82 Mean age: 64.5 (15.5) % male: 63	Falls N=82 Mean age: 63.7 (15.8) % male: 51 (62%) Pressure ulcers N=71 Mean age: 65.7 (15) % male: 57
Guilley- Lerondeau (2017)	Matched cohort study with prospective inclusions Interview 3 days after commencing General sample. France March to July 2012	N=30 First prescription of isolation precaution Median age (range) 69 (32 to 91) % male 47	N=60 Median age (range) 64 (24 to 91) % male 53
Kennedy (1997)	Cross-sectional matched-control study, United Kingdom. May 1994 to November 1996	N = 16 Isolated as a result of being MRSA Mean age: 31.1 All male	N = 16 Matched for age, sex, level of injury, and time since admission or injury
Kirkland (1999)	Observational study - 7 months Medical intensive-care, United States	N=14	N=21
Lau (2016)	Prospective cohort study. Adult patients discharged from internal medicine wards, Canada October 2013 to November 2014,	N=75 Mean age 60.35 (17.83) % male 59	N=420 Mean age 63.31 (18.69) % male 48%
Livorsi (2015)	Case-control study Retrospective January 1, 2012 to	N = 70 On contact precautions for MRSA throughout	N = 139 No significant differences between isolated a

Impact of isolation on hospitalised patients who are infectious: systematic review with quantitative and meta-analysis

#### Abstract

# Objective

To systematically review the literature exploring impact of isolation on hospitalised patients who are infectious: psychological and non-psychological outcomes

#### Design

Systematic review with meta-analysis

## Data Sources

Embase, Medline and Psychinfo were searched from inception until December 2018. Reference lists and Google Scholar were also handsearched.

# Results

Twenty six papers published from database inception until December 2018 were reviewed. A wide range of psychological and non-psychological outcomes were reported. There was a marked trend for isolated patients to exhibit higher levels of depression, the pooled standardised mean difference being 1.28 (95% CI: 0.47 to 2.09) and anxiety 1.45 (95% CI: 0.56 to 2.34), although both had high levels of heterogeneity; and worse outcomes for a range of care-related factors but with significant variation.

# Conclusion

The review indicates that isolation to contain risk of infection has negative consequences for segregated patients. Although strength of the evidence is weak, comprising primarily single centre convenience samples, consistency of the effects may strengthen this conclusion. More research needs to be undertaken to examine this relationship and develop and test interventions to reduce the negative effects of isolation.

# Strengths and limitations of this study

- This review covers a wide variety of literature from a range of different clinical areas.
- Data collected and the methods of collecting data on the impact of isolation is varied across studies.
- These data do not show if these effects are temporary, or in most cases if they are clinically significant.

# **Funding statement**

This research received no specific grant from any funding agency in the public,

commercial or not-for-profit sectors

# **Competing interests statement**

No authors have any competing interests to declare

### Introduction

Isolation is an established part of any infection prevention programme. Its purpose is to prevent the transmission of antibiotic-resistant pathogens, those that are highly contagious or cause serious infection.[1] The effectiveness of isolation has been questioned however [2–5] and it can be challenging to undertake, especially if patients' lack of understanding of the need for segregation, boredom or distress result in uncooperative behaviour. [6] A recent survey exploring the care of patients isolated for infectious conditions suggests that in clinical practice the main issues are identifying which patients need to be isolated as quickly as possible and prioritising which patients should be segregated when isolation accommodation is in short supply. Infection preventionists were aware that isolation could have negative effects on patients such as increased risk of anxiety, depression and falls and felt that more should be done to prevent these risks.[6]

Although single rooms are assumed to reduce infection risk, evidence of ability to contain spread is equivocal [7,8] and a recent study conducted in an all-single-room hospital was unable to demonstrate lower infection rates than in hospitals where most care takes place in open wards. [9] This study identified advantages and disadvantages of single room accommodation, whereas isolating infectious patients is generally assumed to result in adverse outcomes.[10]

A systematic review reported eight years ago indicated higher levels of anxiety, depression, perceptions of stigmatisation and a higher incidence of falls, medication errors and other incidents that detract from patient safety among patients who were isolated compared to those who were not.[11] This review reported studies undertaken

#### **BMJ** Open

before 2010 and included patients whose experiences are unlikely to be comparable: children and adults and those isolated to reduce their own risk of infection as well as infectious patients. The review was not reported according to standards currently expected for systematic reviews [12] and presents a qualitative description of patient outcomes only. A more rigorously reported and up-to-date systematic review is indicated in view of increasing concern about satisfaction with health care and patient safety and increasing emphasis on infection prevention as part of the global strategy to reduce risks of antimicrobial resistance.[13]

We undertook a systematic review of the literature to establish the effects of infection related isolation on psychological and non-psychological care-related outcomes in adults. This review is therefore more focussed than that previously undertaken which also included those in protective isolation, and contains a significant body of literature ien published since 2010.

#### Method

The eligibility criteria for inclusion was that studies should compare quantitative data on psychological or non-psychological outcomes in adult patients who are in infective isolation with those not isolated. Purely symptomatic/disease progression outcomes were not included, neither were those looking at patients isolated due to immunosuppression. Studies not containing comparative data between those isolated and not isolated were also excluded. Search terms were: Patient isolation; cross infection; contact isolation; respiratory, source or contact isolation; droplet, airborne or contact precautions; cubicle; MRSA or methicillin resistant Staphylococcus aureus; patient safety or harm; depression; anxiety; adaptation; stress; patient satisfaction;

Page 7 of 59

#### **BMJ** Open

quality of life. These were searched as free-text and index terms where these existed. The information sources used were Embase, Medline and Psychinfo, which were searched from inception until December 2018. Reference lists and Google Scholar were also handsearched. Characteristics of included and excluded papers are shown in Supplementary File 1. The PRISMA flow-chart is given in Supplementary File 2. No protocol was published in advance.

Studies were initially screened for relevance by one author (EP), with the final stage being undertaken by two (EP, DG). Data were extracted and checked by two authors (DG, EP); where there were disagreements data were rechecked for relevance and accuracy. Where available, raw data were extracted and entered into a spreadsheet, and depending upon the nature of the data either the risk ratio (where numbers of patients were given) or standardised mean difference (where other statistics were given) calculated. Results were then presented as forest plots.

Due to the variety of different settings and methods it was deemed that the methodological and clinical heterogeneity was too broad to pool results; apart from those related to anxiety and depression, for which results were pooled using the random-effects model. This model assumes that the observed effect from each study is estimating a related but different true effect, allowing for between-study variation to be calculated in the form of heterogeneity statistics. All calculations and plots were produced using the meta and metafor packages in R.[14–16] Where raw data were not provided the summary results are given in the text but not the forest plots. All data relevant to the study are included in the article or uploaded as Supplementary File 3.

# **Patient and Public Involvement**

No patient involved.

### Results

A total of 3 879 papers were retrieved from the three databases; of which 34 were assessed for eligibility by reading the full text. Of these 13 studies provided data suitable for the calculation of risk ratio, 5 giving psychological outcomes,[17–21] and 12 non-psychological;[19,22–32] and 8 provided data for the calculation of standardised mean differences, 6 giving psychological outcomes,[21,30,33–36] and 2 non-psychological.[29,37] A further 6 studies did not provide raw data but are included in the results; 3 each giving psychological outcomes[38–40] and non-psychological outcomes.[17,41,42] Meta-analyses were possible on two outcomes: anxiety and depression from 8 studies using standardised mean difference. [19–21,30,33–36] Where only risk ratio data were given[20,21] conversion to standardised mean difference was undertaken using the Campbell Collaboration calculator (https://campbellcollaboration.org/research-resources/effect-size-calculator.html).[43]

Where it was not possible to pool outcome data because of methodological and clinical heterogeneity, the data from studies are shown as forest plots but without meta-analysis. The forest plots contain results from the studies where sufficient data were given to calculate either the risk ratio or standardised mean difference. A number of studies provided data on those under contact precautions, but no comparative data and so were not included.[44–47]

#### **BMJ** Open

Because of the large number of non-psychological outcomes for which RR could be calculated, it was decided that a change of 20% (i.e. a RR of 0.8 or less, or 1.2 or more) would be clinically significant, regardless of the statistical significance. This was a pragmatic decision, and all results are shown in Supplementary File 3. Results are shown in Figures 1 to 6. Supplementary Figure 1 contains results that did not meet our criteria for being clinically significant. Outcomes were classified into one of three categories: those to do with quality of care; satisfaction of care; and adverse events from which median values and interquartile ranges were calculated.

The studies included were primarily single-centre and consisted of case-control, cross-sectional and cohort studies. Risk of bias was assessed using the Newcastle-Ottowa scale, full details of each study and its risk of bias are in the Supplementary File 4.[48] Overall, although these studies have limited generalisability, there did not appear to be significant cause for concern regarding bias within the limitations inherent in these study designs. Most studies used established or validated tools[17–21,23–25,27,29,30,33–37] or clinical outcomes.[22,26,28,31,32]

The data from the comparative studies suggest that although in many cases infective isolation precautions make little difference to psychological outcomes, where it does make a difference this is primarily negative. There were significant declines in mean scores related to control and self-esteem, and in many studies increases in the mean scores for risk of anxiety and depression. However, these findings were not consistent, and some larger studies showed little or no difference between the groups for these outcomes. These are shown in Figures 1 and 2 respectively.

# [INSERT FIGURES 1 and 2 HERE]

#### Figure 1. Risk ratio of psychological events in those isolated versus not isolated

Figure 2. Standardised mean difference of psychological scores in those isolated versus those not isolated

For the 8 studies reporting data on anxiety the pooled SMD was 1.45 (95% CI: 0.56 to 2.34); although within this there was significant heterogeneity (Q = 168.11, df = 7, p < 0.0001; I<sup>2</sup> = 95.84%). This was primarily caused by two studies [30,34] which showed lower levels of anxiety than the remaining studies. For depression the SMD was 1.28 (95% CI: 0.47 to 2.09); again with significant heterogeneity (Q = 154.5, df = 7, p < 0.0001; I<sup>2</sup> = 95.47%), in this case the studies falling into two categories, those with lower [30,34,35] and higher depression scores among those isolated.[19,20,33,36] The forest plots for these outcomes are shown in Figures 3 and 4 respectively.

Page 11 of 59

#### **BMJ** Open

Studies not reporting the raw data showed that contact precautions were associated with depression OR 1.4 (95% CI 1.2 to 1.5) but not anxiety OR 0.8 (95% CI 0.7 to 1.1) in a non-ICU population.[41] There was also an association with delirium OR 1.40 (95% CI 1.24 to 1.51); although this was primarily among those who were newly diagnosed as needing isolation OR 1.75 (95% CI 1.60 to 1.92, p<0.01) rather than those who had been under contact precautions for their entire stay OR 0.97 (95% CI 0.86 to 1.09, p=0.60).[17] Another study showed no difference in the median values for the Hospital Anxiety and Depression Scale anxiety or depression scores (HADS-A and -D), or the EuroQol Visual Analogue Scale EQ VAS scores.[42]

For non-psychological outcomes, using a difference in the risk of +/- 20% of an event as being a measure of clinical significance it appears there was a trend for less attention to be given to, and for more errors to occur in those who were isolated. However, again there was wide variation between studies. Data on these outcomes are given in Figures 5 and 6, and the non-clinically significant risks in the Supplementary Figure 1. For those outcomes associated with quality, the median risk ratio (with positive outcomes reversed so a higher risk ratio is associated with a worse outcome) was 0.94 (IQR 0.92 to 0.98), satisfaction 0.95 (IQR 0.89 to 1.01) and adverse events was 1.27 (0.91 to 2.5). The minimum and maximum risk ratio for each category was 0.49 and 1.72; 0.3 and 8; and 0.3 and 18 respectively.

A study not giving raw data which looked at the rates of falls and pressure ulcers before and after a policy change that resulted in the discontinuation of contact precautions for patients with methicillin resistant *Staphylcoccus aureus* (MRSA) or vancomycin resistant enterococci (VRE) found that falls and pressure ulcers were more common among those with MRSA or VRE both before the change (when they were in isolation) and afterwards (when they were not). Before the change the number of falls was 4.57 vs 2.04 per 1000 patient-days respectively (p< 0.0001) and pressure ulcers 4.87 vs 1.22 per 1000 patient-days (p< 0.0001). After the policy change the same numbers were falls 4.82 vs 2.10 (p<0.0001) and pressure ulcers 4.17 vs 1.19 per 1000 patient-days (p<0.0001).[39] Other studies found that staff spent less time with those on contact precautions: internal medicine interns spent less time with their isolated patients compared to non-isolated patients, the median times being 5.2 and 6.9 minutes respectively (p<0.001)[38]; while the mean number of contacts per hour with healthcare workers was 2.1 compared to 4.2 in those not isolated (p=0.03), although the duration was longer at 4.5 minutes compared to 2.8 (p=0.6).[40]

# Discussion

Current recommendations say that contact precautions should include a single room, with personal protective equipment consisting of a gown and gloves for all patient Page 13 of 59

#### **BMJ** Open

contacts or contacts with potentially contaminated environmental areas.[1] This review has shown that there are a number of apparently negative aspects to contact precautions, in particular with regards to psychological effects and a reduction in the quality of some aspects of care. These data come from studies carried out in a variety of countries and different types of facilities; although there are few data from particularly vulnerable populations such as the elderly.

Although at times there are discussions as to the necessity of contact precautions for drug resistant organisms, with some arguing that that there is mixed evidence for or against their use[49] another recent review has concluded that they are of great importance in the control of epidemic and endemic multidrug-resistant microorganisms.[50] The ethics of using contact precautions and other forms of isolation rely on a positive assessment of the balance between the risks and benefits of this to the individual concerned and that of the broader population of patients and staff.[51] However, even when this assessment is positive, it is important to ensure that any harm to the individual is minimised.

One way of balancing the various priorities is to use the GRADE Evidence to Decision Framework, which provides criteria for making recommendations at the individual, group and policy-levels, and provides a number of highly patient focussed criteria for doing this. In addition to the certainty of evidence and resource requirements, it also requires consideration of: the balance of desirable and undesirable effects; the impact upon equity; and the feasibility and acceptability of the intervention.[52] The last two of these might have very different outcomes when considered at the population and individual levels; and there is certainly evidence here that for the individual patient the balance of desirable and undesirable effects might be very different to that of the broader population.

However, within the broad population of infected or potentially infected patients, some groups might have different needs. For example a study of people isolated for MERS found that while access to telephones reduced anxiety and anger; access to email, text and internet increased these.[53] This was not an area investigated in any depth in these studies. Another area where information may be lacking is that of age, as older people in particular might feel sadness and loneliness more; and gender, as qualitative data suggest that women in isolation were more concerned about precautions and transmission while men were more resigned, rational and tended to cope better.[54]

In some countries, such as the United States single-rooms have become the standard for new hospitals and so one might expect fewer adverse effects if everyone is in a single room, this being the norm. However it may be that a single room is necessary but not sufficient for these findings, and that it is the combination of a single room with an infection that leads to these results. Certainly it is far from clear that the long list of advantages claimed for single rooms which include reduced stress, the ability to deliver better care, and a lower probability of dietary or medication errors apply to this group of patients.[55]

Caring for patients in single-rooms does have many challenges, but there is evidence that these can be mitigated in a general population;[9] however the expanding literature on how this can be done in a general population does not necessarily apply

### **BMJ** Open

here due to the necessity of isolation procedures which are, by design, 'a barrier'. Therefore patients' needs for greater social interaction will need a solution quite different from that which might be used for a different patient population, and the benefit of choice about this which single rooms offer does not apply here.[56]

Although this review has quantified the extent of the problem, we have not been able to find solutions in the literature. Care might be improved through increased staff attention with more resources being allocated to these patients, although the extra cost of contact precautions is already considerable, one estimate being that it was an extra \$158.90 (95% CI \$124.90 to \$192.80) per patient day.[57] Alternatively new ways of working might be developed, perhaps using technology to mitigate some of these problems. Technology might be particularly useful in reducing adverse events such as medication or clinical errors; although increasing satisfaction and some areas of quality are more likely to be achieved by increasing the availability of staff and other people. The extent to which scarce resources are allocated to this may be driven in part by the longevity of any negative effects; which current literature is not really able to clarify. To understand this longituduinal studies are needed.

### Study strengths and limitations

This review suggests that infectious isolation has a number of negative effects on patients. Because this evidence is comprised of cohort and case-control studies, a claim for a causal relationship can not be made on this evidence, although the strong and consistent effects across the studies may increase the confidence in this relationship. There are some qualitative data, although more in-depth mixed-methods data where those reporting negative effects are questioned about them would

### **BMJ** Open

strengthen the evidence on this. In some cases large effect sizes were accompanied by very wide confidence intervals, suggesting that studies were underpowered, thus studies with larger sample sizes would be useful. It would also be useful if there were more consistent methods of examining and reporting these data, particularly outside of the realms of depression and anxiety where the variety of methods makes analysis of the body of evidence difficult. We were also unable to assess whether these effects varied according to reason for isolation; or to understand if they are likely to be longterm or simply temporary phenomena.

Although these data suggest that there is a problem, there is a clear gap both in what we know about improving the experience of isolation and what can be done in practical terms to make it more tolerable for patients and their families. In particular older people who may be most vulnerable to these negative effects were underrepresented in these studies; and this group are likely to represent an increasingly large proportion of those isolated.

### **Contributors**

EP, DG and JC conceived the review, EP conducted the search, EP and DG examined the studies and extracted data, EP undertook the quantitative analysis, EP, DG and JC wrote the discussion.

### Funding

This research received no specific grant from any funding agency in the public, commercial or not-for-profit sector.

# Figure 6. Standardised mean difference of non-psychological scores in those isolated versus those not isolated

321x127mm (300 x 300 DPI)

### Characteristics of studies

Reference	Study type	Isolated	Non isolated
Colorado (2014)	Retrospective matched case control study. Rehabilitation facility- tertiary centre United States July 2009 to December 2010	N20 Patients in contact isolation	N=20 Matched to patients not in contact isolation based on age, rehabilitation diagnosis, and type of insurance
Croft (2015)	Prospective cohort Medical or surgical inpatients admitted to non–intensive care unit hospital wards, United States. January to November 2010.	N=148 Patients on contact precautions Age: 52 (13.8) % male: 53.4	N=148 Individually matched by after an initial 3-day length of stay to patients not on contact precautions. Age 52.3 (14.6) % male: 46.6
Dashiell- Earp (2014)	Collected real-time data on the location of 15 internal medicine interns, United States. October 1, 2012 to December 31, 2012	1156 encounters	2467 encounters
Day (2011)	Patients admitted to the general acute care units, United States. June 1, 2009 to October 30, 2009	N=20 Age: 68.5 (14.7) % male: 85.0	N=83 Age: 63.9 (12.6) % male: 95.2
Day (2011)	A two-year retrospective cohort Tertiary care, United States All general inpatients over 18 years hospitalized for >24 h February 1, 2007 to January 31, 2009.	Contact precautions private room when possible, can be cohorted General N = 3138 Age: 51.2 (17.5) % male 58.9 ITU N=1694 Age: 54.9 (17.5) % male 61.0	General N = 25 426 Age: 49.6 (19.0) % male 46.3% ICU N = 5 854 Age: 56.0 (17.7) % male 59.7
Day (2012)	2-year retrospective cohort study of all non-psychiatric hospital admissions >18 years, United States. February 1, 2007 to January 31, 2009	N = 9 684 Contact precautions as above Mean age: 50.1 (18.8) % male 51.4	N = 50 458 Mean age: 52.3 (16.9) % males 59.1
Day (2013)	Longitudinal frequency-matched cohort study of patients admitted to general medical and surgical units, United States. Day 0, day 3 then weekly. January to November 2010	N = 148 Mean age: 52.0 (13.9) % male 58.1	N = 148 Mean age: 52.3 (14.6) % male 50.7

Evans (2003)	Prospective observation; survey; retrospective review, United States. Tertiary care. June and July 2001	N 48 Mean age: 47.8 (2) % male 85%	N = 48 Mean age: 58.3 (2.4) % male 75%
Findink (2012)	Non-random quasi-experiment, Turkey Age 18 to 65 Administered day 5 January 1, 2009 to December 31, 2009	N = 60 Mean age: 53.95 (18.4) % male 75%	N = 57 Mean age: 56.14 (17.1) % male 76.3%
Gammon (1998)	Quasi experiment Selected if last two numbers on their case notes even. Two large District General Hospitals and one elderly care hospital, United Kingdom	N = 20 Placed in isolation for a minimum of 7days Mean age: 61 years % male: 65	N = 20 Mean age: 52 years % male: 55
Gandra (2014)	Retrospective hospital-wide cohort study, United States. All patients admitted to medical-surgical inpatient units November 1, 2009 to October 31, 2011	Falls N=77 Mean age: 66.1 (14.3) % male: 61% Pressure ulcers N=82 Mean age: 64.5 (15.5) % male: 63	Falls N=82 Mean age: 63.7 (15.8) % male: 51 (62%) Pressure ulcers N=71 Mean age: 65.7 (15) % male: 57
Guilley- Lerondeau (2017)	Matched cohort study with prospective inclusions Interview 3 days after commencing General sample. France March to July 2012	N=30 First prescription of isolation precaution Median age (range) 69 (32 to 91) % male 47	N=60 Median age (range) 64 (24 to 91) % male 53
Kennedy (1997)	Cross-sectional matched-control study, United Kingdom. May 1994 to November 1996	N = 16 Isolated as a result of being MRSA Mean age: 31.1 All male	N = 16 Matched for age, sex, level of injury, and time since admission or injury
Kirkland (1999)	Observational study - 7 months Medical intensive-care, United States	N=14	N=21
Lau (2016)	Prospective cohort study. Adult patients discharged from internal medicine wards, Canada October 2013 to November 2014,	N=75 Mean age 60.35 (17.83) % male 59	N=420 Mean age 63.31 (18.69) % male 48%
Livorsi (2015)	Case-control study Retrospective January 1, 2012 to	N = 70 On contact precautions for MRSA throughout	N = 139 No significant differences between isolated ar

	May 31, 2012/prospective June 1, 2012 to March 31, 2013 'safety-net facility', United States	their hospital stay. Found to be MRSA positive during a previous hospitalization or as an outpatient, not current case	non-isolated patients
Lupión- Mendoza (2015)	Matched case-control study Tertiary hospital, Spain 2011 and 2012	N = 72 Adult patients admitted in isolation for =>5 days. Median age (range) 62 (21-93) % male 73%	N = 72 Median age (range) 69 (23-89), % male 68.1%
Massee (2013)	Retrospective case-control Tertiary care, Canada	N = 111 Matched MRSA patients with an admission diagnosis of heart failure or COPD to similar non-isolated controls Median age (IQR) 80.0 (69.0-86.0) % male 60.4%	N = 111 Median age (IQR) 80.0 (68.0–86.0) % male 60.4%
Mehrotra (2013)	Prospective cohort Admission and on days 3, 7, 14 Tertiary centre, United States	N = 238 Segregation into a private or cohorted room Mean age (SD) 52.4 (13.4) % male 55.7	N = 290 Mean age (SD) 52.9 (14.8) % male 48
Saint (2003)	Prospective cohort study 2 university-affiliated medical centers, United States. October 1999 to March 2000	N=31	N=108
Soon (2013)	Cross-sectional survey of cases and matched controls Teaching hospital Singapore June and August 2011	N=20 Contact isolation in a cohort cubicle for the first time because of colonization or infection with a MDRO for at least 3 days No statistically significant differences in age or gender	N=20
Spense (2011)	Retrospective evaluation of incident reports All patients admitted to acute care facility, United States January 1, 2008 to December 31, 2008.	N=45	N=256
Stelfox (2003)	Case control study Consecutive adults isolated for at least 2 days with MRSA. Canada and United States Controls patients admitted before	General N = 78 Age: 69.6 (17.1) % male: 45% CHF N = 72 Age: 66.9 (14.7)	General N = 156 Age: 65.4 (18.2) % male: 51% CHF N = 144 Age: 66.0 (14.5)

	and after. January 1, 1999,to January 1, 2000	% male: 58	% male: 54
Tarzi (2001)	Cross-sectional matched case-control study Care of the elderly rehabilitation wards, UK	N = 22 Had been in isolation for at least two weeks with MRSA Mean age (SD) 80 (8.4) % male 27.3	N = 20 Mean age (SD) 81 (9.1) % male 33.3
Tran (2017)	Propensity matched cohort study. General internal medicine services, 3 hospitals, Canada January 2010 to December 2012	MRSA Age: 69 % male 57% Respiratory Age: 71.7 % male: 53 Isolated for MRSA or respiratory illness	MRSA Age: 69 % male 58% Respiratory Age: 70.6 % male: 55
Wassenburg (2010)	Cross-sectional matched cohort study Single university hospital, Netherlands November 2006 to February 2007	N = 42 Age: 52 (19) % male: 52	N = 84 Age: 55 (16) % male: 55

	All RR data
	Daily HCW presence (very/satisfied) Human relation with HCW (very/satisfied)
	Global satisfaction (very/satisfied)
	ED visit 30 days
	Overall rating of hospital =>9/10
	Nurses treat you with courtesy and respect
	Nurses listen carefully
	Nurses explain things in an understandable way
	Received help after pressing call button
	Doctors treat you with courtesy and respect
	Doctors listen carefully to you
	Doctors explain things in an understandable way
	Room and bathroom kept clean
	Room quiet at night
	Received help with bathroom/bedpan
	Pain well controlled
	Hospital staff help with pain
	Hospital staff explain new medications
	Hospital staff describe side effects of medications
	Hospital staff discussed help after discharge
	Written information on problems to look for after discharge
	Recommend hospital to friends and family
	Overall satisfaction with the professional treatment received from health care workers
	Nurses treated the patients in polite and respectful manner (totally/partially agree)
	Physicians treated the patients in polite and respectful manner
	Nurses provided clear information about the health problem
	Physicians provided clear information about the health problem
	Clear explanations were provided before all procedures
	Health care workers entered the room whenever the patient called them Blood pressure and temperature recorded at least once a day
	The physician visited daily
	The room was comfortable
	Room cleaning was satisfactory
	I frequently felt lonely during admission
	Medical notes were recorded every day
	Nurses notes were recorded every day
	Daily temperature was recorded at least once a day, every day
	Daily glycemic levels were recorded as indicated, everyday (only diabetic patients)
	Total number of complications
	Nurses treat with courtesy and respect
	Nurses listen carefully
	Nurses explain things in understandable way

# PRISMA 2009 Checklist

5	Section/topic	#	Checklist item	Reported on page #
7	TITLE			
8 9	Title	1	Identify the report as a systematic review, meta-analysis, or both.	1
10	ABSTRACT			
11 12 13 14	Structured summary	2	Provide a structured summary including, as applicable: background; objectives; data sources; study eligibility criteria, participants, and interventions; study appraisal and synthesis methods; results; limitations; conclusions and implications of key findings; systematic review registration number.	1-2
15	INTRODUCTION			
16 17	Rationale	3	Describe the rationale for the review in the context of what is already known.	3
18 19	Objectives	4	Provide an explicit statement of questions being addressed with reference to participants, interventions, comparisons, outcomes, and study design (PICOS).	4-5
20 21	METHODS			
22 23	Protocol and registration	5	Indicate if a review protocol exists, if and where it can be accessed (e.g., Web address), and, if available, provide registration information including registration number.	5
24 25	Eligibility criteria	6	Specify study characteristics (e.g., PICOS, length of follow-up) and report characteristics (e.g., years considered, language, publication status) used as criteria for eligibility, giving rationale.	5
26- 27 28	Information sources	7	Describe all information sources (e.g., databases with dates of coverage, contact with study authors to identify additional studies) in the search and date last searched.	5
29 30	Search	8	Present full electronic search strategy for at least one database, including any limits used, such that it could be repeated.	Suppl information
31- 32 33	Study selection	9	State the process for selecting studies (i.e., screening, eligibility, included in systematic review, and, if applicable, included in the meta-analysis).	5
34 35	Data collection process	10	Describe method of data extraction from reports (e.g., piloted forms, independently, in duplicate) and any processes for obtaining and confirming data from investigators.	5
36 37 38	Data items	11	List and define all variables for which data were sought (e.g., PICOS, funding sources) and any assumptions and simplifications made.	5
	Risk of bias in individual studies	12	Describe methods used for assessing risk of bias of individual studies (including specification of whether this was done at the study or outcome level), and how this information is to be used in any data synthesis.	7
4† 4⊅	Summary measures	13	State the principal summary measures (e.g., risk ratio, difference in means).	6-7
43 44 45	Synthesis of results	14	Describe the methods of handling data and combining results of studies, if done, including measures of consistency (e.g., I <sup>2</sup> ) for each meta-analysis. For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml	6-7

# **PRISMA 2009 Checklist**

Page	1	of	2
LUSC	-	U.	~

Section/topic	#	Checklist item	Reported on page #
Risk of bias across studies	15	Specify any assessment of risk of bias that may affect the cumulative evidence (e.g., publication bias, selective reporting within studies).	7-8
Additional analyses	16	Describe methods of additional analyses (e.g., sensitivity or subgroup analyses, meta-regression), if done, indicating which were pre-specified.	None
RESULTS			
Study selection	17	Give numbers of studies screened, assessed for eligibility, and included in the review, with reasons for exclusions at each stage, ideally with a flow diagram.	6
Study characteristics	18	For each study, present characteristics for which data were extracted (e.g., study size, PICOS, follow-up period) and provide the citations.	Suppl information
Risk of bias within studies	19	Present data on risk of bias of each study and, if available, any outcome level assessment (see item 12).	Suppl information
Results of individual studies	20	For all outcomes considered (benefits or harms), present, for each study: (a) simple summary data for each intervention group (b) effect estimates and confidence intervals, ideally with a forest plot.	Figures
Synthesis of results	21	Present results of each meta-analysis done, including confidence intervals and measures of consistency.	None
Risk of bias across studies	22	Present results of any assessment of risk of bias across studies (see Item 15).	8-9
Additional analysis	23	Give results of additional analyses, if done (e.g., sensitivity or subgroup analyses, meta-regression [see Item 16]).	None
DISCUSSION		·	
Summary of evidence	24	Summarize the main findings including the strength of evidence for each main outcome; consider their relevance to key groups (e.g., healthcare providers, users, and policy makers).	8-11
Limitations	25	Discuss limitations at study and outcome level (e.g., risk of bias), and at review-level (e.g., incomplete retrieval of identified research, reporting bias).	14
Conclusions	26	Provide a general interpretation of the results in the context of other evidence, and implications for future research.	14
FUNDING			
Funding	27	Describe sources of funding for the systematic review and other support (e.g., supply of data); role of funders for the systematic review.	None

Impact of isolation on hospitalised patients who are infectious: systematic review with quantitative and meta-analysis

#### Abstract

## Objective

To systematically review the literature exploring impact of isolation on hospitalised patients who are infectious: psychological and non-psychological outcomes

#### Design

Systematic review with meta-analysis

#### Data Sources

Embase, Medline and Psychinfo were searched from inception until December 2018. Reference lists and Google Scholar were also handsearched.

#### Results

Twenty six papers published from database inception until December 2018 were reviewed. A wide range of psychological and non-psychological outcomes were reported. There was a marked trend for isolated patients to exhibit higher levels of depression, the pooled standardised mean difference being 1.28 (95% CI: 0.47 to 2.09) and anxiety 1.45 (95% CI: 0.56 to 2.34), although both had high levels of heterogeneity; and worse outcomes for a range of care-related factors but with significant variation.

# Conclusion

The review indicates that isolation to contain risk of infection has negative consequences for segregated patients. Although strength of the evidence is weak, comprising primarily single centre convenience samples, consistency of the effects may strengthen this conclusion. More research needs to be undertaken to examine this relationship and develop and test interventions to reduce the negative effects of isolation.

# Strengths and limitations of this study

- This review covers a wide variety of literature from a range of different clinical areas.
- Data collected and the methods of collecting data on the impact of isolation is varied across studies.
- These data do not show if these effects are temporary, or in most cases if they are clinically significant.

# **Funding statement**

This research received no specific grant from any funding agency in the public,

commercial or not-for-profit sectors

# **Competing interests statement**

#### Introduction

Isolation is an established part of any infection prevention programme. Its purpose is to prevent the transmission of antibiotic-resistant pathogens, those that are highly contagious or cause serious infection.[1] The effectiveness of isolation has been questioned however [2–5] and it can be challenging to undertake, especially if patients' lack of understanding of the need for segregation, boredom or distress result in uncooperative behaviour. [6] A recent survey exploring the care of patients isolated for infectious conditions suggests that in clinical practice the main issues are identifying which patients need to be isolated as quickly as possible and prioritising which patients should be segregated when isolation accommodation is in short supply. Infection preventionists were aware that isolation could have negative effects on patients such as increased risk of anxiety, depression and falls and felt that more should be done to prevent these risks.[6]

Although single rooms are assumed to reduce infection risk, evidence of ability to contain spread is equivocal [7,8] and a recent study conducted in an all-single-room hospital was unable to demonstrate lower infection rates than in hospitals where most care takes place in open wards. [9] This study identified advantages and disadvantages of single room accommodation, whereas isolating infectious patients is generally assumed to result in adverse outcomes.[10]

A systematic review reported eight years ago indicated higher levels of anxiety, depression, perceptions of stigmatisation and a higher incidence of falls, medication errors and other incidents that detract from patient safety among patients who were isolated compared to those who were not.[11] This review reported studies undertaken

#### **BMJ** Open

before 2010 and included patients whose experiences are unlikely to be comparable: children and adults and those isolated to reduce their own risk of infection as well as infectious patients. The review was not reported according to standards currently expected for systematic reviews [12] and presents a qualitative description of patient outcomes only. A more rigorously reported and up-to-date systematic review is indicated in view of increasing concern about satisfaction with health care and patient safety and increasing emphasis on infection prevention as part of the global strategy to reduce risks of antimicrobial resistance.[13]

We undertook a systematic review of the literature to establish the effects of infection related isolation on psychological and non-psychological care-related outcomes in adults. This review is therefore more focussed than that previously undertaken which also included those in protective isolation, and contains a significant body of literature ien published since 2010.

#### Method

The eligibility criteria for inclusion was that studies should compare quantitative data on psychological or non-psychological outcomes in adult patients who are in infective isolation with those not isolated. Purely symptomatic/disease progression outcomes were not included, neither were those looking at patients isolated due to immunosuppression. Studies not containing comparative data between those isolated and not isolated were also excluded. Search terms were: Patient isolation; cross infection; contact isolation; respiratory, source or contact isolation; droplet, airborne or contact precautions; cubicle; MRSA or methicillin resistant Staphylococcus aureus; patient safety or harm; depression; anxiety; adaptation; stress; patient satisfaction;

Page 7 of 60

#### **BMJ** Open

quality of life. These were searched as free-text and index terms where these existed. The information sources used were Embase, Medline and Psychinfo, which were searched from inception until December 2018. The full Medline search is shown in Supplementary File 1. Reference lists and Google Scholar were also handsearched. Characteristics of included and excluded papers are shown in Supplementary File 2. The PRISMA flow-chart is given in Supplementary File 3. No protocol was published in advance.

Studies were initially screened for relevance by one author (EP), with the final stage being undertaken by two (EP, DG). Data were extracted and checked by two authors (DG, EP); where there were disagreements data were rechecked for relevance and accuracy. Where available, raw data were extracted and entered into a spreadsheet, and depending upon the nature of the data either the risk ratio (where numbers of patients were given) or standardised mean difference (where other statistics were given) calculated. Results were then presented as forest plots.

Due to the variety of different settings and methods it was deemed that the methodological and clinical heterogeneity was too broad to pool results; apart from those related to anxiety and depression, for which results were pooled using the random-effects model. This model assumes that the observed effect from each study is estimating a related but different true effect, allowing for between-study variation to be calculated in the form of heterogeneity statistics. All calculations and plots were produced using the meta and metafor packages in R.[14–16] Where raw data were not provided the summary results are given in the text but not the forest plots. All data relevant to the study are included in the article or uploaded as Supplementary File 3.

# **Patient and Public Involvement**

No patient involved.

# Results

A total of 3 879 papers were retrieved from the three databases; of which 38 were assessed for eligibility by reading the full text. Of these 13 studies provided data suitable for the calculation of risk ratio, 5 giving psychological outcomes,[17–21] and 12 non-psychological;[19,22–32] and 8 provided data for the calculation of standardised mean differences, 6 giving psychological outcomes,[21,30,33–36] and 2 non-psychological.[29,37] A further 6 studies did not provide raw data but are included in the results; 3 each giving psychological outcomes[38–40] and non-psychological outcomes.[17,41,42] Meta-analyses were possible on two outcomes: anxiety and depression from 8 studies using standardised mean difference. [19–21,30,33–36] Where only risk ratio data were given[20,21] conversion to standardised mean difference was undertaken using the Campbell Collaboration calculator (https://campbellcollaboration.org/research-resources/effect-size-calculator.html).[43]

Where it was not possible to pool outcome data because of methodological and clinical heterogeneity, the data from studies are shown as forest plots but without meta-analysis. The forest plots contain results from the studies where sufficient data were given to calculate either the risk ratio or standardised mean difference. A number of studies provided data on those under contact precautions, but no comparative data and so were not included.[44–47]

#### **BMJ** Open

Because of the large number of non-psychological outcomes for which RR could be calculated, it was decided that a change of 20% (i.e. a RR of 0.8 or less, or 1.2 or more) would be clinically significant, regardless of the statistical significance. This was a pragmatic decision, and all results are shown in Supplementary File 4. Results are shown in Figures 1 to 6. Supplementary Figure 1 contains results that did not meet our criteria for being clinically significant. Outcomes were classified into one of three categories: those to do with quality of care; satisfaction of care; and adverse events from which median values and interquartile ranges were calculated.

The studies included were primarily single-centre and consisted of case-control, cross-sectional and cohort studies. Risk of bias was assessed using the Newcastle-Ottowa scale, full details of each study and its risk of bias are in the Supplementary File 5.[48] Overall, although these studies have limited generalisability, there did not appear to be significant cause for concern regarding bias within the limitations inherent in these study designs. Most studies used established or validated tools[17–21,23–25,27,29,30,33–37] or clinical outcomes.[22,26,28,31,32]

The data from the comparative studies suggest that although in many cases infective isolation precautions make little difference to psychological outcomes, where it does make a difference this is primarily negative. There were significant declines in mean scores related to control and self-esteem, and in many studies increases in the mean scores for risk of anxiety and depression. However, these findings were not consistent, and some larger studies showed little or no difference between the groups for these outcomes. These are shown in Figures 1 and 2 respectively.

## [INSERT FIGURES 1 and 2 HERE]

#### Figure 1. Risk ratio of psychological events in those isolated versus not isolated

Figure 2. Standardised mean difference of psychological scores in those isolated versus those not isolated

For the 8 studies reporting data on anxiety the pooled SMD was 1.45 (95% CI: 0.56 to 2.34); although within this there was significant heterogeneity (Q = 168.11, df = 7, p < 0.0001; I<sup>2</sup> = 95.84%). This was primarily caused by two studies [30,34] which showed lower levels of anxiety than the remaining studies. For depression the SMD was 1.28 (95% CI: 0.47 to 2.09); again with significant heterogeneity (Q = 154.5, df = 7, p < 0.0001; I<sup>2</sup> = 95.47%), in this case the studies falling into two categories, those with lower [30,34,35] and higher depression scores among those isolated.[19,20,33,36] The forest plots for these outcomes are shown in Figures 3 and 4 respectively.

Figure 4. Meta-analysis of the standardised mean difference of depression in those isolated versus those not isolated

Page 11 of 60

#### **BMJ** Open

Studies not reporting the raw data showed that contact precautions were associated with depression OR 1.4 (95% CI 1.2 to 1.5) but not anxiety OR 0.8 (95% CI 0.7 to 1.1) in a non-ICU population.[41] There was also an association with delirium OR 1.40 (95% CI 1.24 to 1.51); although this was primarily among those who were newly diagnosed as needing isolation OR 1.75 (95% CI 1.60 to 1.92, p<0.01) rather than those who had been under contact precautions for their entire stay OR 0.97 (95% CI 0.86 to 1.09, p=0.60).[17] Another study showed no difference in the median values for the Hospital Anxiety and Depression Scale anxiety or depression scores (HADS-A and -D), or the EuroQol Visual Analogue Scale EQ VAS scores.[42]

For non-psychological outcomes, using a difference in the risk of +/- 20% of an event as being a measure of clinical significance it appears there was a trend for less attention to be given to, and for more errors to occur in those who were isolated. However, again there was wide variation between studies. Data on these outcomes are given in Figures 5 and 6, and the non-clinically significant risks in the Supplementary Figure 1. For those outcomes associated with quality, the median risk ratio (with positive outcomes reversed so a higher risk ratio is associated with a worse outcome) was 0.94 (IQR 0.92 to 0.98), satisfaction 0.95 (IQR 0.89 to 1.01) and adverse events was 1.27 (0.91 to 2.5). The minimum and maximum risk ratio for each category was 0.49 and 1.72; 0.3 and 8; and 0.3 and 18 respectively.

FIM – functional independence measure

A study not giving raw data which looked at the rates of falls and pressure ulcers before and after a policy change that resulted in the discontinuation of contact precautions for patients with methicillin resistant *Staphylcoccus aureus* (MRSA) or vancomycin resistant enterococci (VRE) found that falls and pressure ulcers were more common among those with MRSA or VRE both before the change (when they were in isolation) and afterwards (when they were not). Before the change the number of falls was 4.57 vs 2.04 per 1000 patient-days respectively (p< 0.0001) and pressure ulcers 4.87 vs 1.22 per 1000 patient-days (p< 0.0001). After the policy change the same numbers were falls 4.82 vs 2.10 (p<0.0001) and pressure ulcers 4.17 vs 1.19 per 1000 patient-days (p<0.0001).[39] Other studies found that staff spent less time with those on contact precautions: internal medicine interns spent less time with their isolated patients compared to non-isolated patients, the median times being 5.2 and 6.9 minutes respectively (p<0.001)[38]; while the mean number of contacts per hour with healthcare workers was 2.1 compared to 4.2 in those not isolated (p=0.03), although the duration was longer at 4.5 minutes compared to 2.8 (p=0.6).[40]

# Discussion

#### **BMJ** Open

Current recommendations say that contact precautions should include a single room, with personal protective equipment consisting of a gown and gloves for all patient contacts or contacts with potentially contaminated environmental areas.[1] This review has shown that there are a number of apparently negative aspects to contact precautions, in particular with regards to psychological effects and a reduction in the quality of some aspects of care. These data come from studies carried out in a variety of countries and different types of facilities; although there are few data from particularly vulnerable populations such as the elderly.

Although at times there are discussions as to the necessity of contact precautions for drug resistant organisms, with some arguing that that there is mixed evidence for or against their use[49] another recent review has concluded that they are of great importance in the control of epidemic and endemic multidrug-resistant microorganisms.[50] The ethics of using contact precautions and other forms of isolation rely on a positive assessment of the balance between the risks and benefits of this to the individual concerned and that of the broader population of patients and staff.[51] However, even when this assessment is positive, it is important to ensure that any harm to the individual is minimised.

One way of balancing the various priorities is to use the GRADE Evidence to Decision Framework, which provides criteria for making recommendations at the individual, group and policy-levels, and provides a number of highly patient focussed criteria for doing this. In addition to the certainty of evidence and resource requirements, it also requires consideration of: the balance of desirable and undesirable effects; the impact upon equity; and the feasibility and acceptability of the

#### **BMJ** Open

intervention.[52] The last two of these might have very different outcomes when considered at the population and individual levels; and there is certainly evidence here that for the individual patient the balance of desirable and undesirable effects might be very different to that of the broader population.

However, within the broad population of infected or potentially infected patients, some groups might have different needs. For example a study of people isolated for MERS found that while access to telephones reduced anxiety and anger; access to email, text and internet increased these.[53] This was not an area investigated in any depth in these studies. Another area where information may be lacking is that of age, as older people in particular might feel sadness and loneliness more; and gender, as qualitative data suggest that women in isolation were more concerned about precautions and transmission while men were more resigned, rational and tended to cope better.[54]

In some countries, such as the United States single-rooms have become the standard for new hospitals and so one might expect fewer adverse effects if everyone is in a single room, this being the norm. However it may be that a single room is necessary but not sufficient for these findings, and that it is the combination of a single room with an infection that leads to these results. Certainly it is far from clear that the long list of advantages claimed for single rooms which include reduced stress, the ability to deliver better care, and a lower probability of dietary or medication errors apply to this group of patients.[55]

Page 15 of 60

#### **BMJ** Open

Caring for patients in single-rooms does have many challenges, but there is evidence that these can be mitigated in a general population;[9] however the expanding literature on how this can be done in a general population does not necessarily apply here due to the necessity of isolation procedures which are, by design, 'a barrier'. Therefore patients' needs for greater social interaction will need a solution quite different from that which might be used for a different patient population, and the benefit of choice about this which single rooms offer does not apply here.[56]

Although this review has quantified the extent of the problem, we have not been able to find solutions in the literature. Care might be improved through increased staff attention with more resources being allocated to these patients, although the extra cost of contact precautions is already considerable, one estimate being that it was an extra \$158.90 (95% CI \$124.90 to \$192.80) per patient day.[57] Alternatively new ways of working might be developed, perhaps using technology to mitigate some of these problems. Technology might be particularly useful in reducing adverse events such as medication or clinical errors; although increasing satisfaction and some areas of quality are more likely to be achieved by increasing the availability of staff and other people. The extent to which scarce resources are allocated to this may be driven in part by the longevity of any negative effects; which current literature is not really able to clarify. To understand this longituduinal studies are needed.

### Study strengths and limitations

This review suggests that infectious isolation has a number of negative effects on patients. Because this evidence is comprised of cohort and case-control studies, a claim for a causal relationship can not be made on this evidence, although the strong

#### **BMJ** Open

and consistent effects across the studies may increase the confidence in this relationship. There are some qualitative data, although more in-depth mixed-methods data where those reporting negative effects are questioned about them would strengthen the evidence on this. In some cases large effect sizes were accompanied by very wide confidence intervals, suggesting that studies were underpowered, thus studies with larger sample sizes would be useful. It would also be useful if there were more consistent methods of examining and reporting these data, particularly outside of the realms of depression and anxiety where the variety of methods makes analysis of the body of evidence difficult. We were also unable to assess whether these effects varied according to reason for isolation; or to understand if they are likely to be longterm or simply temporary phenomena.

Although these data suggest that there is a problem, there is a clear gap both in what we know about improving the experience of isolation and what can be done in practical terms to make it more tolerable for patients and their families. In particular older people who may be most vulnerable to these negative effects were underrepresented in these studies; and this group are likely to represent an increasingly large proportion of those isolated.

#### **Contributors**

EP, DG and JC conceived the review, EP conducted the search, EP and DG examined the studies and extracted data, EP undertook the quantitative analysis, EP, DG and JC wrote the discussion.

#### Characteristics of studies

Reference	Study type	Isolated	Non isolated		
Colorado (2014)	Retrospective matched case control study. Rehabilitation facility- tertiary centre United States July 2009 to December 2010	N20 Patients in contact isolation	N=20 Matched to patients not in contact isolation based on age, rehabilitation diagnosis, and type of insurance		
Croft (2015)	Prospective cohort Medical or surgical inpatients admitted to non–intensive care unit hospital wards, United States. January to November 2010.	N=148 Patients on contact precautions Age: 52 (13.8) % male: 53.4	N=148 Individually matched by after an initial 3-day length of stay to patients not on contact precautions. Age 52.3 (14.6) % male: 46.6 2467 encounters		
Dashiell- Earp (2014)	Collected real-time data on the location of 15 internal medicine interns, United States. October 1, 2012 to December 31, 2012	1156 encounters			
Day (2011)	Patients admitted to the general acute care units, United States. June 1, 2009 to October 30, 2009	N=20 Age: 68.5 (14.7) % male: 85.0	N=83 Age: 63.9 (12.6) % male: 95.2		
Day (2011)	A two-year retrospective cohort Tertiary care, United States All general inpatients over 18 years hospitalized for >24 h February 1, 2007 to January 31, 2009.	Contact precautions private room when possible, can be cohorted General N = 3138 Age: 51.2 (17.5) % male 58.9 ITU N=1694 Age: 54.9 (17.5) % male 61.0	General N = 25 426 Age: 49.6 (19.0) % male 46.3% ICU N = 5 854 Age: 56.0 (17.7) % male 59.7		
Day (2012)	2-year retrospective cohort study of all non-psychiatric hospital admissions >18 years, United States. February 1, 2007 to January 31, 2009	N = 9 684 Contact precautions as above Mean age: 50.1 (18.8) % male 51.4	N = 50 458 Mean age: 52.3 (16.9) % males 59.1		
Day (2013)	Longitudinal frequency-matched cohort study of patients admitted to general medical and surgical units, United States. Day 0, day 3 then weekly. January to November 2010	N = 148 Mean age: 52.0 (13.9) % male 58.1	N = 148 Mean age: 52.3 (14.6) % male 50.7		

Evans (2003)	Prospective observation; survey; retrospective review, United States. Tertiary care. June and July 2001	N 48 Mean age: 47.8 (2) % male 85%	N = 48 Mean age: 58.3 (2.4) % male 75%		
Findink (2012)	Non-random quasi-experiment, Turkey Age 18 to 65 Administered day 5 January 1, 2009 to December 31, 2009	N = 60 Mean age: 53.95 (18.4) % male 75%	N = 57 Mean age: 56.14 (17.1) % male 76.3%		
Gammon (1998)	Quasi experiment Selected if last two numbers on their case notes even. Two large District General Hospitals and one elderly care hospital, United Kingdom	N = 20 Placed in isolation for a minimum of 7days Mean age: 61 years % male: 65	N = 20 Mean age: 52 years % male: 55		
Gandra (2014)	Retrospective hospital-wide cohort study, United States. All patients admitted to medical-surgical inpatient units November 1, 2009 to October 31, 2011	Falls N=77 Mean age: 66.1 (14.3) % male: 61% Pressure ulcers N=82 Mean age: 64.5 (15.5) % male: 63	Falls N=82 Mean age: 63.7 (15.8) % male: 51 (62%) Pressure ulcers N=71 Mean age: 65.7 (15) % male: 57		
Guilley- Lerondeau (2017)	Matched cohort study with prospective inclusions Interview 3 days after commencing General sample. France March to July 2012	N=30 First prescription of isolation precaution Median age (range) 69 (32 to 91) % male 47	N=60 Median age (range) 64 (24 to 91) % male 53		
Kennedy (1997) Cross-sectional matched-control study, United Kingdom. May 1994 to November 1996		N = 16 Isolated as a result of being MRSA Mean age: 31.1 All male	N = 16 Matched for age, sex, level of injury, and time since admission or injury		
Kirkland (1999)	Observational study - 7 months Medical intensive-care, United States	N=14	N=21		
Lau (2016) Prospective cohort study. Adult patients discharged from internal medicine wards, Canada October 2013 to November 2014,		N=75 Mean age 60.35 (17.83) % male 59	N=420 Mean age 63.31 (18.69) % male 48%		
Livorsi (2015)	Case-control study Retrospective January 1, 2012 to	N = 70 On contact precautions for MRSA throughout	N = 139 No significant differences between isolated a

------	----	----	----

	May 31, 2012/prospective June 1, 2012 to March 31, 2013 'safety-net facility', United States	their hospital stay. Found to be MRSA positive during a previous hospitalization or as an outpatient, not current case	non-isolated patients
Lupión- Mendoza (2015)	Matched case-control study Tertiary hospital, Spain 2011 and 2012	N = 72 Adult patients admitted in isolation for =>5 days. Median age (range) 62 (21-93) % male 73%	N = 72 Median age (range) 69 (23-89), % male 68.1%
Massee (2013)	Retrospective case-control Tertiary care, Canada	N = 111 Matched MRSA patients with an admission diagnosis of heart failure or COPD to similar non-isolated controls Median age (IQR) 80.0 (69.0-86.0) % male 60.4%	N = 111 Median age (IQR) 80.0 (68.0–86.0) % male 60.4%
Mehrotra (2013)	Prospective cohort Admission and on days 3, 7, 14 Tertiary centre, United States	N = 238 Segregation into a private or cohorted room Mean age (SD) 52.4 (13.4) % male 55.7	N = 290 Mean age (SD) 52.9 (14.8) % male 48
Saint (2003)	Prospective cohort study 2 university-affiliated medical centers, United States. October 1999 to March 2000	N=31	N=108
Soon (2013)	Cross-sectional survey of cases and matched controls Teaching hospital Singapore June and August 2011	N=20 Contact isolation in a cohort cubicle for the first time because of colonization or infection with a MDRO for at least 3 days No statistically significant differences in age or gender	N=20
Spense (2011)	Retrospective evaluation of incident reports All patients admitted to acute care facility, United States January 1, 2008 to December 31, 2008.	N=45	N=256
Stelfox (2003)	Case control study Consecutive adults isolated for at least 2 days with MRSA. Canada and United States Controls patients admitted before	General N = 78 Age: 69.6 (17.1) % male: 45% CHF N = 72 Age: 66.9 (14.7)	General N = 156 Age: 65.4 (18.2) % male: 51% CHF N = 144 Age: 66.0 (14.5)

	and after. January 1, 1999,to January 1, 2000	% male: 58	% male: 54
Tarzi (2001)	Cross-sectional matched case-control study Care of the elderly rehabilitation wards, UK	N = 22 Had been in isolation for at least two weeks with MRSA Mean age (SD) 80 (8.4) % male 27.3	N = 20 Mean age (SD) 81 (9.1) % male 33.3
Tran (2017)	Propensity matched cohort study. General internal medicine services, 3 hospitals, Canada January 2010 to December 2012	MRSA Age: 69 % male 57% Respiratory Age: 71.7 % male: 53 Isolated for MRSA or respiratory illness	MRSA Age: 69 % male 58% Respiratory Age: 70.6 % male: 55
Wassenburg (2010)	Cross-sectional matched cohort study Single university hospital, Netherlands November 2006 to February 2007	N = 42 Age: 52 (19) % male: 52	N = 84 Age: 55 (16) % male: 55

3) <u>Adequacy of follow up of cohorts</u> a) complete follow up - all subjects accounted for * b) subjects lost to follow up unlikely to introduce bias - small number lost -> 90 % follow up, or description provided of those lost) * c) follow up rate < 90% and no description of those lost d) no statement	*		37/278 contact; 51/290 non	*	*		*	*

General notes

Community - the population of interest was a hospital population

Time to outcome of interest - question is regarding outcome during isolation or shortly afterwards

# PRISMA 2009 Checklist

Section/topic	#	Checklist item	Reported on page #
TITLE	<u> </u>		
Title	1	Identify the report as a systematic review, meta-analysis, or both.	1
ABSTRACT			
Structured summary	2	Provide a structured summary including, as applicable: background; objectives; data sources; study eligibility criteria, participants, and interventions; study appraisal and synthesis methods; results; limitations; conclusions and implications of key findings; systematic review registration number.	1-2
INTRODUCTION			
Rationale	3	Describe the rationale for the review in the context of what is already known.	3
Objectives	4	Provide an explicit statement of questions being addressed with reference to participants, interventions, comparisons, outcomes, and study design (PICOS).	4-5
METHODS			
Protocol and registration	5	Indicate if a review protocol exists, if and where it can be accessed (e.g., Web address), and, if available, provide registration information including registration number.	5
Eligibility criteria	6	Specify study characteristics (e.g., PICOS, length of follow-up) and report characteristics (e.g., years considered, language, publication status) used as criteria for eligibility, giving rationale.	5
Information sources	7	Describe all information sources (e.g., databases with dates of coverage, contact with study authors to identify additional studies) in the search and date last searched.	5
Search	8	Present full electronic search strategy for at least one database, including any limits used, such that it could be repeated.	Suppl information
Study selection	9	State the process for selecting studies (i.e., screening, eligibility, included in systematic review, and, if applicable, included in the meta-analysis).	5
Data collection process	10	Describe method of data extraction from reports (e.g., piloted forms, independently, in duplicate) and any processes for obtaining and confirming data from investigators.	5
Data items	11	List and define all variables for which data were sought (e.g., PICOS, funding sources) and any assumptions and simplifications made.	5
Risk of bias in individual studies	12	Describe methods used for assessing risk of bias of individual studies (including specification of whether this was done at the study or outcome level), and how this information is to be used in any data synthesis.	7
Summary measures	13	State the principal summary measures (e.g., risk ratio, difference in means).	6-7
Synthesis of results	14	Describe the methods of handling data and combining results of studies, if done, including measures of consistency (e.g., I <sup>2</sup> ) for each meta-analysis. For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml	6-7

# **PRISMA 2009 Checklist**

Page 1 of 2

		1466 1 01 2	
Section/topic	#	Checklist item	Reported on page #
Risk of bias across studies	15	Specify any assessment of risk of bias that may affect the cumulative evidence (e.g., publication bias, selective reporting within studies).	7-8
Additional analyses	16	Describe methods of additional analyses (e.g., sensitivity or subgroup analyses, meta-regression), if done, indicating which were pre-specified.	None
RESULTS			
Study selection	17	Give numbers of studies screened, assessed for eligibility, and included in the review, with reasons for exclusions at each stage, ideally with a flow diagram.	6
Study characteristics	18	For each study, present characteristics for which data were extracted (e.g., study size, PICOS, follow-up period) and provide the citations.	Suppl information
Risk of bias within studies	19	Present data on risk of bias of each study and, if available, any outcome level assessment (see item 12).	Suppl information
Results of individual studies	20	For all outcomes considered (benefits or harms), present, for each study: (a) simple summary data for each intervention group (b) effect estimates and confidence intervals, ideally with a forest plot.	Figures
Synthesis of results	21	Present results of each meta-analysis done, including confidence intervals and measures of consistency.	None
Risk of bias across studies	22	Present results of any assessment of risk of bias across studies (see Item 15).	8-9
Additional analysis	23	Give results of additional analyses, if done (e.g., sensitivity or subgroup analyses, meta-regression [see Item 16]).	None
	1		
Summary of evidence	24	Summarize the main findings including the strength of evidence for each main outcome; consider their relevance to key groups (e.g., healthcare providers, users, and policy makers).	8-11
3 Limitations	25	Discuss limitations at study and outcome level (e.g., risk of bias), and at review-level (e.g., incomplete retrieval of identified research, reporting bias).	14
Conclusions	26	Provide a general interpretation of the results in the context of other evidence, and implications for future research.	14
	<u> </u>		
Funding	27	Describe sources of funding for the systematic review and other support (e.g., supply of data); role of funders for the systematic review.	None
