Example demo files (main.csv & pathway.csv) provided

Figure S1. Proteomic differences between fresh and cryopreserved samples. **(A)** Antibodies from the RPPA were grouped into 31 functional groups (shown as rows), and cluster analysis (Progeny Clustering with K-means) was performed using all samples (fresh and cryopreserved) to identify recurrent functional patterns (shown as columns). Functional patterns that only occur in cryopreserved samples (missing in fresh) were colored in black, whereas patterns that only occur in fresh samples (missing in cryo) were colored in grey. **(B)** Proteins from the *Adhesion group* were shown as an example to demonstrate varied expression distributions by sample source (i.e. peripheral blood (labeled “PB”) or bone marrow (labeled “BM”)) and processing technique (whether protein was prepared from fresh or previously cryopreserved cells (labeled “Cryo”)). The protein expression distributions in cryopreserved bone marrow CD34+ cells from healthy subjects (labeled “CD34+”) were also shown in comparison. See **Table S1** for the functional group category and sample source comparison statistics for each protein.

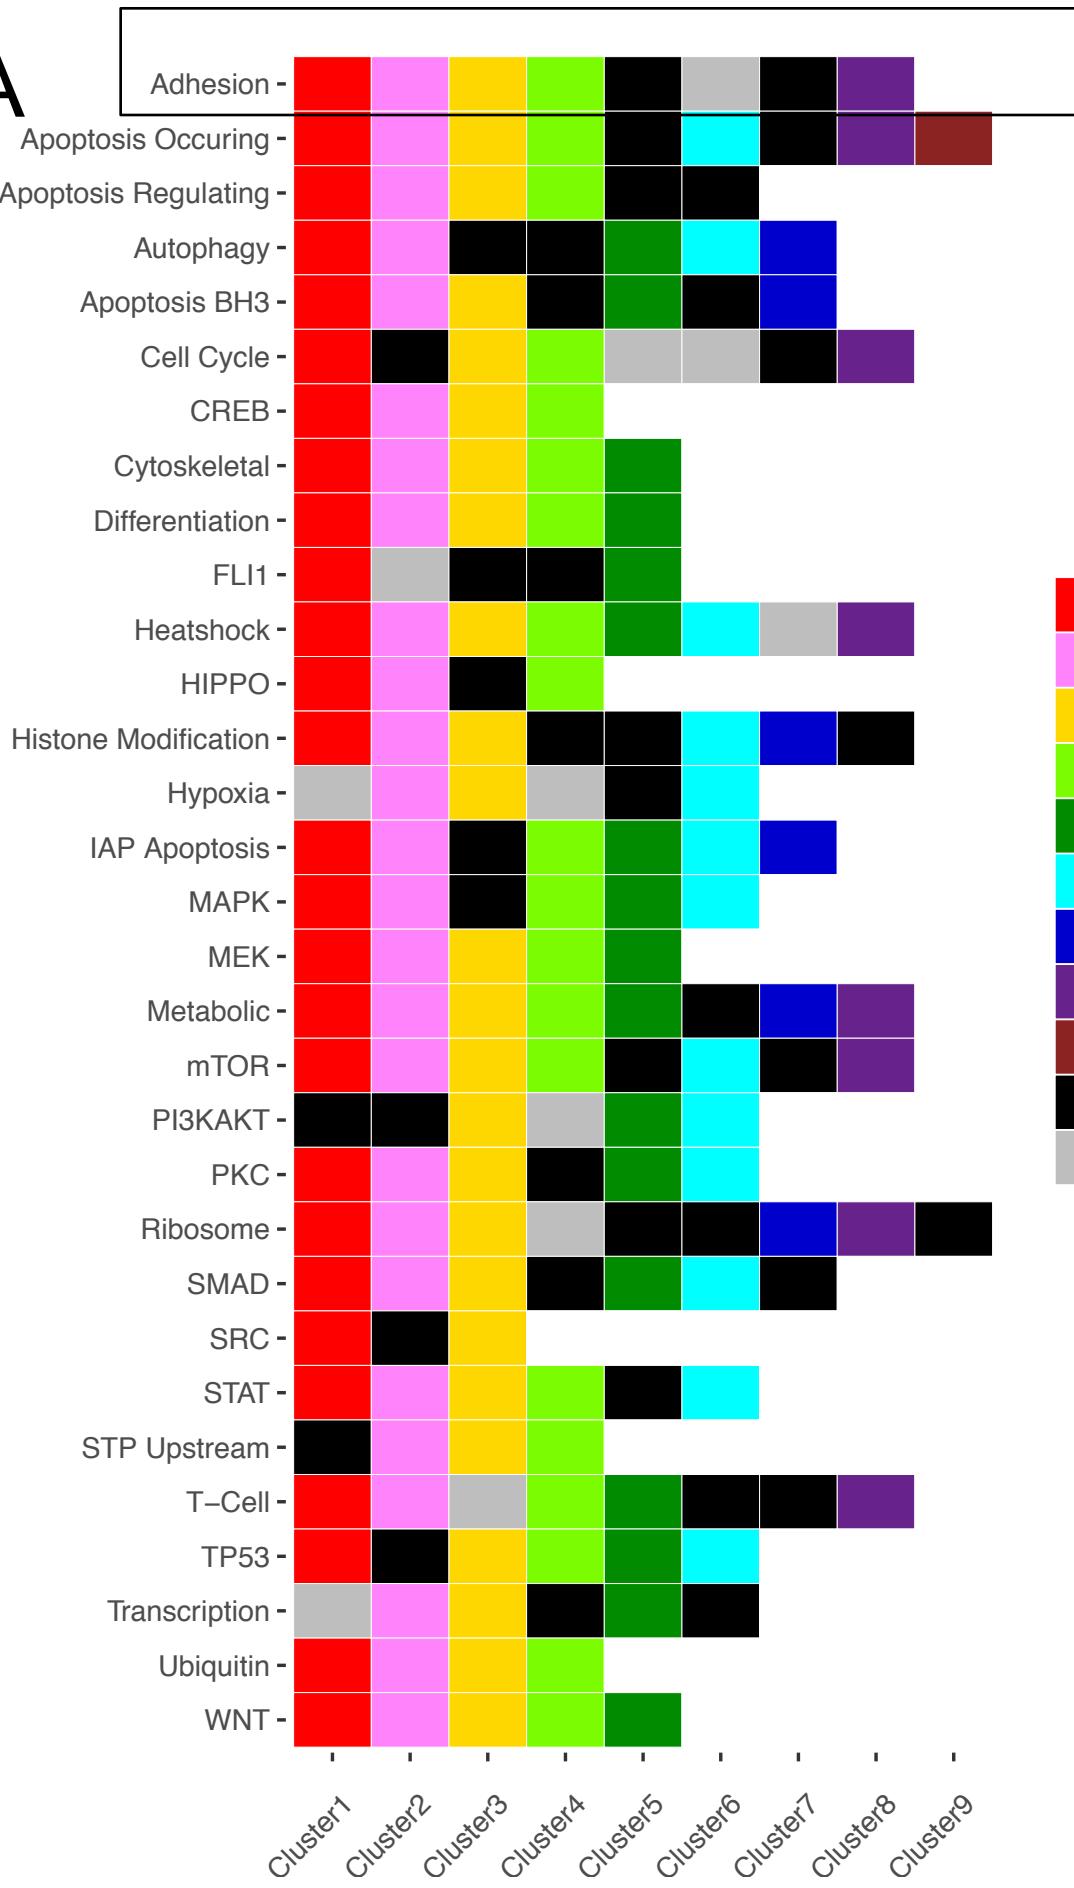

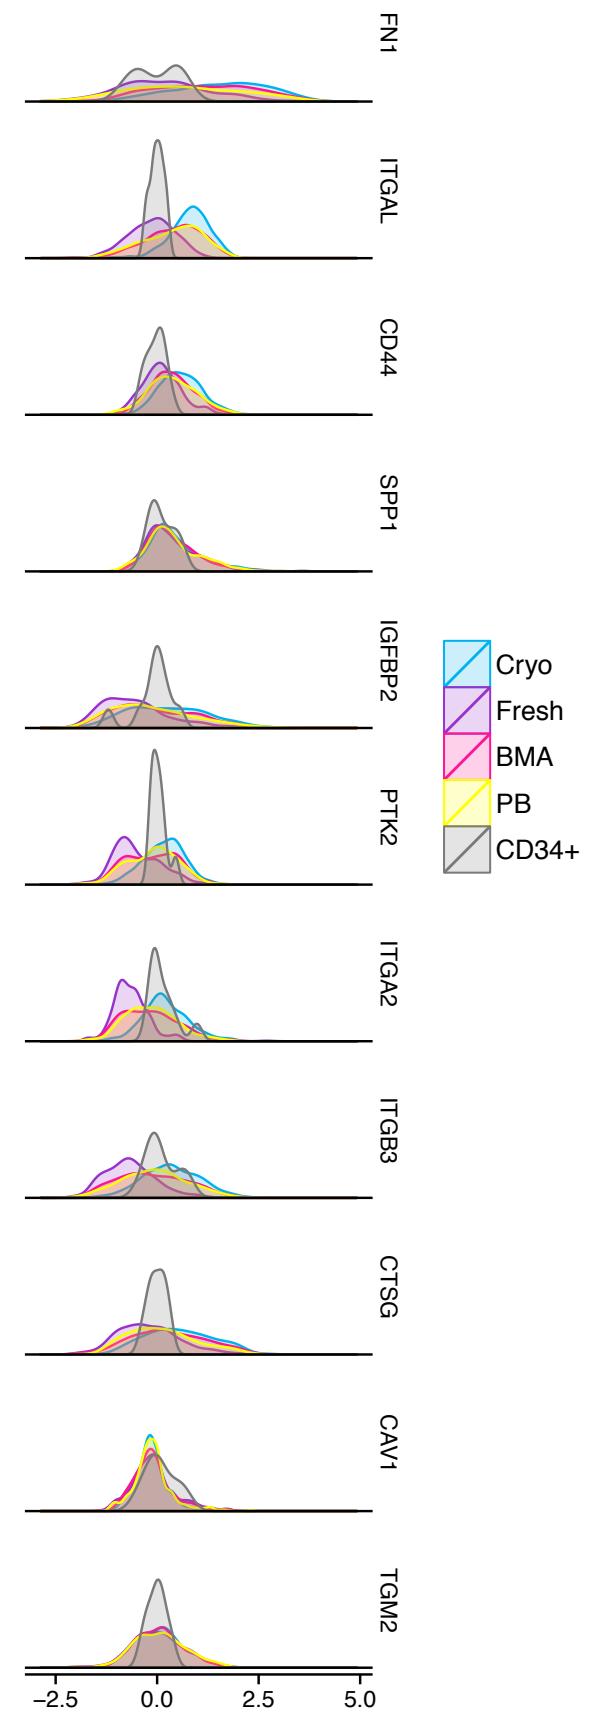

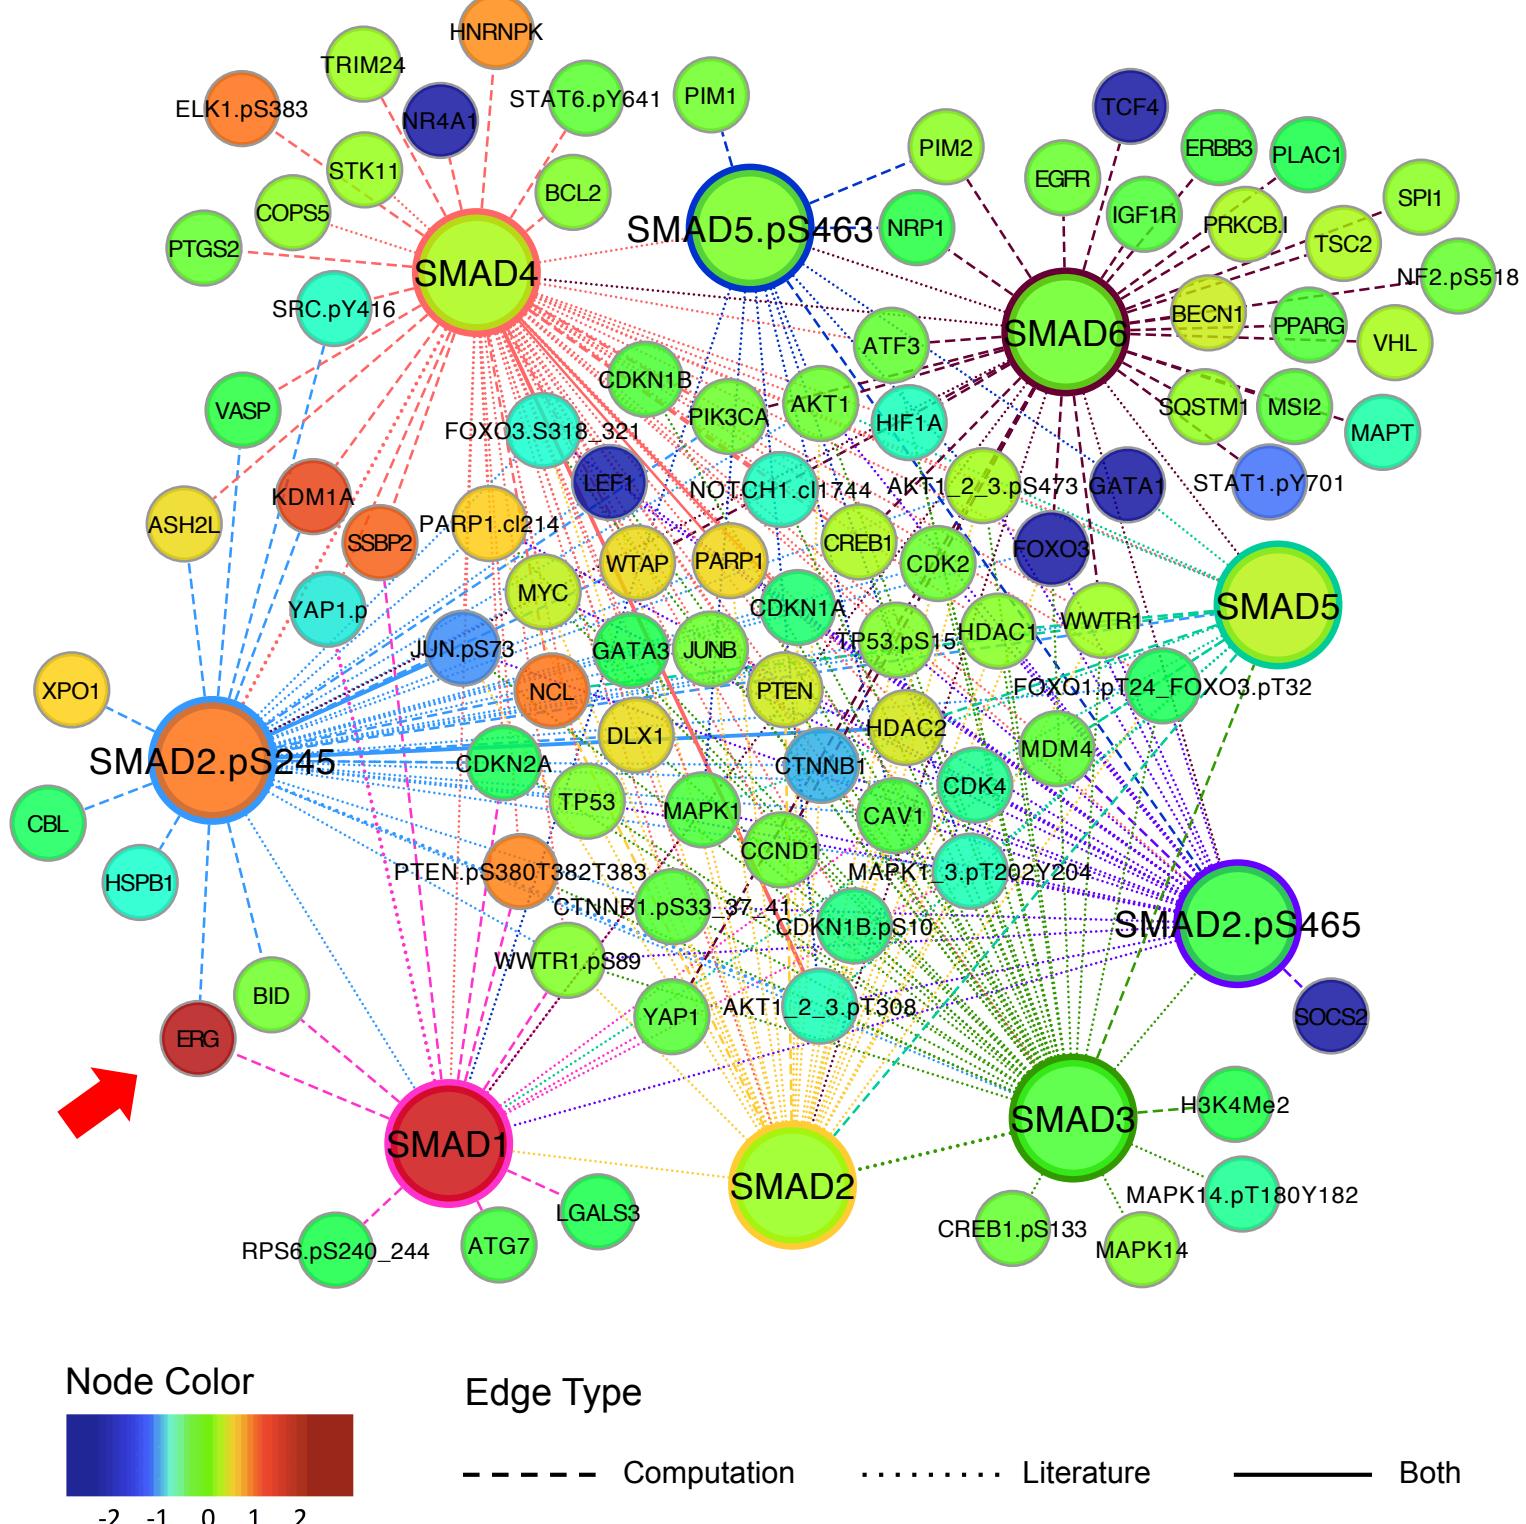

A**B**

Figure S2. Protein networks for discovering potential drug targets beyond individual functional groups. **(A)** The protein network for SMAD-P5 demonstrates the interactions (shown as edges) and expression levels (shown as node colors) of the SMAD proteins (shown in large nodes) and proteins that directly associate with them (shown in small nodes). Highlighted by a red arrow, ERG with abnormally high expression level can serve a potential drug target as an alternative to targeting SMAD2.p and SMAD1. **(B)** Proteins with abnormally high and low expressions compared to the normal range were selected and can potentially be tested as drug targets. The node color reflects the relative expression levels compared to that in control samples.

A

B

Figure S3. Results from clustering patients based on protein expression levels. **(A)** Clustering results of patients (columns) using k-means clustering, where proteins (rows) were ordered based on hierarchical clustering with ward linkage. **(B)** Patients' overall survival based on the k-means clustering memberships (p -value = 0.23). **(C)** Patients' remission duration based on the k-means clustering memberships (p -value = 0.4). **(D)** Clustering results using hierarchical clustering with ward linkage, where columns are patients and rows are proteins. **(E)** Patients' overall survival based on the hierarchical clustering memberships (p -value = 0.47). **(F)** Patients' remission duration based on the hierarchical clustering memberships (p -value = 0.42). The clusters identified by both k-means and hierarchical clustering are less prognostic in comparison to the clustering generated with the MetaGalaxy analysis (see **Figure 4**), in which the signatures are prognostic for overall survival (p -value = 0.00009) and remission duration (p -value = 0.03). $n = 205$ for all graphs. p -values shown for log-rank test, one-sided.

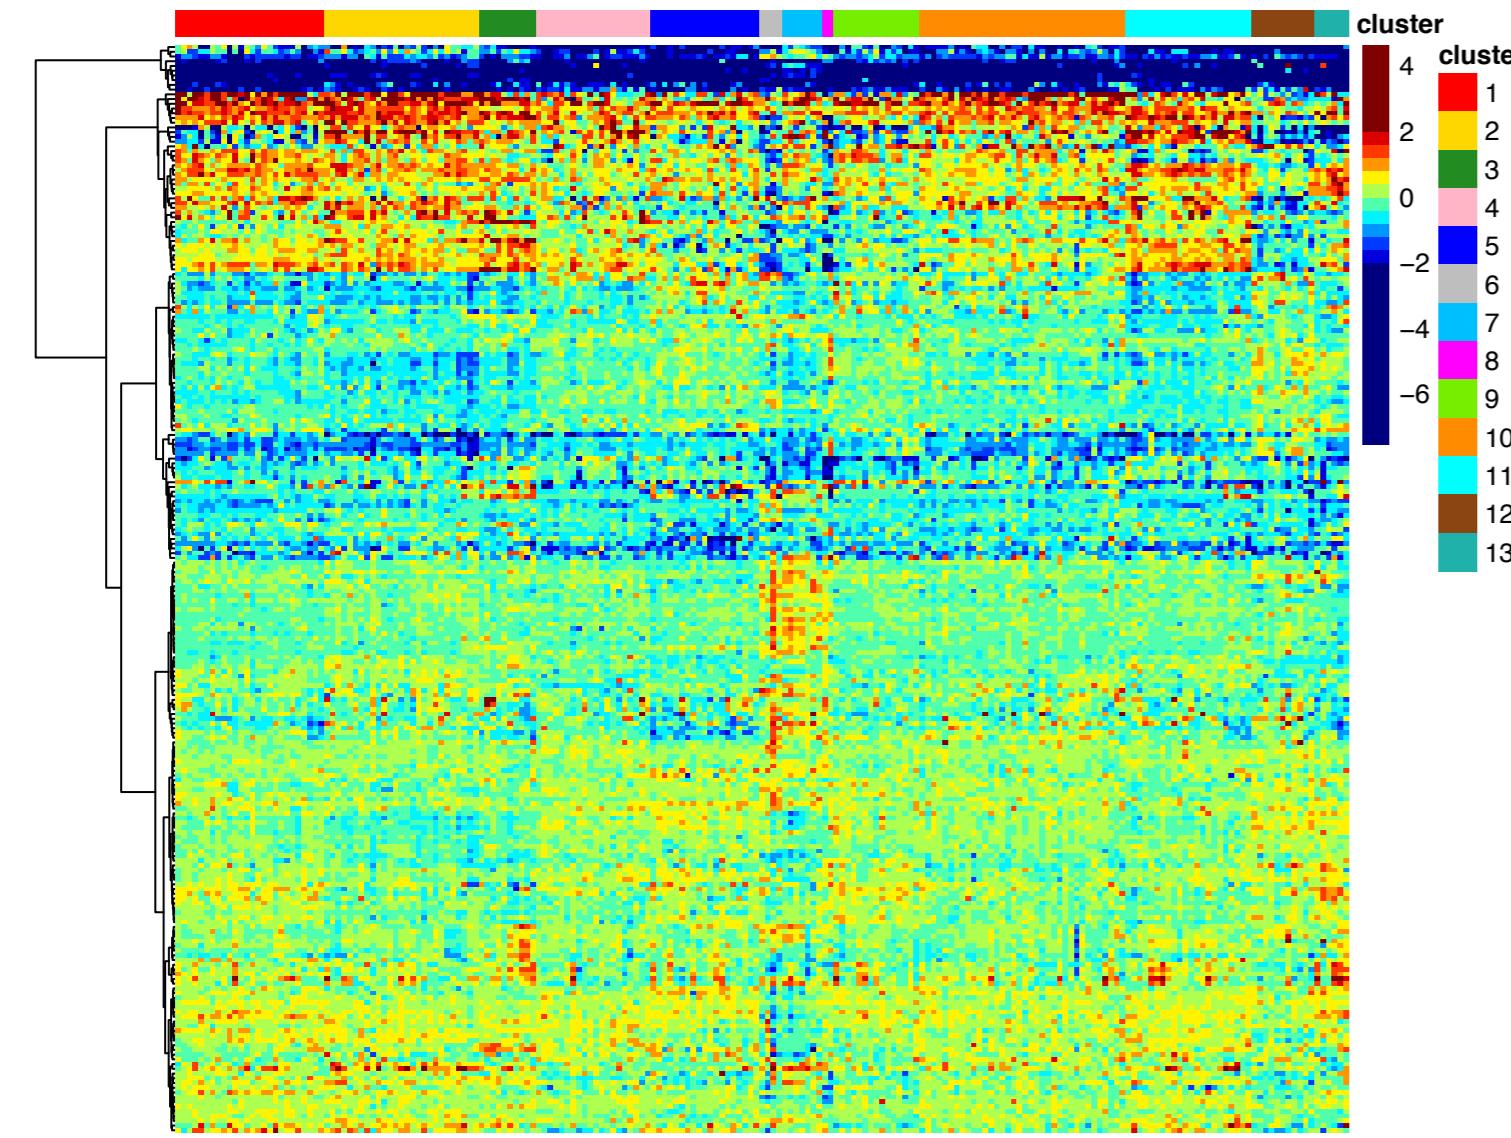

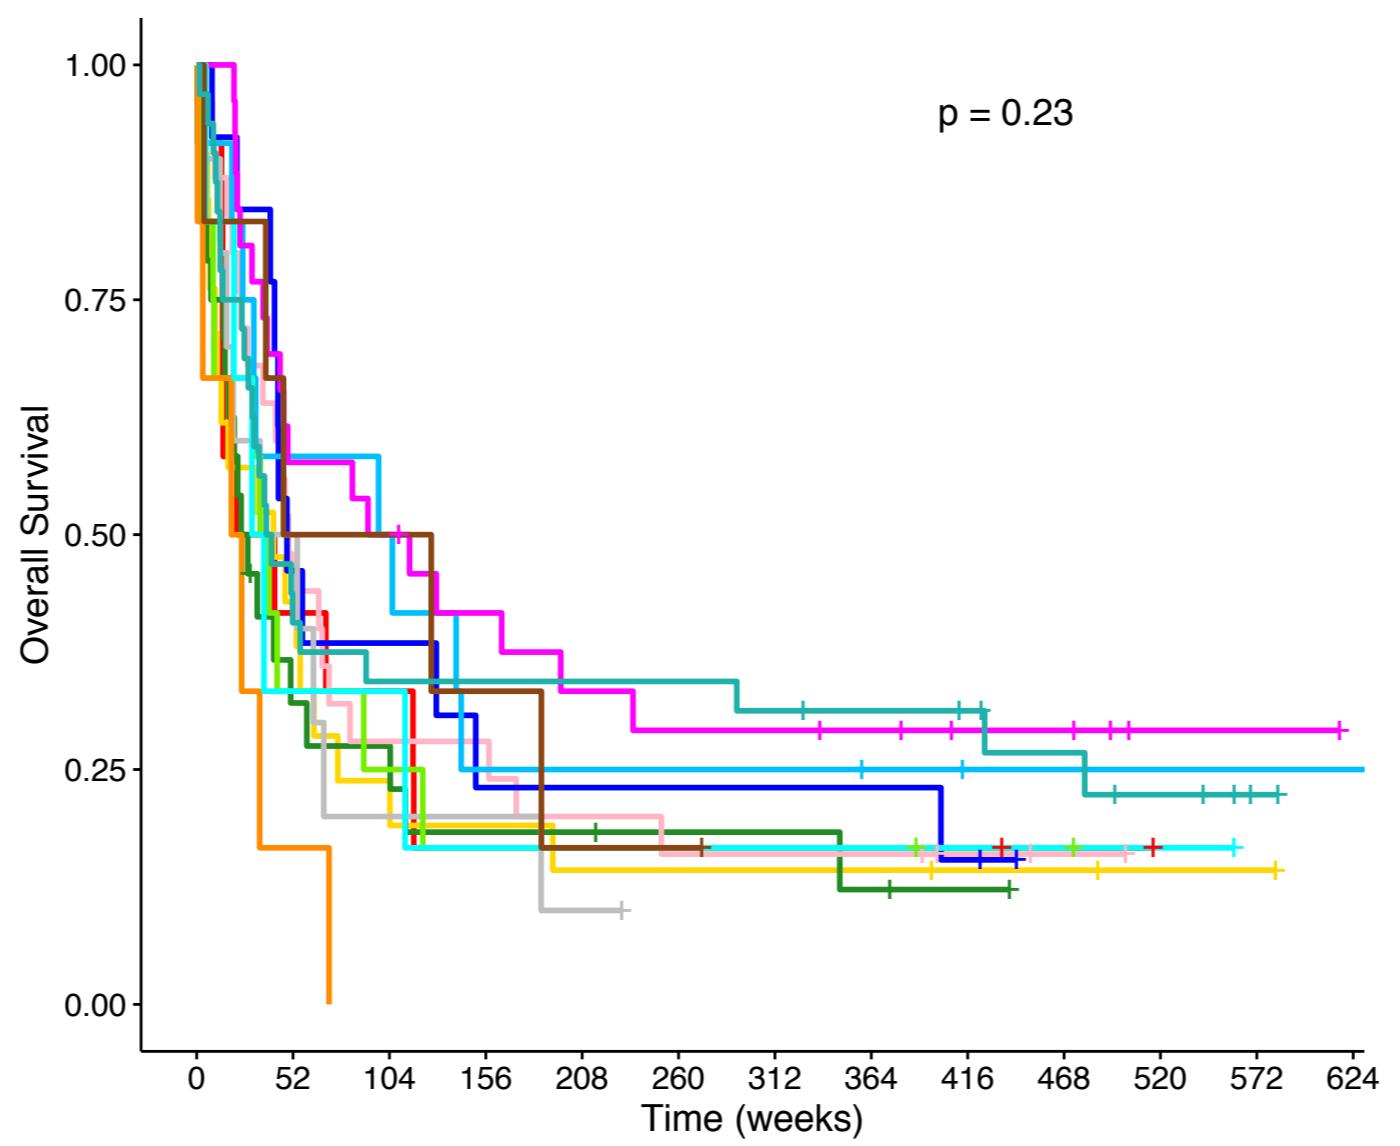

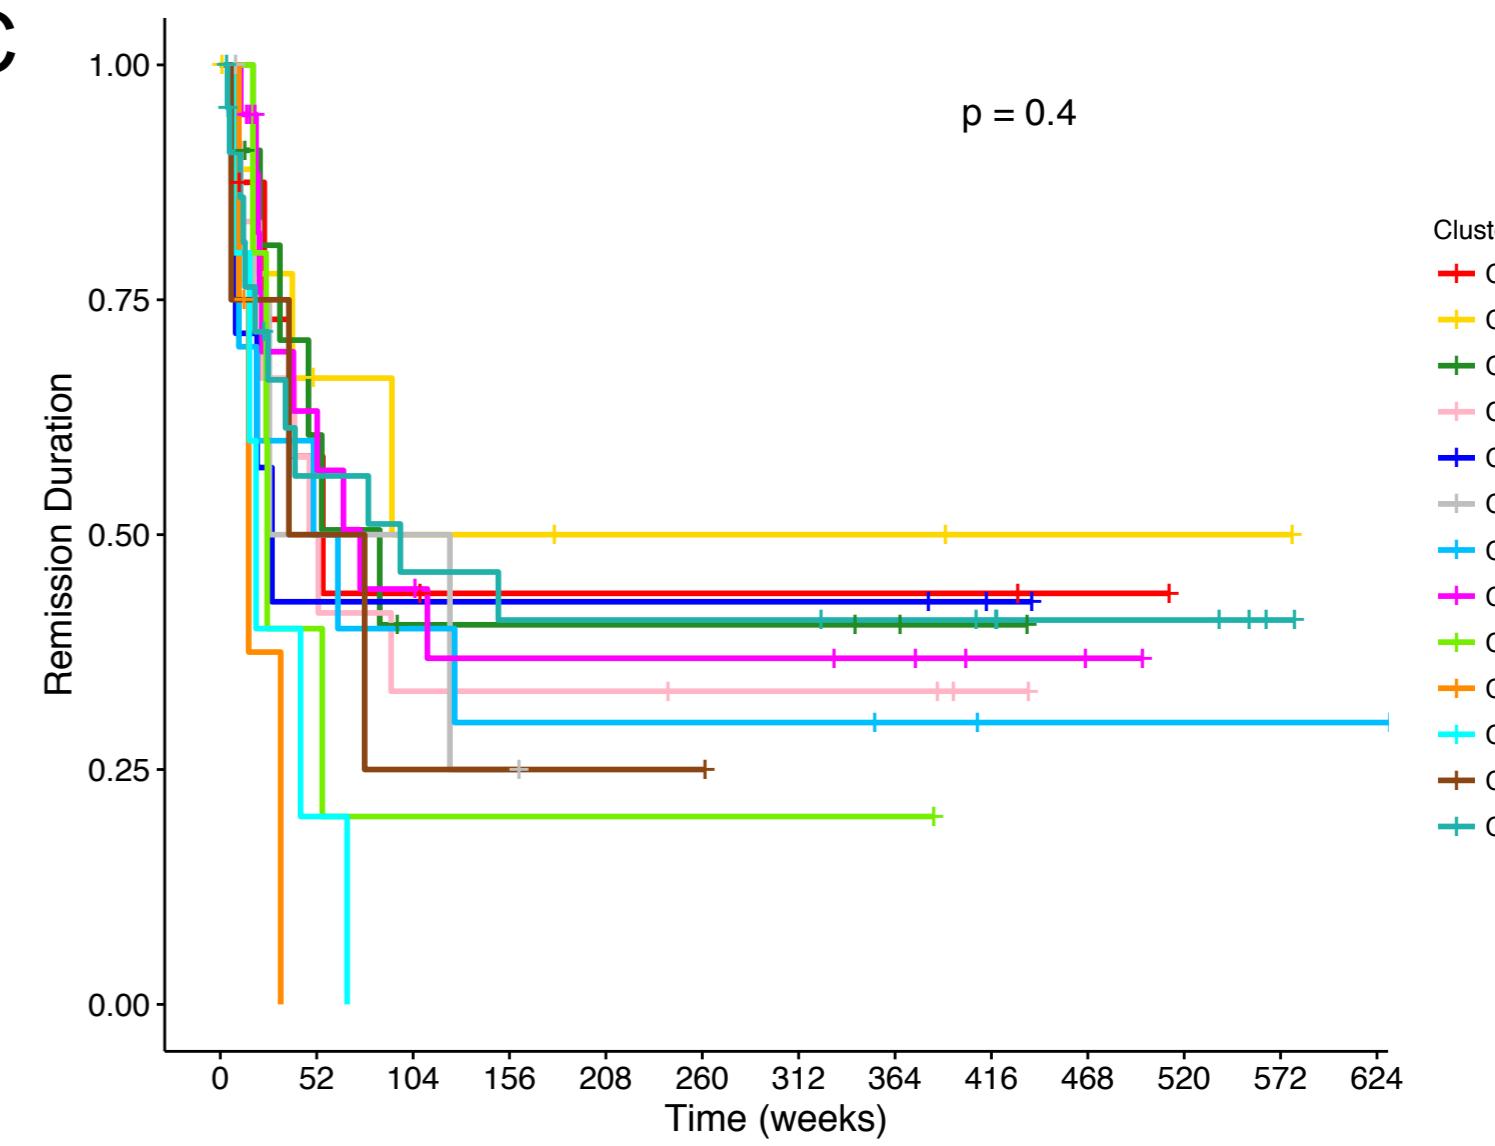

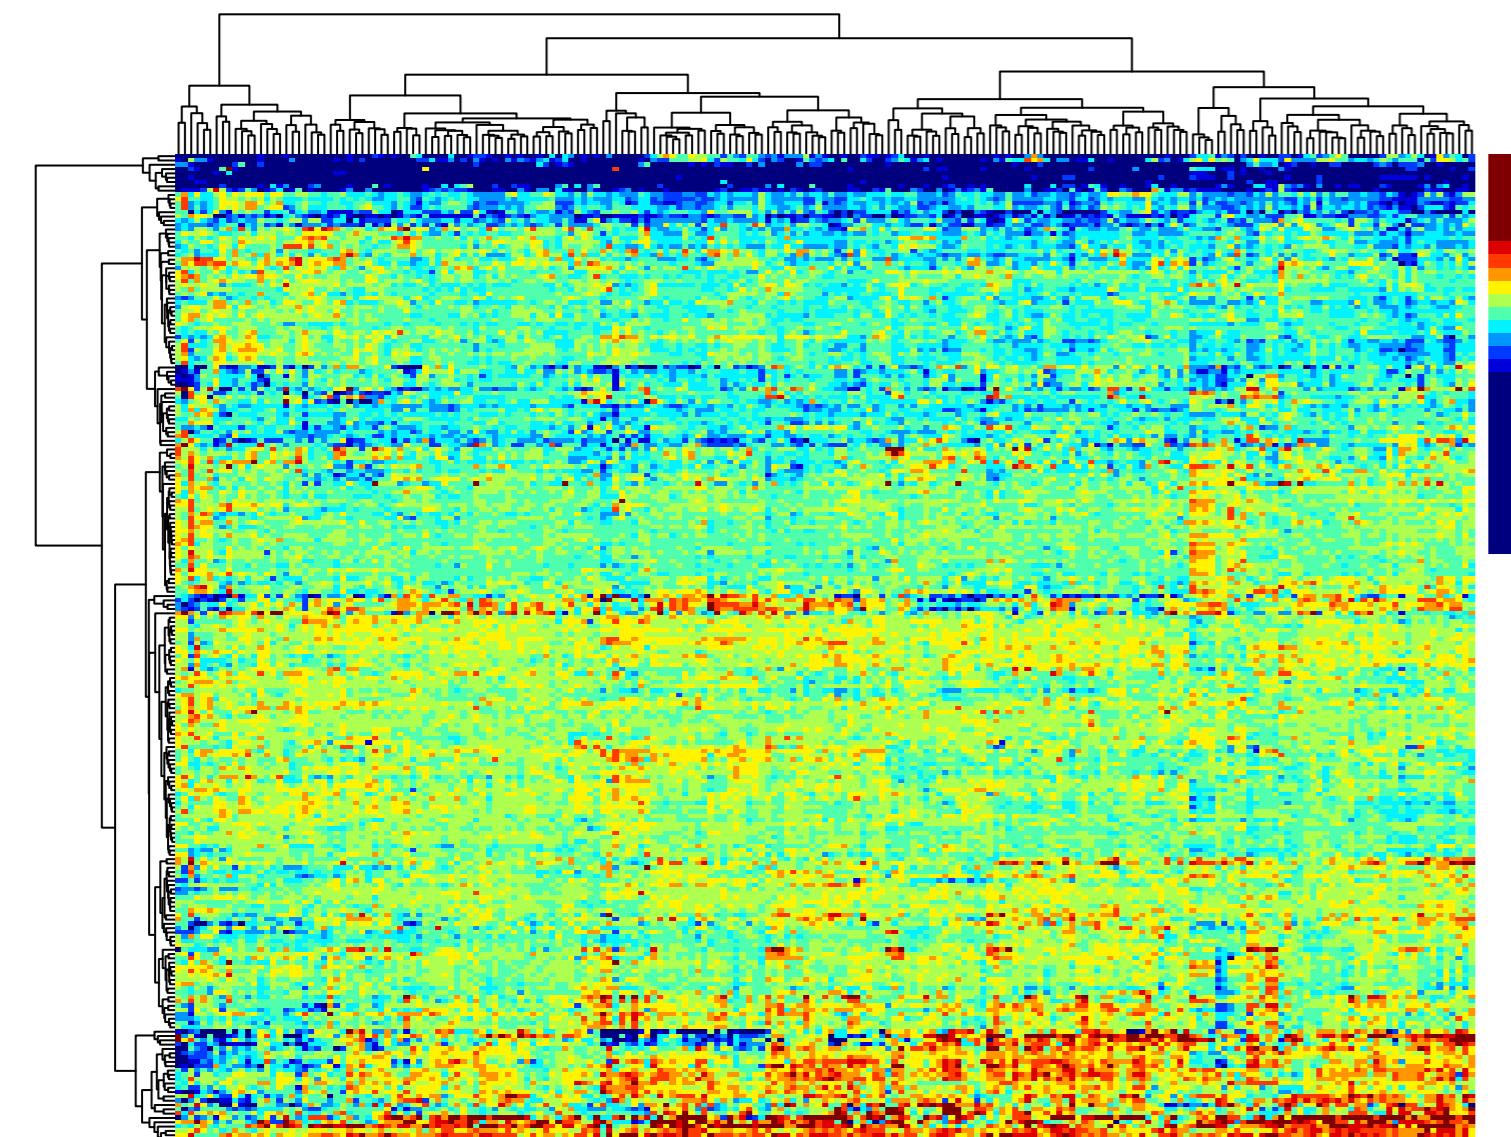

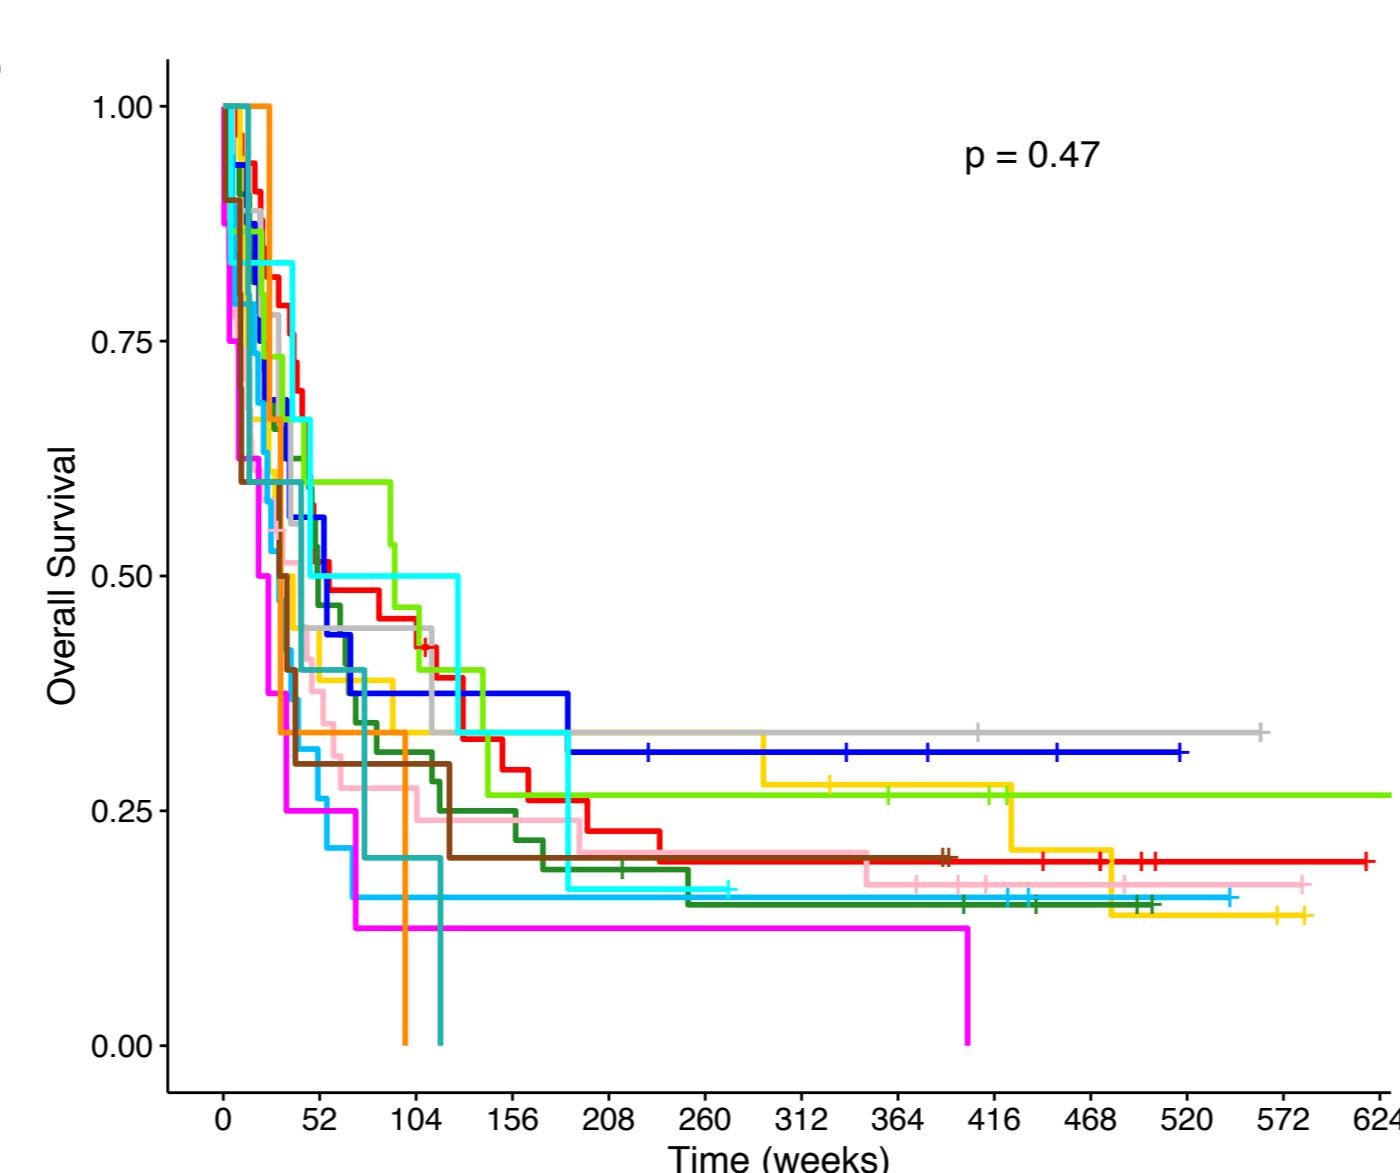

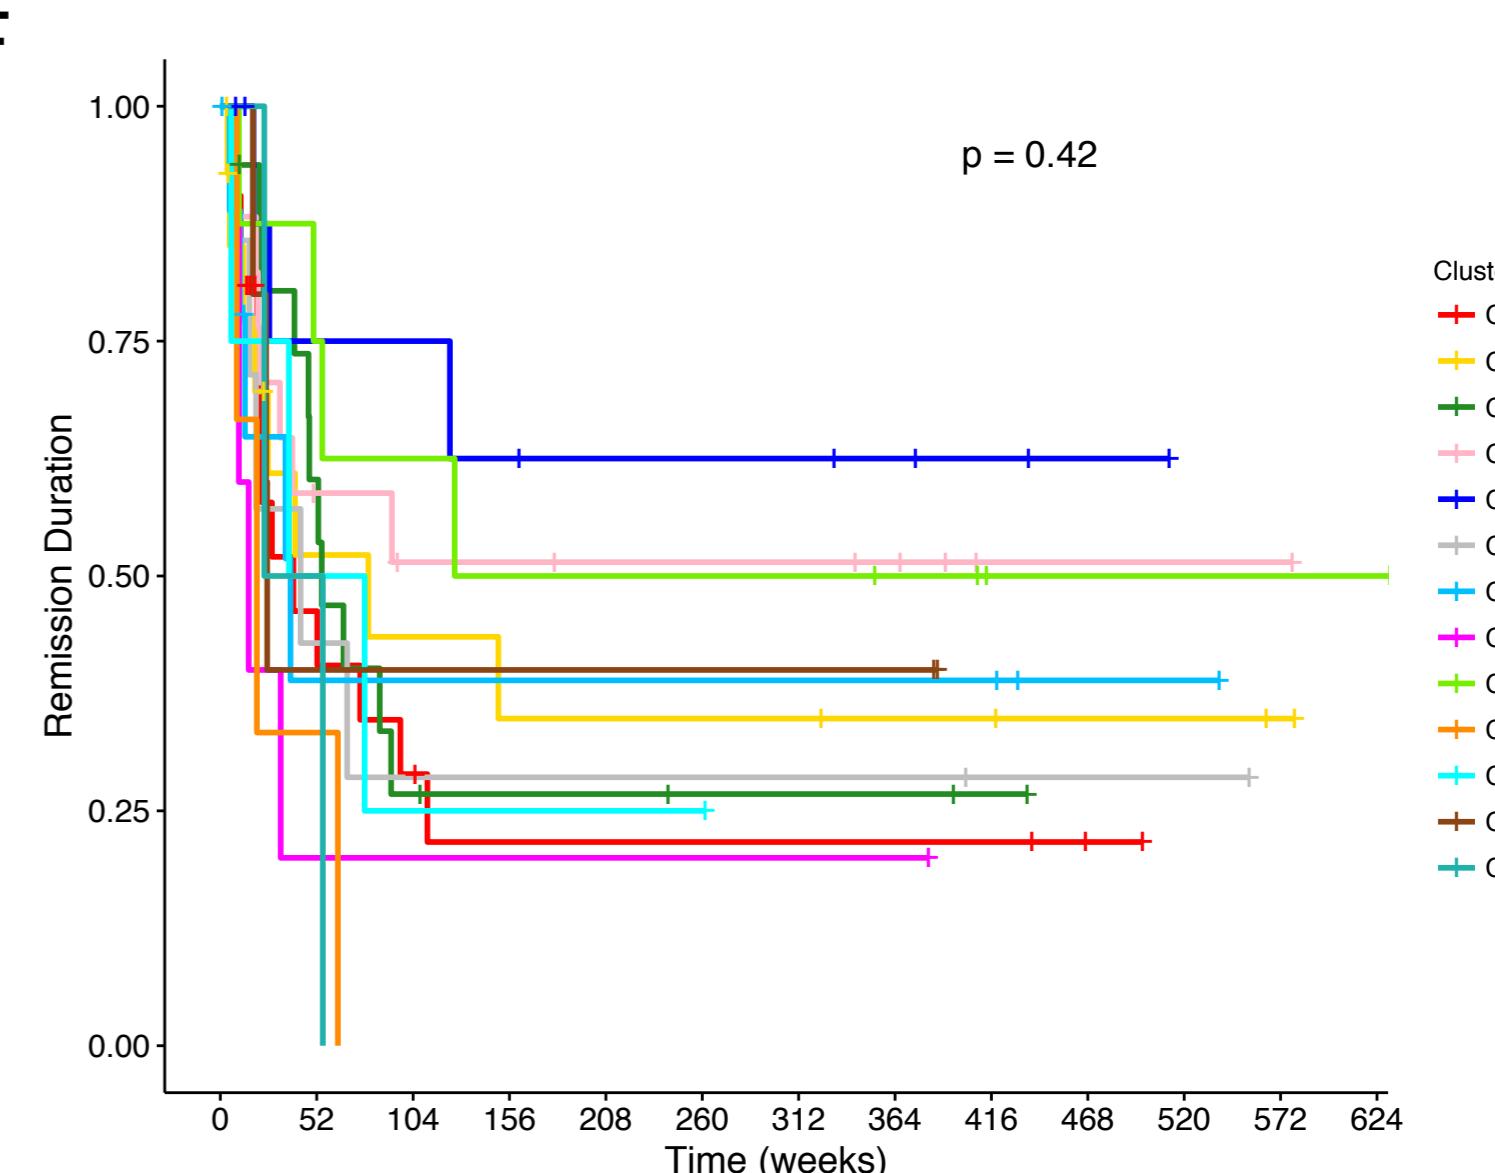

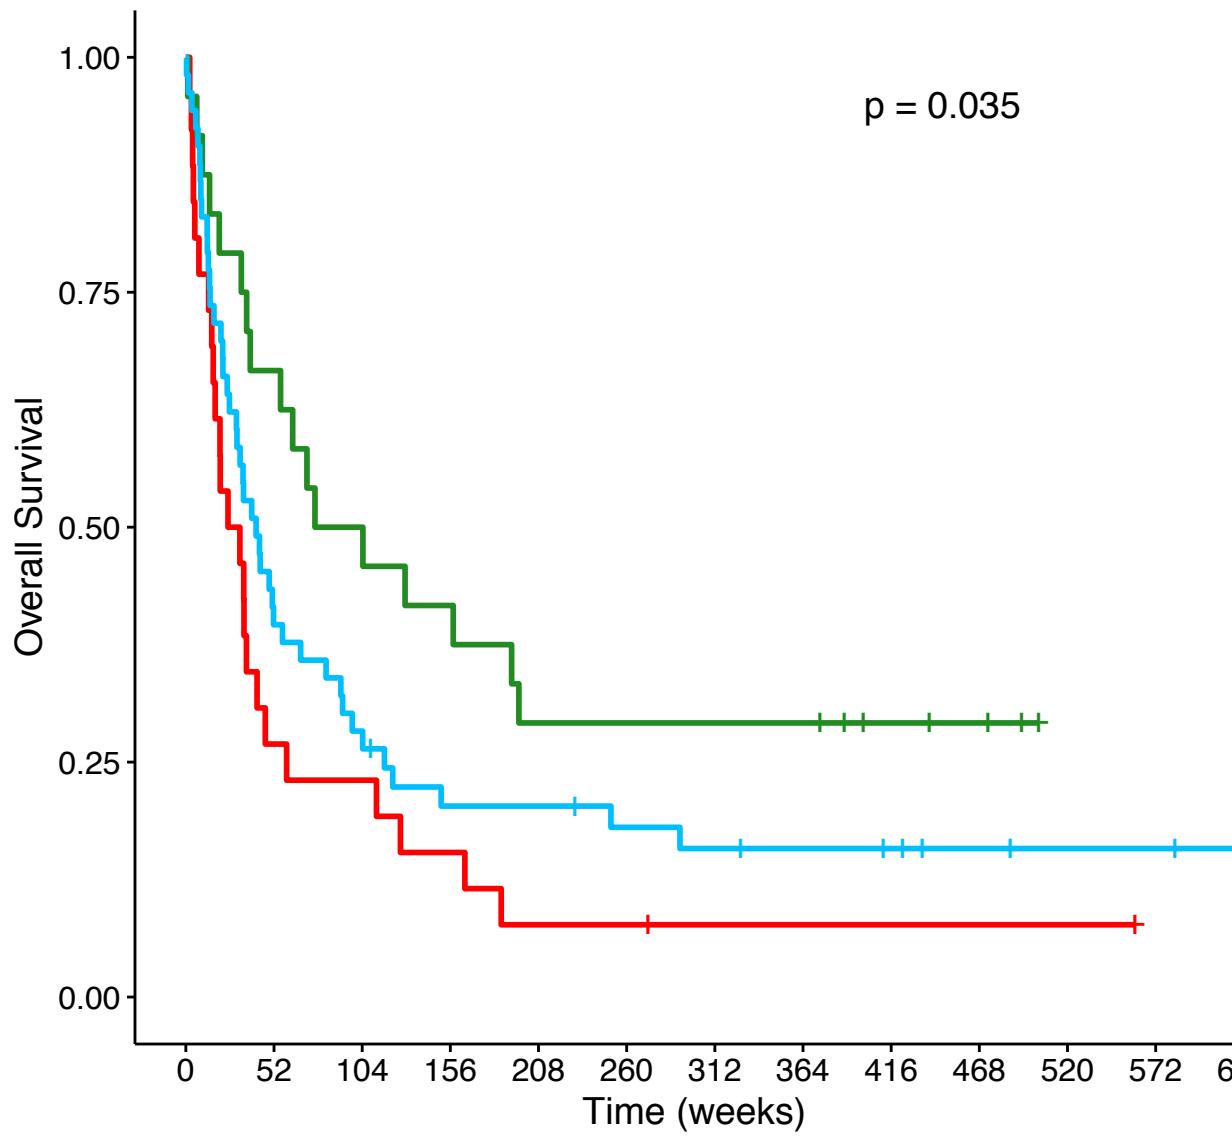

A**B****C****D****E****F**

Figure S4. Kaplan-Meier curves from training and testing data. The four plots display overall survival curves from the training set (upper left), overall survival curves from the testing set (upper right), remission duration curves from the training set (lower left) and remission duration curves from the testing set (lower right). In either overall survival or remission duration, the three signature groups (favorable, intermediate and unfavorable) display consistent outcome between the training and the testing set. Training sample size ($n = 102$); testing samples size ($n = 103$). p-values shown for log-rank test, one-sided.

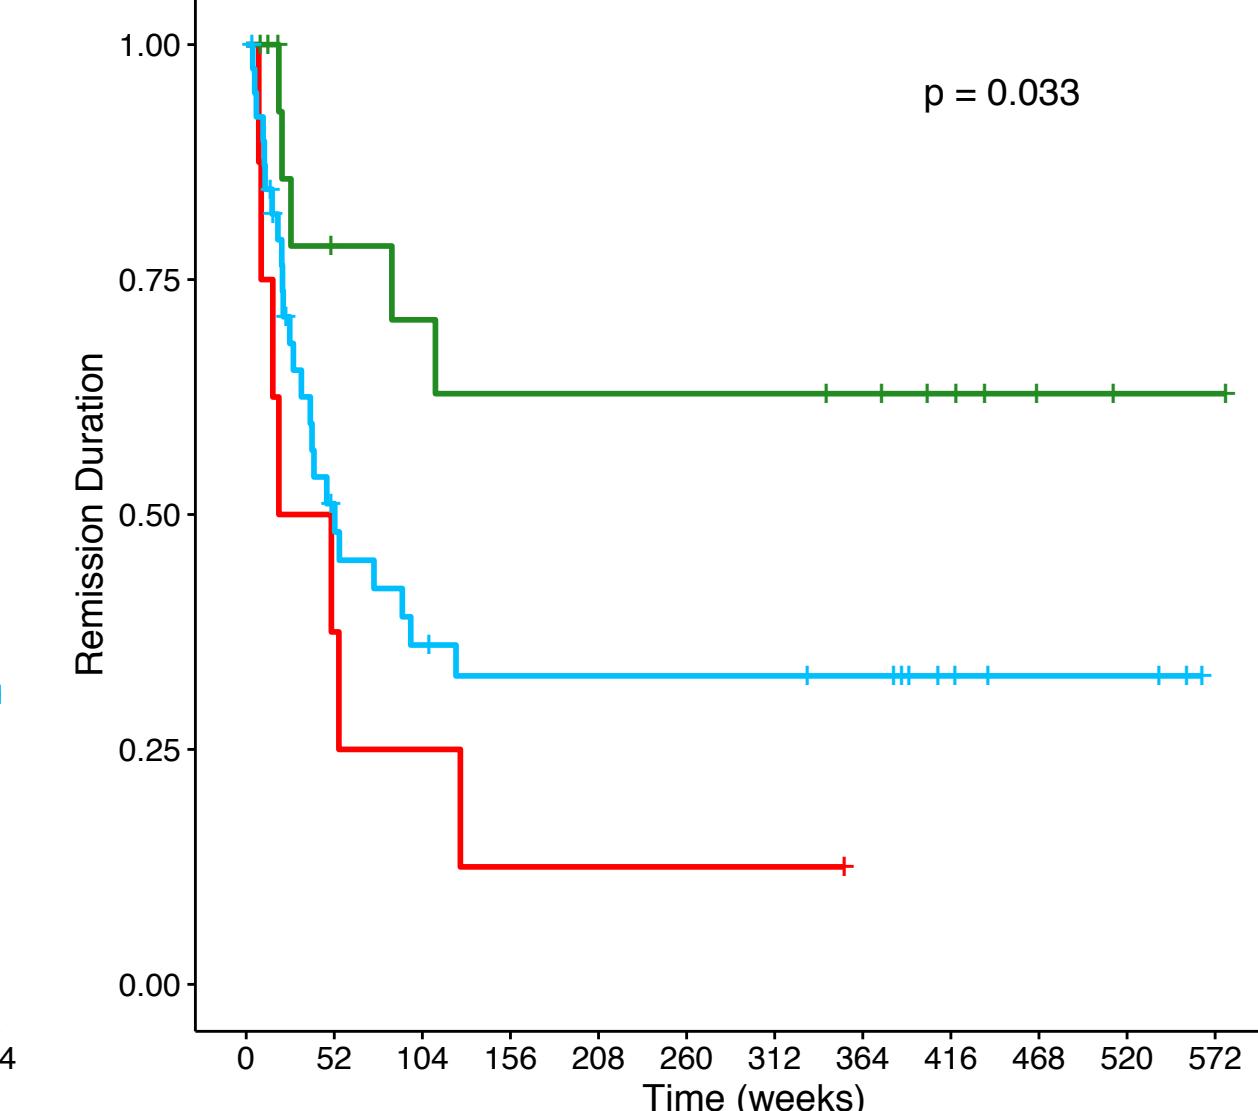

Figure S5. Potential drug targets for signatures. The heatmap shows the mean expression levels of potential drug targets (rows) in each signature (columns). A cell is marked in grey if the protein is not a target in that signature. Note that only proteins that are targets for at least one signature are included, and proteins that are not targets for any of the signatures are excluded. The signature color at the top corresponds to the signature color in **Figure 4A**.

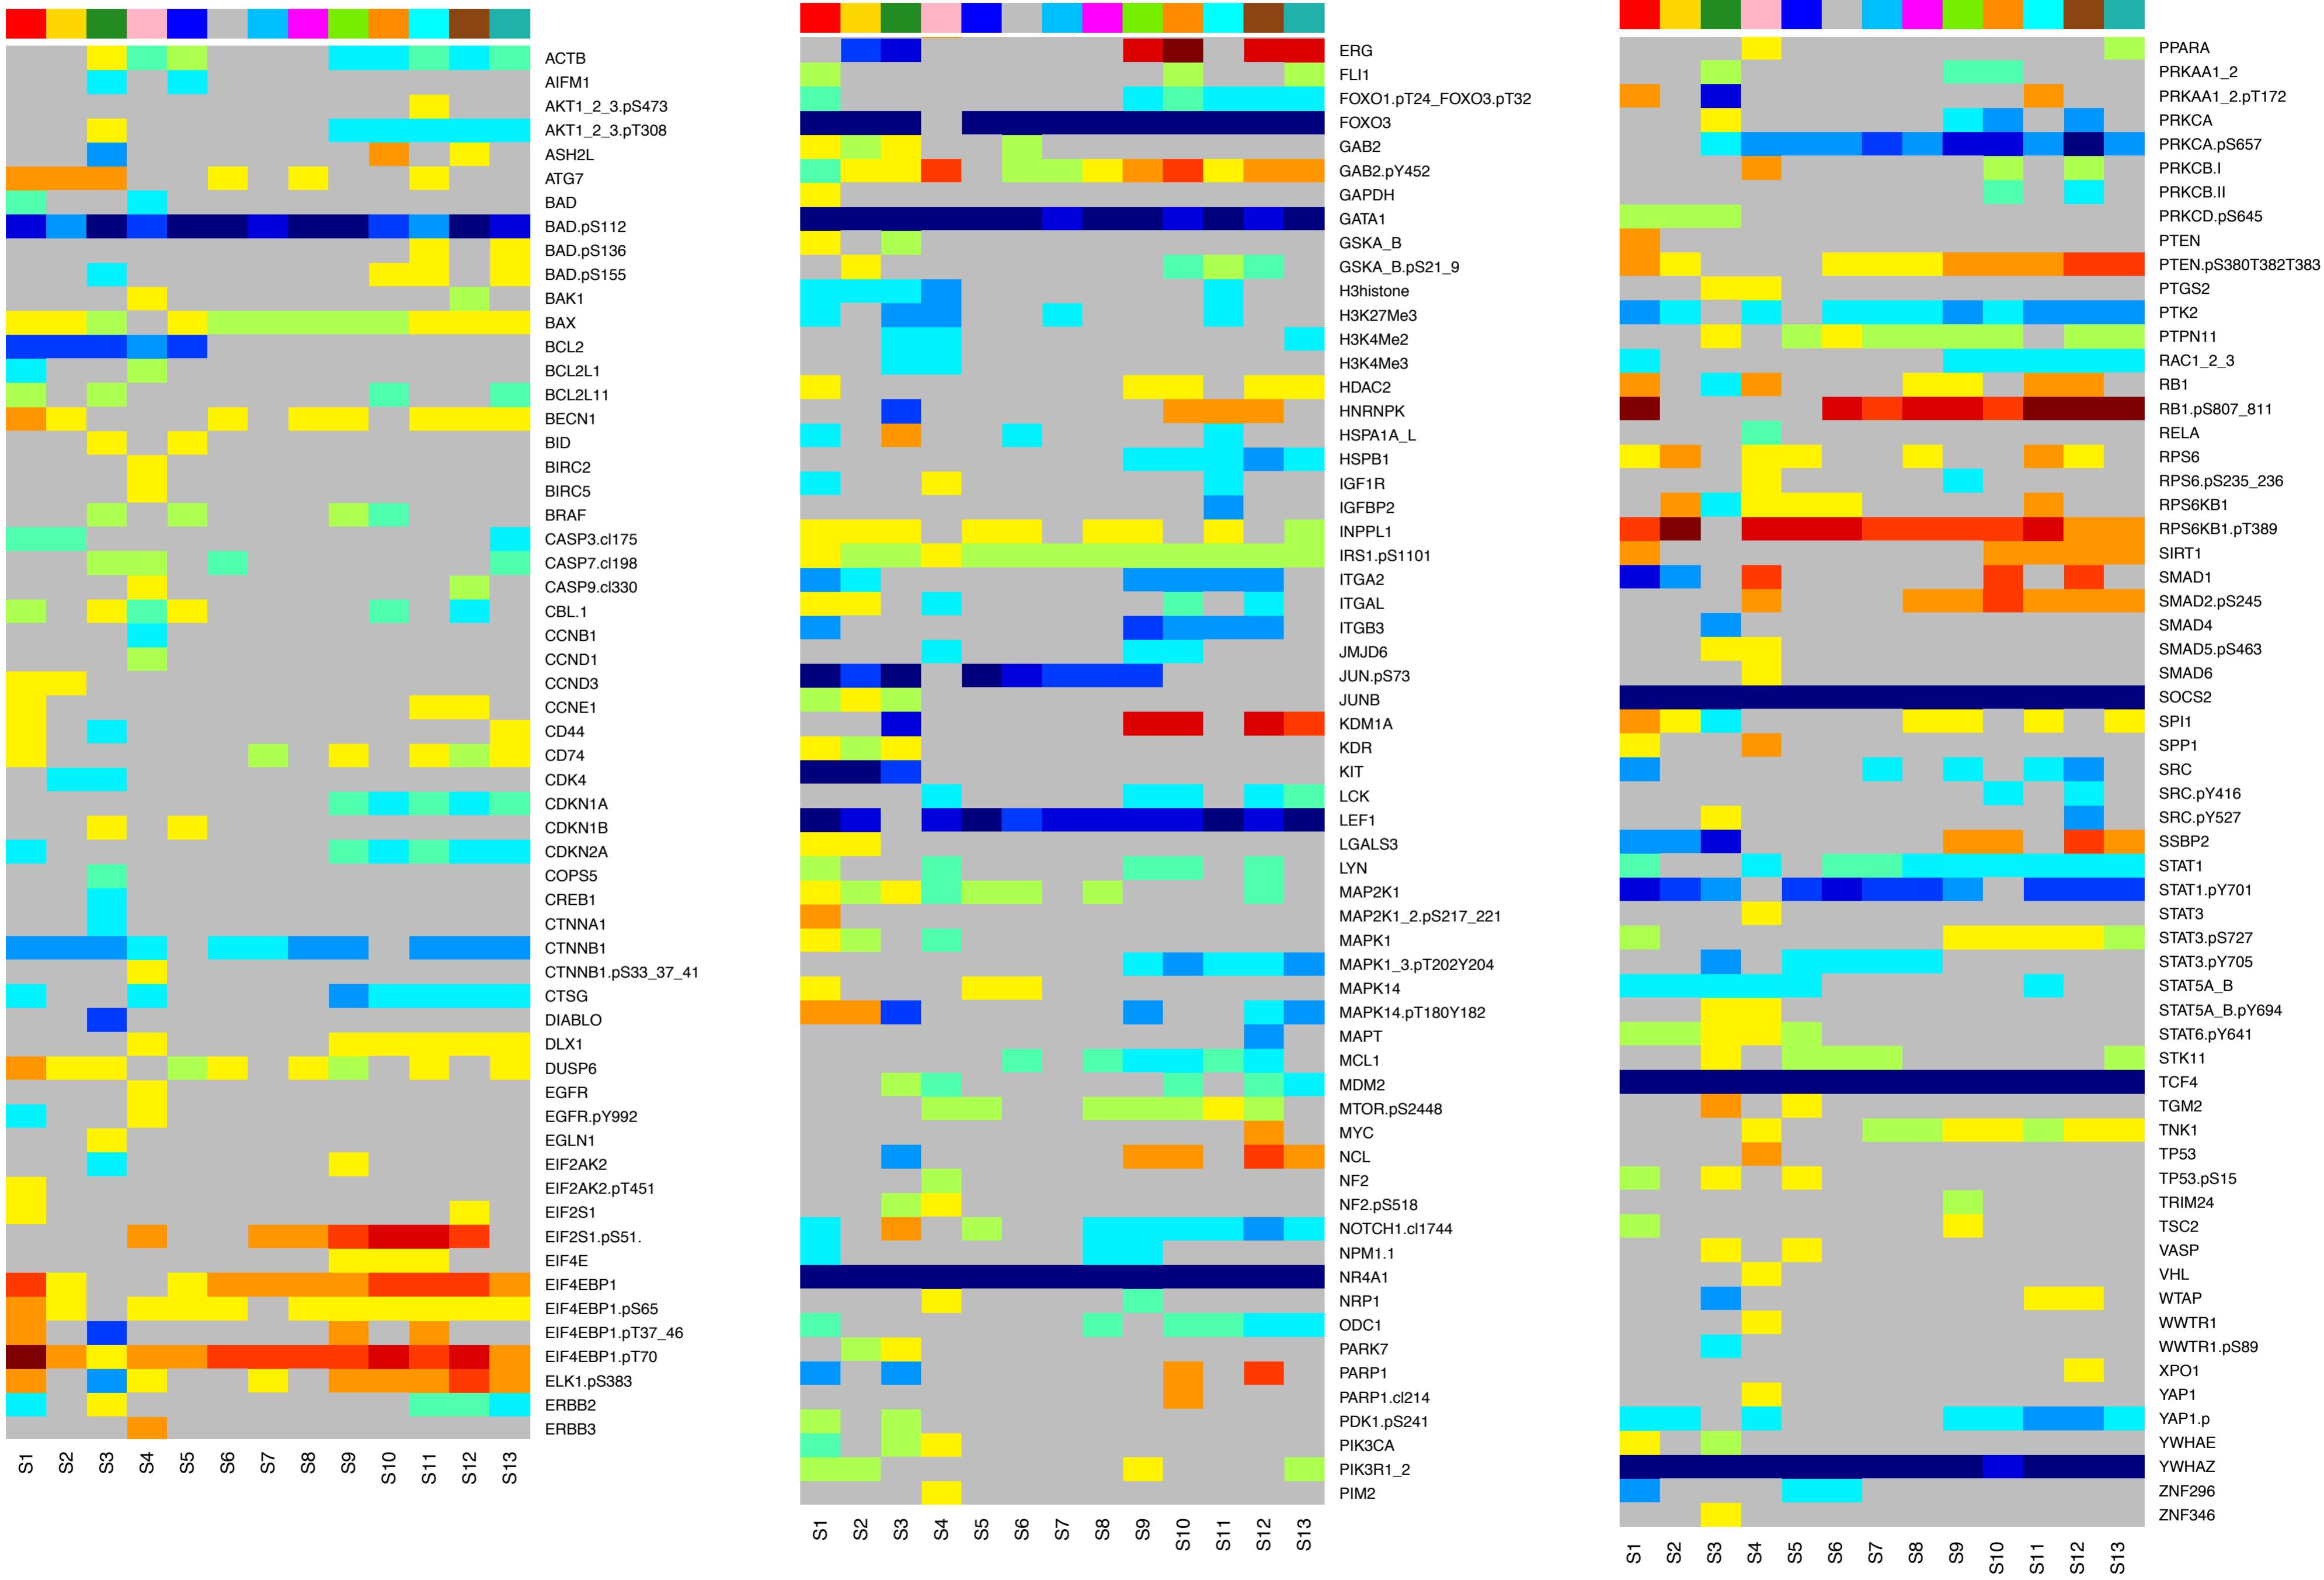

Figure S6. Clustering of cell lines together with AML patient samples. In the heatmap, the columns are proteins and the rows are samples. To distinguish cell lines from patients, we labeled all cell lines (text at the right of the heatmap), whereas we kept all patient samples unlabeled. Hierarchical clustering was applied to both the rows and columns, and the proteins and samples were ordered by the clustering result. It is clear that all cell lines (at the bottom) were separated from all patient samples (at the top) from the clustering. This was true for all the cell lines, regardless of lineage (AML or ALL), or for mycoplasma infected cell lines (n=17) and their uninfected counterparts.

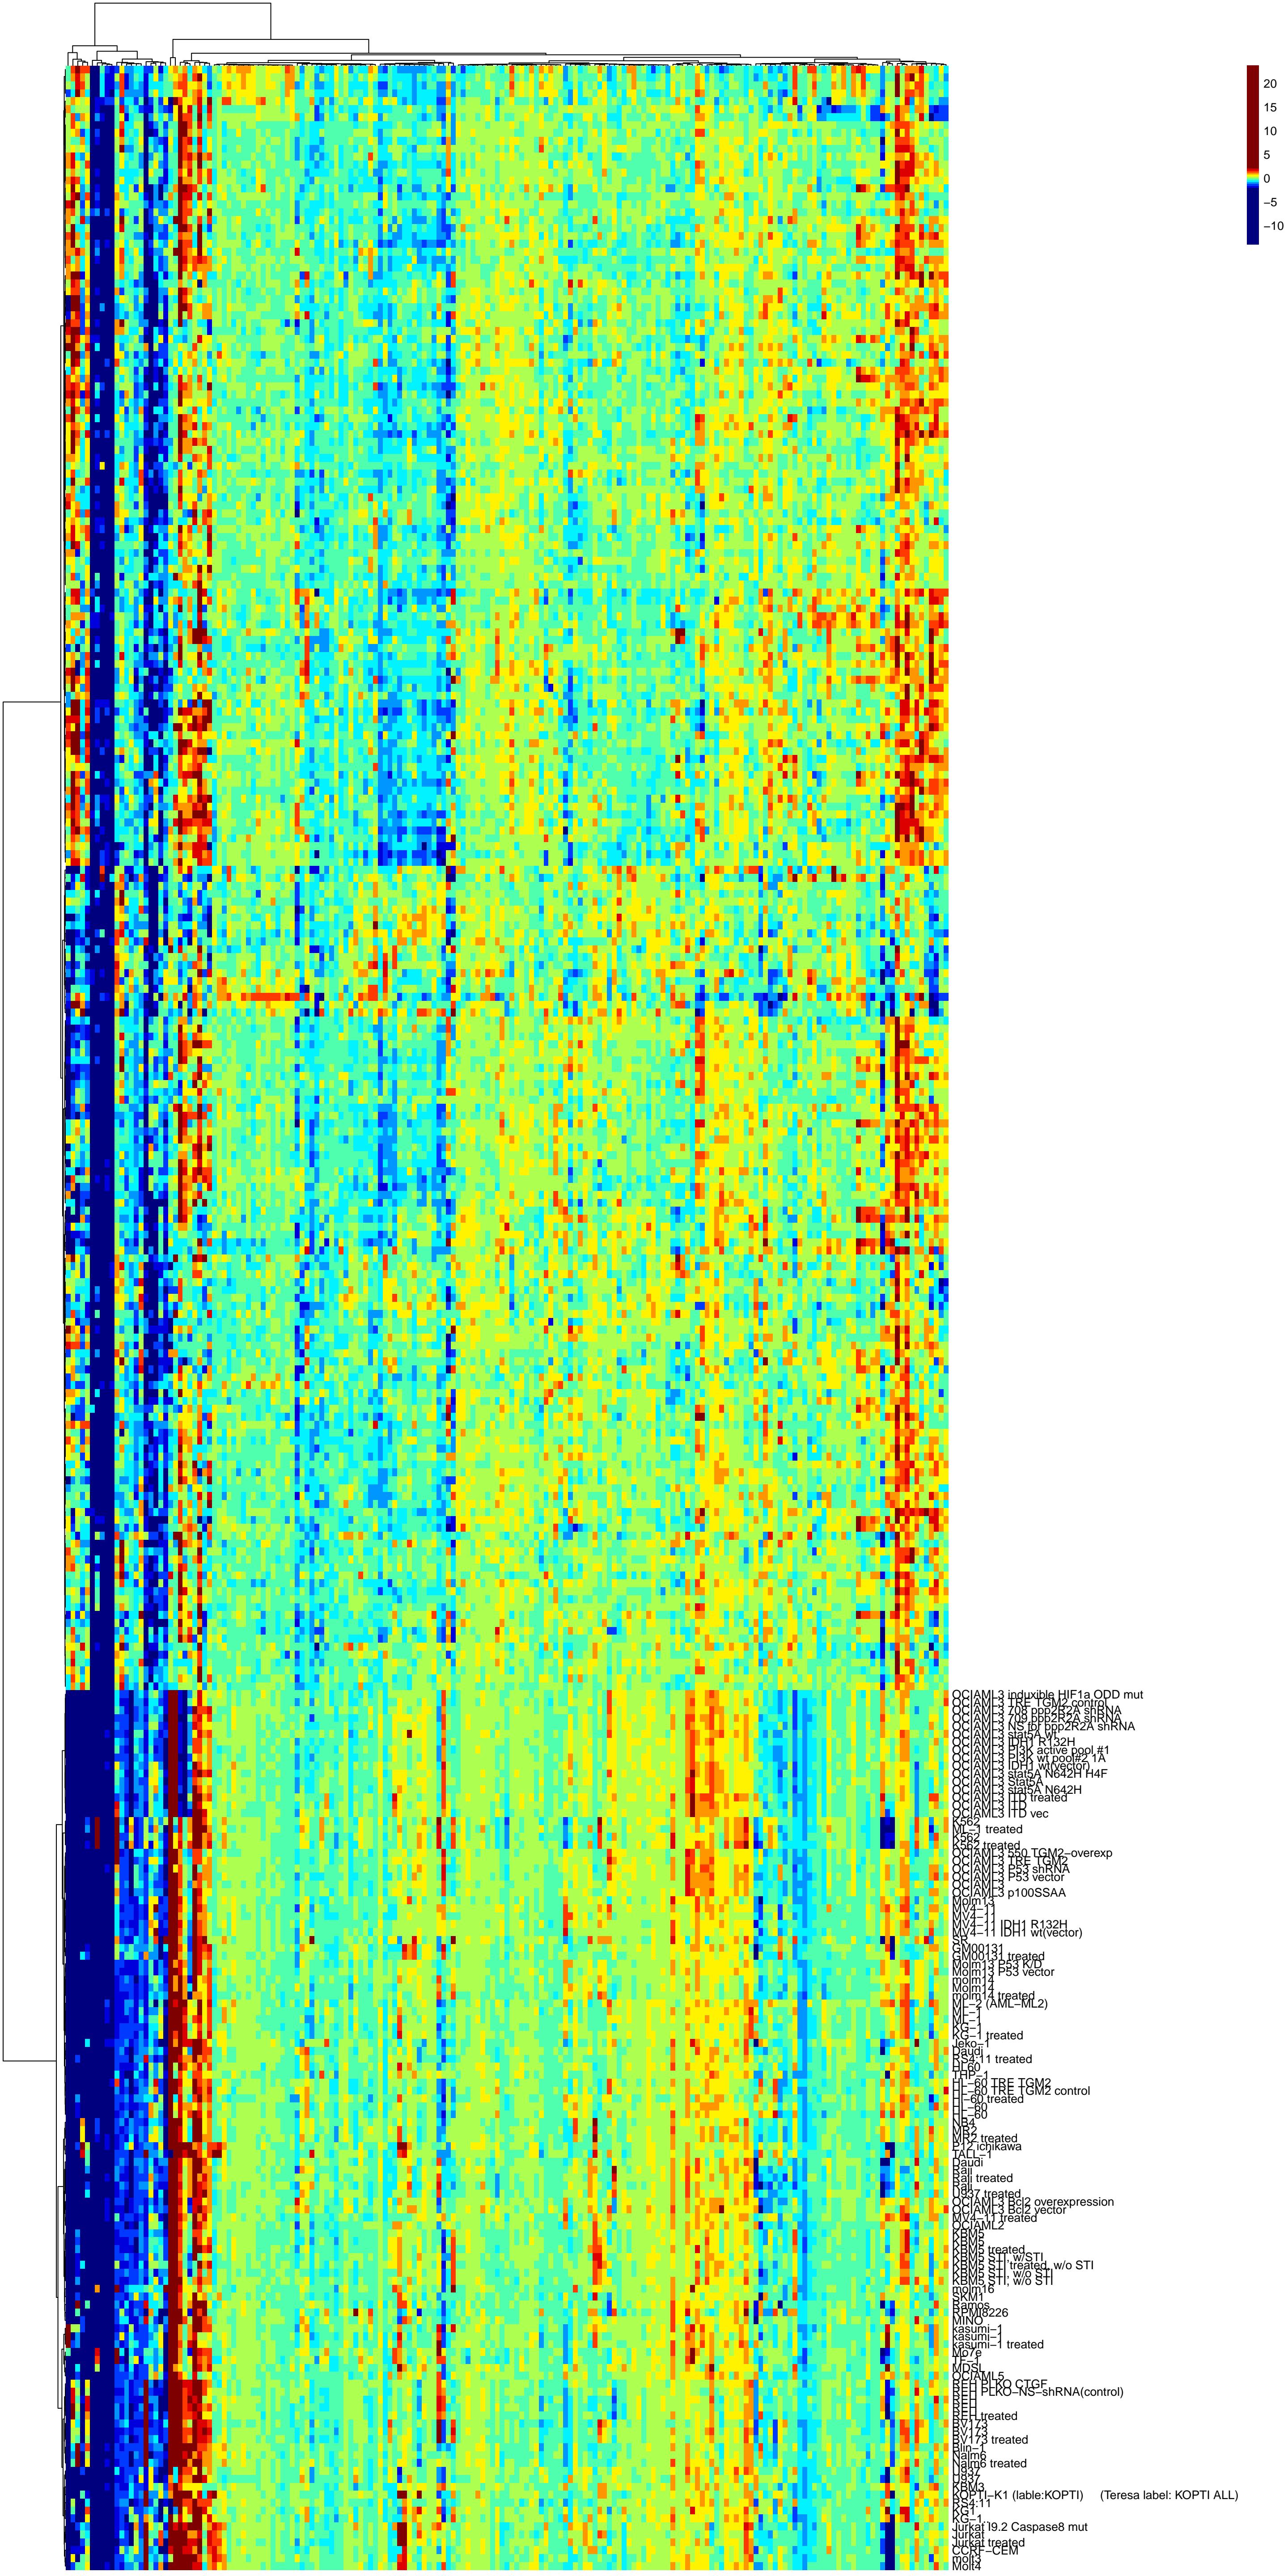

Table S1. Antibody nomenclature table. This table consists of five parts with the first being a protein name “Rosetta Stone” showing the HUGO, MiMI and the RPPA modified HUGO protein name abbreviation, the full protein name, the PTM site and consequence. The second part lists the manufacturer of each antibody along with their antibody name, catalog number, and the primary and secondary antibody concentrations utilized. The third section lists which protein functional group each antibody was assigned to. The fourth section records the p-values (corrected for multiple testing to control the FDR at 5%) and effect sizes for the comparison of sample sources (i.e. blood vs. marrow). The last section indicates the p-values (two-sided t-test, corrected for multiple testing to control the FDR at 5%) and effect sizes for the comparison of processing procedures (i.e. cryopreserved vs. fresh). Last two columns: Blood (n = 282) vs. Marrow (n = 387); Cryo (n = 377) vs. Fresh (n = 292).

Protein Name Rosetta Stone					RPPA Staining Details							Functional Category	Blood vs. Marrow		Cryo vs. Fresh

Notes

- a. Default parameter values are not specified.
- b. Clusters of too small a size were removed (with fewer than 5 fresh samples or clusters with fewer than 25% of the expected number of fresh samples), and samples in those clusters were re-assigned to clusters with the closest center.
- c. Progeny Clustering initially picked 14 signatures by 11 constellations as the optimal clustering solution (see Table S7). However, since Signature 9 contains only 2 patients (which is infeasible for subsequent statistical analyses), we combined Signature 9 with its most similar signature, Signature 8. This combination results in the final structure of 13 signatures as shown in Figure 3A.
- d. The progenyClust code was customized for co-clustering, in which progenies were first constructed for each 2-dimensional cluster block by bootstrapping values within the block, and were then randomly populated within 5 by 5 blocks for re-clustering. The clustering stability was assessed by the chances of progenies within the same blocks being re-clustered together.

Table S8. Stability scores from Progeny Clustering for co-clustering. The Progeny Clustering result showed that the structure of 14 signatures by 11 constellations is the optimal solution. Note that the final 13 signatures were derived from the original 14 by 11 co-clustering result by merging Signature 9 (of only 2 patients) with Signature 8 (the signature closest to Signature 9).

	6 Signatures	7 Signatures	8 Signatures	9 Signatures	10 Signatures	11 Signatures	12 Signatures	13 Signatures	14 Signatures	15 Signatures

Meta-Galaxy Analysis Online Tool Tutorial

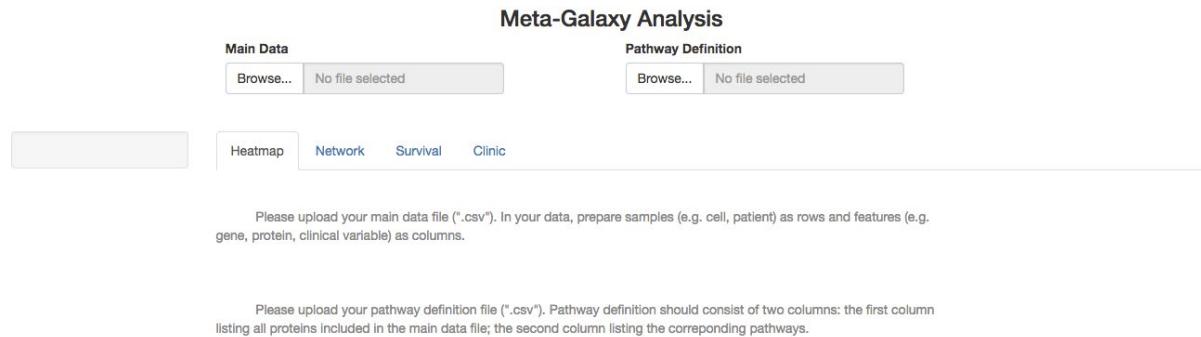

Data Preparation

Before using the tool, please prepare your data in the following two “.csv” files:

- **Main Data.** This file should contain all sample measurements that you wish to analyze via the Meta-Galaxy analysis portal, including numeric measurements such as gene/protein expression (required), as well as clinical attributes such as survival and demographic information (optional, only required in the ‘Clinic’ module). The data should be structured, in which rows are samples and columns are measurements.
- **Pathway Definition.** This file should specify the pathway membership of each gene/protein contained in the main data file. The data should consist of two columns, with gene/protein names in the first column and their pathway names in the second column.

Meta-Galaxy Analysis

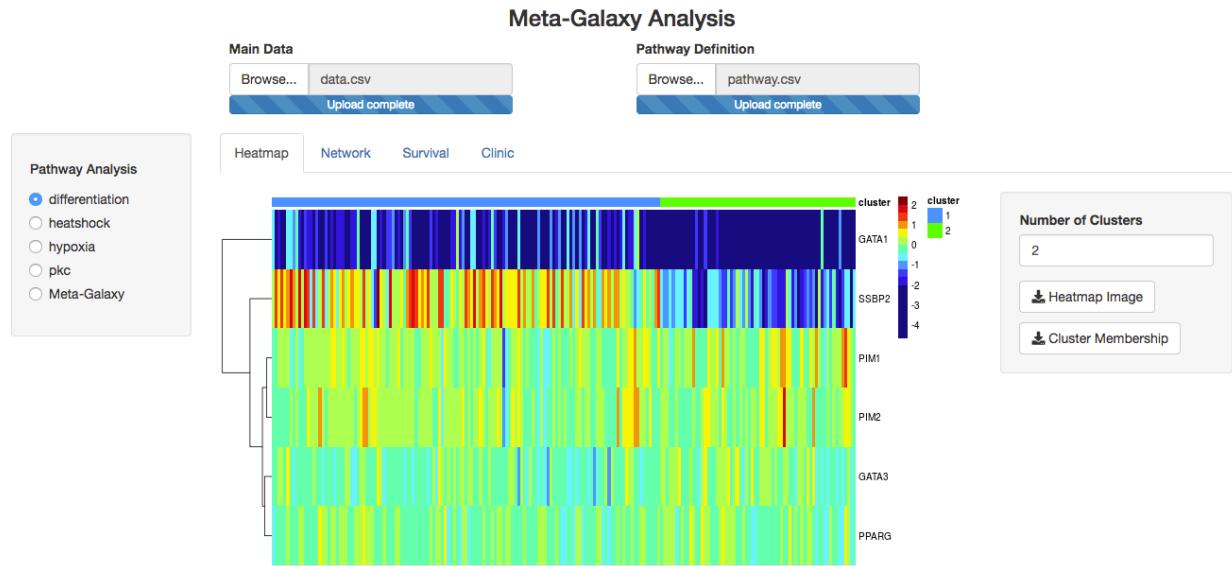

Upon uploading the data files at the portal, the pathway names will be automatically parsed and populated in the left grey column box. By selecting a pathway name in the list, the portal will automatically start the analysis for that pathway.

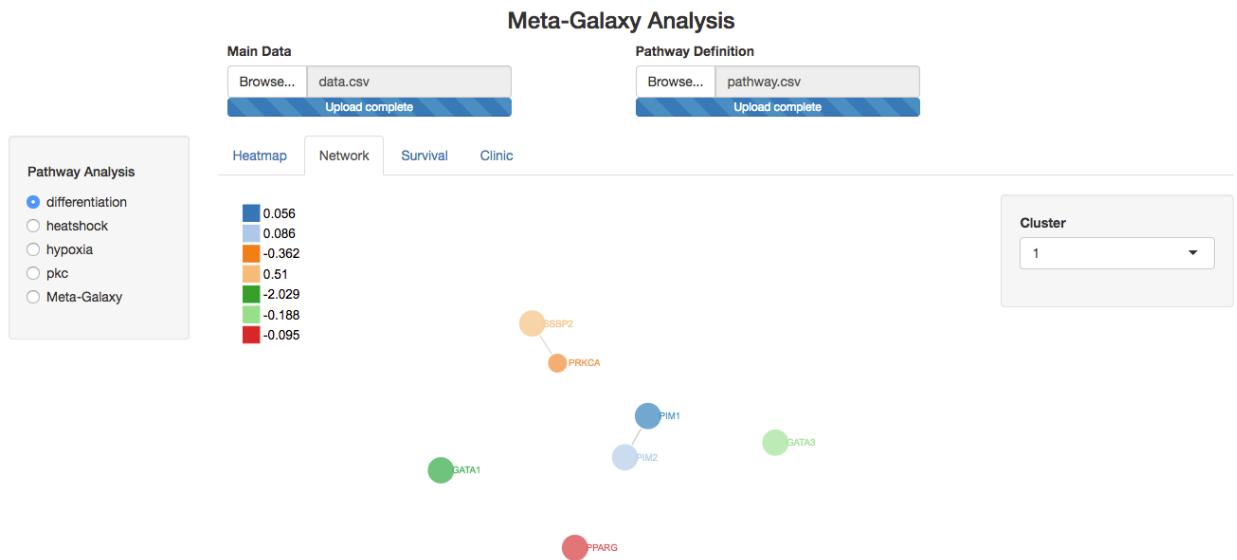

The portal offers four modules of analyses for each pathway: Heatmap, Network, Survival, Clinic. Users can select and switch between analysis modules by clicking on the tabs underneath the data upload panel. In each module, the analysis results (i.e. figures and tables) will be displayed in the central panel underneath the analysis tabs, whereas the grey panel on the right offers options to adjust parameters and download the figures/tables.

Heatmap. This module provides cluster analysis, which clusters samples based on the genes/proteins in the pathway using *k-means* algorithm and clusters genes/proteins using *hierarchical clustering (ward linkage)* algorithm. The optimal number of sample clusters,

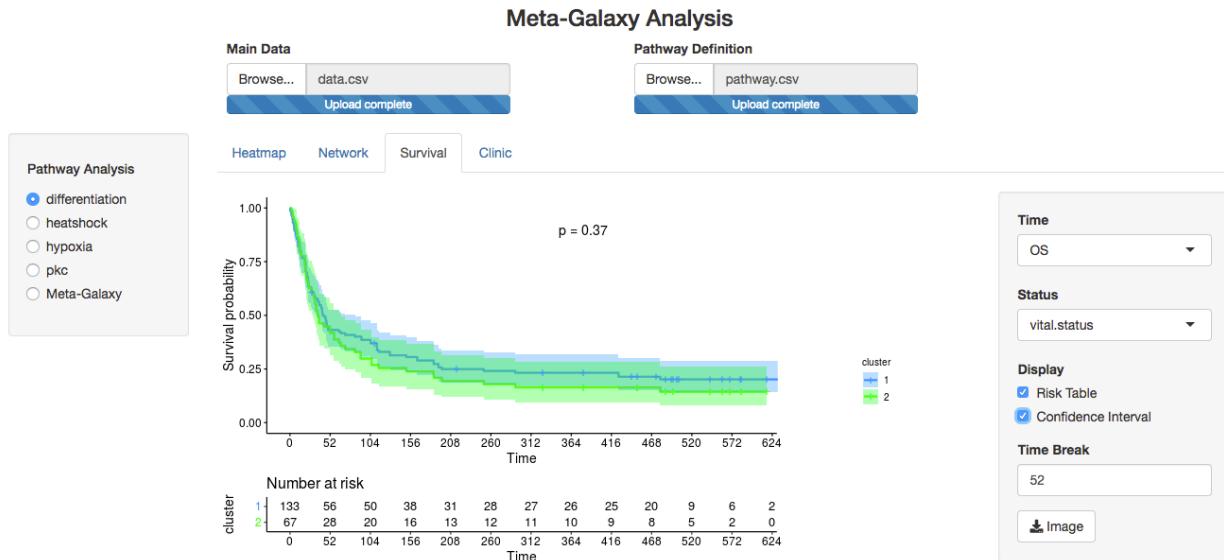

determined using *Progeny Clustering* algorithm, are automatically shown. Users have the option to adjust the number of clusters, and download the figures as well as the cluster memberships.

Network. This module provides network analysis, which uses the *glasso* algorithm to construct the network connections. The network will display all genes/proteins of the pathway (in a bigger node size), as well as genes/proteins from other pathways that are connected to the pathway (in a smaller node size). The node color indicates the median expression level of that gene/protein in the chosen cluster. Users have the option to zoom in and out of the network, move and adjust the network display, and select which cluster to look at.

Survival. This module provides survival analysis, which plots the *Kaplan-Meier* curves for survival stats. Users have the option to choose the variables for creating the survival curves, displaying risk table and confidence intervals, adjusting the time interval for the plot, and downloading the figure.

Clinic. This module analyzes relations between clinical variables and the clusters (as determined in the Heatmap module). Any categorical or numeric measurements except the gene/protein measurements will be automatically extracted and included in the analysis. Users have the option to select the clinical variables of interest, adjust the display length, search for a particular clinical variable, and download the table.

The figure shows a "Meta-Galaxy Analysis" risk table. The table has columns: Category, Type, Count, Freq, C1.freq, C2.freq, pvalue.all, C1.n, C2.n, and pvalue. The table includes the following data:

Category	Type	Count	Freq	C1.freq	C2.freq	pvalue.all	C1.n	C2.n	pvalue
Total	Count	200	1	0.665	0.335	5e-04	133	67	5e-04
SEX	F	108	0.54	0.534	0.552	0.92337	71	37	0.00107
SEX	M	92	0.46	0.466	0.448		62	30	0.00085
PRIOR.MAL	NO	162	0.81	0.812	0.806	1	108	54	2e-05
PRIOR.MAL	YES	38	0.19	0.188	0.194		25	13	0.05158
FLT3	Mutant	66	0.333	0.382	0.239	0.06309	50	16	3e-05
FLT3	Wildtype	132	0.667	0.618	0.761		81	51	0.00902

On the left, a "Pathway Analysis" sidebar lists: differentiation (selected), heatshock, hypoxia, pkc, and Meta-Galaxy. On the right, "Clinical Variables" include: SEX, PRIOR.MAL, FLT3 (all selected), Relapse, and vital.status (unchecked). A "Search" bar and a "Download Table" button are also present.
