

### Supplementary Figure 1. Germination of *Brassica tournefortii* seeds treated with karrikins

**a**, Structures of KAR<sub>1</sub>, KAR<sub>2</sub> and two enantiomers of GR24. **b**, Germination response of the “Merridin” batch of *B. tournefortii* seed treated with KAR<sub>1</sub> and KAR<sub>2</sub> after three days. **c-d**, Germination response of the “Perth” batch to KAR<sub>1</sub> (**c**) and KAR<sub>2</sub> (**d**). Data in Figure 1a are derived from the data shown in **c** and **d**. **e-f**, Rates of KAR<sub>1</sub> and KAR<sub>2</sub> uptake by imbibed seed, as determined by GC-MS. All error bars are mean  $\pm$  SE of n = 3 batches of 75 seed (**b-d**) or 3 samples of 40 mg (**e**) or 20 mg (**f**) seed as described in Methods. Source data are provided as a Source Data file.

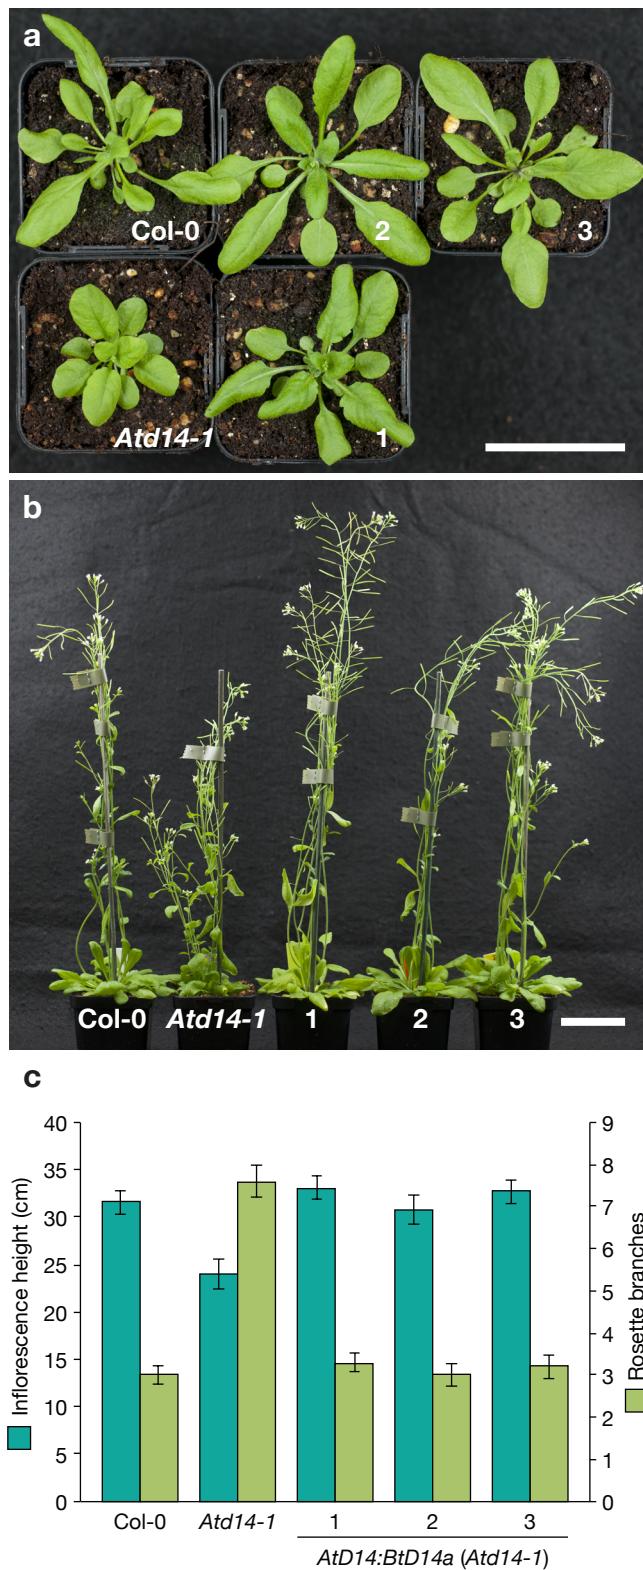

**Supplementary Figure 2. Extended phylogeny of eu-KAI2 and D14 proteins in angiosperms**

Maximum likelihood phylogeny of KAI2 and D14 homologues in the Brassicaceae and monocots, based on nucleotide data. Node values represent bootstrap support from 100 replicates. A KAI2 sequence from *Selaginella moellendorffii* (SmKAI2a) serves as an outgroup for the eu-KAI2 clade. Source data are provided as a Source Data file.

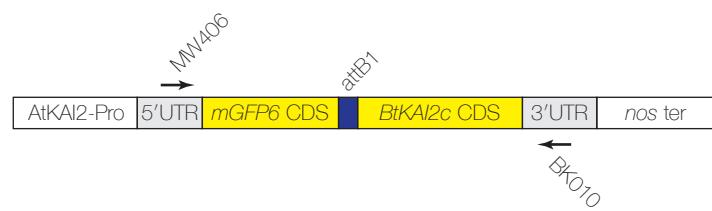

### Supplementary Figure 3. Alignment of *Brassica* KAI2 sequences

Full length protein coding regions of KAI2 homologues from four *Brassica* species (*Brassica tournefortii*, *B. rapa*, *B. nigra* and *B. oleracea*) were translated from database nucleic acid sequences and aligned to *Arabidopsis* KAI2 using MAFFT (ref. 1) implemented in Geneious R10 software (Biomatters Ltd). Amino acid residues are coloured according to polarity: yellow, non-polar (G, A, V, L, I, F, W, M, P); green, polar & uncharged (S, T, C, Y, N, Q); red, polar & acidic (D, E); blue, polar & basic (K, R, H). Residues that are unique to BtKAI2c but otherwise invariant are highlighted with asterisks (\*); residues 98 and 191 are highlighted with red boxes. The underlined region indicates the epitope used to raise the antibody against AtKAI2. Source data are provided as a Source Data file.

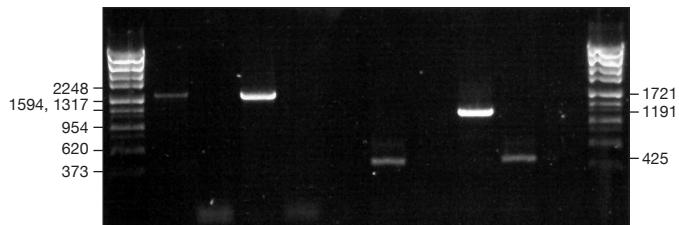

#### Supplementary Figure 4. BtD14a is functionally homologous to AtD14

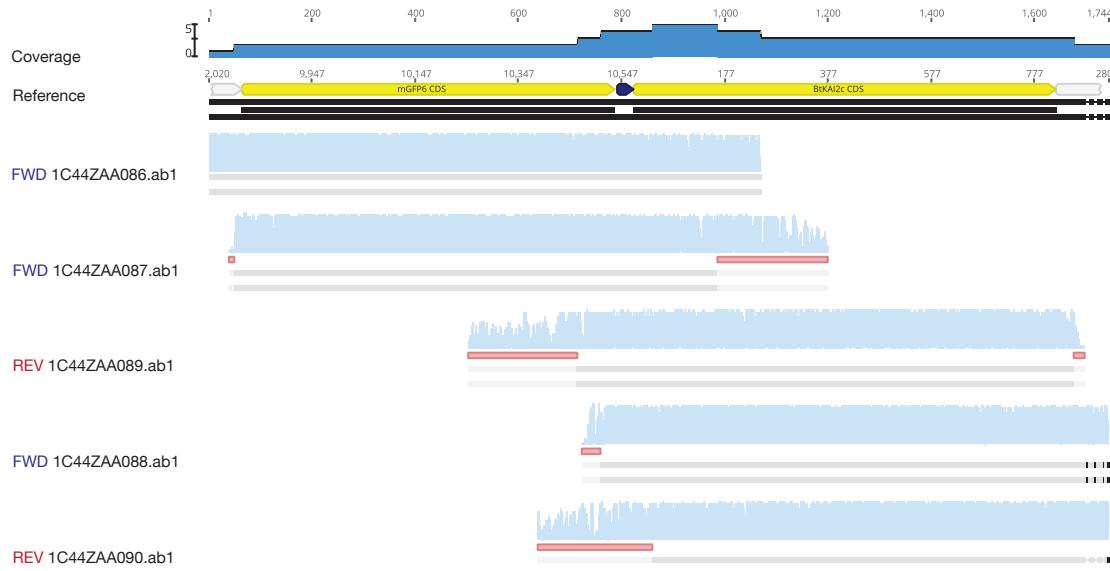

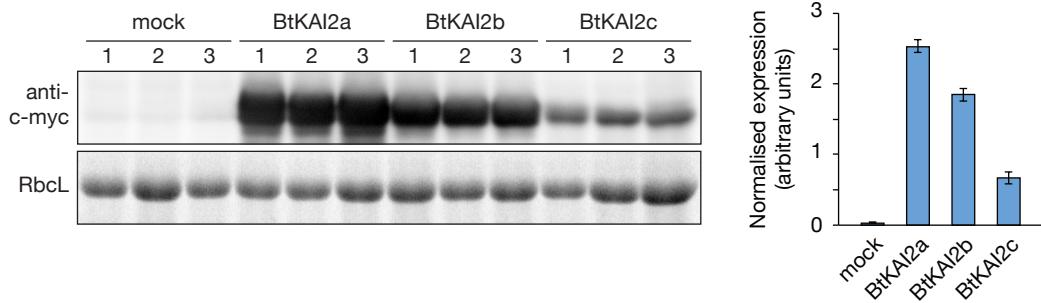

Three independent transgenic lines of Arabidopsis *Atd14-1* were analysed for functional complementation of the mutant phenotype by an *AtD14pro:BtD14a* transgene. **a**, Rosette and leaf morphology at 31 days post-germination. **b**, Plant height and number of primary rosette branches at 45 days post-germination. **c**, Quantification of height and branching parameters, means  $\pm$  SE,  $n = 10$  plants per genotype. Scale bars: 50 mm. Source data are provided as a Source Data file.

MW275 + MW278	425	1191

**c****d**

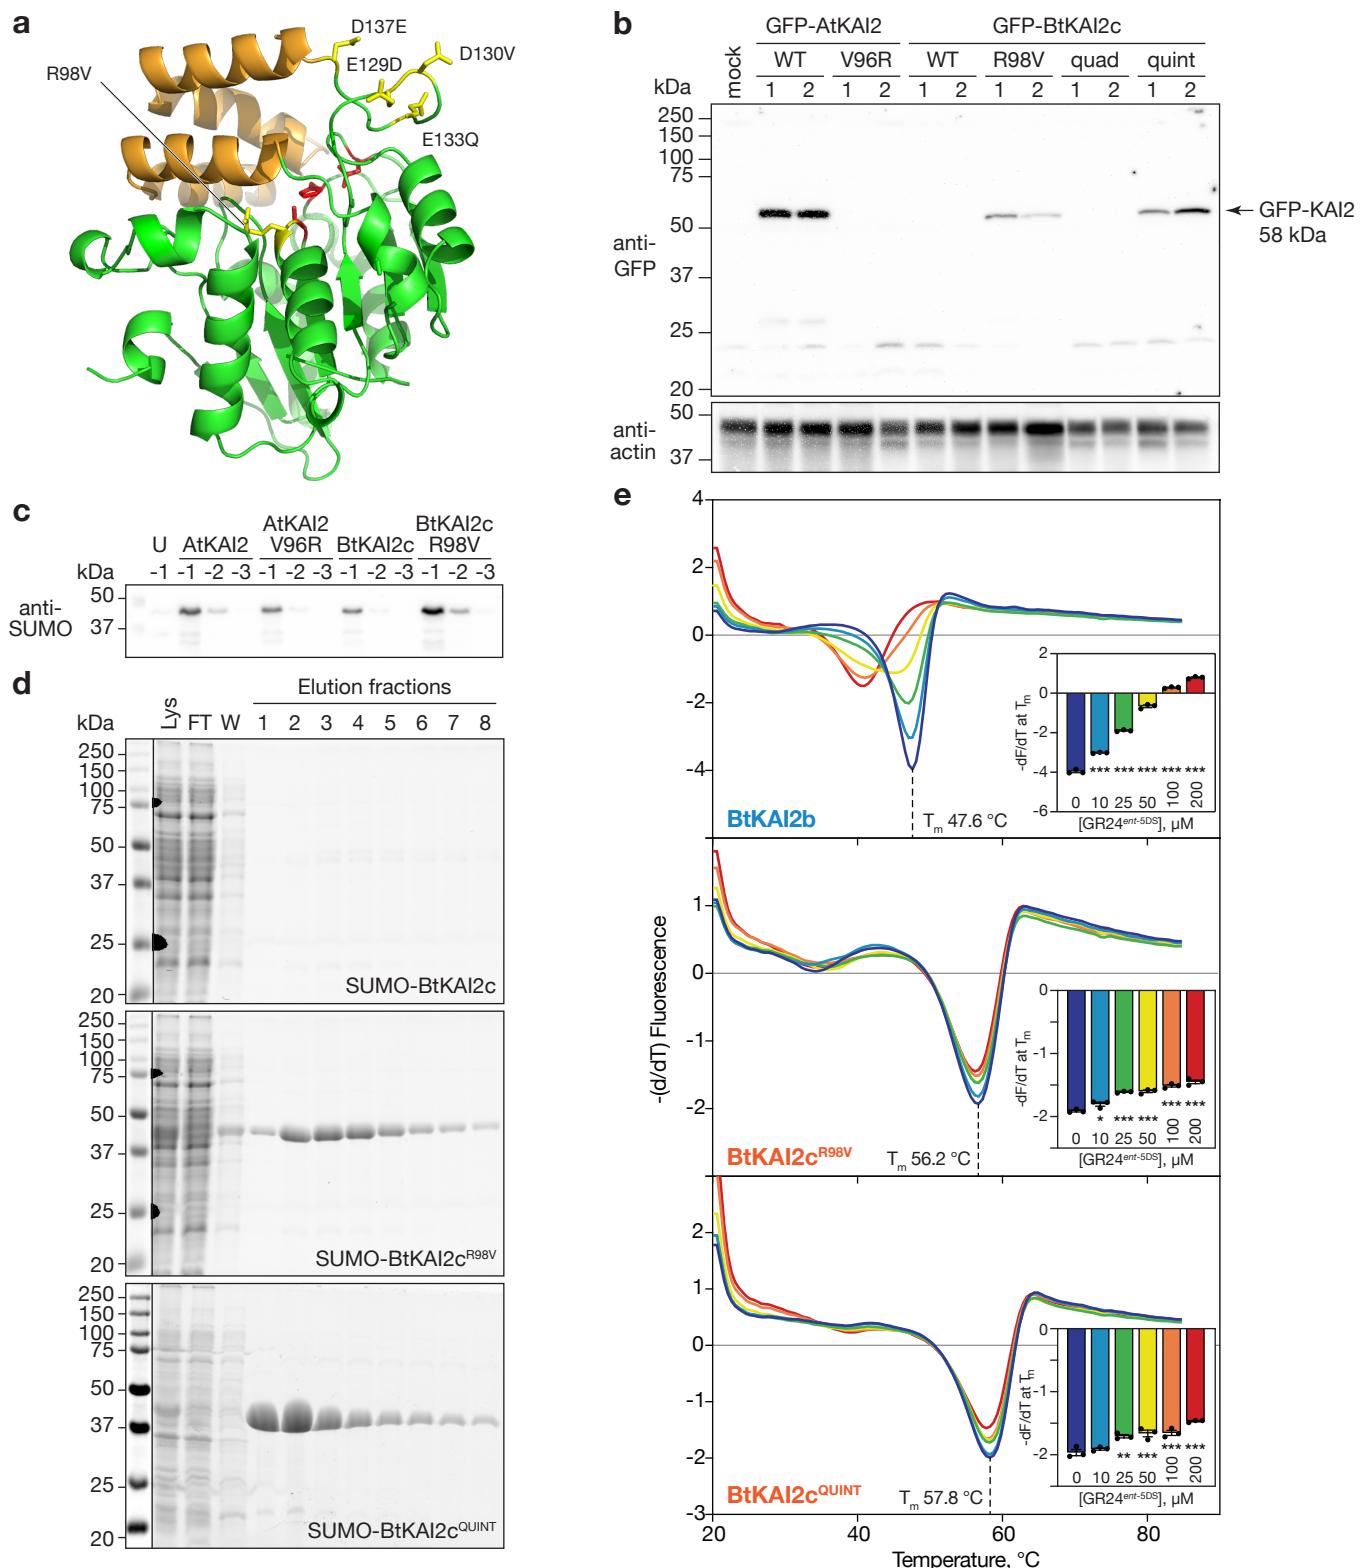

### Supplementary Figure 5. The GFP-BtKAI2c transgene is faithfully transcribed in Arabidopsis

**a**, Structure of the AtKAI2pro:mGFP6-BtKAI2c transgene. Primers used for RT-PCR are shown with arrows. The promoter and 5'UTR are derived from At4g37470 (AtKAI2). attB1, Gateway recombination site that links mGFP6 and BtKAI2c regions; nos ter, nopaline synthase terminator. Not drawn to scale.

**b**, RT-PCR analysis of GFP-BtKAI2c transcripts after 35 cycles of amplification. Primers MW406 + BK010 target the transgene, while a second primer pair (MW275 + MW278) serves as a control and spans five introns of At1g03055. *kai2-2* serves as a non-transgenic control genotype. Templates: R, total RNA; D, genomic DNA; W, water only. RT, reverse transcriptase (Superscript III). DNA size standards (in base pairs) are indicated on the left, with anticipated PCR product sizes shown on the right and defined in the table.

**c**, The RT-PCR product generated with proof-reading polymerase (Q5, New England Biolabs) and primers MW406 and BK010 was cloned into pCR4-TOPO (Life Technologies). Five dideoxy sequence traces were aligned against the GFP-BtKAI2c transgene reference. No disagreements with the reference sequence were observed. Red bars indicate trimmed regions of sequence traces to remove low quality data.

**d**, Transient expression of BtKAI2a, BtKAI2b and BtKAI2c proteins in tobacco. Plasmids encoding N-terminal, c-myc-tagged proteins were transferred to Agrobacterium, and the resulting strains used to infiltrate tobacco leaves. After 96 h, samples were harvested in triplicate (two to three leaves per sample). Mock-treated leaves were transformed with a plasmid encoding a non-tagged protein. Sixty micrograms of total protein were separated by SDS-PAGE, blotted and challenged with anti-c-myc antibody (Genscript A00704). Band intensity was measured using ImageJ, and expression was normalized to intensity of the Rubisco large subunit (RbcL) band on the “stain-free” gel imaged under UV light. Error bars indicate SE,  $n = 3$  replicates. Source data are provided as a Source Data file.

**Supplementary Figure 6. The R98V mutation restores stability of BtKAI2c**

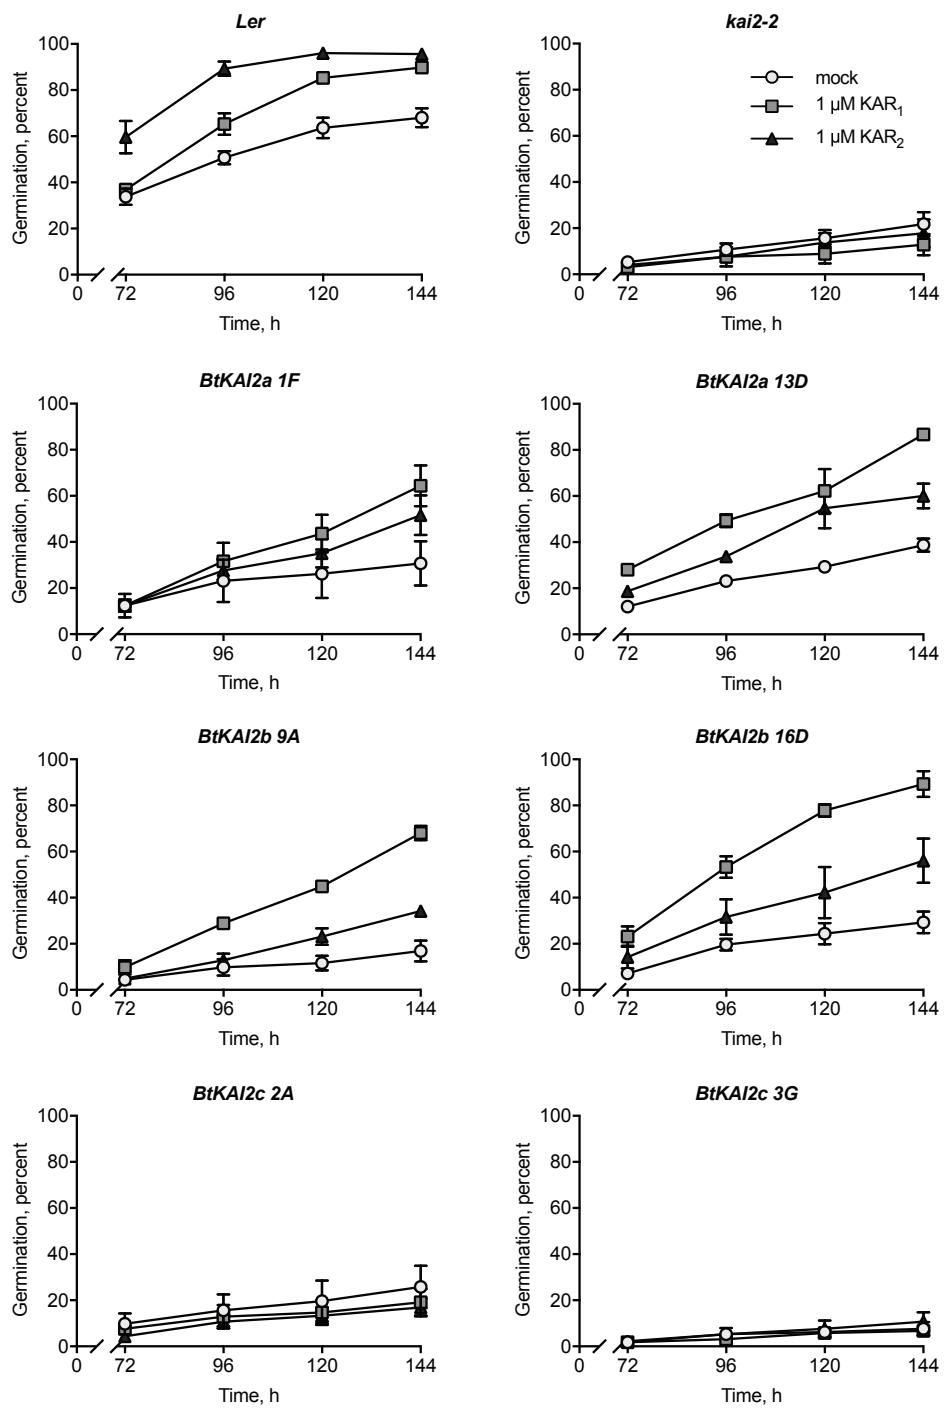

**a**, Homology model of the native BtKAI2c protein. Highlighted in yellow are five residues and their corresponding mutations that were assessed for effects on BtKAI2c stability. The combination of E129D, D130V, E133Q and D173E in the hinge region between the lid domain (orange) and core domain (green) is the quadruple (“quad”) mutant; combining this with R98V yields the quintuple (“quint”) mutant. Red residues are the Ser-His-Asp catalytic triad.

**b**, Transient expression of AtKAI2 and BtKAI2c variants in tobacco leaves following infiltration by Agrobacterium strains encoding GFP-KAI2 variants driven by the CaMV 35S promoter. Three leaves were infiltrated on each of two different plants. After five days, 20  $\mu\text{g}$  soluble protein was electrophoresed, blotted and challenged with antibodies against either anti-GFP (top) or anti-actin (bottom).

**c**, Immunoblot of crude bacterial lysates expressing SUMO fusion proteins and challenged with anti-SUMO antibody. Negative values above each lane indicate  $\log_{10}$  dilution factors of lysate; U, lysate from uninduced bacterial culture expressing SUMO-AtKAI2.

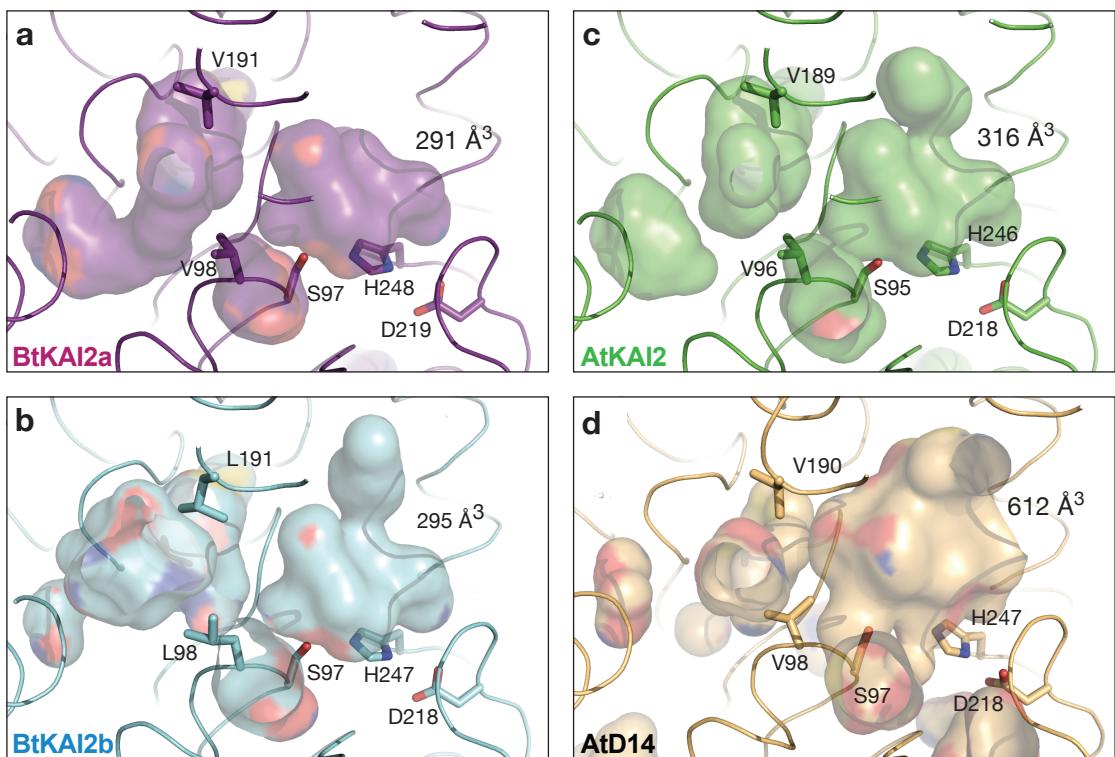

**d**, SDS-PAGE analysis of protein purification runs of SUMO-BtKAI2c, -BtKAI2c<sup>R98V</sup> and -BtKAI2c<sup>QUINT</sup> harvested from 900 mL bacterial culture. Lys, clarified lysate; FT, column flow through after immobilisation on  $\text{Co}^{2+}$  affinity column; W, wash with 10 mM imidazole. Proteins were eluted with 200 mM imidazole in eight successive fractions.

**e**, DSF curves of SUMO fusion proteins treated with 0–200  $\mu\text{M}$  GR24<sup>ent-5DS</sup>. Insets plot the minimum value of  $-(dF/dT)$  at the melting point of the protein as determined in the absence of ligand (means  $\pm$  SE,  $n = 3$ ). Significant differences from untreated control: \*  $P < 0.05$  \*\*  $P < 0.01$  \*\*\*  $P < 0.001$  (ANOVA). Source data are provided as a Source Data file.

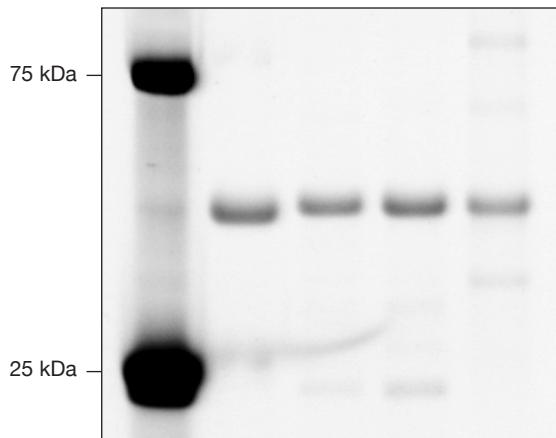

**Supplementary Figure 7. Germination profiles of transgenic Arabidopsis seeds expressing native BtKAI2 homologues**

Freshly harvested seed (three batches per genotype, each batch harvested from four plants) were removed from freezer storage, surface-sterilised and sown on 1% Phytagel supplemented with 0.1% acetone (mock), 1 μM KAR<sub>1</sub> or 1 μM KAR<sub>2</sub>. Seed were incubated under constant light at 25 °C. Seed were examined for germination (radicle protrusion) 72 h after sowing and every 24 h thereafter. Data are means ± SE of three independent seed batches and 75 seed per batch. For each transgene, two independent, homozygous transgenic lines were analysed. Data presented in Figure 3 of the main manuscript are derived from these data. Source data are provided as a Source Data file.

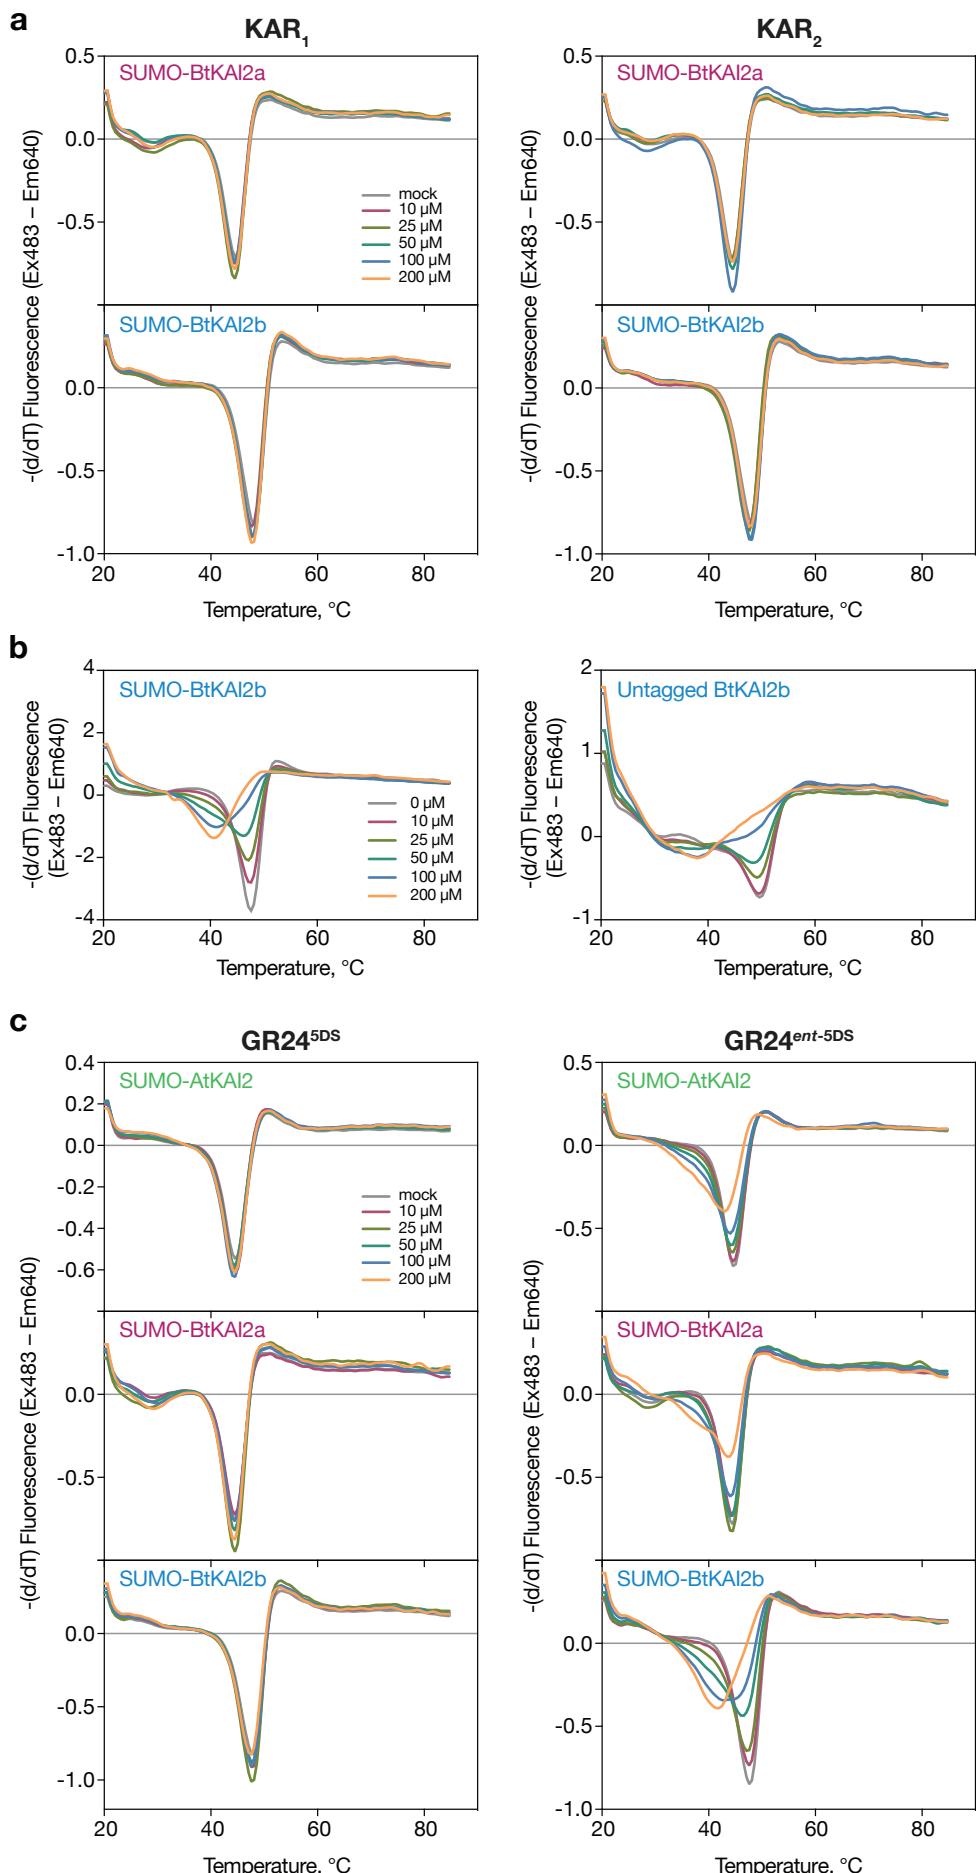

**e**

SUMO-BtKAI2a	SUMO-BtKAI2b	SUMO-AtKAI2	AtD14
L98;L191	V98;V191		

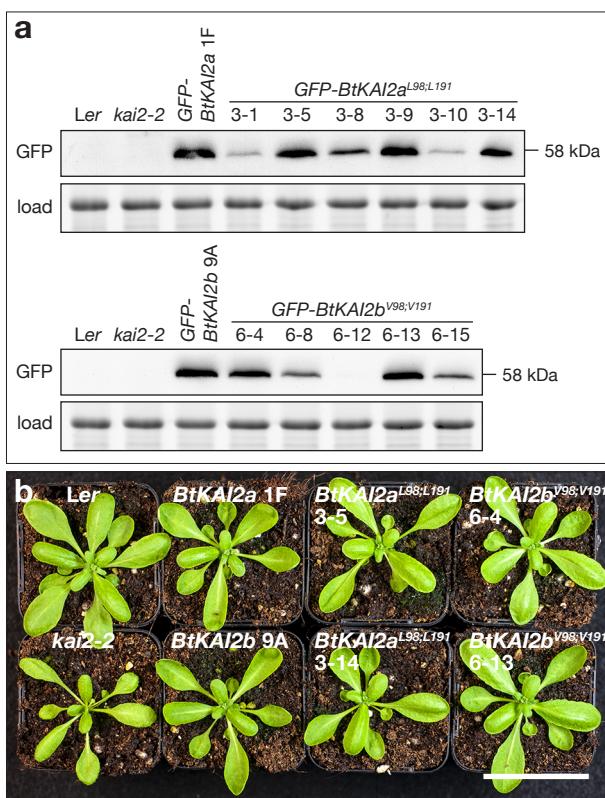

**Supplementary Figure 8. BtKAI2 homology models and SDS-PAGE of SUMO-BtKAI2 fusion proteins used for DSF.**  
**a-d**, Solved structure of AtKAI2 (PDB: 3w06, ref. 2), AtD14 (PDB: 4IH4, ref. 3) and predicted homology models of BtKAI2a and BtKAI2b. Coloured surfaces depict internal cavities; values indicate the volumes of the primary ligand-binding cavities, adjacent to the catalytic Ser-His-Asp residues. Also shown is a variable secondary pocket, to the left of the primary pocket in these images.

**e**, To assess purity after affinity chromatography, five micrograms of each purified protein was electrophoresed on a 12% acrylamide gel containing 2,2,2-trichloroethanol and visualised under UV light. Protein size standards at 75 and 25 kDa (Bio-Rad Precision Plus Dual Colour) fluoresce strongly under UV light. Source data are provided as a Source Data file.

**Supplementary Figure 9. BtKAI2a and BtKAI2b do not respond to karrikins in DSF assays**

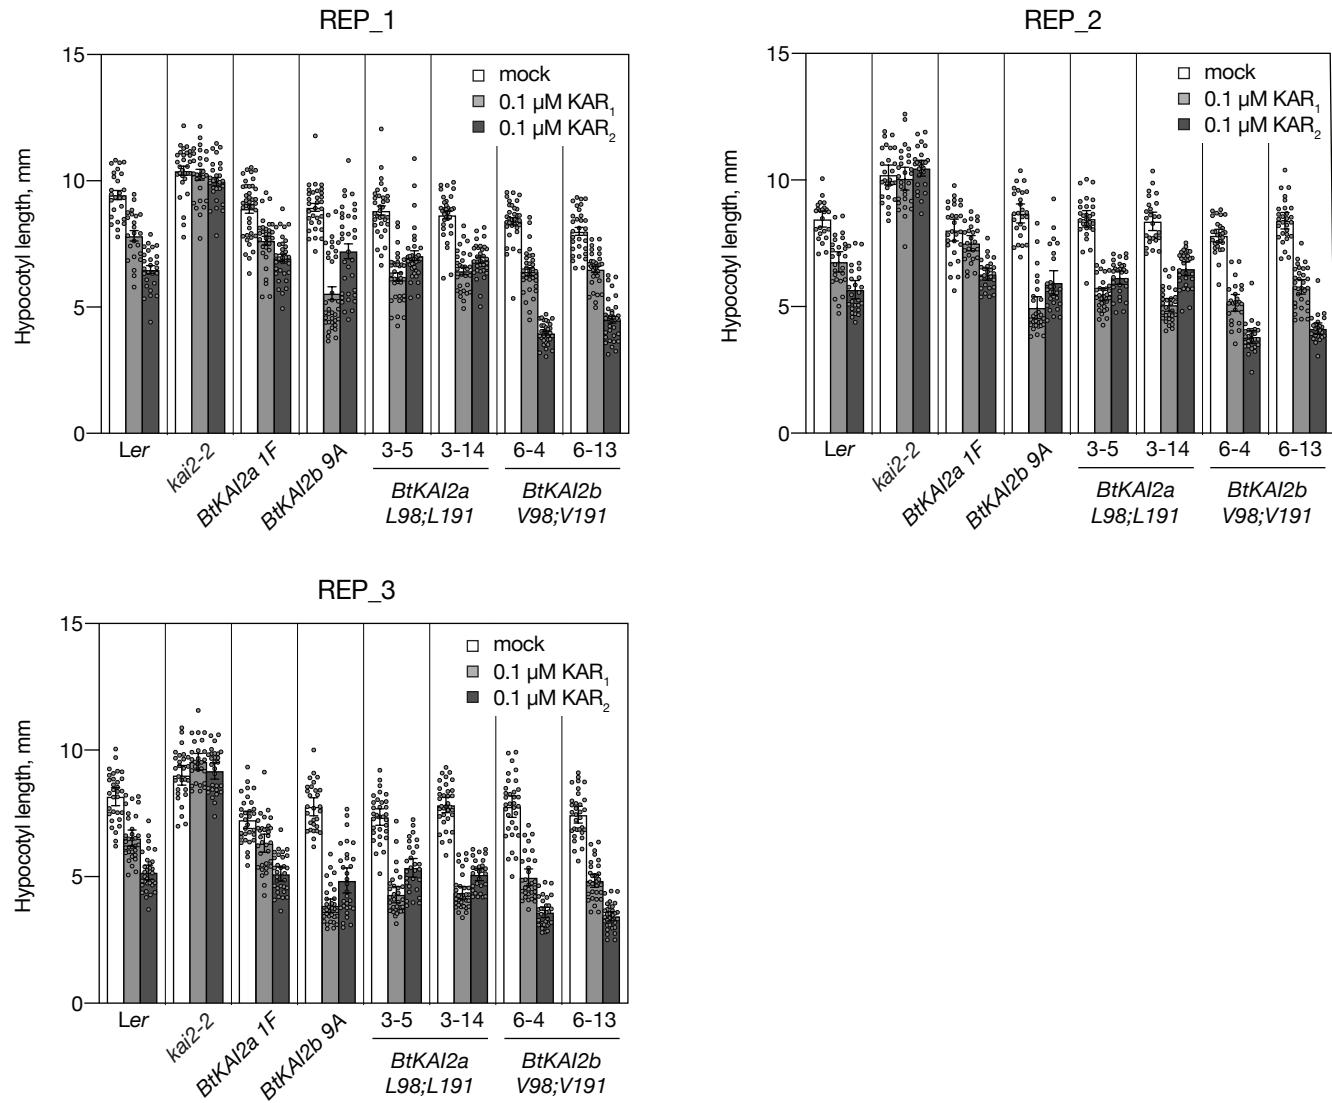

**a**, Differential scanning fluorimetry curves of SUMO-BtKAI2a and SUMO-BtKAI2b in presence of 0–200 μM KAR<sub>1</sub> or KAR<sub>2</sub>. **b**, DSF responses of SUMO-tagged BtKAI2b (left) or untagged BtKAI2b (right) to 0–200 μM GR24<sup>ent-5DS</sup>. **c**, DSF responses to 0–200 μM of the two enantiomers of GR24. Data are means of eight (a and c) or four (b) technical replicates at each concentration of ligand. Source data are provided as a Source Data file.

**Supplementary Figure 10. Stable transgenic expression of BtKAI2 valine-leucine double exchange proteins in Arabidopsis**

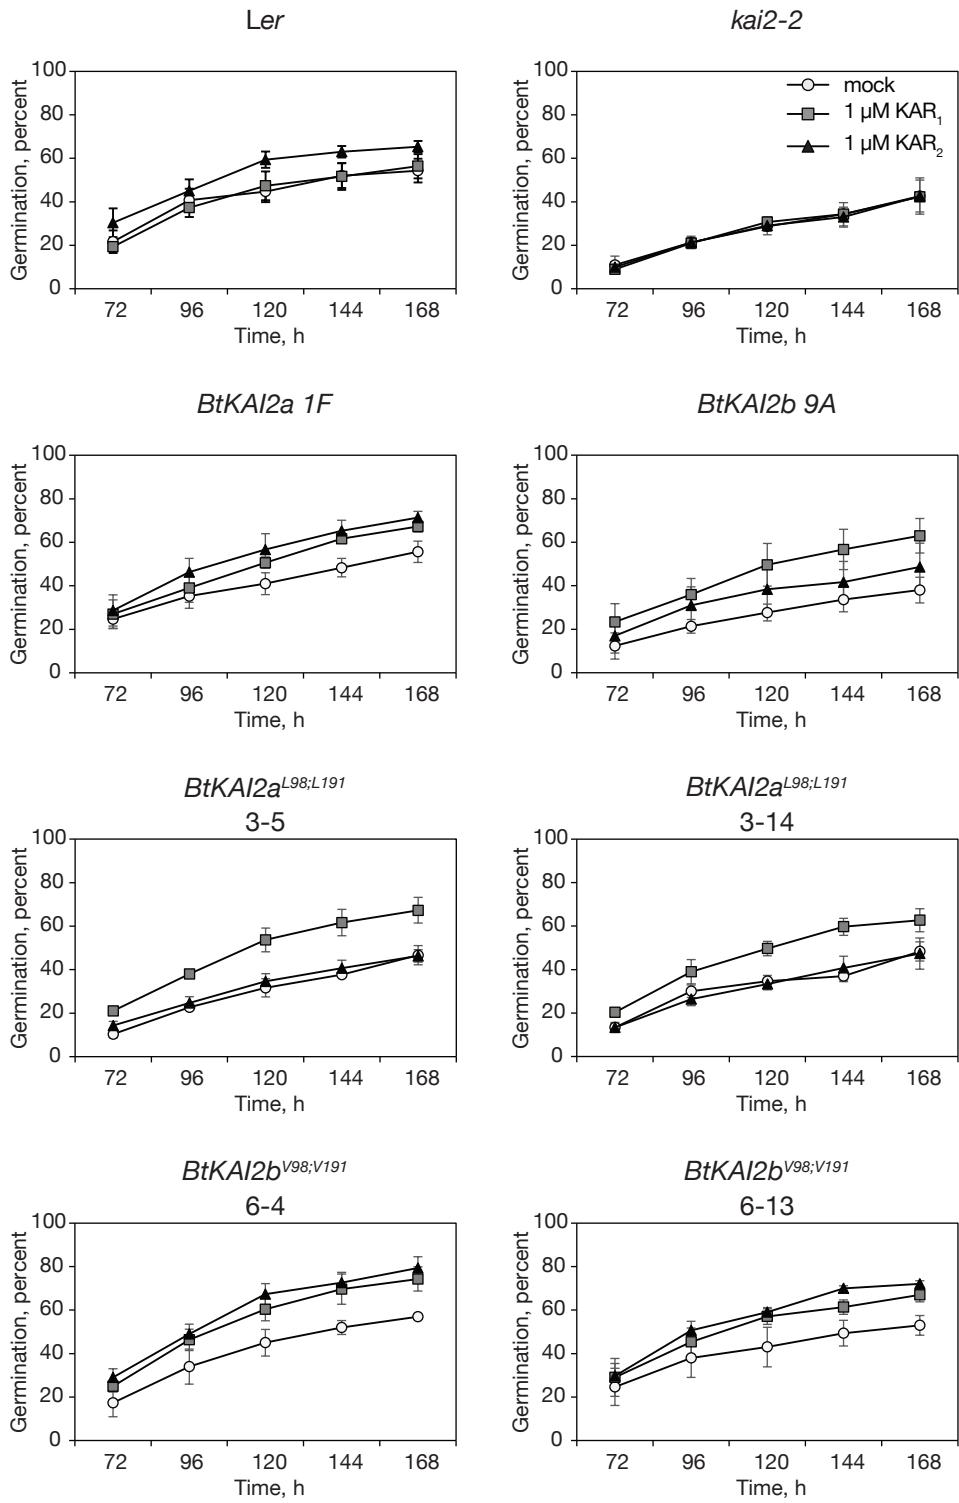

**a**, Immunoblots of total soluble protein extracted from 7-day-old seedlings of independent transgenic lines segregating in a 3:1 ratio for hygromycin resistance. Transgene expression in six lines expressing GFP-BtKAI2a<sup>L98;L191</sup> (upper panels) and five expressing GFP-BtKAI2b<sup>V98;V191</sup> (lower panels) were compared to a representative unmodified control (GFP-BtKAI2a 1F and GFP-BtKAI2b 9A respectively). Based on expression level two lines of each construct (3-5 and 3-14; 6-4 and 6-13) were selected and brought to homozygosity for further experiments. Protein blots were challenged with anti-GFP antibody. Equal gel loading was assessed by imaging total protein prior to blotting; the RbcL band is shown.

**b**, Rosette phenotypes of homozygous individuals expressing native and modified GFP-BtKAI2 transgenes. Plants were 25 days old and grown under long day conditions as described in Methods. Scale bar: 50 mm. Source data are provided as a Source Data file.

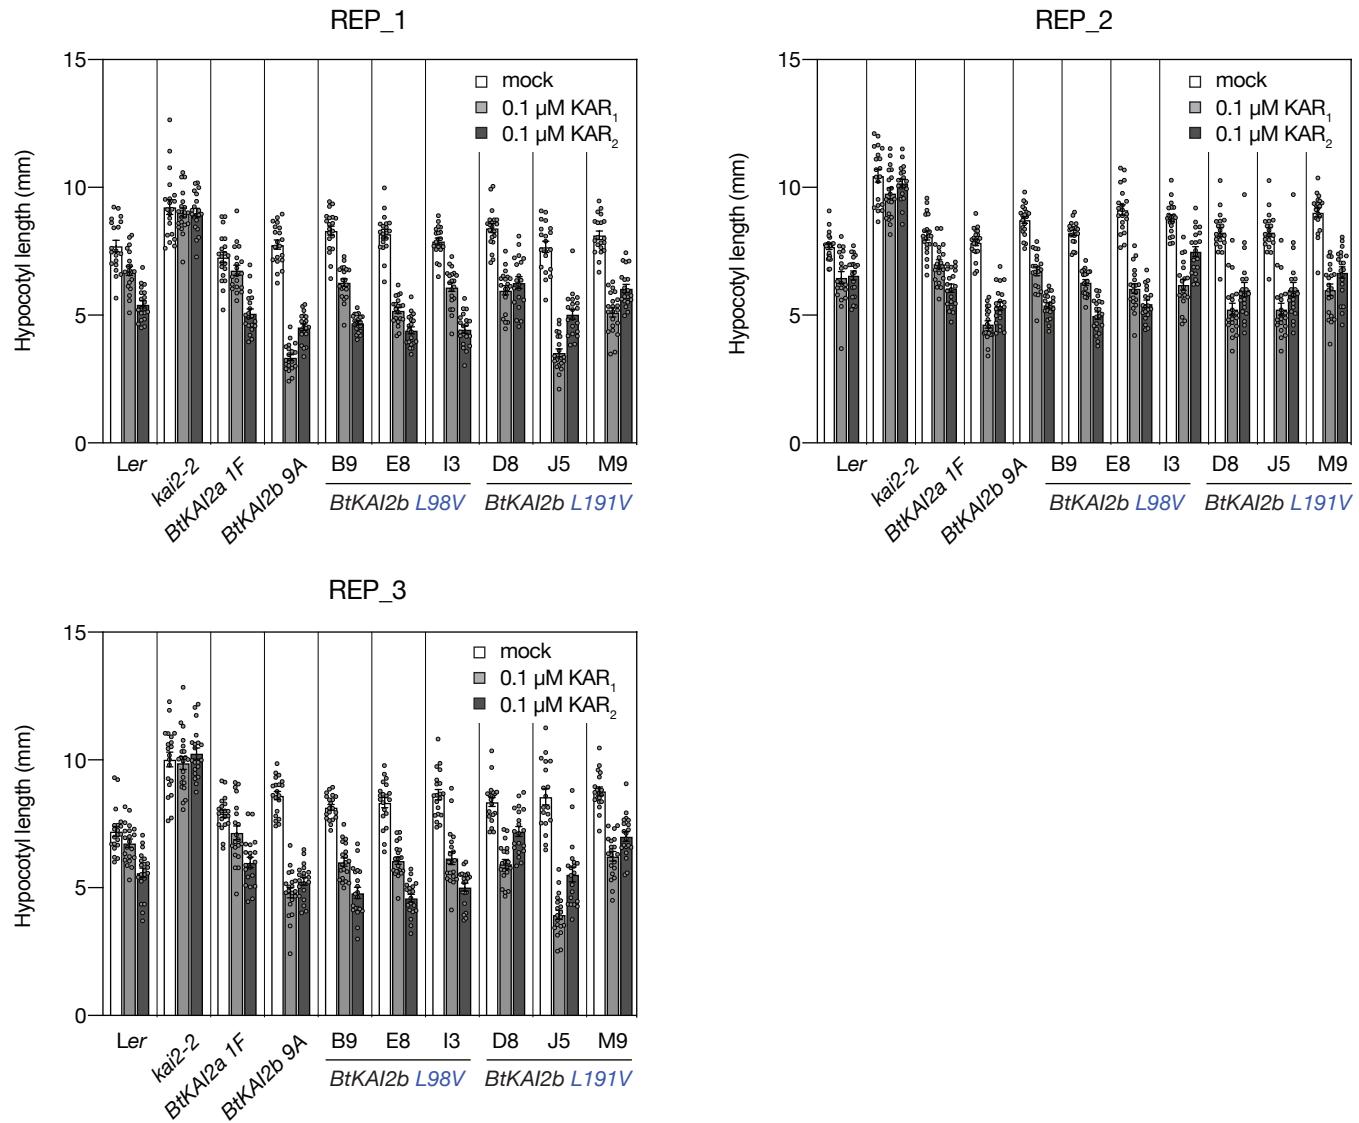

**Supplemental Figure 11. Three experimental replicates of hypocotyl elongation assays with BtKAI2a and BtKAI2b transgenics (double exchange of residues 98 & 191)**

Each panel depicts data from a separate experiment performed on the indicated date, which are shown in summarised format in Figure 4. Data are means  $\pm$  SE, n=24 to 40 seedlings. Each dot corresponds to an individual seedling. Source data are provided as a Source Data file.

**Supplementary Figure 12. Germination profiles of transgenic *Arabidopsis* seeds expressing BtKAI2 homologues (double exchange of residues 98 and 191)**

Freshly harvested seeds (three batches per genotype, each batch harvested from three plants) were removed from freezer storage, surface-sterilised and sown on 0.7% agar supplemented with 0.02% acetone (mock), 1  $\mu$ M KAR<sub>1</sub> or 1  $\mu$ M KAR<sub>2</sub>. Seeds were incubated under constant light at 25 °C. Seeds were examined for germination (radicle protrusion) 72 h after sowing and every 24 h thereafter. Data are means  $\pm$  SE of three independent seed batches and 100 seed per batch. For the BtKAI2a<sup>L98;L191</sup> and BtKAI2b<sup>V98;V191</sup> transgenes, two independent, homozygous transgenic lines were analysed. Source data are provided as a Source Data file.

**Supplemental Figure 13. Three experimental replicates of hypocotyl elongation assays with BtKAI2b transgenics (individual exchange of residues 98 & 191)**

Each panel depicts data from a separate experiment performed on the indicated date, which are shown in summarised format in Figure 5. Data are means  $\pm$  SE, n = 19-21 seedlings. Each dot corresponds to an individual seedling. Source data are provided as a Source Data file.

9	T	257	S	S257T	0.829	Neutral
10	I	263	L	L263I	-1.363	Neutral

#### Notes

1. Consensus is based on most common amino acid among KAI2 sequences from *Brassica* and *Arabidopsis*.
2. All variants were replaced with the consensus residue, and then resubmitted to PROVEAN with revertant mutations to recapitulate BtKAI2c sequence
3. This analysis only considers each substitution in turn, not the combined effect of multiple mutations
