ESM Methods

Questionnaire at the follow-up visit in PPP-Botnia

Questions:

- Myocardial infarction: Has a doctor ever diagnosed you with myocardial infarction or a thrombus in the heart?
- Angina pectoris: Has a doctor ever diagnosed you with coronary disease (coronary artery stenosis or angina pectoris)?
- Coronary bypass: Have you undergone coronary bypass surgery?
- Angioplasty: Have you undergone percutaneous coronary intervention?
- Stroke: Has a doctor ever diagnosed you with stroke?

Patients who replied no to all five questions at the basal visit but yes at the follow-up were considered incident cases. Patients who replied yes at the basal visit but no at follow-up were excluded from the analysis.

ESM Results

Sensitivity analyses

In order to rule out that the increased mortality was a result of patients being diabetic and hence contributing to a larger extent to total mortality, analyses on associations of GIP and mortality as well as cardiovascular mortality in both cohorts excluding subjects with prevalent diabetes, are presented in Supplementary **ESM Table 3-5**.

PPP-Botnia

Sensitivity analysis including only individuals who were normoglycemic both at the basal visit and at follow-up were performed. Logistic regression analysis was performed for incident CVD and total CVD (including both prevalent at baseline and at follow-up) in model 1 (adjusted for age and sex and model 2 (adjusted for age, sex, BMI, SBP, fasting/post-challenge plasma glucose, fasting/post-challenge insulin, LDL, HDL and smoking (**Table 4**). CVD includes both prevalent and incident cardiovascular disease. Number of cases was 62 for incident CVD and 130 for total prevalent CVD. The number of controls was 2151.

MDC-CC

Sensitivity analyses excluding subjects with prevalent (n=545) and incident (n=249) diabetes (n_{total}=794) were performed for associations of fasting GIP, post-challenge GIP, , and prevalent and incident CVD (**ESM Table 5**). Logistic regressions were carried out in model 1 (adjusted for age, sex and time to follow-up) and model 2 (adjusted for age, sex, time to follow-up, BMI, SBP, fasting/(post-challenge glucose), fasting/(post-challenge) insulin, LDL, HDL and smoking).

Exploratory analysis of cardiovascular endpoints

Finally, we performed a cross-sectional, exploratory analysis of GIP concentrations and CVD in order to investigate if the GIP association was specific to any subtype of CVD.

PPP-Botnia

In PPP-Botnia, fasting GIP was associated with total prevalence of CVD (n=4375; 408 events; OR[CI95%]=1.16[1.04-1.31]; p=0.009) in *Model 2*. This association was attenuated in *Model 3* (OR[CI95%]=1.10[0.98-1.24]; p=0.125). Post-challenge GIP was associated with total prevalence of CVD (n=4360; 358 events; OR[CI95%]=1.26[1.02-1.55]; p=0.031) in *Model 3*.

In cross-sectional, logistic regression analyses of the five subcategories of CVD defined in the questionnaire (myocardial infarction, angina pectoris, coronary artery bypass grafting, angioplasty and stroke), fasting GIP concentration was associated with myocardial infarction (OR[CI95%]=1.25[1.01-1.55]; p=0.048) in *Model 3* (non-significant associations not shown).

No analyses of GIP levels and prevalent heart failure were carried out in PPP-Botnia due to lack of data on heart failure.

MDC-CC

In MDC-CC, fasting GIP was associated with total prevalence of CVD at follow-up (n=3268; 638 events; OR[CI95%]=1.14[1.03-1.26]; p=0.009) in *Model 3*. As for post-challenge GIP, each 1 SD increment in post-challenge GIP was associated with total CVD at follow-up in *Model 2* (n=2898; 501 events; OR [CI95%]=1.18[1.00-1.25]; p=0.047), but the association was attenuated when the model was further adjusted according to *Model 3* (OR[CI95%]=1.08[0.97-1.21]; p=0.164).

Further, logistic regression analyses of subcategories of prevalent CVD revealed no significant associations of fasting and post-challenge GIP for any of the five subtypes of CVD (angioplasty, coronary events, major adverse cardiac events, coronary artery bypass grafting, and stroke) when adjusted according to *Model 3* (data not shown).

Additional exploratory analyses revealed that fasting GIP concentration was border-line significantly associated with prevalent heart failure (OR[CI95%]=1.42[1.00-2.00]; p=0.051) in *Model 3*.
