Supplementary Methods

UK Biobank cognitive test battery

UK Biobank Pairs Matching Test (UKB Pairs Matching). The UKB Pairs Matching test was used to assess visual memory. Before starting the test, participants were shown a demonstration video. In this test, participants were shown a screen with pairs of matching cards arranged randomly in a grid on the screen. The pairs of cards were then turned face down and the participant was to touch the cards to match up all the pairs of cards in the fewest number of touches. When the participant correctly identified two matching cards, the cards disappeared from the screen. If the participant made a mistake, the cards were turned face down again and they continued. All participants completed two trials. In the first trial, 6 cards consisting of 3 pairs were shown. In the second trial, 12 cards consisting of 6 pairs were shown. The score for each trial was the number of errors made before matching all pairs. If participants made 2 or fewer errors on the second trial (12 cards; 6 pairs), they completed a third trial with 16 cards consisting of 8 pairs. For the current study we used only the number of errors made on the second trial (12 cards; 6 pairs). This was because the first trial (6 cards; 3 pairs) was very easy and few participants made errors, and because the third trial (16 cards; 8 pairs) was only completed by a subsample of participants.

UK Biobank Reaction Time Test (UKB RT). UK Biobank created a Go/No-Go test to measure reaction time. Before the test began, participants were shown a video demonstration. For each trial, participants were shown two cards with a symbol on them, side-by-side on the screen. The two cards either had matching symbols, or different symbols on them. Participants were instructed that, when the cards matched, they were to push a button-box that was on the desk in front of them as quickly as possible. When the cards were different, the participant was to do nothing, and, after a short delay, the cards disappeared and a new pair would appear. There were 12 trials in total. The first 5 trials (rounds 0-4) were regarded as practice trials. Of the remaining 7 trials, 4 contained

matching cards. The score is the mean time, in milliseconds, to press the button-box for these four trials with matching cards. For this test, UK Biobank provided us with the same button-box as used at the UK Biobank clinic.

UK Biobank Prospective Memory Test (UKB Prospective Memory). Prospective memory was assessed using a one-trial task. At the start of the UK Biobank cognitive test battery, participants were shown a screen with the following instructions: “At the end of the games we will show you four coloured symbols and ask you to touch the Blue Square. However, to test your memory, we want you to actually touch the Orange Circle instead.” Participants then completed all other tests in the UK Biobank cognitive test battery. At the end of the UK Biobank tests, participants were shown a screen with four shapes (blue square, pink star, grey cross, orange circle) and were instructed to touch the Blue Square. If participants touched the Orange Circle (correct answer) the test ended. If the participant touched any other shape, they received the following prompt: “At the start of the games we asked you to remember to touch a different symbol when this screen appeared. Please try to remember which symbol it was and touch it now.” If the participant touched the blue square, the prompt was repeated (ad infinitum). If the participant touched any other shape, the test ended. In this study, the score we used was a dichotomous variable, coded 1 if the participant correctly touched the orange circle on the first attempt, and 0 if they touched any other shape.

UK Biobank Fluid Intelligence Test (UKB Fluid IQ). The UKB Fluid IQ test was designed to assess verbal and numerical reasoning. This task involved participants answering 13 multiple-choice questions. For each question, the question was presented at the top of the screen and between three and five multiple-choice options were presented underneath. The participant was to select which of the possible options they thought was the correct answer, or select “Do not know” or “Prefer not to answer”. The questions assessed verbal (e.g., “Bud is to flower as child is to...?” Possible answers: Grow/Develop/Improve/Adult/Old) and numerical (e.g.,

“150...137...125...114...104... What comes next?” Possible answers: 96/95/94/93/92) reasoning abilities. The score was the number of questions answered correctly in two minutes.

UK Biobank Numeric Memory Test (UKB Numeric Memory). A backward digit span task was used to assess working memory. Participants watched an instructional video demonstration before they started the task. Participants were briefly shown a two-digit number on the screen. The number then disappeared and, after a short delay, the participants were asked to enter the number in the reverse order using a keypad on the screen. The to-be-remembered digit sequence then became one digit longer each time the participant correctly remembered the digits in the reverse order. If the participant incorrectly remembered a sequence, they were then asked to recall a different number sequence of the same length. The test ended when the participant incorrectly recalled two trials of the same digit length, or once the participant correctly remembered a 12-digit number. The score was the maximum number of digits correctly remembered in the reverse order. We note that, for this test, all of the to-be-remembered digit-sequence appeared on the screen at once (e.g., participants saw “48951” on the screen). Therefore it was possible to get the correct answer either by carrying out a backward digit span (e.g., reading the numbers left-to-right and mentally reversing the digits) or a forward digit span (e.g., reading from right-to-left and remembering “15981”).

UK Biobank Trail Making Test (UKB TMT). The UKB TMT is a computerised version of the popular Halstead-Reitan Trail Making Test [1], often described as a test of executive function. This test consisted of two parts and each part started with a practice test. In part A, participants were shown a screen with the numbers 1-25 arranged pseudo-randomly on it. The participants were instructed to touch the numbers in numerical order. In part B, the numbers 1-13 and the letters A-L were arranged pseudo-randomly on the screen. Participants were instructed to switch between touching the numbers in numeric order and letters in alphabetical order (i.e., 1-A-2-B-3-C). For each part, participants were instructed to work as quickly and as accurately as possible. If the participant touched an incorrect number or letter, the screen flashed red to inform the participant that they had

made a mistake and the participant was required to touch the correct number or letter before they could move on. The score was the time, in deciseconds, to complete each part.

UK Biobank Symbol Digit Substitution Test (UKB Symbol Digit). A substitution test was used to measure processing speed. This test is similar to other commonly-used substitution tests including the Wechsler Adult Intelligence Scale IV (WAIS-IV) Coding test [2] and the Symbol Digit Modalities Test [3]. Participants were shown a key which paired symbols (top row) with numbers (bottom row). Underneath the key was a row of symbols. The participant's task was to enter the number, using a keypad on the screen that is paired with the symbol. Before starting the test proper, participants completed a practice trial. Participants were instructed to work as quickly and accurately as possible. The score was the number of correct symbol-digit matches made in 60 seconds.

UK Biobank Picture Vocabulary (UKB Picture Vocabulary). To measure vocabulary, an adapted version of the NIH Toolbox Picture Vocabulary test [4] was used. In the UKB Picture Vocabulary test, participants were shown a screen with four pictures and a written word underneath. The participant was instructed to click on which of the pictures was most closely related to the written word. The items varied in difficulty. To reduce the administration time, this test used computerised adaptive testing which means that the difficulty of the items presented to the participant depended on the correctness of their answers to previous items. Before starting the test proper, participants completed two practice items. The score was an estimate (theta score) of the participant's level of vocabulary, and it could range from -11 to 11, with higher scores representing better vocabulary.

UK Biobank Paired Associate Learning (UKB PAL). An adapted version of the Paired Associate Learning test from Test the Nation [5] was used to measure verbal declarative memory. Participants were instructed that they were going to see a screen containing word pairs and that they were to try to remember the word pairs as they will be tested on them later. Participants were then presented with a screen containing twelve pairs of words for 30 seconds (learning phase). After the learning phase, the participants completed another test (the UK Biobank Matrix Pattern test). Then,

participants were presented with the first word of a pair (the target word) and were asked to select, from a list of four options, which word was paired with the target word, or select “Prefer not to answer”. There were 10 questions in total. The score was the number of questions answered correctly.

UK Biobank Tower Rearranging Test (UKB Tower Test). An adapted version of the One-touch Tower of London test [6] was used to assess planning abilities, often described as a component of executive function. In this test, participants were shown a display (display A) with three pegs on it and three different coloured hoops placed on the pegs. Underneath display A was another display (display B). Display B again had three pegs and the same three coloured hoops; however, the hoops were arranged in different locations to that shown in display A. The participant’s task was to work out the number of moves that it would take to make display A look like display B. The number of moves required for each item could range between 1 and 6. The score was the number of items answered correctly in 3 minutes.

UK Biobank Matrix Pattern Completion (UKB Matrices). An adapted version of the COGNITO Matrices test [7] was used as a measure of non-verbal fluid reasoning. For each item, participants were presented with a matrix design, with a piece missing in the lower right hand corner. The pattern has a logical structure, which can be used to work out what the missing piece should look like. The task was to work out the rules of the patterns and select, from a list of between 6 and 8 alternatives, the correct missing piece of the puzzle. Participants completed two practice examples before starting the test proper. The items ranged in difficulty from easy to difficult. There were 15 items in total, and the score was the number of items answered correctly in 3 minutes.

General tests

Cambridge Examination of Mental Disorders of the Elderly (CAMDEX) Self-rated memory [8]. To assess subjective memory complaints, the tester asked participants four questions about their self-reported memory. The questions assessed general memory problems, difficulties remembering

where they left common objects, difficulties remembering names, and whether participants have ever become lost in a familiar environment. For each question participants answered yes (scored 1) or no (scored 0). A higher score reflected poorer self-rated memory.

Mini Addenbrooke's Cognitive Examination UK Version B [9] (M-ACE). The M-ACE is a 30-item abbreviated version of the Addenbrooke's Cognitive Examination III [10]. The test assesses attention (orientation in time), memory (immediate and delayed memory of a name and address), fluency (animal naming), and visuospatial abilities (clock drawing). This test has been validated in dementia patients and has been found to be more sensitive and less prone to ceiling effects than the commonly used Mini-Mental State Examination [11].

Reference tests

Peabody Picture Vocabulary Test, Fourth Edition [12] (PPVT). The PPVT was chosen as a reference test for UKB Picture Vocabulary. Participants were shown a page with four pictures on it and the tester read out a word. The participant's task was to decide which of the four pictures shows the meaning of the word. Prior to beginning the test proper, participants were presented with two practice items. The test consisted of 19 sets of 12 words (228 items). Each set of words was progressively harder than the last. Participants started at set 14 (item number 157). If the participant made one or fewer errors on set 14, participants moved on to set 15 and full marks were awarded for sets 1-13. If two or more errors were made in set 14, lower sets were administered (in reverse order), until the participant made one or fewer errors in a set. Again, full marks were awarded for easier sets not administered. The test ended when participants completed set 19, or when participants made 8 or more errors on a set. One point is given for each correctly answered question. The scores is the number of questions answered correctly.

National Adult Reading Test [13] (NART). The NART was selected as a reference test for UKB Picture Vocabulary. Participants were given a piece of paper with 50 irregularly-pronounced words written on it. The participant was asked to read the words aloud. One cannot rely on the spelling to correctly

pronounce the word; therefore, prior knowledge of the word is required to know how to pronounce it correctly [13]. One point was given for each correctly pronounced word. This brief test is often used as a measure of premorbid ability because it has been found to be robust to the effects of cognitive decline [14, 15].

NIH Toolbox Picture Vocabulary [4]. To compare the UKB Picture Vocabulary to the original version of this test, participants were administered the NIH Toolbox Picture Vocabulary. The UKB Picture Vocabulary uses the same visual stimulus and words as in the original NIH Toolbox Picture Vocabulary test. This test was administered on an iPad tablet computer. The participant was presented with a screen with four pictures on it and heard a spoken word. The word was spoken with an American accent in the NIH Toolbox Picture Vocabulary test. Like the UK Biobank version, this original version was adaptive and therefore the items presented depended on the correctness of participant's previous answers. The score was an estimate (theta score) of the participants level of vocabulary. Higher scores reflected a higher vocabulary level.

Rivermead Behavioural Memory Test - Extended Version, Appointments [16] (RMBM

Appointments). The RMBM Appointments test was selected as a reference test for UKB Prospective Memory. In this test, participants were informed that the tester was going to set the alarm to ring in 20 minutes time. Before starting the test proper, the tester played the alarm to let the participant know what the alarm sounded like. The tester then set the alarm for 20 minutes. The participant was instructed that when the alarm rings, they should ask the tester 2 questions (“When do I have to see you again?” and “When does this session end?”). When the alarm sounded, participants who spontaneously asked the two questions were awarded 2 points per question (max score = 4). If the participant did not spontaneously ask the tester the two questions, the tester prompted the participant by asking them “What [else] were you going to do when the alarm rings?” If the participant provided the questions following the prompt, 1 point was awarded per question.

Wechsler Memory Scale IV (WMS-IV) Designs [17]. The WMS-IV Designs test was chosen as a reference test for the UKB Pairs Matching test. This is a test of visuospatial memory and it consists of two parts: Designs I and Designs II. In Designs I, a blank 4x4 grid was placed in front of the participant. Participants were then presented with a page containing a 4x4 grid with between 4 and 8 abstract designs in some of the cells of this grid. The page was shown for 10 seconds and then removed. A pack of cards with designs on them was then handed to the participant. The participant's task was to select from the pack of cards which designs were on the page, and then place the designs on the grid in the same configuration as on the previous page. A practice example using two designs was used to help participants understand the task. There were 4 trials in total; one containing 4 designs, two containing 6 designs, and one containing 8 designs. Points were awarded if participants selected the correct design (2 points awarded for selecting the correct design, 1 point awarded for selecting the distractor design), placed a design in the correct location (1 point awarded if participants placed *any* design in one of the correct locations), and placed the correct design in the correct location (2 points awarded if correct design was placed in the correct location). The maximum score for Designs I was 120 points.

Approximately 20 minutes after completing Designs I, in which participants completed other cognitive tests, Designs II was administered. The 4x4 grid was placed in front of the participant. For each trial, participants were presented with a pack of cards and asked to select from the pack which designs were shown earlier and they were asked to place these designs on the grid in the same configuration as on the page shown earlier. The same scoring system as used in Designs I was used for Designs II. The maximum score for Designs II was 120.

WMS-IV Verbal Paired Associates [17] (VPA). WMS-IV VPA is a test of verbal declarative learning and memory and was chosen as a reference test for the UKB Paired Associates Learning test. VPA is made up of two parts: VPA I and VPA II. In the learning phase of VPA I the tester read aloud a list of 14 word-pairs to the participant. Immediately after reading the word-pairs, the tester said the first

word of each pair, and the participant was to recall the word that went with it (test phase). The test consisted of four trials and, for each trial, the same 14 word-pairs were used in the learning and test phase. The order of the word-pairs differed each trial. The score for VPA I is the number of correctly recalled word-pairs across the four trials (maximum score = 56).

Approximately 20 minutes after completing VPA I, VPA II was administered. Participants completed other cognitive tests in the delay between VPA I and VPA II. Without hearing the word-pairs again, the tester read out the first word of each pair and the participant was to recall which word was paired with it. The score was the number of correctly recalled words (maximum score = 14).

WAIS-IV Digit Span [2]. The WAIS-IV Digit Span test is a measure of working memory and it was chosen as a reference test for UKB Numeric Memory. This test is made up of three different tasks. For Digit Span Forwards, the tester read aloud a sequence of numbers to the participant, and the participant was required to immediately recall the numbers in the same order. For Digit Span Backwards, the tester read aloud a sequence of numbers and the participant was required to recall the numbers in the reverse order. For the Digit Span Sequence, the tester read a sequence of numbers and the participant had to recall the numbers in ascending order. For each task, the participants were first read a two-digit sequence. After completing two trials of the same length, the number of digits in the to-be-recalled sequence increased by one. The task ended when the participant incorrectly recalled 2 trials of the same length, or when the participant had completed 16 trials. For Digit Span Backwards and Digit Span Sequence (but not Digit Span Forwards) participants completed two practice trials before starting the test proper. For each task, one point was awarded for each correctly recalled trial (maximum score = 16).

Symbol Digit Modalities Test [3] (SDMT). The SDMT is a measure of processing speed and was chosen as a reference test for the UKB Symbol Digit test. Participants were provided with a piece of paper with a key pairing symbols and numbers at the top of the page. Below the key were rows of boxes with symbols in them and empty boxes underneath. The participant's task was to write the

number in the empty box that was matched with the symbol. Before starting the test proper, participants completed a practice consisting of 8 symbol-digit matches. The score was the number of correct symbol-digit matches made in 90 seconds.

Deary-Liewald Reaction Time Test [18] (DLRT). The DLRT is a computerised task made up of two parts—Simple reaction time (RT) and Choice RT—and was chosen as a reference test for UKB RT. Both parts began with a practice example consisting of 8 trials. In the Simple RT task, participants were shown a screen with a blue background and a white square in the middle. The task was to push the spacebar on a keyboard as quickly as possible each time a cross appeared in the box. There were 20 trials. The score was the mean time, in milliseconds, to press the spacebar when the cross appeared. In the Choice RT test, there were four white boxes on the computer screen. Participants were instructed to place their index and middle fingers on the “Z”, “X”, comma and full stop keys on the keyboard. These four keys corresponded to the four boxes on the screen. A cross could appear in any of the four boxes. The participant’s task was to press the correct key when a cross appeared in one of the four boxes on the screen as quickly as possible. There were 40 trials. The score was the mean time, in milliseconds, to press the correct key.

Trail Making Test (TMT). The Halstead-Reitan [1] TMT test was used to measure switching ability, often described as a component of executive function. This test was used as a reference test for UKB TMT. This paper-and-pencil test consisted of two parts and each part started with a short practice example that the tester completed to show the participant what they were to do. In part A, participants were provided with a piece of paper with the numbers 1 to 25 arranged on the page. The participant’s task was to draw a line trail through each number in numeric order. In part B, participants were provided with a piece of paper with the numbers 1 to 13 and the letters A to L arranged on the page. The participant’s task was to switch between joining up the numbers in ascending order and letters in alphabetical order (e.g., 1-A-2-B-3-C). If the participant made a

mistake, the tester would instruct the participant to start from the last correct number or letter. The score used in this study was the time, in seconds, to complete part A and part B.

Delis-Kaplan Executive Function System (D-KEFS) Tower Test [19]. The D-KEFS Tower Test is a test of planning ability—often described as a component of executive function— and was used here as a reference test for the UKB Tower Test. In this test, the participant was given a wooden base with three pegs on it. The tester placed between 2 and 5 wooden disks of varying size on to the wooden pegs. The participant was shown a page with an illustration of the peg board with the discs arranged in the target sequence. The participant’s task was to move the wooden discs on the board to match the target display using the fewest possible moves. Participants were instructed to follow two rules: they must move only one disc at a time, and they cannot place a larger disc on top of a smaller disc. There were 9 trials in total that started easy (2 discs) and became progressively harder (up to 5 discs). Each trial had a time limit. For each trial, a score of 0 was given if participants failed to match the peg board to the target sequence or if they ran out of time. Between 1 and 4 points were allocated based on the number of moves taken to correctly make the peg board look like the target display. Higher scores reflect better performance (maximum score = 30).

COGNITO Matrices [7]. The COGNITO Matrices task is a measure of non-verbal reasoning and was used as a reference test for UKB Matrices. UKB Matrices is an adapted version of the COGNITO Matrices test. UKB Matrices uses the same items as the original version. In this computerised test, participants were presented with a matrix design on the computer screen with a piece missing in the lower right hand corner. The participant was to touch which of the puzzle pieces, from a list of 6 to 8 alternatives, completed the design. There were 15 items in total, and each item had a 30 second time limit. If participants had not provided an answer in this time limit, the next question would appear and a score of 0 would be given for that item. Two points were awarded for each correctly answered question, and a score of 0 was awarded for incorrect items (maximum score = 30).

Correlations shown in bold show the correlations between the UK Biobank tests and the chosen reference test.

UKB, UK Biobank; RT, Reaction Time; Prosp Memory, Prospective Memory; Fluid IQ, Fluid Intelligence; TMT, Trail Making Test; PAL, Paired Associate Learning; M-ACE, Mini Addenbrooke's Cognitive Examination; PPVT, Peabody Picture Vocabulary Test – Fourth Edition; NART, National Adult Reading Test; NIH TB Picture Vocabulary, NIH Toolbox Picture Vocabulary; RMBM, Rivermead Behavioural Memory Test – Extended Version; WMS-IV, Wechsler Memory Scale – Fourth Edition; VPA, Verbal Paired Associates; WAIS-IV, Wechsler Adults Intelligence Test – Fourth Edition; SDMT, Symbol Digit Modalities Test; DLRT, Deary-Liewald Reaction Time Test; D-KEFS, Delis-Kaplan Executive Function System.

* $p < .05$, ** $p < .01$, *** $p < .001$

Supplementary Results

Sensitivity analysis

The UKB Picture Vocabulary and UKB Matrices tests shared items with the NIH Toolbox Picture Vocabulary and the COGNITO Matrices tests. To check whether the high correlation found between *g:reference-11* and *g:UKB-11* was because of this overlap in items, another measure of general cognitive ability was created using the same tests as in *g:reference-11*, but excluding scores on the COGNITO Matrices and NIH Toolbox Picture Vocabulary (*g:reference-9*). The results of a PCA using 9 reference tests are reported in Supplementary Fig 5 (scree plot of the eigenvalues) and Supplementary Table 15. The correlations between *g:reference-9* and *g:UKB-11* ($r = 0.85, p < .001$; age-adjusted $r = 0.78, p < .001$) and between *g:reference-9* and *g:UKB-5* ($r = 0.73, p < .001$; age-adjusted $r = 0.67, p < .001$) were similar in size to that found when using *g:reference-11*.

Supplementary Fig 5. Scree plot of eigenvalues from 9 reference cognitive tests (excluding reference tests with overlapping items with the UK Biobank tests).

Supplementary Table 15. Loadings from a principal component analysis of 9 reference cognitive tests (n = 155). Eigenvalues indicated two components. Unrotated and rotated loadings, using oblique (oblimin) rotation, are reported.
