

Supplementary Figure 1. Evaluation of quantitative phosphoproteome data from mouse skeletal myotubes following treatment with IGF-1 or LY294002. a. C2 myotubes were starved over night and treated with EPS for 4 h. Lysates were subjected to SDS-PAGE and immunoblot analysis using total and phospho-specific antibodies. b. Overview of the number of identified proteins and phosphoproteins as well as the number of counted, localized (\geq 0.75) and quantified phosphosites obtained by SILAC-MS and MaxQuant data analysis. c. Distribution of peptides identified to be phosphorylated at serine (pS) threonine (pT) or tyrosine (pY). d. Distribution of singly, doubly and triply phosphorylated peptides. e. Distribution of the charge state of phosphopeptides. f. Overlap of localized and quantified phosphosites between independent experiments. In sum, 8,441 phosphosites (73%) of all localized sites were quantified in two out of three replicates. g-i. Multi-scatter plots with Pearson correlation analysis between biological replicates for each condition (i.e. control, IGF-1 and LY294002 treatment). j. Box-plot analysis of \log_2 -transformed phosphopeptide ratios in replicates 1-3. Only a small fraction of all quantified phosphospetides exhibits a \log_2 ratio \geq 0.584 or \leq -0.584 (i.e. minimum fold-change of 1.5). **k** and I. Scatter plots of quantified proteins after 1 h treatment with IGF-1 (k) and LY294002 (l) in comparison to DMSO-treated control. No changes in the relative abundance of proteins were found (n=3 independent experiments; two-tailed moderated student's t-test).

Supplementary Figure 3. Sequence motif analysis for proteins with phosphosites downregulated in response to PI3K/Akt/mTOR pathway activation or upregulated following inhibition. **a**, **b**. Volcano plots of phosphopeptides with localized phosphosites quantified in contracting C2 myotubes following IGF-1 (a) or LY294002 (b) treatment. Log₂-transformed mean SILAC ratios (control/treatment) were plotted against -log₁₀ adjusted p-values. Phosphopeptides with a minimum fold change of 1.5 and a FDR lower than 0.05 (n=3 independent experiments; moderated two-tailed student's t-test) are shown as larger dark gray circles. Among these, phosphopeptides are color-coded according to their phosphorylation sequence motif as indicated and regions of interest are highlighted in each plot. **c**, **d**. Motif-X analysis of regulated phosphopeptides. The proline-directed motif pSxxxSP was 30-fold and ad 26-fold enriched following treatment with IGF-1 (c) and LY294002 (d), respectively. x, any amino acid. **e**. Overlap of unique phosphopeptides comprising the proline-directed motif p[S/T]xxxp[S/T]P in Group 4 (IGF-1 downregulated) and Group 5 (LY294002 upregulated). **f**. Combined GO enrichment analysis of phosphopeptides in group 4 and 5 (G4, G5) shown in (e). GO analysis was performed with the Cytoscape app ClueGO using Benjamini-Hochberg correction for p-value calculation. Only pathways with a p-value \leq 0.05 were considered to be enriched. **g**. STRING network analysis of proteins with regulated phosphopeptides (fold-change \geq 1.5; FDR < 0.05; n=3; moderated two-tailed student's t-test) following treatment of C2 myotubes with LY294002 or IGF-1. Proteins annotated as components of the PI3K/Akt pathway are highlighted by red bullets, proteins annotated with the G0 term "gene expression" by yellow bullets. Gene names of proteins comprising a regulated phosphorylation sing the within a short or extende

Supplementary Figure 4. Study of the PI3K/Akt/mTOR signaling landscape in contracting C2 myotubes using LY294002 (LY) and MK-2206 (MK). a. Contracting C2 myotubes, differentially labeled by SILAC amino acids, were treated for 30 min with IGF-1 in combination with LY or MK as indicated. Immunoblot analysis of PI3K/Akt/mTOR pathway activity using phospho-specific antibodies against established readouts. b. Overview of the number of identified proteins and phosphoproteins as well as the number of counted, localized (≥ 0.75) as well as localized and reproducibly quantified phosphosites in 3 out of 6 independent experiments obtained by quantitative MS-based phosphoproteome analysis and MaxQuant data analysis together with the IGF-1/LY data. c. Pearson correlation analysis of the phosphoproteomic data for the three different treatments (IGF-1, IGF-1+LY, IGF-1+MK, n=6). d. Z-score for the top down-regulated kinases based on kinasesubstrate enrichment analysis (KSEA) for the different treatments as indicated. e. Hierarchical cluster analysis of all peptides that were significantly regulated in at least one of the four treatments (fold-change > ±1.5, adjusted p-value < 0.05 for IGF-1/LY dataset and < 0.01 for the LY/MK dataset) in the combined analysis (left panel). Two main cluster were obtained, the upper with 317 phosphopeptides, the lower with 560 phosphopeptides (right panel) f. Phosphosites of endogenous FLNc from mouse skeletal myotubes identified and quantified in this study. pS2234 and pS2237 are located in the extended basophilic motif RxRxxpSxxpS within the conserved Ig-like domain 20 of FLNc. g. Mean intensities of FLNc phosphopeptides with pS2234, pS2237 or pS2239 (n=3 independent experiments, SEM) h. Immunoblot analysis and quantification of signals detected for endogenous FLNc-pS2234 in comparison to total FLNc following treatment of mouse skeletal myotubes with IGF-1 or LY. Shown are normalized values from 14 replicates ± SEM. A paired two-tailed student's t-test was performed. i. FLNc phosphopeptides with the sequence 2232-LGSFGSITR-2240, either singly or doubly phosphorylated at S2234 and S2237, were regulated in abundance following activation (IGF-1) or inhibition (LY, IGF-1+MK, IGF-1+LY) of PI3K/Akt signaling. Shown are the log, ratios and adjusted p-values calculated for each of the phosphosites.

mammals

Supplementary Figure 6. Analysis of phosphorylation status of endogenous mouse (m) FLNc as well as human (h) FLNc d18-21 S2233D and S2233A mutants. a. Kinase prediction for pS2233 and pS2236 of mFLNc and hFLNc using the algorithms NetPhorest and Scansite 3. Both phosphosites are part of the extended basophilic motif located in the unique 82-amino acid insert in domain 20, which is highly conserved in mammals. b. Immunoblot analysis of mFLNc phosphorylation at S2234 in C2 myotubes in dependency of MK-2206 and LY294002 inhibition in combination IGF-1 as indicated. c, d. C2 cells expressing hFLNc d18-21 in which S2233 was mutated to alanine (A) or aspartate (D) were treated with PMA for activation of PKC followed by phosphopeptide analysis in a targeted MS approach using higher collisional dissociation (HCD) as outlined in Figure 4c. HCD spectrum of the phosphopeptide (a) LGAFGpSITR from the FLNc d18-21 S2233A mutant. The site-exchanged amino acids (S to A, S to D) are highlighted in green. e. Precurs sor and transition areas determined by Skyline analysis of the targeted MS data obtained for the phosphopeptide shown in (c) and (d).

Supplementary Figure 7. FLNc phosphosite mutants and fusion proteins used in this work. a. Schematic illustration of human FLNc d18-21 constructs used for bacterial transformations comprising a 6xHis tag and an EEF tag fused to the carboxy-terminus. Phosphosite mutants were generated from the respective wild-type construct by exchange of one or two serines (S) to alanine (A) or aspartate (D) as indicated. WT, wild-type; d, domain b. Schematic illustration of human FLNc d18-21 constructs used for transfections of mammalian cells comprising a Myc-tag and a BirA* sequence fused to the amino-terminus. Additionally, wild-type and single site mutants contain a 6xHis tag and an EEF tag fused to the carboxy-terminus. Phosphosite mutants were generated as described in (a). BirA*, promiscuous biotin ligase. c. Schematic illustration of human FLNc d1-3 construct used for bacterial transformations comprising a T7 tag and a 6xHis tag fused to the amino- and carboxy-terminus, respectively. d. Schematic illustration of human FLNc d22-24 construct used for transfections of mammalian cells comprising a Myc-tag and a BirA* sequence fused to the amino-terminus. e. Schematic illustration of FILIP1 carboxy-terminal constructs. For transformation of bacterial cells, the construct was fused to GST at its amino-terminus. For transfection of mammalian cells, the construct was fused to GFP at its carboxy-terminus. CT, carboxy-terminus. f. Schematic illustration of the phosphomimicking human FLNc d19-21 construct used for fluorescence correlation spectroscopy analysis comprising a 6xHis tag fused to the amino-terminus. The phosphomimicking mutant was generated from the respective wild-type construct by exchange of two serine residues (SS) to aspartate (DD) as indicated. WT, wild-type. g. Schematic illustration of constructs used for co-expression of FLNa, FLNc and FILIP1. FLNa and FLNc full-length constructs were fused to GFP at its carboxy-terminus. FLNc double phosphosite mutants were generated from the respective WT construct by exchange of two serine residues (SS) to alanine (AA) or aspartate (DD) as indicated. FILIP1-2 was fused to an HA-tag at its amino-terminus. FL, full-length. h. Schematic illustration of FLNc constructs used for fluorescence recovery after photobleach fused to a carboxy-terminal EGFP. Phosphomimicking mutants were generated from the respective wild-type construct by exchange of two serine residues (SS) to aspartate (DD) or alanine (AA) as indicated. FL, full length. WT, wild-type.

Supplementary Figure 8. Identification and validation of the interaction of FLNc and FILIP1. a. Hierarchical cluster analysis of the SILAC data obtained in the study of the protein nano-environment around hFLNc d18-21 by in vivo proximity labeling in skeletal myotubes. Mean log₁₀ transformed SILAC ratios of quantified proteins were used (n=3 independent experiments). Only proteins in cluster 1 were deemed components of the hFLNc d18-21 interactome, since they were strongly enriched in comparison to both controls. Cluster 2 and 3 mainly contained unspecific binding partners and contaminants. Cluster 1, light red; cluster 2, light blue; cluster 3, gray. b. GO enrichment analysis. Shown are the cellular compartments containing proteins enriched in cluster 1. Z-disc and Z-disc-associated ontologies were overrepresented in cluster 1. c. Schematic illustration of FILIP1 isoforms. Shown are exons and slicing events. The isoforms FILIP1-1 and FILIP1-2 represent the Uniprot entries Q7Z7B0-1 and Q7Z7B0-2, respectively. The isoform FILIP1-4 lacks exon 6 as a result of alternative splicing. d. Sequence alignment of the carboxy-termini of FILIP1 isoforms 1 to 4 using Clustal Omega. e. Immunoblot analysis using an antiserum directed against its carboxy-terminus shows expression of FILIP1 (~130 kDa) in mouse skeletal muscle (lane 1) and cultured C2C12 myotubes (lane 3). The specificity of the antiserum was shown by adding the antigen (T7-tagged FILIP1-2 CT) to the antibody solution ("block", lanes 2 and 4). Binding to FILIP1 was abolished, but a distinct band above the 180 kDa marker band appeared, indicating binding of the antibody/antigen complex to another protein in the extracts. The presence of FILIP1-2 CT was confirmed using T7-tag antibody (lane 5), whereas binding of the antibody/antigen complex to endogenous FLNc was confirmed using anti-FLNc antibody (lane 6). f. Yeasttwo hybrid analysis indicates binding of FILIP1-4 to FLNc d16-19, d17-19, d18-21 and d20-21 in yeast cells. -: no binding; +: weak binding; ++: moderate binding; +++: strong binding g. Coomassie-stained gel from FLNc d1-3 and FLNc d18-21 pulldown with myotube lysates. Bands of recombinant FLNc d1-3 (*) and recombinant FLNc d18-21 (#) are marked. For identification of FILIP a gel band at approx. 130 kDa was cut from each lane as indicated and analyzed by LC-MS. FILIP1 was unambigously identified in the pulldown with FLNc d18-21, but not FLNc d1-3 as illustrated by the respective LFQ-based intensity bar chart. Myh8, Myosin-8 h. Identification of endogenous FLNc in FILIP1 CT pull-down by LC-MS analysis. FLNc was identified with a sequence coverage of 78%. Identified peptides are shown in red.

Supplementary Figure 9. Analysis of FILIP1 binding to human (h) FLNc in dependency of S2233/S2236 phosphorylation. a. Pull-down experiments using GST-FILIP1 CT as bait and His₆-tagged hFLNc d18-21 wild-type or S2233/S2236 phosphosite mutants as prey as indicated. Wild-type hFLNc d1-3 served as negative control. WT, wild-type; CT, carboxy-terminus; d, domain. b. Quantification of immunoblot data shown in (a). Calculated signal intensities were normalized to hFLNc d18-21. SEMs were calculated and a two-tailed student's t-test was performed (n = 3 independent experiments; *p ≤ 0.05). c. Mean MS intensities of phosphopeptides derived from recombinantly expressed hFLNc d18-21 in HEK293T cells. Peptides phosphorylated at S2233, S2236 or both 2233 and S2236 were summed and for each the mean MS1 intensity is shown (n=3 independent experiments, \pm SEM). d. Fluorescence correlation spectroscopy analysis of co-expressed FILIP CT-GFP and Myc-hFLNc d18-21 in competition with recombinantly expressed hFLNc d19-21 WT (Kd = 22.85 + 2.86 μ M) and hFLNc d19-21 DD mutant (Kd = n.a.), respectively. Data of 3 independent experiments are shown.

area in boxes shown in Fig. 6f

Supplementary Figure 11. Uncropped bright-field microscopy images from FILIP1 knockdown or control C2C12 cells, shown in Fig. 7c.

Supplementary Figure 12 area in boxes shown in Fig. 7d

Supplementary Figure 12. Uncropped fluorescence microscopy images of FILIP1 knockdown or control C2C12 cells, shown in Fig. 7d.

Supplementary Figure 13: Immunoblot analysis of control samples performed for experiment shown in Figure 7h. C2 cells were transfected with FLNc d18-21 WT or mutant forms in the presence or absence of HA-FILIP1. Cells were treated 6 h with DMSO before lysis and anti-Myc IP was performed. The first lane of the immunoblot corresponds to the last lane of the immunoblot shown in Figure 7h.
