Supplementary Video S1. Time-lapse of initial building activity after setup of a hive.

This recording of a full-sized camera view in a pre-experiment in 2015 started right after setup of the hive. The wax of the cells adjacent to the glass (first cell layer) of the provided well-constructed combs was remodelled to fixate the combs to the glass. Therefore, the cells of the first cell layer initially appear to shrink in size and are extended again afterwards. In later experiments, the full-sized image was divided into six images as shown in Supplementary Video S2 to increase performance of the space-time image generation script. Furthermore, this initial building phase was not recorded to save hard-disk space since no feeding behaviour was present. Over the course of the video, adjustments were being made to the camera hardware to optimise image brightness, contrast and hard-disk requirements (capturing frequency). This material is protected by copyright. All rights reserved.

Supplementary Video S2. Comb stipe in a control colony, demonstrating the development in the breeding area within the observation hives.

This video footage was used for analysis. However, quality has been reduced to enable online publication. The colony was setup on May 17th 2016. Recording started on May 22nd and ended on June 5th, as displayed in the upper left corner. We recorded with 1 frame per second throughout the experiment, as shown in the initial 14 seconds of the video (running speed displayed at the top). Afterwards, the video is in time-lapse to demonstrate colony development. Eggs were visible shortly after colony setup and appeared descending only when workers pushed them during a deep visit in the cell, or when the larva hatched. As seen in numerous cells, young larvae of the initial eggs were cannibalized (though initially fed) until development in the invisible inner cells progressed to a certain degree (almost all inner cells were capped when colonies were disassembled at the end of the experiment). After observable development in the second layer of cells, nurses started to rear brood in the first layer shortly after, displaying that inner cells were prioritised.

Supplementary Video S3. Complete worker ontogenesis within a truncated cell.
This video was recorded from May – June 2018 for illustrational purposes in a setup specially designed for macro recordings. On the top right is the playback speed. On the top left is the date and below it the day of worker ontogenesis. Initially, the queen inspects the cell with frequent antennal movements, which are also characteristic for inspections by workers. Hereafter, the queen places an egg at the bottom of the cell. The video now focuses a different cell in which oviposition was not recorded. We approximated the larval hatch after 72 hours of development in this cell. Workers showed release of a clear substance on the glass that was taken up shortly afterwards. We assume cooling purposes since the colony stood in a very well-heated location and this behaviour was not observed in experiment colonies. On the end of day eight, after five days of larval development, the cell is capped and cocoon spinning starts for about 36 hours. The prepupa state lasts approximately 48 hours showing some movement during the first of the two days. On day twelve pupal metamorphoses takes place: The larval skin is ripped open on the side of the individual from caput to abdomen, opening zipper-like within 20 minutes. Approximately an hour later, the pupa remains motionless until day 19. The last pupal ecdysis is observable at noon on June 7th and shortly after, the imago outstretches its third pair of legs to prepare for wing development. Within 10 minutes the wings are extended and the imago does some longitudinal movements for another 15 hours before perforating the cell capping during day 20 of development. The estimated total development time of about 19.5 days is below the mean duration described in literature, possibly due to setup circumstances.

Supplementary Table S1. Descriptive statistics of nursing parameters in all experiments and the mean of all experiments. Data is displayed in reversed larval development day (LDD) order to allow comparability with Figure 2 in the manuscript. Red cells represent significant ANOVA *p*-value. We used Student's *t*-test for post-hoc analysis. If significance level was below $\alpha = 0.05$ we adjusted *p*-values after Bonferroni-Holm for type I error-correction (number of tests used for adjustment was 3). Green cells represent significant differences to the control after *p*-value adjustment compared to the control; yellow cells show non-significant values after adjustment.

Abbreviations: LDD = Larval development day; n = sample size; ANOVA = Univariate analysis of variance; SEM = standard error of mean; C = control; C1 = 1 ppb clothianidin; C10 = 10 ppb clothianidin; T200 = 200 ppb thiacloprid; Sig. = significance level of Student's *t*-test.
