Cat Recruitment

36

54

55

37 As stipulated by the inclusion criteria, all cats were over seven years old. Cat owners completed 38 a consent form and three-page questionnaire about their cat's home environment. If multiple cats 39 were recruited from the same home (n=10), owners completed a consent form and questionnaire 40 for each cat individually. 41 The diagnosis of hyperthyroidism (n=39) was established on the basis of clinical signs consistent 42 with the disease (e.g. weight loss despite good appetite), a palpable thyroid nodule on physical 43 examination, high basal total thyroxine (TT_4) and free T_4 (fT_4) concentrations, and a good 44 clinical response to treatment for hyperthyroidism. Hyperthyroid cats who had recently 45 undergone treatment with radioiodine or were currently undergoing anti-thyroid drug treatment 46 were eligible. 47 Non-hyperthyroid, or euthyroid, cats (n=39) were considered healthy on the basis of history, 48 physical examination findings (e.g. lack of palpable thyroid tumors), and results of routine 49 laboratory examinations (e.g. serum biochemical analysis) and serum thyroid profile. The serum 50 thyroid profile included concentrations of fT₄, TT₄, total triiodothyronine (TT₃), and thyroid-51 stimulating hormone (TSH) (see next section). 52 If an enrolled cat did not regularly wear a collar, researchers provided a complimentary collar. 53 Cats wore the pet tag for seven days before the owner removed the tag from the collar, resealed it

Serum Thyroid Hormone Panel

in the PTFE bag, and returned it to the study coordinator.^{1,2}

Non-hyperthyroid cats were required to undergo a serum thyroid panel of tests, including free thyroxine (fT₄), total T₄ (TT₄), total triiodothyronine (TT₃), and thyroid-stimulating hormone (TSH), to assess his or her thyroid status and to determine eligibility for this study. After the cat owner completed the consent form and questionnaire, the recruiting veterinarian examined the cat for clinical findings of feline hyperthyroidism (e.g. palpable goiter). If no clinical features of feline hyperthyroidism were detected, then the veterinarian drew two to three mL of blood, and the sample was shipped to IDEXX Laboratories for the analysis of serum fT₄, TT₄, TT₅, and TSH, conducted by assays validated for cats as previously reported.³⁻⁵ If fT₄ and TT₄ concentrations were within the respective reference intervals (Table S1), then the cat was eligible to be a non-hyperthyroid participant for the study.

Flame Retardant Extraction

56

57

58

59

60

61

62

63

64

65

- The pet tags underwent post-deployment cleaning to remove particulate matter with two rinses of
- 68 18 MΩ·cm water and one of isopropanol. The tags were stored in amber glass jars at -20 °C, and
- 69 then extracted and analyzed as previously reported.^{2, 6} Briefly, FBDE-118 and 2-bromobiphenyl
- were added as a recovery surrogates, with respective average recoveries of $91\pm18\%$
- 71 (median=92%) and 90±19% (median=91%). Pet tags were extracted with two 100 mL volumes
- of ethyl acetate at ambient temperature. Sample extracts were combined and quantitatively
- reduced to one mL under nitrogen (Turbo-Vap L, Biotage, Charlotte, NC, USA; RapidVap,
- LabConco, Kansas City, MO, USA; N-EVAP 111, Organomation Associates, Berlin, MA,
- 75 USA). Sample extracts were stored at 4 °C prior to instrument analysis.
- 76 The sample extract aliquots were combined with FBDE-126 as the internal standard. Targeted
- analysis of 44 FRs occurred using an Agilent 7890A gas chromatograph coupled with an Agilent

78 5975C mass spectrometer (Santa Clara, CA). The gas chromatograph was operated in electron

impact mode (70 eV) and select ion monitoring.

98

The instrument parameters were configured as previously reported.² Briefly, an Agilent 7890A gas chromatograph was coupled with an Agilent 5975C mass spectrometer (Santa Clara, CA) for analysis of 44 flame retardant analytes. An Agilent DB-5MS column (30 m \times 0.25 mm \times 0.25 μm) was operated in electron impact mode (70 eV) and select ion monitoring. Samples were loaded using an Agilent 2 mm dimpled liner and pulsed splitless injection. The temperatures of the MS source, quadruple, and detector transfer line were set to 250°C, 150°C, and 300°C respectively. The pulse pressure was 30 psi (0.5 min) at a 3 mL/min purge and a 35 mL/min purge after 1 minute. The temperature profile started at 90°C (1.25 min), ramped to 240°C (10 °C/min), ramped to 310°C (20 °C/min), and held at 310°C (10 min). The limits of detection (LODs) and limits of quantitation (LOQs) were determined as previously reported.² Briefly, for each analyte, the lowest standard with a 15:1 signal-to-noise ratio was run seven times. The resulting standard deviation was used to calculate a 99% confidence interval with the Student's t-value and appropriate degree of freedom. LOOs were five times higher than the LODs. The method LODs and LOQs for all analytes, surrogate standards, and internal standard are reported in Table S2.

Quality Control

To ensure pet tags met the data quality objectives, QC samples^{1,7} accounted for 47% of the total samples analyzed. QC samples included cat tag conditioning verifications (n=4), trip blanks

(n=1), laboratory control blanks (n=4), sample duplicates (n=1), sample overspikes (n=2), instrument solvent blanks (n=43), and continuing calibration verifications (n=13). All target analytes were below their respective LODs in all blank QC. All calibration verifications were within data quality objectives at $\pm 30\%$ of the true value for 70% of the target analytes. A "cat collar" QC sample was included because two cat tags were returned with the collars still

attached. Only TCIPP was detected in this QC, below the LOQ. Because the TCIPP LOQ was over 10-fold lower than either pet tag TCIPP concentration, no correction was made to the samplers returned with the collars.

Particulate-Bound Fraction

A measure of bioavailability is the octanol-air partition coefficients (K_{oa}) of individual chemicals.⁸ Because LMW PBDE congeners have lower log K_{oa} values (e.g. 2 to 13),¹ they partition more readily into the air than particulate matter.^{9, 10} Consequently, the LMW congeners also partition more readily into the silicone pet tags than particulate matter. In contrast, HMW PBDE congeners have higher log K_{oa} values and are more frequently detected in house dust than in air.^{8, 9}

For this study, any particulate matter on the silicone pet tags was removed during the post-deployment cleaning process (Section 2.4). Some previous studies did not include this step prior to laboratory extractions. In general, particulate-bound FRs are "biologically unavailable" for uptake by silicone PSDs. Washing the samplers prior to extraction enabled this study to focus only on FRs sequestered by the polymer matrix.

Table S1. Reference ranges and summary statistics are reported for hormones included in the serum thyroid profile for the 39 non-hyperthyroid cats recruited for the study. Out of free thyroxine (fT_4) , total T4 (TT_4) , total triiodothyronine (TT_3) , and thyroid-stimulating hormone (TSH) concentrations, a cat was eligible to be a non-hyperthyroid participant if the fT_4 and TT_4 concentrations were within the respective reference intervals.

Thyroid	Reference	Geometric	Standard	Median	Cat Study
Hormone	Range	Mean	Deviation		Range
$fT_4 (ng/dL)$	0.7-2.6	1.15	0.41	1.10	0.50-2.10
TT ₄ (ug/dL)	0.8-4.7	2.27	0.47	2.20	1.70-3.50
TT ₃ (ng/dL)	52-182	34.0	7.12	35.0	4.1-48.0
TSH (ng/mL)	0.05-0.42	0.04	0.07	0.05	0.01-0.41

Table S2. Target analytes, CAS numbers, and method limits of detection and quantification are reported.
