ABSTRACT

Objectives: The first objective of this study was to describe the prevalence of chronic diseases and multimorbidity among unemployed and employed persons. The second objective was to investigate sociodemographic determinants of chronic diseases and multimorbidity.

Design: Data linkage of cross-sectional nation-wide registries on employment status, medication use and sociodemographic characteristics in 2016 was applied.

Participants: 5,074,227 persons aged 18-65 years were selected with information on employment status, medication use and sociodemographic characteristics.

Outcome measures: Multivariate logistic regression analysis and descriptive statistics were performed to examine associations of employment and sociodemographic characteristics with the prevalence of chronic diseases and multimorbidity. The age-specific prevalence of six common chronic diseases was described, and venn diagrams were applied for multimorbidity among unemployed and employed persons.

Results: Unemployed persons had a higher prevalence of psychological disorders (18.3% vs 5.4%), cardiovascular diseases (20.1% vs 8.9%), inflammatory diseases (24.5% vs 15.8%), and respiratory diseases (11.7% vs 6.5%) than employed persons. Unemployed persons were more likely to have one (OR 1.30 (1.29-1.31)), two (OR 1.74 (1.73-1.76)) and at least three chronic diseases (OR 2.59 (2.56-2.61)) than employed persons. Among unemployed persons, psychological disorders and inflammatory conditions increased with age but declined from middle age onwards, whereas a slight increase was observed among employed persons. Older persons, women, lower educated persons and migrants were more likely to have chronic diseases and multimorbidity.

Conclusion: Large inequalities exist in the prevalence of chronic diseases and multimorbidity among unemployed and employed persons, indicating employment status to be an important determinant of health. Policy measures and health interventions should focus more on promoting employment among unemployed persons with chronic diseases.

Strengths and limitations of this study

- This is the first study that describes the prevalence of chronic diseases and multimorbidity among unemployed and employed persons, using objective register-based data rather than self-reported health outcomes.
- A strength of this study is applying data linkage of nation-wide registries that capture the whole population, providing enormous statistical power and thus smaller confidence intervals.
- Except for back pain and musculoskeletal disorders, this study investigated a broad range of chronic diseases such as cardiovascular diseases, psychological disorders, diabetes and respiratory diseases.
- Causal effects of having a chronic disease on employment status, or vice versa cannot be distinguished by the use of cross-sectional data.

INTRODUCTION

The relationship between unemployment and health has been well established (1, 2). In general, unemployed individuals have worse mental and physical health compared to employed individuals (2-5). These health inequalities between employed and unemployed persons can be explained by two different hypotheses. First, according to the causation mechanism, persons who become unemployed will deteriorate in health, whereas unemployed persons who enter paid employment will improve in health (6). Second, the selection mechanism describes that persons who leave paid employment already have lower levels of health before leaving employment compared to those who remain employed, whereas persons who enter paid employment already have a better health status before entering employment compared to persons who remain unemployed (7).

Chronic diseases can affect an individual's employment status due to experienced functional limitations and a poor quality of life (8). Two studies have shown that long term health conditions such as cardiovascular diseases and diabetes were associated with unemployment (9, 10). In addition, a recent systematic review provided evidence that individuals with diabetes were more likely to be out of the labour force (9). However, studies investigating the role of chronic diseases in employment have mostly focused on a single disease, whereas many persons with a chronic disease are likely to suffer from multiple chronic diseases, especially among older age groups. There is increasing evidence that persons with multimorbidity - the co-occurrence of at least two chronic diseases within an individual - may be more likely to have poorer functional outcomes and thus may be also more often out of the labour market than those with a single chronic disease or no chronic disease. For instance, a study among Australian workers with multiple health problems showed that individuals with four or more health problems were far less likely to be employed compared to those with no health condition (11). Another study among persons with back complaints found that the co-occurrence of cardiovascular diseases resulted in a 10-fold increased risk of unemployment compared to those with back complaints alone (12).

So far, findings on the association of chronic diseases and multimorbidity with unemployment have been based mostly on self-reported health outcomes. Self-reported health outcomes are known to be vulnerable to reporting bias and justification bias. Therefore, a more objective approach is preferred in order to make more precise estimations of the prevalence of diseases. One way to objectively

1
2
3 investigate the presence of chronic diseases is by using pharmacy data (13). Pharmacy data provide a
4 reliable information source and often cover a large population (14). Administrative databases such as
5 drug prescription can be used to identify persons with chronic diseases. So far, only a few studies have
6 used register-based data in order to investigate chronic diseases among unemployed persons. A Danish
7 register-based study found a higher prevalence of mental disorders and cardiovascular disorders among
8 unemployed persons receiving social benefits compared to employed persons (15). In line with this,
9 another register-based study showed that long-term unemployment was associated with a higher risk of
10 antidepressant use (16).

17

18 To our knowledge, none of the evidence on the association between multimorbidity and employment
19 status has been based on register-based data. Therefore, the present study aimed to investigate the
20 prevalence of chronic diseases and multimorbidity among unemployed and employed persons. The
21 second aim was to examine associations of employment and sociodemographic characteristics with
22 chronic diseases and multimorbidity. Nation-wide data from the Netherlands on drug prescription,
23 employment status and sociodemographic characteristics in 2016 were used.

METHODS

Study population and design

Register data covering information on all Dutch residents in 2016 were used. Statistics Netherlands provided individual-level databases on demographics, education, labor market status and prescribed medication. All Dutch residents were pseudonymized using a personal unique number. Data registries were linked at the individual level using these pseudonymized numbers.

Employment status

Individuals aged between 18 and 64 years with available information on employment status were selected (n=10,514,271). This selection captured individuals who were not eligible for exit from paid employment through statutory national retirement schemes. The database on social economic category per month (SECM) provided information on employment status of participants for each month in the year 2016. The main source of income for each consecutive month was used to classify persons as employed or unemployed. Individuals who were in paid employment or self-employed for at least 9 months in 2016 were classified as employed (n=4,566,644). Individuals who were out of the labour market and received either social benefits or unemployment benefits for at least 9 months were classified as unemployed (n=507,583). Individuals who did not meet one of these criteria or had missing data on educational level were excluded (n=5,440,044). In total, 5,074,227 subjects were included in the present study.

Chronic diseases and multimorbidity

The database on medication use in 2016 (Medicijntab) provides information on purchased drugs that were reimbursed by the health care insurances. The drugs were identified using the World Health Organization Anatomical Therapeutic Chemical (ATC) classification codes (17). In line with the study of Huber et al, specific chronic diseases were identified based on these ATC-codes (13). For instance, psychological disorders were identified by ATC-codes that were assigned to drugs such as antidepressants and anxiolytics, whereas inflammatory conditions were identified by the ATC-code that was assigned to non-steroidal anti-inflammatory drugs (NSAID's) (Supplementary Table 1). In total, 21 chronic diseases were identified. The presence of a chronic disease was dichotomized into having or not having a chronic condition. The total number of chronic diseases was computed for each participant. This measure of multimorbidity of chronic diseases was categorized into four groups: no chronic disease,

1
2
3 one chronic disease, two chronic diseases, and at least three chronic diseases. Chronic diseases with a
4 prevalence higher than 5% were presented. The total number of chronic diseases included also those
5 with a prevalence lower than 5%, capturing all 21 chronic diseases. All 21 chronic diseases
6 with identifying medications are described by Huber et al (13).
7
8
9

10 11 *Sociodemographic variables*

12
13 The databases on sociodemographic characteristics provide information on age, gender, education and
14 ethnicity. A dichotomous variable was computed for employment status (employed vs. unemployed).
15 Educational level was categorized into three educational groups: high (higher vocational training or
16 university), intermediate (higher secondary and intermediate vocational training) and low education
17 (pre-primary education, primary education, and lower secondary education). Age was categorized into
18 four age groups (18-30, 30-45, 45-55, 55-65). Ethnicity was categorized as native Dutch, Moroccan,
19 Turkish, Surinamese and Antillean, other Western, other non-Western.

22
23
24
25

26 27 *Analyses*

28
29 Descriptive statistics were used to describe the prevalence of chronic diseases and multimorbidity
30 among employed and unemployed persons. The association of sociodemographic characteristics (age,
31 sex, education, and ethnic background) and employment status with (multiple) chronic diseases was
32 examined using multivariate logistic regression analysis in the total study population (employed and
33 unemployed persons). Separate logistic regression analyses were done for each dependent variable: i)
34 one chronic disease ii) two chronic diseases and iii) three or more chronic diseases. The association
35 between employment status and multimorbidity stratified by age and educational level was also
36 investigated. To test for possible selection bias, sensitivity analyses were performed by including
37 individuals with missing data on educational level.
38
39
40
41
42
43
44

45
46 The prevalence of multimorbidity was described as the proportion of individuals with all potential
47 combinations of four chronic diseases: cardiovascular diseases, psychological disorders, inflammatory
48 conditions and respiratory diseases. All combinations of co-occurrence between these four chronic
49 diseases were presented in a venn diagram for employed and unemployed persons. The age-specific
50 prevalence of these four chronic diseases among unemployed and employed persons was presented.
51 For cardiovascular diseases and psychological disorders, the age-specific prevalence of medicines used
52 was also presented.
53

RESULTS

Unemployed persons were more often older than 45 years (58.2%), female (54.5%), lower educated (51.8%) and from non-Dutch origin (48.1%) compared to employed persons (48.1%). Differences in the prevalence of chronic diseases between unemployed and employed persons were highest for psychological disorders. Compared to employed persons, unemployed persons had a higher prevalence of psychological disorders (18.3% vs 5.4%), cardiovascular diseases (20.1% vs 8.9%), inflammatory conditions (24.5% vs 15.8%), psychotic illness (6.2% vs 0.8%), respiratory diseases (11.7% vs 6.5%) and diabetes (7.2% vs 2.0%). (Table 1)

Psychotic illness	31.308 (6.2)	34.377 (0.8)

1
2
3 The prevalence of multimorbidity was higher for unemployed persons compared to employed persons.
4
5 The co-occurrence of both psychological disorders and inflammatory conditions was higher among
6
7 unemployed persons (6.2%) than among employed persons (1.5%). In addition, the co-occurrence of
8
9 cardiovascular diseases and inflammatory conditions was higher among unemployed persons (5.7%)
10
11 compared to employed persons (2.1%). The prevalence of having both cardiovascular diseases and
12
13 psychological disorders was 4.9% among unemployed persons compared to 0.9% among employed
14
15 persons. (Figure 1, Supplementary Table 2)

16
17 At all ages, unemployed individuals had a higher prevalence of all four chronic diseases compared to
18
19 employed individuals. The prevalence of psychological disorders increased with age followed by a
20
21 decrease from middle age onwards among unemployed persons, whereas a slight increase was
22
23 observed among employed persons. The same pattern was observed for inflammatory conditions. The
24
25 prevalence of cardiovascular diseases and inflammatory conditions increased with age among both
26
27 unemployed and employed persons. (Figure 2)

28
29 Among unemployed persons, the use of antidepressants, anxiolytics and, hypnotics and sedatives
30
31 increased with age and decreased from middle age onwards. The prevalence of antidepressants was
32
33 higher than the use of anxiolytics, hypnotics and sedatives among unemployed persons for all age
34
35 groups. The use of antithrombotic and cardiac agents, beta blockers and angiotensin-convertin-enzyme
36
37 (ACE) inhibitors, and diuretics and calcium-channel blockers increased with age among unemployed and
38
39 employed persons. The prevalence of beta blockers and ACE inhibitors, and antithrombotic agents was
40
41 higher than diuretics and calcium-channel blockers, and cardiac agents among unemployed persons of
42
43 all age groups. (Supplementary Figure 1)

44
45 Unemployed persons were more likely to have (multiple) chronic conditions compared to employed
46
47 persons. Unemployed persons were more likely to have one (OR 1.30, 95% CI 1.29-1.31), two (OR 1.74,
48
49 95% CI 1.73-1.76) and at least three chronic conditions (OR 2.59, 95% CI 2.56-2.61) than employed
50
51 persons. Among unemployed persons, 23% had at least three chronic diseases compared to 6% among
52
53 employed persons. Women (OR 1.49, 95% CI 1.49-1.50), older individuals (OR 1.32 - 2.27), middle and
54
55 low educated persons (OR 1.32 – 1.49), and non-western migrants (OR 1.01 - 1.34) were also more likely
56
57 to have a chronic disease. In addition, women (OR 1.61, 95% CI 1.60-1.63), older persons (OR 2.72 -
58
59 17.08), lower educated persons (OR 2.11 - 3.32) and non-western migrants (OR 1.02 - 2.03) were also
60

1
2
3 more likely to have multiple (≥ 3) chronic conditions (Table 2). Comparable results were found in
4 sensitivity analyses on the total study population with inclusion of individuals who had missing data
5 (n=7,576,196) on educational level.
6
7

8
9
10 Within all age groups, unemployed persons had a higher risk of having one, two and at least three
11 chronic diseases than employed persons. Especially, among persons aged 18-30 years, unemployed
12 persons were more likely to have one (OR 1.65, 95% CI 1.61-1.69), two (OR 2.84 (95% CI 2.75-2.93) and
13 at least three (OR 5.20, 95% CI 4.99-5.42) chronic diseases compared to employed persons. These effect
14 estimates were lower among older age groups. (Supplementary Table 3)

DISCUSSION

In this large register-based study, unemployed persons had a higher prevalence of cardiovascular diseases, psychological disorders, inflammatory conditions, respiratory diseases and multimorbidity compared to employed persons. Between unemployed and employed persons, the largest differences were observed for cardiovascular diseases and psychological disorders. The prevalence of psychological disorders and inflammatory conditions increased with age but declined from middle age onwards among unemployed persons. Women, older individuals, lower educated persons and non-western migrants were more likely to have one chronic disease as well as multiple chronic diseases. Among younger persons (18-30 years), a stronger association between chronic disease and unemployment was found compared to higher age groups.

The higher prevalence of chronic diseases among unemployed persons in the current study is in line with other studies showing a negative association between unemployment and health. Several studies have shown that unemployed persons have a poorer mental and physical health status (2, 5, 18). For instance, unemployed persons had high risks of common mental disorders such as depression (19-21). Our study added to the current literature by comparing the age-specific prevalence of chronic diseases between unemployed and employed persons. A remarkable finding was the different pattern of the age-specific prevalence of psychological disorders between unemployed and employed persons. Among both employed and unemployed persons, the prevalence of psychological disorders increased with age. However, this increase was more profound among unemployed persons with a peak around middle age. This pattern among unemployed persons can be explained by studies arguing that before and after middle age, individuals tend to suffer less from unemployment compared to persons of middle age (22). Persons of middle age often have family responsibilities, increasing the financial importance of a job, whereas younger and older persons experience less financial pressure and thus less psychological distress due to unemployment (23). The other way around, it can also be that the combination of family responsibilities and work lead to pressure and cause both health problems as well as unemployment. Furthermore, it has also been hypothesized that persons of middle age are more likely to aim for a successful career which leads to employment being more important for their mental health than it is for older persons who are almost finishing their careers, and for younger persons who have recently entered paid employment (24). The age-specific prevalence of antidepressants use, anxiolytics, and hypnotics and sedatives among unemployed persons confirms this theory by showing the highest

1
2
3 prevalence at middle age and a lower prevalence at younger and older ages. It was checked whether the
4 selection of unemployed individuals could explain the decline in the prevalence of antidepressants use,
5 anxiolytics, hypnotics and sedatives after the age of 50. This does not appear to be the case as also
6 among other groups, such as disabled individuals, a decline was observed.
7
8
9

10
11 Another interesting finding was an increase in the prevalence of inflammatory conditions with
12 increasing age followed by a decrease from middle age onwards among unemployed persons. This
13 finding can be explained by the medicines NSAID's that have been used to identify inflammatory
14 conditions as a chronic disease in the present study. NSAID's are pain killers with anti-inflammatory
15 effects and are known to cause serious adverse effects (25). In the Netherlands, NSAID's are therefore
16 cautiously or not prescribed among individuals aged 60 years or older, who suffer from cardiovascular
17 diseases and already use other medicines for other (chronic) health conditions. In the present study, the
18 prevalence of cardiovascular diseases and multimorbidity was higher among unemployed persons
19 compared to employed persons. Thus, it may be that NSAID's are less prescribed among older persons
20 because of multimorbidity with CVD and associated polypharmacy – the use of multiple medicines.
21 Therefore, the higher prevalence of multimorbidity among unemployed persons may explain the
22 decrease in the prevalence of inflammatory conditions with increasing age.

32

33 The strength of the present study is the use of register-based data, which is a more objective method to
34 investigate the association between health and unemployment. In earlier studies, the relationship
35 between health and unemployment has often been examined using self-reported outcomes of health
36 and disability (18). However, a major concern of self-reported health outcomes is that unemployed
37 individuals may over-report their level of disability or work limitations to justify that they are not in paid
38 employment (26). In the current study, this problem has been minimized using register-based data on
39 medication use that has been collected independently of the study. Another strength of the current
40 study is that in our register-based data the whole Dutch population is involved and therefore the data
41 provide enormous statistical power resulting in smaller confidence intervals. Lastly, the use of register-
42 based data is less expensive since no additional efforts have to be made for data collection and no
43 concerns are present about health-related non-response.
44
45
46
47
48
49
50
51
52

53 Register-based data also have some limitations. Although a broad range of chronic diseases has been
54 investigated in this study, several conditions that are associated with unemployment have not been
55
56
57
58
59
60

1
2
3 included, such as back pain or musculoskeletal disorders. In the current study, it was not possible to
4 identify these chronic conditions by the use of medication data. For instance, medication that is
5 prescribed for back pain includes over the counter pain killers such as paracetamol or ibuprofen.
6
7 However, since pain killers are used for various forms of bodily pain and no information was available
8 regarding the reason of prescription, it was not possible to identify these health conditions. Yet,
9 conditions such as back pain and musculoskeletal disorders are known to lead to exit from paid
10 employment (12) and therefore should be investigated among unemployed persons in future studies.
11
12 Another limitation of this study was that almost 33% of the eligible study population was excluded due
13 to missing data on educational level. However, sensitivity analyses including individuals with missing
14 data showed comparable results.
15
16
17
18
19
20
21

22 This study showed that health inequalities exist between unemployed and employed persons.
23 Specifically, among the younger age group, a strong association of chronic diseases and multimorbidity
24 with unemployment was found. Due to the cross-sectional design, it was not possible to investigate
25 causal relationships between unemployment and health. However, several studies have shown
26 beneficial effects of employment on health (27, 28). Although it may be a challenge to increase
27 employment rates among unemployed persons with chronic diseases, it may lead to improvements in
28 health. In order to reduce health inequalities between unemployed and employed persons, it is
29 therefore important that re-integration policies focus more on promoting employment among
30 unemployed persons with chronic diseases.
31
32
33
34
35
36
37

38 In conclusion, the current study showed that unemployed persons more often have chronic diseases and
39 multimorbidity than employed persons, indicating employment status to be an important determinant
40 of health. Policy measures are needed to improve health and promote employment among unemployed
41 persons.

STROBE Statement—Checklist of items that should be included in reports of *cross-sectional studies*

	Item No	Recommendation	Page No
Title and abstract	1	(a) Indicate the study's design with a commonly used term in the title or the abstract	0/1
		(b) Provide in the abstract an informative and balanced summary of what was done and what was found	1
Introduction			
Background/rationale	2	Explain the scientific background and rationale for the investigation being reported	3
Objectives	3	State specific objectives, including any prespecified hypotheses	4
Methods			
Study design	4	Present key elements of study design early in the paper	5
Setting	5	Describe the setting, locations, and relevant dates, including periods of recruitment, exposure, follow-up, and data collection	5
Participants	6	(a) Give the eligibility criteria, and the sources and methods of selection of participants	5
Variables	7	Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable	5/6
Data sources/ measurement	8*	For each variable of interest, give sources of data and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group	6
Bias	9	Describe any efforts to address potential sources of bias	6
Study size	10	Explain how the study size was arrived at	5
Quantitative variables	11	Explain how quantitative variables were handled in the analyses. If applicable, describe which groupings were chosen and why	6
Statistical methods	12	(a) Describe all statistical methods, including those used to control for confounding	6
		(b) Describe any methods used to examine subgroups and interactions	6
		(c) Explain how missing data were addressed	6
		(d) If applicable, describe analytical methods taking account of sampling strategy	n.a
		(e) Describe any sensitivity analyses	6
Results			
Participants	13*	(a) Report numbers of individuals at each stage of study—eg numbers potentially eligible, examined for eligibility, confirmed eligible, included in the study, completing follow-up, and analysed	n.a/ 7
		(b) Give reasons for non-participation at each stage	6
		(c) Consider use of a flow diagram	
Descriptive data	14*	(a) Give characteristics of study participants (eg demographic, clinical, social) and information on exposures and potential confounders	7
		(b) Indicate number of participants with missing data for each variable of interest	5
Outcome data	15*	Report numbers of outcome events or summary measures	7-9
Main results	16	(a) Give unadjusted estimates and, if applicable, confounder-adjusted estimates and their precision (eg, 95% confidence interval). Make clear which confounders were adjusted for and why they were included	8-9

		(b) Report category boundaries when continuous variables were categorized	7
		(c) If relevant, consider translating estimates of relative risk into absolute risk for a meaningful time period	n.a
Other analyses	17	Report other analyses done—eg analyses of subgroups and interactions, and sensitivity analyses	9
Discussion			
Key results	18	Summarise key results with reference to study objectives	11
Limitations	19	Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss both direction and magnitude of any potential bias	12-13
Interpretation	20	Give a cautious overall interpretation of results considering objectives, limitations, multiplicity of analyses, results from similar studies, and other relevant evidence	11
Generalisability	21	Discuss the generalisability (external validity) of the study results	13
Other information			
Funding	22	Give the source of funding and the role of the funders for the present study and, if applicable, for the original study on which the present article is based	14

*Give information separately for exposed and unexposed groups.

Note: An Explanation and Elaboration article discusses each checklist item and gives methodological background and published examples of transparent reporting. 3 1 **ABSTRACT**
4
5 2

6 3 **Objectives:** The first objective of this study was to describe the age specific prevalence of chronic
7
8 4 diseases and multimorbidity among unemployed and employed persons. The second objective was to
9
10 5 examine associations of employment status and sociodemographic characteristics with chronic diseases
11
12 6 and multimorbidity.

13 7 **Design:** Data linkage of cross-sectional nation-wide registries on employment status, medication use and
14
15 8 sociodemographic characteristics in 2016 was applied.

16 9 **Setting:** Register based data covering residents in the Netherlands.

17
18 10 **Participants:** 5,074,227 persons aged 18-65 years were selected with information on employment
19
20 11 status, medication use and sociodemographic characteristics.

21
22 12 **Outcome measures:** Multiple logistic regression analysis and descriptive statistics were performed to
23
24 13 examine associations of employment and sociodemographic characteristics with the prevalence of
25
26 14 chronic diseases and multimorbidity. The age-specific prevalence of six common chronic diseases was
27
28 15 described, and venn diagrams were applied for multimorbidity among unemployed and employed
29
30 16 persons.

31
32 17 **Results:** Unemployed persons had a higher prevalence of psychological disorders (18.3% vs 5.4%),
33
34 18 cardiovascular diseases (20.1% vs 8.9%), inflammatory diseases (24.5% vs 15.8%), and respiratory
35
36 19 diseases (11.7% vs 6.5%) than employed persons. Unemployed persons were more likely to have one
37
38 20 (OR 1.30 (1.29-1.31)), two (OR 1.74 (1.73-1.76)) and at least three chronic diseases (OR 2.59 (2.56-2.61))
39
40 21 than employed persons. Among unemployed persons, psychological disorders and inflammatory
41
42 22 conditions increased with age but declined from middle age onwards, whereas a slight increase was
43
44 23 observed among employed persons. Older persons, women, lower educated persons and migrants were
45
46 24 more likely to have chronic diseases..

47
48 25 **Conclusion:** Large differences exist in the prevalence of chronic diseases and multimorbidity among
49
50 26 unemployed and employed persons. The age specific prevalence follows a different pattern among
51
52 27 employed and unemployed persons, with a relatively high prevalence of psychological disorders and
53
54 28 inflammatory conditions among middle aged unemployed persons. Policy measures should focus more
55
56 29 on promoting employment among unemployed persons with chronic diseases.

Strengths and limitations of this study

- This is the first study that describes the prevalence of chronic diseases and multimorbidity among unemployed and employed persons, using objective register-based data rather than self-reported health outcomes.
- A strength of this study is applying data linkage of nation-wide registries that capture the whole population, facilitating precise estimations of associations between health and employment, and offering us the possibility to investigate specific subgroups (age specific prevalence).
- Except for back pain and musculoskeletal disorders, this study investigated a broad range of chronic diseases such as cardiovascular diseases, psychological disorders, diabetes and respiratory diseases.
- Causal effects of having a chronic disease on employment status, or vice versa cannot be distinguished because of the use of cross-sectional data and the bidirectional nature of health and employment.

INTRODUCTION

The relationship between unemployment and health has been well established. (1, 2) In general, unemployed individuals have worse mental and physical health compared to employed individuals.(2-5) These health inequalities between employed and unemployed persons can be explained by two different hypotheses. First, according to the causation hypothesis, persons who become unemployed will deteriorate in health, whereas unemployed persons who enter paid employment will improve in health. (6) Second, the selection hypothesis describes that persons who leave paid employment already have lower levels of health before leaving employment compared to those who remain employed, whereas persons who enter paid employment already have a better health status before entering employment compared to persons who remain unemployed. (7)

Chronic diseases can affect an individual's employment status due to experienced functional limitations and a poor quality of life.(8) Two studies have shown that long term health conditions such as cardiovascular diseases and diabetes were associated with unemployment. (9, 10) In addition, a recent systematic review provided evidence that individuals with diabetes were more likely to be out of the labour force. (9) However, studies investigating chronic diseases and employment have mostly focused on a single disease, whereas many persons with a chronic disease are likely to suffer from multiple chronic diseases, especially among older age groups. There is increasing evidence that persons with multimorbidity - the co-occurrence of at least two chronic diseases within an individual - may be more likely to have poorer functional outcomes and thus may be also more often out of the labour market than those with a single chronic disease or no chronic disease. For instance, a study among Australian workers with multiple health problems showed that individuals with four or more health problems were far less likely to be employed compared to those with no health condition. (11) Another study among persons with back complaints found that the co-occurrence of cardiovascular diseases resulted in a 10-fold increased risk of unemployment compared to those with back complaints alone. (12)

So far, findings on the association of chronic diseases and multimorbidity with unemployment have been based mostly on self-reported health outcomes. Self-reported health outcomes are known to be vulnerable to reporting bias and justification bias. Therefore, a more objective approach is preferred in order to make more precise estimations of the prevalence of diseases. One way to objectively investigate the presence of chronic diseases is by using pharmacy data. (13) Pharmacy data provide a

1
2
3 1 reliable information source and often cover a large population. (14) Administrative databases such as
4
5 2 drug prescription can be used to identify persons with chronic diseases. So far, only a few studies have
6
7 3 used register-based data in order to investigate chronic diseases among unemployed persons. A Danish
8
9 4 register-based study found a higher prevalence of mental disorders and cardiovascular disorders among
10
11 5 unemployed persons receiving social benefits compared to employed persons. (15) In line with this,
12
13 6 another register-based study showed that long-term unemployment was associated with a higher risk of
14
15 7 antidepressant use. (16)
16
17 8

18
19 9 To our knowledge, none of the evidence on the association between multimorbidity and employment
20
21 10 status has been based on register-based data. Therefore, the present study aimed to investigate the
22
23 11 prevalence of chronic diseases and multimorbidity among unemployed and employed persons. The large
24
25 12 register data enabled to investigate specific subgroups (e.g. age specific prevalences and associations).
26
27 13 The second aim was to examine associations of employment status and sociodemographic
28
29 14 characteristics with chronic diseases and multimorbidity. Nation-wide data from the Netherlands on
30
31 15 drug prescription, employment status and sociodemographic characteristics in 2016 were used.

1
2
3 1 Huber et al, specific chronic diseases were identified based on these ATC-codes. (13) For instance,
4 2 psychological disorders were identified by ATC-codes that were assigned to drugs such as
5 3 antidepressants and anxiolytics, whereas inflammatory conditions were identified by the ATC-code that
6 4 was assigned to non-steroidal anti-inflammatory drugs (NSAID's) (Supplementary Table 1).
7
8
9

10 5
11 6 The presence of a specific chronic disease was dichotomized into having or not having a chronic disease.
12 7 Multimorbidity was investigated as 1) the number of chronic diseases and 2) the combinations of four
13 8 common chronic diseases with the highest prevalence in the study population. For the first approach of
14 9 multimorbidity, the total number of chronic diseases was computed for each participant, based on 21
15 10 different chronic diseases that could be identified by medication prescription. (13) This measure of
16 11 multimorbidity was categorized into four groups: no chronic disease, one chronic disease, two chronic
17 12 diseases, and at least three chronic diseases.. For the second approach, we used the following four
18 13 chronic diseases to describe their co-occurrence: cardiovascular diseases, psychological disorders,
19 14 inflammatory conditions, and respiratory diseases.

28 16 *Sociodemographic variables*

29 17 The databases on sociodemographic characteristics provide information on age, gender, education and
30 18 migration background. A dichotomous variable was computed for employment status (employed vs.
31 19 unemployed). Educational level was categorized into three educational groups: high (higher vocational
32 20 training or university), intermediate (higher secondary and intermediate vocational training) and low
33 21 education (pre-primary education, primary education, and lower secondary education). Age was
34 22 categorized into four age groups (18-30, 30-45, 45-55, 55-65). Migration background was categorized as
35 23 native Dutch, Moroccan, Turkish, Surinamese and Antillean, other Western, and other non-Western.

42

43 25 *Analyses*

44 26 Descriptive statistics were used to describe the prevalence of chronic diseases and multimorbidity
45 27 among employed and unemployed persons. The association of sociodemographic characteristics (age,
46 28 sex, education, and ethnic background) and employment status with (multiple) chronic diseases was
47 29 examined using multiple logistic regression analysis in the total study population (employed and
48 30 unemployed persons). Separate logistic regression analyses were done for each number of chronic
49 31 diseases (dependent variable): i) one chronic disease ii) two chronic diseases and iii) three or more
50 32 chronic diseases. In these analyses, having no chronic diseases was used as the reference category.
51
52
53
54
55
56
57
58
59
60

1
2
3 1 Logistic regression analyses were adjusted for age, sex, educational level and migration background. The
4
5 2 association between employment status and multimorbidity stratified by age was also investigated. To
6
7 3 test for possible selection bias, sensitivity analyses were performed by including individuals with missing
8
9 4 data on educational level.
10
11 5

12 6 The prevalence of multimorbidity was also described as the proportion of individuals with all potential
13
14 7 combinations of four exclusive chronic diseases. All combinations of co-occurrence between the four
15
16 8 chronic diseases were presented in a venn diagram for employed and unemployed persons. The age-
17
18 9 specific prevalence of these four chronic diseases among unemployed and employed persons was
19
20 10 presented. In order to distinguish specific conditions within a chronic disease, the age-specific
21
22 11 prevalence of specific medicines was also investigated for cardiovascular diseases and psychological
23
24 12 disorders. The latter was not investigated for the other chronic diseases because less specific medicines
25
26 13 could be distinguished within the other chronic disease.
27
28 14

29 15 *Patient and public involvement*

30 16 No patients were involved.

RESULTS

Unemployed persons were more often older than 45 years (58.2%), female (54.5%), lower educated (51.8%) and from non-Dutch origin (48.1%) compared to employed persons (19.4%). Differences in the prevalence of chronic diseases between unemployed and employed persons were highest for psychological disorders. Compared to employed persons, unemployed persons had a higher prevalence of psychological disorders (18.3% vs 5.4%), cardiovascular diseases (20.1% vs 8.9%), inflammatory conditions (24.5% vs 15.8%), psychotic illness (6.2% vs 0.8%), respiratory diseases (11.7% vs 6.5%) and diabetes (7.2% vs 2.0%). (Table 1)

The prevalence of multimorbidity was also higher for unemployed persons compared to employed persons. The co-occurrence of both psychological disorders and inflammatory conditions was higher among unemployed persons (3.6%+0.9%+1.2%+0.5%=6.2%) than among employed persons (1.0%+0.2%+0.2%+0.1%=1.5%). In addition, the co-occurrence of cardiovascular diseases and inflammatory conditions was higher among unemployed persons (5.5%) compared to employed persons (2.1%). The prevalence of having both cardiovascular diseases and psychological disorders was 4.9% among unemployed persons compared to 0.9% among employed persons. (Figure 1, Supplementary Table 2)

At all ages, unemployed individuals had a higher prevalence of all four chronic diseases compared to employed individuals. The prevalence of psychological disorders increased with age followed by a decrease from middle age onwards among unemployed persons, whereas a slight increase was observed among employed persons. The same pattern was observed for inflammatory conditions. The prevalence of cardiovascular diseases and respiratory diseases increased with age among both unemployed and employed persons. (Figure 2)

Among unemployed persons, the use of antidepressants, anxiolytics and, hypnotics and sedatives was highest at middle age. The prevalence of antidepressants was higher than the use of anxiolytics, hypnotics and sedatives among unemployed persons for all age groups. The use of antithrombotic and cardiac agents, beta blockers and angiotensin-converting enzyme (ACE) inhibitors, and diuretics and calcium-channel blockers was highest among older unemployed and employed persons. The prevalence of beta blockers and ACE inhibitors, and antithrombotic agents was higher than diuretics and calcium-channel blockers, and cardiac agents among unemployed persons of all age groups. (Supplementary Figure 1)

Unemployed persons were more likely to have (multiple) chronic diseases compared to employed persons. Unemployed persons were more likely to have one (OR 1.30, 95% CI 1.29-1.31), two (OR 1.74, 95% CI 1.73-1.76) and at least three chronic diseases (OR 2.59, 95% CI 2.56-2.61) than employed persons. Among unemployed persons, 23% had at least three chronic diseases compared to 6% among

1
2
3 1 employed persons. Women (OR 1.49, 95% CI 1.49-1.50), older individuals (OR 1.32 - 2.27), middle and
4 2 low educated persons (OR 1.32 – 1.49), and non-western migrants (OR 1.01 - 1.34) were also more likely
5 3 to have a chronic disease. In addition, women (OR 1.61, 95% CI 1.60-1.63), older persons (OR 2.72 -
6 4 17.08), lower educated persons (OR 2.11 - 3.32) and non-western migrants (OR 1.02 - 2.03) were also
7 5 more likely to have multiple (≥ 3) chronic diseases (Table 2). Comparable results were found in sensitivity
8 6 analyses on the total study population with inclusion of individuals who had missing data (n=7,576,196)
9 7 on educational level.
10 8

11 9 Within all age groups, unemployed persons had a higher risk of having one, two and at least three
12 10 chronic diseases than employed persons. Especially, among persons aged 18-30 years, unemployed
13 11 persons were more likely to have one (OR 1.65, 95% CI 1.61-1.69), two (OR 2.84 (95% CI 2.75-2.93) and
14 12 at least three (OR 5.20, 95% CI 4.99-5.42) chronic diseases compared to employed persons. These effect
15 13 estimates were lower among older age groups. (Supplementary Table 3)

*persons having no chronic diseases constituted the reference group.

DISCUSSION

In this large register-based study, unemployed persons had a higher prevalence of cardiovascular diseases, psychological disorders, inflammatory conditions, respiratory diseases and multimorbidity compared to employed persons. Between unemployed and employed persons, the largest differences were observed for cardiovascular diseases and psychological disorders. The prevalence of psychological disorders and inflammatory conditions was highest among unemployed persons in the middle age group. Women, older individuals, lower educated persons and non-western migrants were more likely to have one chronic disease as well as multiple chronic diseases. Among younger persons (18-30 years), a stronger association between chronic disease and unemployment was found compared to higher age groups.

The higher prevalence of chronic diseases among unemployed persons in the current study is in line with other studies that unemployed persons have a poorer mental and physical health status. (2, 5, 18) For instance, unemployed persons had high risks of common mental disorders such as depression. (19-21) Our study added to the current literature by comparing the age-specific prevalence of chronic diseases between unemployed and employed persons. Between unemployed and employed persons, the largest differences were observed for cardiovascular diseases and psychological disorders. Although the overall prevalence of cardiovascular diseases was much higher among unemployed persons, the age-specific patterns showed small differences, indicating that the higher age among unemployed persons was largely responsible for the higher prevalence of cardiovascular diseases.

A remarkable finding was the different pattern of the age-specific prevalence of psychological disorders between unemployed and employed persons. Among both employed and unemployed persons, the prevalence of psychological disorders increased with age. However, this increase was more profound among unemployed persons with a peak around middle age. This pattern among unemployed persons can be explained by studies arguing that before and after middle age, individuals tend to suffer less from unemployment compared to persons of middle age. (22) Persons of middle age often have family responsibilities, increasing the financial importance of a job, whereas younger and older persons experience less financial pressure and thus less psychological distress due to unemployment. (23) The other way around, it can also be that the combination of family responsibilities and work lead to pressure and cause both health problems as well as unemployment. Furthermore, it has also been

1
2
3 1 hypothesized that persons of middle age are more likely to aim for a successful career which leads to
4 2 employment being more important for their mental health than it is for older persons who are almost
5 3 finishing their careers, and for younger persons who have recently entered paid employment. (24) The
6 4 age-specific prevalence of antidepressants use, anxiolytics, and hypnotics and sedatives among
7 5 unemployed persons confirms this theory by showing the highest prevalence at middle age and a lower
8 6 prevalence at younger and older ages.
9 7

10 8 It was checked whether the decline in the prevalence of use of antidepressants, anxiolytics, hypnotics
11 9 and sedatives after the age of 50 would be different among persons receiving a disability benefit.
12 10 Namely, it might be possible that older unemployed persons with chronic diseases are more likely to
13 11 receive disability benefits rather than unemployment or social benefits, and therefore the age-specific
14 12 prevalence of these medicines declines among unemployed persons. However, also among persons with
15 13 disability benefits, a decline was observed from middle age onwards for these medicines (results not
16 14 shown).
17 15

18 16 Another interesting finding was an increase in the prevalence of inflammatory conditions with
19 17 increasing age followed by a decrease from middle age onwards among unemployed persons. This
20 18 finding can be explained by the medicines NSAID's that have been used to identify inflammatory
21 19 conditions as a chronic disease in the present study. NSAID's are pain killers with anti-inflammatory
22 20 effects and are known to cause serious adverse effects. (25) Therefore, NSAID's are cautiously or not
23 21 prescribed among individuals aged 60 years or older, who suffer from cardiovascular diseases and
24 22 already use other medicines for other (chronic) health conditions. (26) In the present study, the
25 23 prevalence of cardiovascular diseases and multimorbidity was higher among unemployed persons
26 24 compared to employed persons. Thus, it may be that NSAID's are less prescribed among older persons
27 25 because of multimorbidity with cardiovascular disorders and associated polypharmacy – the use of
28 26 multiple medicines. Therefore, the higher prevalence of multimorbidity among unemployed persons
29 27 may explain the decrease in the prevalence of inflammatory conditions with increasing age.
30 28

31 29 Unemployed persons had a higher prevalence of multimorbidity than employed persons. It is likely that
32 30 the healthy worker selection process is more prominent among persons with multiple diseases than
33 31 single diseases. (27) According to the causation mechanism, it could also be that persons who become
34 32 unemployed will deteriorate in health. Underlying mechanisms have been proposed by Jahoda who

1
2
3 1 posits that unemployed persons may lack five latent functions usually observed among employed
4 persons such as a time structure, being useful, social contacts, social status and being active. (28) The
5 2 latter causation mechanism suggests that it is important that next to addressing chronic diseases, these
6 3 psychosocial factors are targeted as well by interventions, in order to improve the health of unemployed
7 4 persons. Improving health and employment opportunities for persons with chronic diseases is also
8 5 important in the light of an aging workforce with an expected increase of multimorbidity during the next
9 6 decades.
10 7
11 8

12 9 The strength of the present study is the use of register-based data, which is a more objective method to
13 10 investigate the association between health and unemployment. In earlier studies, the relationship
14 11 between health and unemployment has often been examined using self-reported outcomes of health
15 12 and disability. (18) However, a major concern of self-reported health outcomes is that unemployed
16 13 individuals may over-report their level of disability or work limitations to justify that they are not in paid
17 14 employment. (29) In the current study, this problem has been minimized using register-based data on
18 15 medication use that has been collected independently of the study. Another strength of the current
19 16 study is that our register-based data capture the whole Dutch population and therefore the data provide
20 17 statistical power to investigate age-specific prevalences. This facilitates precise estimations of
21 18 associations between health and employment. Lastly, the use of register-based data is less expensive
22 19 since no additional efforts have to be made for data collection and no concerns are present about
23 20 health-related non-response.
24 21

25 22 Register-based data also have some limitations as the register only includes individuals who fulfill three
26 23 criteria: 1) they are considered to need a particular drug by their general practitioner or specialist, 2)
27 24 they purchase the prescribed medicine at the pharmacy, and 3) the costs of the medicines are
28 25 reimbursed by health insurances. For instance, persons with psychological disorders who are treated
29 26 with a cognitive behavioral therapy rather than medication are not included in our analysis, and this may
30 27 lead to an underestimation of persons with psychological disorders. Moreover, although a broad range
31 28 of chronic diseases has been investigated in this study, several conditions that are associated with
32 29 unemployment have not been included, such as back pain or musculoskeletal disorders. In the current
33 30 study, it was not possible to identify these chronic conditions by the use of medication data. For
34 31 instance, medication that is prescribed for back pain includes over the counter pain killers such as
35 32 paracetamol or ibuprofen. However, since pain killers are used for various forms of bodily pain and no

1
2
3 1 information was available regarding the reason of prescription, it was not possible to identify these
4
5 2 health conditions. Nevertheless, it is possible that inflammatory conditions include musculoskeletal
6
7 3 problems, as NSAID's are a common treatment. (26) Conditions such as back pain and musculoskeletal
8
9 4 disorders are known to lead to exit from paid employment and therefore should be investigated among
10
11 5 unemployed persons in future studies.(12)
12
13 6

13 7 A second limitation of this study was that the cross-sectional design did not allow to gain insight into the
14
15 8 bi-directional association between unemployment and health. However, this study provided pivotal
16
17 9 evidence for the large differences in the prevalence of chronic diseases between unemployed and
18
19 10 employed persons. Longitudinal or (quasi-) experimental studies are needed to further elaborate how
20
21 11 chronic diseases lead to unemployment, and unemployment may result in chronic diseases and
22
23 12 multimorbidity. A third limitation of this study relates to the selection of the study population of
24
25 13 unemployed persons. Since the criteria for unemployment was defined as being unemployed for at least
26
27 14 9 months during a period of one year, our results and conclusions mainly apply to persons who are long-
28
29 15 term unemployed. It may be that associations found in this study are less strong among short-term
30
31 16 unemployed persons as they may have less health problems. Lastly, a limitation of the current study was
32
33 17 the exclusion of individuals with missing data on educational level. Unemployed persons in this study
34
35 18 more often had a lower educational level than employed person. Since there is an association between
36
37 19 lower educational level and poorer health status, it was important to adjust for educational level in
38
39 20 several statistical analyses. The sensitivity analysis showed comparable results in the total population
40
41 21 and the population with educational information, indicating that education was most likely missing at
42
43 22 random.
44
45 23

42 24 This study showed that health inequalities exist between unemployed and employed persons.
43
44 25 Specifically, among the younger age group, a strong association of chronic diseases and multimorbidity
45
46 26 with unemployment was found. Several studies have shown the beneficial effects of employment on
47
48 27 health. (30, 31) According to these studies, interventions that can support unemployed persons with
49
50 28 chronic diseases are needed to improve employment opportunities and thus health. In order to reduce
51
52 29 health inequalities between unemployed and employed persons, it is therefore important that re-
53
54 30 integration policies will focus more on promoting employment among unemployed persons with chronic
55
56 31 diseases.
57
58 32

1
2
3 1 In conclusion, the current study showed that unemployed persons more often have chronic diseases and
4 2 multimorbidity than employed persons. The age specific prevalence follows a different pattern among
5 3 employed and unemployed persons, with a relatively high prevalence of psychological disorders and
6 4 inflammatory conditions among middle aged unemployed persons. Policy measures are needed to
7 5 improve health and promote employment among unemployed persons.

Figure 1. Multimorbidity of cardiovascular diseases (CVD), psychological disorders (PD), inflammatory conditions (IC) and respiratory diseases (RD) among unemployed (n=507,583) and employed persons (n=4,566,644).

view only

Figure 2. Prevalence of four chronic diseases by age among unemployed (n=507,583) and employed (n=4,566,644) persons in 2016.

Supplementary Table 1. Description of ATC-codes used to identify chronic diseases among unemployed (n=507,583) and employed (n=4,566,644) persons.

Chronic disease	ATC-code	Medication class	Prevalence (%) Unemployed	Prevalence (%) Employed
Cardiovascular disease	B01A	Antithrombotic agents	8.5	3.2
	C01	Cardiac agents	1.9	0.7
	C03A	Low-ceiling drugs	3.8	1.5
	C08	Calcium channel blockers	5.4	1.9
	C07	Beta blocking agents	9.6	3.7
	C09A, C09B	ACE inhibitors	7.0	2.8
Psychological disorders	N05B	Anxiolytics	6.0	0.9
	N05C	Hypnotics and sedatives	3.4	0.4
	N06A	Antidepressants	14.4	5.0
Inflammatory and antirheumatic products	M01A	Anti-inflammatory and antirheumatic products, non-steroids	24.5	15.8
Respiratory diseases	R03A, R03C	Adrenergics (inhalants)	10.5	5.8
	R03B, R03D	Other drugs for obstructive airway diseases	4.8	2.3
Psychotic illness	N05A	Antipsychotics	6.2	0.8
Diabetes mellitus	A10A	Insulins and analogues	2.5	0.8
	A10B	Blood glucose lowering drugs	6.4	1.5

Supplementary Table 2. Combinations and prevalence of multimorbidity of four chronic diseases among unemployed (n=507,583) and employed (n=4,566,644) persons.

Combination	Chronic disease				Prevalence	
	Cardiovascular diseases (CVD)	Psychological disorders (PD)	Inflammatory conditions (IC)	Respiratory diseases (RD)	N (%) Unemployed	N (%) Employed
1	1	0	0	0	49,124 (9.7)	248,948 (5.5)
2	0	1	0	0	38,549 (7.6)	137,314 (3.0)
3	0	0	1	0	64,535 (12.7)	524,452 (11.5)
4	0	0	0	1	19,832 (3.9)	181,148 (4.0)
5	1	0	0	1	8,611 (1.7)	28,834 (0.6)
6	1	0	1	0	15,533 (3.1)	72,591 (1.6)
7	1	1	0	0	12,046 (2.4)	25,049 (0.5)
8	0	1	1	0	18,098 (3.6)	45,499 (1.0)
9	0	0	1	1	9,124 (1.8)	46,741 (1.0)
10	0	1	0	1	6,699 (1.3)	14,651 (0.3)
11	1	1	1	0	5,995 (1.2)	11,376 (0.2)
12	0	1	1	1	4,683 (0.9)	7,041 (0.2)
13	1	1	0	1	4,165 (0.8)	4,798 (0.1)
14	1	0	1	1	3,722 (0.7)	10,812 (0.2)
15	1	1	1	1	2,721 (0.5)	2,792 (0.1)

Supplementary Table 3. The association of employment status with multimorbidity stratified by age.

	Chronic diseases		
	1	2	≥3
	OR (95% CI)		
<i>Employment status (n=5,074,227)</i>			
Employed	1	1	1
Unemployed	1.30 (1.29-1.31)	1.74 (1.73-1.76)	2.59 (2.56-2.61)
<i>Age 18-30 (n=1,278,018)</i>			
Employed	1	1	1
Unemployed	1.65 (1.61-1.69)	2.84 (2.75-2.93)	5.20 (4.99-5.42)
<i>Age 30-45 (n=1,965,512)</i>			
Employed	1	1	1
Unemployed	1.41 (1.39-1.43)	2.12 (2.09-2.16)	3.52 (3.45-3.59)
<i>Age 45-55 (n=1,180,955)</i>			
Employed	1	1	1
Unemployed	1.22 (1.20-1.23)	1.64 (1.61-1.67)	2.66 (2.62-2.70)
<i>Age 55-65 (n=649,742)</i>			
Employed	1	1	1
Unemployed	1.09 (1.07-1.11)	1.29 (1.26-1.31)	1.78 (1.76-1.81)

Logistic regression analyses were adjusted for sex, educational level and migration background.

Supplementary Figure 1. Prevalence of medicines for psychological disorders (a and b) and cardiovascular diseases (c and d) by age among unemployed (n=507,583) and employed (n=4,566,644) persons in 2016.

STROBE Statement—Checklist of items that should be included in reports of *cross-sectional studies*

	Item No	Recommendation	Page No
Title and abstract	1	(a) Indicate the study's design with a commonly used term in the title or the abstract	0/1
		(b) Provide in the abstract an informative and balanced summary of what was done and what was found	1
Introduction			
Background/rationale	2	Explain the scientific background and rationale for the investigation being reported	3
Objectives	3	State specific objectives, including any prespecified hypotheses	4
Methods			
Study design	4	Present key elements of study design early in the paper	5
Setting	5	Describe the setting, locations, and relevant dates, including periods of recruitment, exposure, follow-up, and data collection	5
Participants	6	(a) Give the eligibility criteria, and the sources and methods of selection of participants	5
Variables	7	Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable	5/6
Data sources/ measurement	8*	For each variable of interest, give sources of data and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group	6
Bias	9	Describe any efforts to address potential sources of bias	6
Study size	10	Explain how the study size was arrived at	5
Quantitative variables	11	Explain how quantitative variables were handled in the analyses. If applicable, describe which groupings were chosen and why	6
Statistical methods	12	(a) Describe all statistical methods, including those used to control for confounding	6
		(b) Describe any methods used to examine subgroups and interactions	6
		(c) Explain how missing data were addressed	6
		(d) If applicable, describe analytical methods taking account of sampling strategy	n.a
		(e) Describe any sensitivity analyses	6
Results			
Participants	13*	(a) Report numbers of individuals at each stage of study—eg numbers potentially eligible, examined for eligibility, confirmed eligible, included in the study, completing follow-up, and analysed	n.a/ 7
		(b) Give reasons for non-participation at each stage	6
		(c) Consider use of a flow diagram	
Descriptive data	14*	(a) Give characteristics of study participants (eg demographic, clinical, social) and information on exposures and potential confounders	7
		(b) Indicate number of participants with missing data for each variable of interest	5
Outcome data	15*	Report numbers of outcome events or summary measures	7-9
Main results	16	(a) Give unadjusted estimates and, if applicable, confounder-adjusted estimates and their precision (eg, 95% confidence interval). Make clear which confounders were adjusted for and why they were included	8-9

		(b) Report category boundaries when continuous variables were categorized	7
		(c) If relevant, consider translating estimates of relative risk into absolute risk for a meaningful time period	n.a
Other analyses	17	Report other analyses done—eg analyses of subgroups and interactions, and sensitivity analyses	9
Discussion			
Key results	18	Summarise key results with reference to study objectives	11
Limitations	19	Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss both direction and magnitude of any potential bias	12-13
Interpretation	20	Give a cautious overall interpretation of results considering objectives, limitations, multiplicity of analyses, results from similar studies, and other relevant evidence	11
Generalisability	21	Discuss the generalisability (external validity) of the study results	13
Other information			
Funding	22	Give the source of funding and the role of the funders for the present study and, if applicable, for the original study on which the present article is based	14

*Give information separately for exposed and unexposed groups.

Note: An Explanation and Elaboration article discusses each checklist item and gives methodological background and published examples of transparent reporting. The STROBE checklist is best used in conjunction with this article (freely available on the Web sites of PLoS Medicine at <http://www.plosmedicine.org/>, Annals of Internal Medicine at <http://www.annals.org/>, and Epidemiology at <http://www.epidem.com/>). Information on the STROBE Initiative is available at www.strobe-statement.org.
