### **Supplemental Text 1. Purity determination by GC-MS**

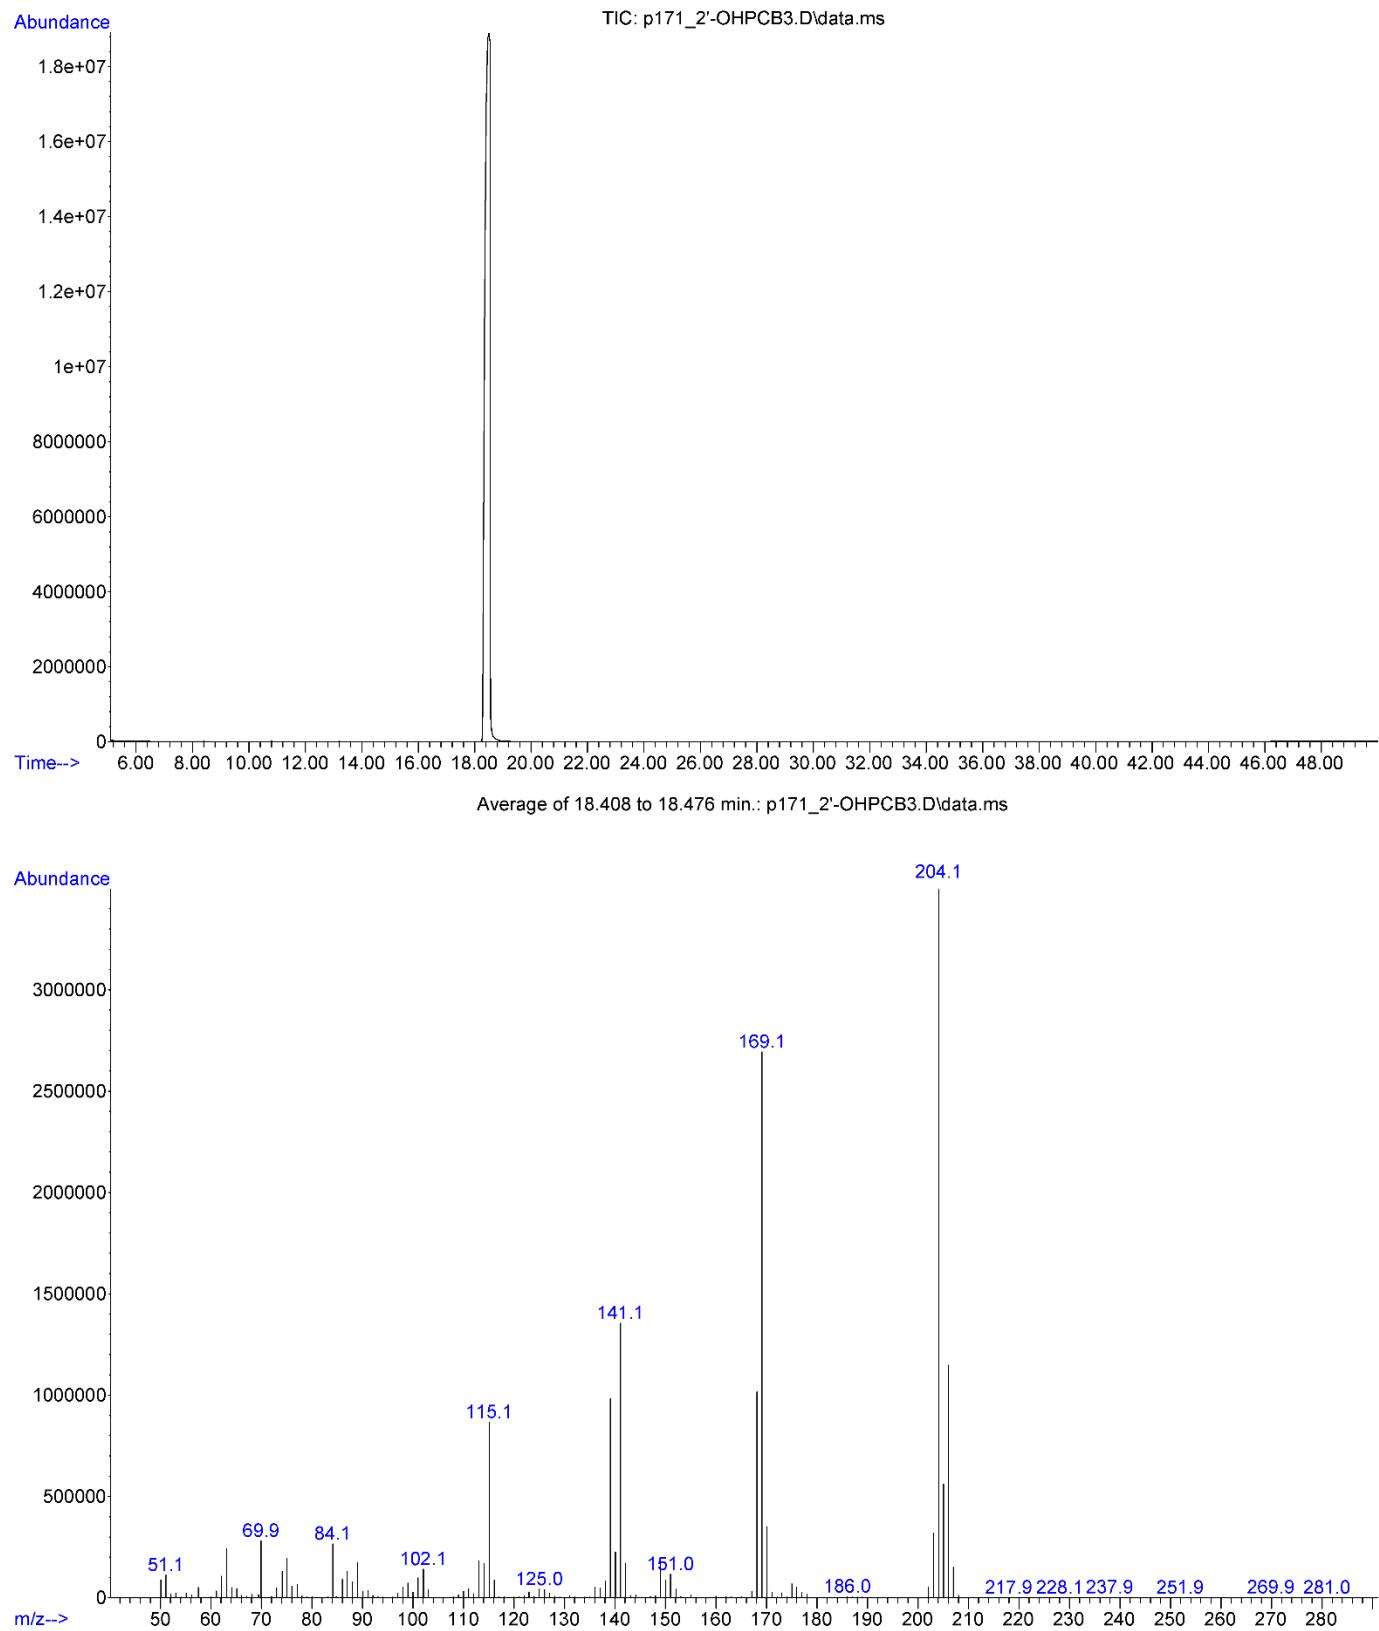

All PCBs, hydroxylated PCBs, methoxylated PCBs, and the PCB quinone were analyzed on an Agilent 7890A gas chromatography equipped with an Agilent 5975 Inert Mass Selective Detector (Agilent Technologies, CA, USA) operated in electronic ionization mode on a SLB-5MS capillary column (30 m length, 250 µm inner diameter, 0.25 µm film thickness; Supelco, Bellefonte, PA, USA). The temperature program was as described previously (Li et al. 2018). Briefly, the oven temperature started at 50 °C, 10 °C/min to 150 °C, then 5 °C/min to 280 °C, hold for 6 min, and then 10 °C/min to 300 °C, hold for 10 min. Helium was used as carrier gas with a constant flow rate of 1.5 mL/min. The injector temperature was 280 °C. The temperatures of transfer line, source and quadrupole were 280 °C, 230 °C and 150 °C, respectively.

### **Supplemental Text 2. Enantiomeric purity determination**

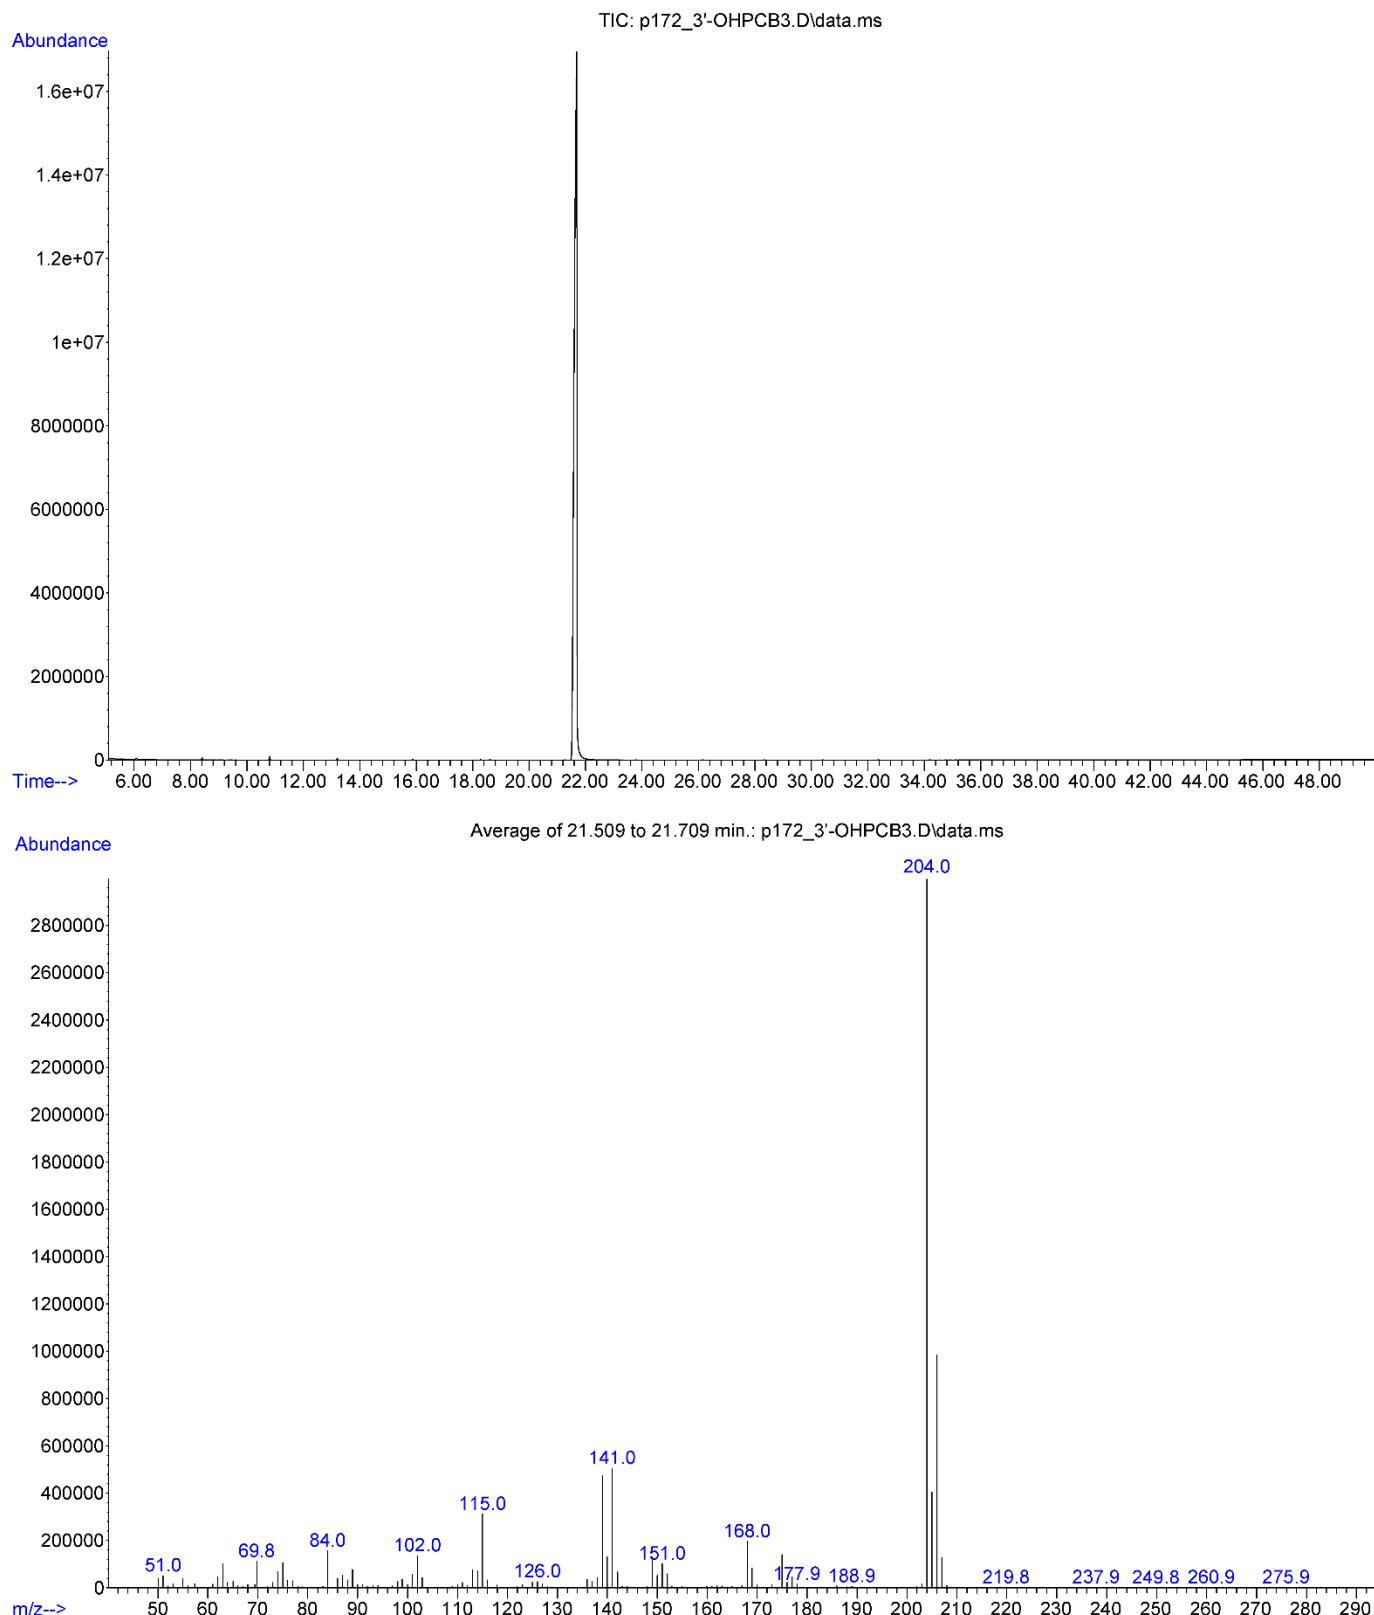

The purity of the enantiomeric pure PCB 136 was performed on an Agilent 7890A gas chromatography with a  $^{63}\text{Ni}$ - $\mu\text{ECD}$  detector and a Chiralsil-Dex (CD column, 25 m length, 250 µm inner diameter, 0.25 µm film thickness; Varian, Palo Alto, CA, USA). The temperature program was based on a previously published method (Wu et al. 2013) with minor modification: starting at 50 °C, then 10 °C/min to 155 °C, hold for 90 min, 20 °C/min to 200 °C, hold for 20 min. The temperatures of the injector and detector were 250 °C and 300 °C, respectively. Helium was used as carrier gas with a constant flow rate of 3 mL/min. Argon 95%-methane 5% was used as makeup gas with a constant flow rate of 60 mL/min.
