"JOURNEY OF A THOUSAND MILES" CHALLENGES ENCOUNTERED BY INTERNATIONAL MEDICAL GRADUATES AND COMPARATIVE PROBLEMS FACED BY AMERICAN GRADUATES DURING INTERNAL MEDICINE RESIDENCY TRAINING AT A COMMUNITY HOSPITAL IN ILLINOIS.

Gauri Pethe. Internal Medicine, Amita Saint Francis Hospital, Evanston, IL. (Control ID #3392714)

BACKGROUND: International physicians make up 25% of the physician work force in the United States, a majority of international applicants pursue Internal Medicine. Based on their accents, religious symbolism or ethnicity, they are often perceived as being different. American-Graduates, although being in a familiar environment, face huddles such as student-loan debt and face challenges such as having to compete with International-Graduates who have more clinical experience.

METHODS: A cross sectional study was done at Saint Francis Hospital. Questionnaires included a basic survey about questions including wellness, personal and work life balance, burnout, and discrimination at the workplace. International students had additional questions including ease of availability and access to basic necessities such as housing, cultural food, and community and learning curve. Questions also included communication barriers faced, and other perceived challenges. American Graduates were inquired about challenges and their perception regarding integration of international students.

RESULTS: Total residents were 60; 39-IMGs-65%, 2-US-IMGs 3.33%, 19-AMG-31.66% with 22- IMGs-56.4% and 10-AMGs-52.63% replied. Within IMGs: 12-females(54.54%) and 10-males(45.45%). AMGs: there were 5 females(50%) and 5 males(50%). 100%-IMGs applied for US residency match for: Better opportunities, 36.36%-Better pay, 90.9%-Quality of life, 86.36%-Work hours. 95.45%-IMGs reported better work hours. 31.81%-IMGs stayed late for work vs 20%-AMGs. 22.73%-IMGs had difficulty finding apartment vs 0%-AMGs. 68.19%-IMGs reported difficulty in finding local food, 77.28%-reported difficulty finding home community. 90.9%-IMGs feel compensated enough for the work they do vs 60%-AMGs. 27.27%-IMGs face discrimination; 83.33% were discriminated based on race vs 30%-AMGs; 66.66% was racial and 33.33% sexual. 45.45%-IMGs reported depression vs 60% AMGs. 80% IMG and 83.33% AMGs are likely to seek help, mostly from family. Both IMGs and AMGs reported to feel burned out at least once a month, most during long-call days. 63.63%-IMGs reported ease in balancing work/personal life vs 80%- AMGs. Most IMGs and AMGs interact with each other during work, and have no problems making friendsips, but rarely meet socially. 36.36%-IMGs think they are treated differently than AMGs. Biggest challenge for IMGs when adjusting to the US system was cultural change and getting used to EMRs. 81.81%- IMGs and 90%-AMGs stated that this is their intended specialty. Most IMGs are able to visit home 1-2 time/year, 4 cannot due to civil war. 100% IMGs do not regret their decision to pursue residency in USA.

CONCLUSIONS: This study outlines different difficulties faced by IMGs and AMGs alike. IMGs reported more racial discrimination and the biggest challenge was to learn the Electronic-Medical-Records and culture. Despite these challenges, IMGs reported that 100% of them do not regret their decision to pursue residency in the United States.

A MULTI-SITE FOCUS GROUP STUDY OF U.S. ADULT WOMEN'S BELIEFS AND ASSUMPTIONS ABOUT BLADDER HEALTH AND FUNCTION

Beverly R. Williams[1]; Missy D. Lavender[3]; Kathryn L. Burgio[1,2]; Yvette LaCoursiere[4]; Diane K. Newman[5]; Sonya S. Brady[6]; Lisa K. Low[7]; Prevention of Lower Urinary Tract Symptoms (PLUS) Research Consoritum[8]. [1]Medicine, University of Alabama at Birmingham, Birmingham, AL; [2]Medicine, Birmingham/Atlanta GRECC, Birmingham VA Medical Center, Birmingham, AL; [3]Independent Researcher, Chicago, IL; [4]Obstetrics, Gynecology, and Reproductive Health, UC San Diego Health - La Jolla, La Jolla, CA; [5]Medicine, University of Pennsylvania, Philadelphia, PA; [6]School of Public Health, University of Minnesota, Minneapolis, MN; [7]School of Nursing, University of Michigan, Ann Arbor, MI; [8]NIH-NIDDK, District of Columbia, DC. (Control ID #3360438)

BACKGROUND: The Study of Habits, Attitudes, Realities, and Experiences (SHARE), a qualitative study of the Prevention of Lower Urinary Tract Symptoms (PLUS) Research Consortium, explored women's knowledge experiences, perceptions, knowledge, and behaviors about bladder health/function. The purpose of this analysis was to characterize women's lay beliefs and assumptions about bladder health and function.

METHODS: Forty-four focus groups were conducted across seven U.S. research centers with 360 women and adolescents, organized by six age categories. Focus groups were audio-recorded and transcribed. Following transcript and fieldnote coding, multi-level qualitative content analyses was used to classify emergent themes. A transdisciplinary lens and inductive approach guided data interpretation of the" bladder beliefs and assumptions code". A team of investigators articulated interpretive insights, which were validated by a community engagement panel.

RESULTS: Women exhibited limited understanding of bladder health and function, with assumptions and beliefs shaped by personal experience and hearsay. Except for the rare occasion when women had input from a medical professional, notions about bladder health and function were characterized by uncertainty, tentativeness, and unconfirmed impressions. Women speculated on (1)the function of the urinary tract system in cleansing or flushing the bodily system of impurities and toxins, (2) the functional relationship between and among the kidneys, bladder, urethra, vagina, pelvic floor and (3)the impact on bladder function of medications for chronic conditions. Women's assumptions and beliefs about bladder health were framed within a "cause and effect" perspective, covering a wide array of habits/behaviors while conjecturing about the physiological mechanisms through such practices promote or deter bladder health. Finally, there was agreement on the importance of bladder friendly habits and the inadvisability of potentially harmful practices. This was acompanied by an assumption that bladder problems could be prevented by developing community- based programs for educating women about bladder health and function, encouraging women to practice healthy bladder habits, eliminating taboos about discussing bladder health, and empowering women to speak out about their bladder-related experiences and concerns.

CONCLUSIONS: Community-engaged public health messaging can inform women's assumptions and beliefs about bladder health/function, educating women about the promotion of bladder health and the prevention of LUTS.

BEHAVIORAL INCENTIVES TO IMPROVE MOBILITY AND DECREASE OPIOID USE IN VETERANS WITH CHRONIC PAIN

Manik Chhabra[2]; Krisda Chaiyachati[3]; Peggy Compton[1]. [1]School of Nursing, University of Pennsylvania, Philadelphia, PA; [2]Corporal Michael Crescenz VA Medical Center, Philadelphia, PA; [3]University of Pennsylvania, Philadelphia, PA. (Control ID #3389698)

BACKGROUND: An estimated 88.5 million adults suffer from daily pain, resulting in an estimated cost of $635 billion in lost productivity and $300 billion in health care expenditures. To manage their chronic pain, 5 to 8 million Americans take an opioid medication daily. However, the risks associated with ongoing opioid use (overdose, abuse, diversion) temper their analgesic effects. Appreciating the gains in health outcomes that behavioral incentives produce, we tested the hypothesis that loss-framed financial incentives combined with technology enabled care (TEC) can improve patient mobility, reduce pain, and decrease opioid use in patients with chronic pain.

METHODS: We conducted a randomized controlled trial, allocating 40 patients 1:1 to a lottery-based behavioral incentive program combined with TEC vs. TEC alone (e.g., text-message communication and activity trackers). Patients were eligible if they received care from a VA pain-focused primary care program, on opioid therapy, and had a cell phone with text messaging capabilities. Patients were excluded if they had cancer-related pain, sensory impairments precluding the use of TEC, or had mobility limitations precluding them from walking. The primary outcome was the change in mobility (number of steps taken), and secondarily, pain severity, physical function, and opioid use using self-reported questionnaires over 12-weeks. Data were collected weekly using activity trackers, and text-messaged questionnaires. We measured baseline mobility using a two-week pre-study period observation before randomization. For the lottery + TEC arm, participants were eligible for a weekly regret lottery if their steps increased by 5% from the prior week. Once the subject reached 150% of baseline, they were always entered into the lottery. The eligible lottery participants could win either $30 or $100; those not meeting the walking goals were told what they would have won had they met their goal.

RESULTS: Forty subjects have been enrolled and 38 have completed the study. The remaining two subjects will complete the trial by January 31, 2020. The results of the full sample will be available for presentation. Based on interim data analyses on the first 20 subjects, the lottery + TEC arm increased weekly average by 2004 steps, whereas the TEC only arm decreased by 1239 steps. For secondary outcomes, the lottery + TEC arm had improvements in pain severity and physical function but not chronic pain.

CONCLUSIONS: Combining a regret lottery incentive with TEC improved mobility in patients with chronic pain, as well as increased participation in exercise and decreased pain severity and interference. While additional interventions or longer-term follow-up may be needed to observe decreases in opioid use, our findings provide important insights into the potential for behavioral incentives to improve the quality of life for Veterans on opioids for chronic pain.

A BILINGUAL PATIENT PORTAL: WHO ARE THE SPANISH-SPEAKING PORTAL USERS?

Jorge A. Rodriguez[1]; Chenxi Gao[1]; Lipika Samal[2]. [1]General Internal Medicine, Brigham and Women's Hospital, Boston, MA; [2]Brigham and Women's Division of General Internal Medicine, Harvard Medical School, Boston, MA. (Control ID #3391863)

BACKGROUND: Patient portals are a standard part of care and have an impact on health outcomes. However, limited English proficient (LEP) patients lag in their use of portals. This gap has been attributed to a lack of multilingual portals. Our hospital offers a bilingual (English and Spanish) portal, but little data exists on who are Spanish-speaking portal users. The goal of our study was to understand factors associated with the use of a bilingual portal among Spanish-speaking patients.

METHODS: We used institutional data from an academic medical center using Epic's MyChart. Our study population was Spanish-speaking patients, defined as those who had Spanish as their preferred language and who had at least 1 encounter or portal login since the implementation of the Spanish portal in October 2016. Our primary outcome was portal use, defined as having an active registration status. We evaluated factors associated with portal use including demographics and patient complexity (defined as number of problems on their problem list). We also examined the relationship of portal use to Emergency Department (ED) and outpatient visits. We performed unadjusted and adjusted analysis comparing Spanish-speaking portal users and nonusers. Analyses were performed using R software version 3.5.

RESULTS: From the 36,256 Spanish-speaking patients included in our study, we found that only 3,789 patients were portal users, accounting for 0.7% of all portal users. This number represents 10.5% of Spanish- speakers. In multivariate analysis of Spanish-speaking patients only, the characteristics associated with portal use were being younger, female, married or widowed, and having more health problems (Table). We also found Spanish-speaking portal users to have a higher number of outpatient visits, as compared to Spanish- speaking nonportal users.

CONCLUSIONS: Despite a bilingual portal, Spanish-speakers made up a small percentage of portal users. Portal users tended to have worse health status and more outpatient visits, in contrast to descriptions of portal users as the "worried well." Our study is limited by inaccuracies of patient language in administrative data. Ultimately, language is only one barrier to portal use among Spanish-speakers, training and institutional commitment are critical to achieve technology equity.

Table. Association Between Patient Characteristics and Patient Portal Use

	Bivariate Analysis			Multivariate Analysis	
	Spanish-speaking Portal User N= 3789	Spanish-speaking non-Portal User N=32467	p-value	OR	p-value
Age, mean(sd)	50.2 (16.9)	52.2 (17.6)	<0.001	0.97	<0.001
Sex			<0.001		
Female, n(%)	2074 (70.6)	21019 (64.7)		1.17	<0.001
Marital status, n(%)			<0.001		
Married	1857 (49.1)	12424 (38.3)		1.96	<0.001
Single	1367 (36.1)	15049 (46.4)		ref	
Divorced/Separated	407 (10.7)	3626 (11.2)		1.31	
Widowed	158 (4.2)	1368 (4.2)		1.80	
Number of Medical Problems, median (IQR)	9 (4-16)	4 (1-11)	<0.001	1.04	<0.001
ED visits, mean (sd)	1.7 (2.7)	1.4 (2.7)	<0.001	0.93	<0.001
Outpatient Visits, median (IQR)	12(5-27)	2 (0-12)	<0.001	1.02	<0.001

A BRIEF PRE-VISIT EDUCATIONAL VIDEO IMPROVED PATIENT ENGAGEMENT AFTER CLINICAL VIDEO TELEHEALTH VISITS; RESULTS FROM A RANDOMIZED CONTROLLED TRIAL

Howard Gordon[1,5]; Oksana Pugach[2]; Pooja Solanki[3]; Ravi K. Gopal[4]. [1]Medicine, JBVAMC, Chicago, IL; [2]IHRP, Chicago, IL; [3]Research, Hines VA Hospital, Chicago, IL; [4]Dept of Medicine, Denver VAMC, Denver, CO; [5]Medicine, University of Illinois, Chicago, Chicago, IL. (Control ID #3391084)

BACKGROUND: Interactive video telehealth primary care visits are increasingly used to improve access to care, but the technology may limit provider-patient communication and the development of the provider-patient relationship. We evaluated the efficacy of a brief pre-visit video to improve patient engagement in their video visits.

METHODS: Patients (N=87) with type 2 diabetes mellitus and elevated HbA1c (≥7%) were enrolled in a randomized controlled trial to test the efficacy of the pre-visit video. Patients were US Veterans living in rural communities who received primary care with video telehealth. The intervention was a 12-minute video that was developed using communication and social behavioral theories, patient interviews, and a panel of communication and clinical experts. The video encouraged patients to use active communication behaviors showing positive role models overcoming common communication challenges in medical visits. Using these resources, we also developed a pamphlet for patients that describes how to use active communication behaviors in medical visits. Patients were randomized 1:1 to receive the video DVD and pamphlet (intervention) or the pamphlet alone (control) by US mail prior to their scheduled video visit. Patients completed pre-visit and post-visit telephone interviews to collect demographics, covariates, and outcomes. Analyses compared the intervention and control groups using bivariate statistics and multiple regression. Here we report outcomes from survey measures; data collection for clinical outcomes is ongoing.

RESULTS: There were no statistically significant differences in age, gender, race, education, income, social support, depression screen, and physical or mental functional status between intervention and control groups (P>0.05). Mean baseline HbA1c did not differ in intervention and control groups (8.5% vs 8.6%; P=0.92). There were no statistically significant differences in intervention vs. control for patients' post-visit ratings of communication (94.2 vs. 89.0; P=.16), shared decision-making (17.2 vs 15.2; P=0.08), patient centered care (90.2 vs 84.9; P=0.21), or patient satisfaction (24.2 vs 23.5; p=0.53). Ratings of post-visit empathy were higher (44.6 vs 40.6; P=0.05) in the intervention group than control group. After adjusting for baseline outcomes using multiple regression, there was no difference in post-visit self-efficacy to communicate between intervention and control groups, but the intervention group reported higher scores on post-visit therapeutic alliance with the provider and higher patient engagement, compared with patients in the control group, [Beta 3.7 (SE 1.8); P=0.05] and [Beta 1.9 (SE 0.9) P=0.04], respectively.

CONCLUSIONS: This study showed the efficacy of a pre-visit video to improve patient engagement and therapeutic alliance after video telehealth visits with their provider. Future studies should be conducted to evaluate the effectiveness of pre-visit videos that promote patients' active participatory communication.

A CALL TO MEDICINE: A MULTICENTER STUDY OF SENSE OF CALLING AND PHYSICIAN WELLBEING

Janaki Patel[2]; Lars Osterberg[3]; Wei Wei Lee[1]; Helene Starks[4]; Shobha W. Stack[4]; Molly Jackon[4]. [1]General Internal Medicine, University of Chicago, Chicago, IL; [2]Pritzker School of Medicine, University of Chicago, Chicago, IL; [3]Stanford University School of Medicine, Menlo Park, CA; [4]Medicine, University of Washington, Seattle, WA. (Control ID #3388655)

BACKGROUND: Medicine is often viewed as a "calling"- a desire to commit one's life to work that is personally meaningful and socially significant. A sense of calling in arduous fields, such as music and academia, has been associated with greater job satisfaction, commitment, and wellbeing. No studies have determined if similar outcomes exist in medicine. In the setting of strenuous training and demanding careers, sense of calling has the potential to protect physician wellbeing. We aim to evaluate associations between sense of calling and physician wellbeing

METHODS: We conducted an anonymous multi-institutional cross-sectional survey of 1143 faculty internists and neurologists. The survey included five validated scales measuring sense of calling,[1] emotional exhaustion, depersonalization, cynicism, resilience, and work engagement. Primary outcomes were associations between sense of calling and these markers of wellbeing. Multivariate regressions were used, controlling for site, physician age, gender, race, specialty, years in practice, practice setting, compensation, clinical time, and faculty track.

RESULTS: A total of 433 physicians (37.8%) responded. Respondents were similar in gender and specialty to the invited population; most were clinician educators (183/393, 47%). Mean sense of calling was 5.04/6.00 (SD 1.17). Twenty-eight percent had symptoms of emotional exhaustion and 12% had symptoms of depersonalization. Sense of calling was negatively associated with emotional exhaustion (*beta* -0.57, 95% CI -0.69 to -0.44, $p<0.001$), depersonalization (*beta* -0.46, 95% CI -0.63 to -0.29, $p<0.001$), and cynicism (*beta* -0.60, CI -0.74 to -0.47, $p<0.001$), and positively associated with resilience (*beta* 0.14, 95% CI 0.07 to 0.21, $p<0.001$) and work engagement (*beta* 0.45, 95% CI 0.36 to 0.53, $p<0.001$).

CONCLUSIONS: Our findings show that sense of calling has beneficial associations with multiple aspects of physician wellbeing. Educators should find ways to cultivate, advance, and protect sense of calling in the process of learner professional identity formation to produce well and engaged doctors.

ACCEPTABILITY OF VIDEO DECLARATIONS OF ADVANCE CARE PLANNING PREFERENCES BY CANCER PATIENTS

Lisa M. Quintiliani[1,2]; Katherine Waite[2]; Angelo E. Volandes[3]; Michael K. Paasche-Orlow[1,2]. [1]Medicine, Boston University, Boston, MA; [2]General Internal Medicine, Boston Medical Center, Boston, MA; [3]Medicine, Massachusetts General Hospital, Boston, MA. (Control ID #3377375)

BACKGROUND: A videotaped declaration by patients of their advance care planning preferences could be an opportunity to supplement advance directive forms and allow patients to more fully express their preferences in a manner that is compelling for families and clinicians. The objective of this study is to examine the acceptability of video declarations among patients with advanced cancer from the patients' perspective.

METHODS: Participants were from outpatient and inpatient settings of a large urban safety-net hospital with a diagnosis of any type of advanced cancer. After viewing a brief educational video describing approaches to end-of-life care, we used a tablet computer to videotape participants as they described their wishes for medical care including specific medical treatments (i.e., CPR/intubation). Afterwards, we administered a questionnaire to participants about the acceptability of this process including close-ended rating scales (e.g., helpfulness, ease) and open-ended questions to allow the participant to provide further detail. Descriptive statistics were calculated and answers to open-ended questions were summarized and grouped by thematic category.

RESULTS: There were 29 participants; mean age was 61.3 (SD=10.1) years. About half were female (48%); the most prevalent race/ethnicity group was black/African American (41%), followed by white (34%), Hispanic (14%), and other (11%); 41% had ≤ high school degree. About half (48%) reported their health was fair or poor and half (55%) reported

having a previous conversation about end-of-life wishes with family/clinicians. The majority rated 'quite a bit' or 'extremely' to the following indicators of acceptability: confidence about what they said in their video (96%), making the video was helpful (86%), making the video was easy (65%), and recommending others make a video like this (79%). Several thematic categories described benefits of the video declaration process: authenticity ("Feels more from the heart"), face the issue head on ("… instead of avoiding conversation. Made me deal with it. Kept putting it off."), convey wishes to family ("Those that [are] concerned in your care that they know [my] position and can honor it."), and reassurance for family ("Easy for family to know what to do. Takes pressure off."). Participants also noted that the video could be difficult to make ("Not everyone thinks like I do").

CONCLUSIONS: Findings show patients with advanced cancer from diverse groups found the video declaration process to be acceptable, with almost all being confident in expressing their wishes and most finding the process helpful. Further research will examine the acceptability of the videos from the family member caregiver and clinician perspectives. If integrated into widespread use, video declarations may be an acceptable way to help promote care concordant with patients' preferences.

ACO AWARENESS AND PERCEPTIONS AMONG SPECIALIST PHYSICIANS VERSUS PRIMARY CARE PHYSICIANS: A SURVEY OF A LARGE MEDICARE SHARED SAVINGS PROGRAM

Adam A. Markovitz[1,3]; Michael Rozier[2]; Andrew Ryan[1,3]; John Z. Ayanian[3,1]; Edward C. Norton[4,3]; Timothy Peterson[6]; John M. Hollingsworth[5,3]. [1]Health Management and Policy, University of Michigan School of Public Health, Ann Arbor, MI; [2]Health Management and Policy, Saint Louis University, St. Louis, MO; [3]Institute for Healthcare Policy and Innovation, University of Michigan, Ann Arbor, MI; [4]Health Management and Policy, University of Michigan, Ann Arbor, MI; [5]Urolgoy, University of Michigan, Ann Arbor, MI; [6]Emergency Medicine, University of Michigan, Ann Arbor, MI. (Control ID #3388302)

BACKGROUND: Medicare Shared Savings Program (MSSP) Accountable Care Organizations (ACOs) have achieved only modest savings. One possible explanation for their limited success is organizational failure to engage frontline ACO providers, particularly those specialist physicians (e.g., cardiologists) and surgeons who serve as gatekeepers to expensive testing and procedures. However, it is unknown whether awareness and perceptions differ between specialist physicians versus primary care physicians (PCPs) in ACOs.

METHODS: We compared awareness and perceptions of ACOs between specialist physicians and PCPs. To do so, we designed and administered a survey to physicians in the Physician Organization of Michigan ACO, one of the ten largest MSSP ACOs. Our primary exposure was whether a respondent was a specialist physician, including internal medicine subspecialists (e.g., cardiologist), surgeons, and other specialist physicians (e.g., dermatology) versus a PCP. Outcomes pertained to ACO awareness and perception of ACO effects on physician behavior (e.g., clinical practice), quality of care (e.g., care coordination, health of complex patients), and physician satisfaction (e.g., professional satisfaction, administrative burden). We used multivariable fixed-effect models to test within-organization associations between physician type and ACO awareness and perceptions. Multiple imputation and survey weights were used to reduce bias from missing data and survey non-response.

RESULTS: Survey respondents included 900 physicians: specialist physicians (75%), comprising internal medicine subspecialists (23%), surgeons (14%), and other specialist physicians (35%), and PCPs (25%). Response rate was 34%. ACO awareness and perceived ACO effects on physician behavior and clinical outcomes varied substantially between specialist physicians and PCPs. Compared to PCPs, specialist physicians were less likely to know they were in an ACO (47% vs. 71%, difference: -24 percentage points [pp]), that the ACO was held accountable for spending and quality (25% vs. 47%, -22 pp), or that their ACO had lowered spending (10% vs. 19%, -9 pp). Furthermore, specialist physicians were less likely to perceive that the ACO had a positive impact on care quality (26% vs. 40%, -14 pp), care coordination (-14 pp), or the health of medically complex patients (-11 pp). Specialist physicians were also less likely to perceive that the ACO had any effect on clinical practice (17% vs. 27%, -10 pp), compensation (23% vs. 36%, -13 pp), or receiving useful feedback (15% vs 29%, -14 pp). In contrast, the perceived effect of ACOs on physician satisfaction did not systematically vary between specialist physicians and PCPs.

CONCLUSIONS: In one of the largest surveys of ACO physicians to date, we found that specialist physicians reported substantially lower ACO awareness and more negative perceptions of ACO effects on patient outcomes. Limited engagement of specialist physicians may hamper ACO efforts to reduce spending and improve quality.

A COST-BENEFIT ANALYSIS OF MEDICAL SCRIBES ACROSS MEDICAL SPECIALTIES

Tyler Miksanek[1]; Mohammed Reza Skandari[2]; Wei Wei Lee[1]; Valerie G. Press[1]; Marie T. Brown[3]; Sandra Ham[4]; Neda Laiteerapong[1]. [1]Pritzker School of Medicine, University of Chicago, Chicago, IL; [2]Imperial College London, London, United Kingdom; [3]IM, Rush University, Riverside, IL; [4]Center for Health and the Social Sciences, University of Chicago, Chicago, IL. (Control ID #3377531)

BACKGROUND: Electronic Health Record (EHR) use has been shown to increase time spent on documentation and worsen physician burnout. One potential solution to EHR-related burnout is the use of medical scribes, nonclinical staff members who document clinic visits under physician supervision. Data show that scribes can increase physician efficiency, allowing physicians to see more patients per day without decreasing physician well-being. Increased productivity from the use of medical scribes has led to increased net revenue for clinics in multiple single-specialty studies. To our knowledge, no study to date has performed a cost-benefit analysis of medical scribes in multiple medical specialties. To generalize findings from single- specialty studies, we modeled the number of additional patient visits required to recover the costs of hiring scribes for 32 medical specialties.

METHODS: We modeled scribe costs and productivity-associated revenue increases from the perspective of an outpatient clinic contracting with a third-party scribe provider. Scribe costs were estimated from costs our institution faced when contracting to hire scribes, which paralleled costs previously reported in other studies. To estimate revenue from additional visits, we used 2015 Centers for Medicare & Medicaid Services (CMS) national billing data from the Medicare Provider Utilization and Payment Data dataset. We calculated the percentage of outpatient visits in each specialty billed at each Evaluation and Management level of service code. Using 2015 non-facility price CMS reimbursement rates, we then calculated the mean and standard deviation for the revenue generated by each additional visit across specialties. Specialty-specific data from the 2012-2016 National Ambulatory Medical Care Survey was used to estimate additional revenue from laboratory tests. Our primary outcome was the number of additional patients a provider would need to see per year and per day to have 90% confidence in recovering scribe costs.

RESULTS: Adding two new or three return patients per day was sufficient to not only recover scribe costs, but actually increase net revenues for all specialties. Across all specialties, the mean number of additional new patient visits required to recover costs was 1.34 visits per day (295 visits per year). The mean number of additional return patient visits required to recover costs was 2.15 visits per day (472 visits per year). Internal

Medicine required 1.20 new patient visits per day (263 visits per year) or 1.90 return patient visits per day (417 visits per year) to recover costs.

CONCLUSIONS: Across medical specialties, scribes offer an economically feasible way to address physician documentation burden, as long as physicians are willing to increase their patient load. Our results likely underestimate the full potential of scribes because our work does not include potential downstream revenue from future visits, procedures, and surgeries, or account for changes in physician well-being.

ACROSS RACE, ETHNICITY, AND LANGUAGE: AN INTERVENTION TO IMPROVE ADVANCE CARE PLANNING DOCUMENTATION UNMASKS HEALTH DISPARITIES

Sarah J. Flynn, Molly A. Kantor, Michelle Mourad. Medicine, University of California, San Francisco, San Fransisco, CA. (Control ID #3390874)

BACKGROUND: Conversations around advance care planning (ACP) allow patients to direct the type and intensity of the medical care that they receive. Known ethnic and racial disparities in ACP exist, with racial and ethnic minorities less likely to have living wills and DNR orders. We aimed to understand the impact of an intervention to improve the documentation of ACP conversations for hospitalized patients on health disparities at our institution.

METHODS: In February 2019 the Division of Hospital Medicine at an urban, academic health system launched an initiative to improve rates of documented ACP conversations using new tools available in the electronic medical record (EMR). Hospitalists and trainees were encouraged to document ACP conversations for all patients >75 or with advanced illness as measured by recognized ICD-10 codes. EMR-generated reports provided patient-level compliance and demographics for 5563 discharged or deceased patients who met criteria from July 2018 to October 2019 prior to and following the intervention. ACP completion by discharge was analyzed by self-reported race, ethnicity, and preferred language. Patients with unknown/declined race or language were excluded. We used ANOVA analyses to determine baseline differences as well as chi-square tests to assess the effect of the intervention on racial/ethnic and language groups.

RESULTS: Using the quarter prior to the intervention as a baseline, November 2018-January 2019, overall rates of ACP documentation improved significantly when compared to the most recent 3 months of the intervention, August–October 2019 (356/1012 [35.4%] compared to 740/1090 [64.6%], P<0.001). At baseline there were no disparities by race/ethnicity (P=0.182) but significant disparities were associated with patient preferred language (P=0.035), with Russian speaking patients less likely to have ACP documentation compared to English speaking patients (P=0.0042). In the most recent 3 months of the intervention, race/ethnicity (P=0.035) and language (P=0.036) were associated with significant differences in ACP documentation. Using White/Caucasian race as a reference, patients identifying as Hispanic/Latino were significantly less likely to have ACP documentation (P=0.0003). Using English language as a reference, Spanish speaking patients were significantly less likely to have ACP documentation (P=0.0254); there was no longer a difference in ACP documentation rates for Russian speaking patients.

CONCLUSIONS: An intervention designed to improve ACP documentation resulted in overall improved rates of documented ACP conversations for hospitalized medical patients. However, the intervention was associated with new disparities especially for Hispanic/Latino and Spanish speaking patients. Further analysis is needed to explore the interaction between ethnic and language disparities and the underlying patient, provider, and system-level factors associated with these identified disparities.

ADAPTATION OF AN MHEALTH INTERVENTION FOR LATINX PEOPLE LIVING WITH HIV IN THE SOUTHERN U.S.

Tabor E. Flickinger[1]; Jacqueline Sherbuk[1]; Kristen Petros de Guex[1]; Diego A. Villarreal[2]; Kathleen McManus[1]; Karen S. Ingersoll[3]; Rebecca Dillingham[1]. [1]Medicine, University of Virginia, Charlottesville, VA; [2]School of Medicine, Universidad San Francisco de Quito, Quito, Ecuador; [3]Psychiatry and Neurobehavioral Sciences, University of Virginia, Charlottesville, VA. (Control ID #3390302)

BACKGROUND: Latinx people in the United States are disproportionately diagnosed with HIV and experience health disparities when living with HIV. They face many challenges, including language barriers, discrimination, stigma, and immigration status concerns. In the non-urban South, a low density of Spanish speaking People Living with HIV and a paucity of Spanish-speaking healthcare providers leads to a lack of social support and difficulty accessing services. PositiveLinks (PL) is a successful mHealth intervention for PLWH developed with a mostly African-American population. PL includes daily tracking of medication adherence, mood and stress; appointment reminders; educational resources; lab results; a community message board; and secure messaging with the clinic. We aimed to conduct formative work to guide adaptation of PL for Spanish-speaking Latinx PLWH.

METHODS: We conducted semi-structured interviews to explore participants' attitudes toward technology, desired mHealth features, and feedback on a Spanish-language PL prototype. Participants were Spanish-speaking Latinx patients recruited from a non-urban Ryan White HIV/AIDS Program clinic and a community-based organization. Interviews were conducted in Spanish, audio-recorded, transcribed, and translated to facilitate analysis. Each interview was coded by at least two team members with discrepancies resolved by consensus. The codebook was developed iteratively until high reliability was achieved.

RESULTS: Participants (n=22) included 10 men, 10 women, and 2 transgender women. Mean age was 41.1 (SD 11.6) years and all were foreign born. Prior negative experience with technology was described by 73% of participants. Positive associations with technology included personal connection (91%) and access to information (68%). In discussing PL features, participants expressed desire for access to information (86%), positive reinforcement/support (82%), personal connection (64%), ease of use (45%), and connection to their care team (41%). Most participants (n=16) suggested improvements. Priorities included creation of an integrated Spanish-language community board to bring together different clinical sites, rather than the current single-site board, and redesign of the labs feature. Participants (n=3) who expressed difficulty with the lab result feature had follow-up interviews for feedback on the redesigned display and reported improved understanding of the visuals and text.

CONCLUSIONS: Spanish-speaking Latinx PLWH, who face many barriers to care, voiced a need for reliable information and social support, and they felt that a linguistically and culturally tailored adaption of the PL mHealth intervention could help meet these goals. Our team continues to work with participants to improve the fit of features to their needs. This work will inform the next phase of larger scale implementation of PL for Spanish speakers with evaluation of app usage and quantification of associated clinical outcomes.

ADDRESSING HEALTH LITERACY NEEDS IN SHARED DECISION-MAKING FOR BREAST CANCER SCREENING: PATIENT AND PRIMARY CARE PROVIDER PERSPECTIVES

Christine Gunn[1]; Tracy A. Battaglia[2]; Michael Paasche-Orlow[2]; Mara A. Schonberg[3]; Ariel Maschke[2]; Nancy R. Kressin[4]. [1]Department of Medicine, Boston University, Boston, MA; [2]Medicine, Boston University

Medical Center, Boston, MA; [3]Medicine, Beth Israel Deaconess Medical Center, Boston, MA; [4]Medicine/Section of General Internal Medicine, Dept of Veterans Affairs and Boston University, West Roxbury, MA. (Control ID #3387461)

BACKGROUND: Women with low health literacy (LHL) are at risk for not receiving recommended shared decision-making (SDM) for breast cancer screening. This study characterized approaches to, challenges with, and desired conditions to promote SDM for breast cancer screening between primary care providers (PCPs) and women with LHL ages 40-54.

METHODS: Women ages 40-54 with LHL(<7 on the Health Literacy Skills Instrument-10) who had no history of breast cancer or mammogram in the prior 9 months, were approached prior to a primary care well- visit at an academic safety-net hospital. PCPs practicing at this site were eligible for PCP interviews. Qualitative, in-depth interviews explored experiences with mammography counseling and SDM. For analysis, 2 individuals developed a codebook by coding 6 transcripts and establishing consensus. One person coded remaining transcripts with second coder review. Thematic analysis identified key themes regarding mammography knowledge, decision-making, and context desired for SDM.

RESULTS: Of 25 patients, 18 identified as black, 3 as Hispanic/Latina, 2 as non-Hispanic white, and 3 did not disclose. Average patient age was 46.5 years; 12 had a prior mammogram. Of 20 PCPs, 15 were female; 12 had practiced for >5 years. Patients with LHL described that doctors had critical knowledge that they did not possess. Patients ascribed embodied knowledge ("I know my own body") only to themselves; but described a lack of technical knowledge (what tests are appropriate and what they do) and process knowledge (what happens during a mammogram visit) and attributed such expertise to their PCPs. Women desired more technical and process knowledge, viewing these as necessary for decision-making and in reducing screening- related fear. PCPs aspired to conduct SDM, but varied in efforts to elicit patient preferences. PCPs were reluctant to engage patients with LHL in SDM due to time constraints and fearing that increased information might confuse patients or deter them from having mammograms. Patients described mammography as providing a high amount of certainty. PCPs also noted that the idea that mammography is not a "crystal ball" is not well-known and counseling should better prepare women for uncertain results and call backs. PCPs and patients felt education would be best delivered by support personnel outside of visits to facilitate mammography-related SDM during clinical visits with limited time. Notably, only 2 PCPs supplied patients with educational materials as part of mammography discussions.

CONCLUSIONS: Patients indicated they had little process and technical mammography knowledge, which hampered participation in SDM. Patient experience was reflected in PCP descriptions of their own counseling styles, which they recognized provided few details and rarely included the provision of supportive educational materials. Research on optimizing tools that relay technical and process knowledge about mammography prior to clinical encounters and facilitate SDM during visits is needed.

A DESCRIPTION OF PATIENTS SERVED AND DIAGNOSES AT THE CRIMSON CARE STUDENT-FACULTY COLLABORATIVE CLINICS IN MASSACHUSETTS.

Gaurav Luthria[2]; Mie Hashimoto[1]; Marya J. Cohen[1]; Gina R. Kruse[1]. [1]Massachusetts General Hospital, Boston, MA; [2]Harvard University, Cambridge, MA. (Control ID #3391536)

BACKGROUND: The Crimson Care Collaborative (CCC) is a group of student-faculty collaborative clinics that provides evening primary care and urgent care services at seven different sites throughout the greater Boston area. In addition to providing clinical care, CCC aims to link patients to primary care practitioners and provide health professional students with longitudinal primary care experiences. To understand the patients served and clinical experience for student volunteers, we assessed the demographic and socioeconomic characteristics of patients and visit diagnoses at two CCC sites.

METHODS: Retrospective cross-sectional observational analysis of patients seen at two different CCC clinic sites: Massachusetts General Hospital (MGH) Internal Medicine Associates (IMA) and MGH Chelsea Health Center (CHC). The IMA is a hospital-based clinic that receives referrals for patients without PCPs who are seen at the MGH Emergency Department as well as evening visits for established IMA patients. CHC serves established patients and a post-incarceration population. Patient level social and demographic measures and visit level diagnoses were collected for 503 patients (287 IMA patients and 216 CHC patients from 2016-2018).

RESULTS: At CCC IMA, the mean age was 49.7 years (SD=18.3); most patients were male (48.1%), white (61.2%; black: 13.2%; asian: 6.9%, other: 10.5%), and commercially insured (50.5%). At CCC CHC, the mean age was 43.0 years (SD=12.7), most were male (70.6%), Hispanic (34.6%; white: 15.4%, black: 7.4%, asian: 1.4%, other: 37.3%) and received Medicaid (71.0%). Using ICD-9/10 codes from patient visit data, diagnoses were classified for patients at both sites. The prevalence of musculoskeletal and connective tissue diseases (ICD10 710-739) and respiratory system diseases (ICD9 460-519) was significantly higher for patients seen at the IMA clinic ($p<0.005$; z-test). In terms of longitudinal experience, the average number of visits per patient during this period was different between clinics with 1.7 visits (SD=1.7) at IMA and 3.01 visits (SD=2.2) at CHC with no significant association between the number of visits, type of insurance, gender, or race.

CONCLUSIONS: Understanding the populations served and diagnoses treated at student-faculty collaborative clinics is important both for assessing the service these evening clinics provide to the larger hospital system and the clinical experience students gain from volunteering. The two clinics studied offer volunteers experience with different patient populations, clinical diagnoses, and longitudinal care. Future work could explore how these differing experiences influence things like student specialty choice or healthcare utilization by CCC patients.

ADMISSION PRACTICES, COST AND THERAPIES OFFERED AT RESIDENTIAL ADDICTION TREATMENT PROGRAMS IN THE US: A NATIONAL AUDIT SURVEY

Tamara Beetham[2]; Brendan Saloner[4]; Marema Gaye[1]; Sarah E. Wakeman[3]; Richard Frank[5]; Michael L. Barnett[1]. [1]Health Policy and Management, Harvard T.H. Chan School of Public Health, Boston, MA; [2]Social and Behavioral Sciences, Harvard T.H. Chan School of Public Health, Cambridge, MA; [3]Medicine, Massachusetts General Hospital, Charlestown, MA; [4]Johns Hopkins University, Baltimore, MD; [5]Harvard Medical School, Boston, MA. (Control ID #3391102)

BACKGROUND: Residential treatment ("rehab") programs are a common setting for treating opioid use disorder and frequently highlighted in policy proposals to improve access to addiction care, though their clinical effectiveness compared to standard outpatient care is uncertain. Concerns have also been raised about high costs, substandard quality and patient exploitation in these settings, particularly at for-profit programs. Together, questions about the effectiveness of residential treatment and reported lapses in accountability call for further assessment of the conduct of these programs nationally, but little data are available.

METHODS: We performed an audit survey of residential treatment programs in the US identified from public databases. Three trained research assistants called 613 randomly sampled programs posing as 27-year old individuals seeking care who actively use heroin and lack insurance. Callers inquired about paying for treatment, treatment offered

at the program, and when admission was possible. Main outcomes included admission acceptance and wait time, types of recruitment techniques used, treatment cost, availability of opioid agonist therapy (OAT, e.g. buprenorphine), and anti-OAT messaging. We stratified outcomes by nonprofit vs. for-profit ownership, and presence of external accreditation (e.g. The Joint Commission) or state licensure. We tested differences across groups using z-tests for proportions, t-tests and chi-squared tests.

RESULTS: We obtained data from 368 of 453 in-sample programs (81% response rate), representing 26% of all non-federal programs nationally. Beds were available for admission the same or following day at 202 (64%) programs and 122 (33%) of programs offered admission to callers by phone. Recruitment techniques (e.g. offering paid transportation) were used frequently by for-profit, but not nonprofit, programs (146 [65%] vs. 13 [9%], p<0.001). The average daily cost for treatment was $758 at for-profit and $357 at nonprofit programs (p<0.001), with 264 (74%) programs requiring upfront payment on average totaling $17,434 and $5,712 at for-profit and nonprofit programs respectively). Nationally, 107 (29%) programs offered OAT with the option to continue maintenance while 78 (21%) actively discouraged callers from using OAT. Rates of OAT availability and anti-OAT messaging were similar regardless of programs' external accreditation or state licensure.

CONCLUSIONS: Residential programs offered rapid treatment access, though with frequent use of inducements for recruitment and substantial upfront cost, particularly at for-profit programs. A minority of programs offered OAT as maintenance therapy, the standard of care for OUD, while many actively discouraged the use of OAT to callers. These findings raise concerns about the quality of care offered by residential treatment programs and the adequacy of state licensure and accreditation to provide program accountability and protect vulnerable patients.

ADVANCE CARE PLANNING BY AN EMBEDDED SOCIAL WORKER FOR PATIENTS WITH ADVANCED HEART FAILURE DESIRING HEART TRANSPLANT

Codie Lieto[1]; Anne M. Walling[2]; Neil Wenger[1]. [1]Medicine, University of California, Los Angeles, Los Angeles, CA; [2]Medicine, UCLA, Los Angeles, CA. (Control ID #3392701)

BACKGROUND: Patients with advanced heart failure desiring the most technically advanced and aggressive cardiac care are at risk for severe adverse events and long hospital stays leading to death. We embedded a social worker within a Cardiomyopathy service to implement timely advance care planning (ACP) with patients considered for mechanical circulatory support and/or heart transplant and evaluated the impact on goals of care (GOC) conversation documentation and inpatient utilization.

METHODS: After developing a shared mental model with cardiologists, surgeons and the transplant team, an ACP social worker implemented disease-targeted discussion with all patients admitted to the hospital for transplant evaluation or potential mechanical support to (1) clarify understanding of their condition and treatment options, (2) identify and document appropriate proxy decision makers, (3) conduct conversations about and document GOC including preferences concerning disease- and procedure-specific adverse outcomes, and (4) ensure proxies are aware of patient preferences. A structured visit note reflected discussions, decisions and obstacles to decision making. We evaluated whether patients receiving the intervention had documented GOC including goals for future health states and an advance directive (AD), and compared inpatient utilization after an index hospitalization among all patients before (4/2013-5/2015) and after (6/2015-9/2019) the ACP intervention.

RESULTS: The ACP social worker approached 556 of 638 admitted cardiomyopathy patients and documented GOC and a designated surrogate for every patient; 71% of patients were about to effectively explore preferences concerning future health states and 68% completed a valid AD. Compared to the 390 patients admitted during the 26 months pre-intervention, index admission length of stay (25d post v 26d pre) and inpatient mortality (13% post v 14% pre) were similar. However intervention period length of stay in the hospital (26d v 43d, p<0.001) and ICU (21d v 35d, p<0.01) was shorter among decedents.

CONCLUSIONS: Implementing an ACP program on a Cardiomyopathy inpatient service is feasible even among inpatients desiring the most aggressive treatment. This ACP intervention facilitated most patients to meaningfully consider GOC and may decrease hospital use among decedents.

ADVANCED APPROACH TO THROUGHPUT: ADVANCED PRACTICE CLINICIAN (APC) AND PHYSICIAN COLLABORATION IN EARLY DISCHARGE OF A HIGH VOLUME HOSPITALIST SERVICE

Sarah J. Puim[1]; Dipali R. Sahoo[2]; Andrew Glover[1]; Jonathan Pangia[1]; Christopher Waybright[1]. [1]Grand Strand Medical Center, Myrtle Beach, SC; [2]Internal Medicine, Grand Strand Medical Center, Myrtle Beach, SC. (Control ID #3391899)

BACKGROUND: The timing of discharges of admitted patients has a significant impact on hospital efficiency and throughput. Earlier discharges are associated with improved boarding times, admissions arriving to inpatient units earlier in the day, and decreased length of stay. Discharges that occur later in the day creates a bottleneck effect, causing emergency room congestion, overcrowding, and higher inpatient mortality. This project was developed to address a high volume hospitalist service challenged with meeting early discharge goals. Our goal was to have 25% of discharge orders placed by 9am, and 40% placed by 11am.

METHODS: This retrospective study was developed as a targeted initiative to improve throughput by increasing the rate of early discharges before 9 and 11am in an acute community-based academic medical center. Our model implemented a staffing model change of an Advanced Practice Clinician (APC) to standardize the discharge process of hospitalized patients. An APC-assisted discharge assessment was launched for all clinicians on the Hospital Medicine service. On each calendar day, an APC was designated as the Discharge APC. The day prior to expected discharge, the hospitalists compiled a list of potential discharges and outlined any anticipated barriers. On the day of discharge, the APC reviewed and assessed these patients, determined if any barriers could be resolved and prepared necessary discharge documentation. Those patients determined clinically appropriate for discharge by the APC were reported to the hospitalist, and the plan of care was finalized. When the discharge planning was complete, the discharge order was submitted in the EHR. The rate of early discharge orders electronically submitted were analyzed through a 6 month period during the initiative and compared to the same 6 month period the year prior to the launch of the study.

RESULTS: Prior to the staffing model change, the hospitalist group averaged 28.8% of discharge orders placed before 11am. After the initiative, the discharge orders before 11am rose above our goal to 43.2%, and continues to be successful. This study continues to be at an early stage and represents preliminary data that was gathered to ensure that our intervention is yielding positive improvement to discharge rates. Data analysis is ongoing to obtain the rate of discharges prior to 9am, which are expected to be above our goal for this time period.

CONCLUSIONS: The collaboration of our APC and Physician discharge initiative has resulted in significant improvements in the rate of early discharge orders. Our data has shown promising results for discharge orders placed prior to 11am. Future goals will analyze length of stay to ensure that our early discharge intervention does not compromise length of stay. Although still in early stages, our team-based approach to discharge planning has

demonstrated an efficient model to improve hospital throughput by overcoming challenges associated with timely discharge of patients.

ADVANCE DIRECTIVES AND HEALTH SURROGACY IN LOW INCOME AND UNINSURED POPULATIONS

Oliver J. Shore, Paige Barker, Melanie Hagen. College of Medicine, University of Florida, Gainesville, FL. (Control ID #3392401)

BACKGROUND: Advance directives (ADs) allow patients express their preferences for medical treatments and to choose healthcare surrogates so that they can continue to control their healthcare in the event they lose the capacity to make decisions. Belonging to a racial minority group, having a low income, and being less educated strongly reduces the likelihood that adults will have an AD. For lower income and uninsured adults, little has been done to investigate the unmet needs concerning their end of life planning and effective strategies to meet those needs. Our goal was to evaluate the utility of giving low income and uninsured adults over 50 years of age in-person advance directive counseling at a free student-run clinic in Gainesville, Florida.

METHODS: All patients that presented to the Equal Access clinic who were over 50, spoke English, and had the capacity to make medical decisions were asked to participate in the study. Consented subjects were given a pre- survey and 'part one' of a two-part questionnaire to assess knowledge of ADs. Subjects were then educated about ADs using the UF Health AD forms. Subjects were then given the opportunity to complete an AD in clinic, take AD forms home, or decline taking or completing an AD. Participants then completed 'part two' of the two-part questionnaire as well as a post-survey. Participants who filled out an advance directive were given a copy of their directive. The original was scanned in to their electronic medical record.

RESULTS: We found that 94.12% of study participants lacked health insurance for an average of 3.08 years. The prevalence of ADs in study participants was 5.88% prior to intervention, with 35.29% of subjects knowing what ADs were by name. Most participants, 70.58%, had never previously discussed ADs with a medical professional. Following intervention, 12% of subjects chose to complete an AD (health surrogate form) in clinic, and the remaining 88% of subjects chose to take an AD home with the intention of completing it. Additionally, 58.82% of participants chose to take home an AD packet for a community member.

CONCLUSIONS: Results suggest that a single intervention may raise awareness about ADs but may not be as effective at increasing AD completion. Follow up interventions are likely needed to increase AD adoption in patients who choose to complete ADs at home.

ADVANCING RESEARCH EQUITY: ENHANCING RESEARCH PARTICIPATION AMONG AFRICAN AMERICANS THROUGH A CONFERENCE-BASED WORKSHOP

Maarya Pasha[1]; Pernessa Seele[3]; Sumedha Penheiter[4]; Richard O. White[5]; Floyd Willis[6]; Monica Albertie[7]; Christopher Pullins[8]; LaPrincess Brewer[2]. [1]General Internal Medicine, Mayo Clinic, Apple Valley, MN; [2]Cardiovascular Medicine, Mayo Clinic College of Medicine, Rochester, MN; [3]The Balm in Gilead, Incorporated, Midlothian, VA; [4]Office of Health Disparities Research, Mayo Clinic, Rochester, MN; [5]Community Internal Medicine, Mayo Clinic, Jacksonville, FL; [6]Family Medicine, Mayo Clinic College of Medicine, Jacksonville, FL; [7]Clinical Studies Unit, Office of Health Disparities Research, Mayo Clinic Florida, Jacksonville, FL; [8]Family Medicine, Mayo Clinic College of Medicine, Scottsdale, AZ. (Control ID #3391175)

BACKGROUND: African Americans (AAs) and other racial/ethnic minority groups continue to be underrepresented in medical research and clinical trials. Failure to create more racially diverse research cohorts can exacerbate existing health disparities among these groups. There is a critical need for innovative and culturally-sensitive approaches to enhance AA participation in research.

Objective: To evaluate the impact of a preconference workshop focused on best practices and strategies for enhancing the participation of AAs into medical research among attendees of a faith-based public health conference. We hypothesized that our 3-hour workshop would positively influence the views of workshop attendees on medical research and engagement in the research process.

METHODS: Twenty-one attendees (95% of total attendance) of a preconference workshop held at the 2017 Healthy Churches 2020 National Conference participated in semi-structured interviews one year following the workshop. The culturally tailored workshop was led by AA researchers with a content focus on the current state of underrepresentation of AAs in medical research, and barriers and facilitators to research participation through community engagement. Message retention of the workshop learning objectives and perspectives on research participation were assessed. Interviews were audio-recorded, transcribed verbatim and reviewed using thematic analysis.

RESULTS: The majority of workshop attendees (71% women, mean age 56 years [range 34-72]) reported they were more likely to participate in medical research as a result of the workshop and felt it increased their knowledge of the topics presented. Salient workshop learning points reported by attendees demonstrated attainment of the workshop objectives. These included the implications of AA underrepresentation in research and key techniques for recruiting AAs into medical research. The most common reported barriers preventing AAs from participating in medical research were fear/lack of trust, lack of knowledge/information, and not being approached to participate. The most common facilitators reported for AA participation in medical research were researchers clearly communicating the benefits of participation, being equipped with necessary information to make informed decisions on participation, and trust in the researchers. Almost all participants (20/21; 95%) stated they were likely or highly likely to recommend this workshop to a friend or colleague, and would disperse what they learned to their local communities.

CONCLUSIONS: Perceptions of a conference-based community workshop aimed to address the underrepresentation of AAs in medical research were largely positive and the workshop showed clear impact on attendees' willingness to participate in medical research. Our culturally-tailored approach to disseminate knowledge of the research process could extend to other national conferences prioritizing AAs and other racial/ethnic minority populations to improve research participation.

AFTER HOURS OUTPATIENT CRITICAL LAB MANAGEMENT: VARIATION IN PROVIDERS' RESPONSES AND ASSOCIATED PATTERNS OF HEALTHCARE UTILIZATION

Albert Lee, Laveena Meriga, Todd Smith. Medicine, Louis Stokes VA Medical Center, Cleveland, OH. (Control ID #3387811)

BACKGROUND: Managing critical laboratory values is a fundamental part of outpatient clinical practice. However, little is known about how providers currently handle these values after they are called and how this may impact healthcare utilization. Moreover, when the test is completed outside of normal working hours, the covering provider is often unfamiliar with the patient and may default towards sending the patient to the emergency department (ED). The purpose of this study is to explore providers' responses to common critical laboratory values and associated patterns of healthcare utilization.

METHODS: The laboratory at the Louis Stokes Cleveland Veterans Affairs Medical Center (VAMC) processes blood samples from 14 outpatient phlebotomy clinics. Off-hour (4pm-8am weekdays, weekends) outpatient critical values are communicated to a designated hospitalist, as opposed to the ordering provider, who then calls the patient. We retrospectively studied patients with outpatient critical lab values reported off- hours between 6/1/18 – 6/1/19 at our VAMC. We identified documentation of these telephone encounters and reviewed each encounter to evaluate successful provider-patient communication, recommended plans of care, and patient disposition. We excluded anticoagulation, point-of-care and ED tests, which are managed separately.

RESULTS: During the study period, 811 telephone encounters were documented encompassing 896 off-hour critical test results, successfully reaching a patient or caregiver 71% (579/811) of the time. Of the telephone encounters that resulted in contact, urgent evaluation in an ED was recommended for 33% (191/579). Within 7 days of the encounter, 18% (143/811) of the patients presented to an outside hospital ED (OSH), 16% (126/811) to the Cleveland VAMC's ED of which 67% (85/126) were admitted. The most commonly called critical lab values were abnormal glucose (227/896), potassium (187/896), and platelet (102/896) levels. Among the most common critical lab tests, anemia (Hct<20%) was the most likely to result in an ED visit (VAMC: 37%, 23/62, OSH: 23%, 14/62) and hypoglycemia (glucose <50 mg/dL) was the least likely (VAMC: 2%, 2/111, OSH: 5%, 5/111). We also found significant variation in the hospitalist's recommendation based on the type of critical lab value reported. For hypoglycemia, only 3% (2/75) were advised to go to the ED whereas for anemia, it was 56% (29/52); at a lower threshold (Hct<18%), it was 71% (12/17).

CONCLUSIONS: We found significant variation in the way outpatient critical lab values are managed clinically. Management of critical values with high variation, such as anemia, not only present a clinical decision-making challenge, but may be associated with higher emergency healthcare utilization, making it an attractive target for further investigation. Other critical values, such as hypoglycemia, have low variation and low rates of ED referral, encouraging future efforts to better define what is truly "critical" in the outpatient setting.

AFTER-HOURS PRIMARY CARE IN THE VHA NOT ASSOCIATED WITH REDUCED EMERGENCY DEPARTMENT USE: A LONGITUDINAL ANALYSIS

Matthew R. Augustine[1,2]; Bjarni Haraldsson[3]; Karin M. Nelson[6,4]; Peter J. Kaboli[5,7]. [1]Geriatric Research Education and Clinical Center (GRECC), Department of Veterans Affairs, Bronx, NY; [2]Department of Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; [3]Center for Access & Delivery Research and Evaluation (CADRE), Department of Veterans Affairs, Iowa City, IA; [4]Department of Medicine, University of Washington, Seattle, WA; [5]Internal Medicine, Iowa City VAMC, Iowa City, IA; [6]VA Puget Sound Health Care System, Department of Veterans Affairs, Seattle, WA; [7]Carver College of Medicine, University of Iowa, Iowa City, IA. (Control ID #3390628)

BACKGROUND: The majority of Emergency Department (ED) visits occur outside of regular business hours. Extending primary care hours may shift care into the outpatient clinic and reduce ED use. The Veterans Health Administration (VHA) has required most clinics at VA Medical Centers (VAMCs) to extended hours of care; however, the impact upon ED use remains unknown.

METHODS: We performed a longitudinal analysis of extended hours at 101 primary care clinics at VAMCs with established EDs over a 15-month period from July 2017 to September 2018. We identified all primary care face-to-face encounters completed during regular (8:00AM-4:30PM), morning (12:00AM-8:00AM), evening (4:30PM-12:00AM), and weekend hours from the VHA Corporate Data Warehouse. Outcomes included all ED visits, after-hours ED visits, and time-concordant ED visits occurring during mornings, evenings, or weekends. We used negative binomial multilevel regression with time fixed effects and applied between- within approach to determine association of extended hours with ED visits between and within VAMCs. Models adjusted for time-variant clinical factors, including clinic size and panel fullness based upon 1200 patients per full-time provider, and clinic-level aggregated patient factors, including age, race/ethnicity, patient risk based upon health care costs (Nosos score), drive time, and rurality.

RESULTS: Of the 101 clinics, 99 offered extended hours primary care, encompassing an average of 2.8% of all primary care appointments with an average of 47% of appointments occurring in mornings, 14% evenings, and 39% on weekends over the study period. On average, 76 per 1000 primary care patients presented to the ED each month with 49% of these visits occurring after-hours (i.e., 9.1% mornings, 17.9% evenings, and 22.2% weekends). In adjusted analyses, changes in extended hours primary care appointments within individual clinics over this timeframe was not associated with overall, extended hours, or time-concordant ED visits. However, between clinics, more extended hours primary care encounters was associated with higher incidence of overall (IRR 1.009, 95% CI 1.006-1.013, p <0.001), extended hours (IRR 1.008, 95% CI 1.005-1.012, p <0.001), and time-concordant morning (IRR 1.002, 95% CI 1.001-1.003, p <0.002) and weekend (IRR 1.004, 95% CI 1.002-1.007, p <0.001) ED visits.

CONCLUSIONS: VHA clinics with extended hours primary care did not experience a significant change in ED utilization; however, some clinics may be more likely to refer patients to the ED, particularly in mornings and weekends, for evaluation and treatment.

ALCOHOL, TOBACCO, BUT NOT FIREARMS: NATURAL LANGUAGE PROCESSING OF MEDICAL RECORDS TO CHARACTERIZE CLINICAL PRACTICE AT HEALTH SYSTEM SCALE

Chana A. Sacks[1]; Peter Masiakos[2]; Thomas McCoy[3]. [1]Medicine, Massachusetts General Hospital, Boston, MA; [2]Pediatric Surgery, MGH, Boston, MA; [3]Center for Quantitative Science, Massachusetts General Hospital, Boston, MA. (Control ID #3391088)

BACKGROUND: Many professional health organizations and medical societies in the US assert that physicians have the right and, in many cases, a responsibility to discuss firearm safety with patients. Existing small studies suggest that these conversations are uncommon.

METHODS: We developed a token matching natural language processing algorithm to identify documentation in the electronic health related to firearms. This included the presence of firearm or related words (for example, gun, handgun, shotgun, rifle, pistol, revolver). As positive controls and points of comparison we developed similar algorithms to identify documentation of tobacco and alcohol. This work builds on our prior work using token matching as an interpretable and scalable approach to characterization of difficult to quantify healthcare concepts. We extracted demographic and clinical meta data from the electronic health record for all in-patient hospitalizations at two large academic medical centers in Boston, Massachusetts between January 1, 2017 and December 31, 2017. We selected this year as all data were available in our research data repository, and all inpatient documentation occurred in the electronic system (as opposed to prior years when some documentation still occurred on paper). Using each hospitalization as the unit of analysis, we used descriptive statistics to report the frequency of documentation related to firearms, tobacco, and alcohol and multivariable regression to identify predictors of the presence of firearm-related documentation.

RESULTS: Encounters for a total of 80,447 hospitalizations for 59,858 unique patients were included in the study cohort. The mean age at hospitalization was 58 years; 45% of the cohort was male; 77% were white, and 47% had private insurance. 63% of admissions were to Medicine services, 13% to Obstetrics/Gynecology, 10% to Surgery, 8% to Orthopedics, 5% to Neurology, 0.9% to Psychiatry and 0.3% to Pediatrics.

Among the 80,447 hospitalizations, alcohol was mentioned in 55,415 (69%) encounters; tobacco was mentioned in 40,478 (50%). Firearms were identified in 425 encounters (0.5%). In the multivariable analysis, those who had mention of a firearm in the electronic health record were more likely to be male (OR 3.2, 95% CI 2.5-4.0, p<0.001), admitted to a psychiatry service (OR 9.7, 95% CI 7.2-13.0, p<0.001) and less likely to be White (OR 0.8, 95%CI 0.6-0.99, p=0.037) or have private insurance (OR 0.5 95% CI 0.4-0.7, p<0.001).

CONCLUSIONS: Documentation related to firearms rarely appears in hospitalized patients' electronic health records. This may represent important missed opportunities to implement screening and to have conversations with patients about firearm safety. Whether observed variation in this documentation stemmed from relevance to the specific encounter or reflects implicit or explicit bias requires further study.

ALCOHOL-RELATED MORTALITY AND SERVICE UTILIZATION AMONG PEOPLE EXPERIENCING HOMELESSNESS IN SAN FRANCISCO

Elizabeth Abbs[4]; Caroline Cawley[1]; Barry Zevin[2]; Triveni DeFries[4,3]. [1]Department of Emergency Medicine, University of California, San Francisco, SAN FRANCISCO, CA; [2]Street Medicine, San Francisco Department of Public Health, SAN FRANCISCO, CA; [3]Center for Vulnerable Populations, University of California, San Francisco, SAN FRANCISCO, CA; [4]Department of Internal Medicine, University of California, San Francisco, SAN FRANCISCO, CA. (Control ID #3391474)

BACKGROUND: More than 8,000 people experience homelessness on any given night in San Francisco; over half (63%) report use of alcohol or other substances. Unintended overdose is a leading cause of death among people experiencing homelessness, with higher mortality in cases with mixed toxicology. We evaluated alcohol-related deaths among people experiencing homelessness in San Francisco to better understand service utilization patterns and circumstances of their mortality as to inform future prevention strategies.

METHODS: We conducted a descriptive analysis of people (n=84) who died between 2016-2018 while experiencing homelessness in San Francisco with a toxicology report on autopsy that was positive for alcohol. We utilized data from death reports by the Office of the Chief Medical Examiner, the integrated Coordinated Care Management System database, and electronic health records to assess demographics, location at time of death, medical and psychiatric co-morbidities, and care utilization histories. To further examine needs among individuals engaged in care, we conducted pilot case reviews (n=11) of individuals determined to comprise top 1% High Utilizers of Multiple Systems (HUMS) within the year of their death.

RESULTS: Among 84 deaths, 93% were among men, 55% white, 20% African-American, and 17% LatinX. The median age was 49 years (IQR 21, 74). Over one-third (35%, n=25) of deaths with available housing records (n=72) experienced homelessness for more than a decade, while 24% (n=17) were homeless less than a year prior to death. Of the 60 cases with autopsy results, 37% (n=22) died of acute intoxication, 28% (n=17) from accidental trauma, and 35% (n=21) from complications of underlying medical problems. Over half (63%, n=53) of people used medical services during their last year of life in highly variable patterns, predominantly in emergency settings. Poly-substance related deaths were more common than alcohol alone (77%, n=65 with mixed toxicology versus 23%, n=19 with mono alcohol). Concurrent methamphetamine use was common (35%, n=29). In review of HUMS cases, we noted discrepancies between documented substance use histories versus toxicology at time of death, particularly for opioid and sedative use.

CONCLUSIONS: Toxicology reports of people who died while experiencing homelessness show deaths involving alcohol often occurred with concurrent use of other substances. Despite frequent documentation of alcohol use disorder in health records, there is a paucity of documented polysubstance use. Healthcare utilization patterns vary; some individuals engage in many services often while others use no services. A Homeless Death Review process in San Francisco may better identify what factors impact substance-related deaths. Medical outreach to newly homeless individuals may help reduce the utilization gap while creation of safer environments for acutely intoxicated individuals, with focus on chronic disease management, may mitigate harm.

AMBULATORY CARE FRAGMENTATION AND SUBSEQUENT HOSPITALIZATION AMONG VETERANS WITH DIABETES

Mangala Rajan[1,2]; Drew Helmer[3]; Mazhgan Rowneki[4]; Dennis Fried[5]; Lisa M. Kern[6]. [1]Department of Medicine, Weill Cornell Medicine, New York, NY; [2]Veterans BioMedical Research Institute, Veterans Health Administration, East Orange, NJ; [3]WRIISC, VA-NJHCS, East Orange, NJ; [4]WRIISC, Veterans Health Administration, East Orange, NJ; [5]WRIISC, US Dept. of Veterans Affairs, OCEAN, NJ; [6]Healthcare Policy and Research, Weill Cornell Medical College, New York, NY. (Control ID #3389643)

BACKGROUND: Ambulatory care fragmentation occurs when an individual's care is distributed across multiple providers, with no single provider accounting for a substantial proportion of visits. With recent legislation (Choice Act of 2014 and MISSION Act of 2018) requiring the Veterans Health Administration (VHA) to offer more care in the community to Veterans, the risks of fragmented care among Veterans has increased, which may lead to greater risk of hospitalization.

The objective was to determine if highly fragmented ambulatory care and use of both Veterans Health Administration (VHA) and non-VHA as usual providers of care (UPC) increased the risk of hospitalization among Veterans with diabetes. This will serve as a baseline to understand how Veterans use multiple providers within and outside the VHA for ambulatory care prior to the recent legislations.

METHODS: We selected Veterans with diabetes enrolled in VHA and Medicare from 2004-2010 and examined the associations among care fragmentation, usual provider of care (VHA vs. non-VHA) and hospitalization. We linked VHA and Medicare data from 2004 to 2010. A Veteran in each year (2004 - 2009) was followed until first hospitalization or end of subsequent year (2006-2010). Fragmentation was defined using the Bice Boxerman Index, a validated measure of dispersion of ambulatory care. Longitudinal Generalized Estimating Equation (GEE) models were used to test if ambulatory care fragmentation (high (defined as top quartile) vs. low) and UPC (VHA vs. non-VHA as dominant provider) in the baseline year warer associated with hospitalization in the following year. The adjusted Odds Ratios (AOR) and their 95% confidence intervals (CI) are reported.

RESULTS: Among Veterans with diabetes, having fragmented healthcare in any given year was associated with an 11% increase in the odds of hospitalization in the following year. Separately, having a non-VHA UPC in any given year was associated with a 5% increased odds of hospitalization in the following year. Having both highly fragmented care

and a non-VHA UPC in any given year was associated with a 19% increased odds of hospitalization in the following year (Table).

CONCLUSIONS: Highly fragmented ambulatory care and having usual providers of care outside the VHA were independent risk factors for subsequent hospitalization, among Veterans with diabetes enrolled in both VHA and Medicare.

A MIXED METHODS APPROACH TO UNDERSTANDING DISPARITIES IN CANCER SCREENING BETWEEN ADULTS WITH AND WITHOUT SERIOUS MENTAL ILLNESS

Karly A. Murphy[1]; Elizabeth Stone[2]; Rachel Presskreischer[2]; Beth McGinty[2,3]; Gail L. Daumit[1,2]; Craig E. Pollack[1,2]. [1]Medicine, Johns Hopkins University School of Medicine, Baltimore, MD; [2]Health Policy and Management, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [3]Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD. (Control ID #3391085)

BACKGROUND: Persons with serious mental illness (SMI) die 10-20 years earlier than the general population, primarily due to physical health conditions; cancer is the second leading cause of death. Yet differences and perceptions towards cancer screening between SMI and non-SMI populations are not well understood. We used a mixed methods approach to (1) describe the likelihood of receipt of cancer screening among individuals with versus without SMI and (2) explore clinicians' perceptions around cancer screening for people with SMI.

METHODS: We used MarketScan commercial insurance administrative claims data from 2010-2016 to identify eligible sub-populations for cervical, breast, prostate, and colorectal cancer screening based on USPSTF guidelines. We defined SMI as schizophrenia or bipolar disorder. We estimated the likelihood of screening for people with or without SMI using multivariate logistic regression analyses, adjusted for demographic characteristics, major depression, substance use disorder, comorbidity, healthcare utilization, calendar year, time in cohort, and clustered by individual across years. Between February-April 2019, we conducted semi-structured interviews with 17 primary care providers (PCPs) and 15 psychiatrists across 3 primary care and 4 psychiatry clinics. Interviews were analyzed using an inductive approach to identify barriers to cancer screening among people with SMI.

RESULTS: We identified 32,224,180 individuals for inclusion in the cervical cancer sub-population, 12,050,595 individuals for breast cancer, 7,189,649 individuals for prostate cancer, and 22,784,006 individuals for colorectal cancer. Per sub-population, 0.5-0.9% had a diagnosis of SMI. Individuals with SMI (versus without SMI) were less likely to receive screening for cervical cancer (adjusted Odds Ratio [aOR] 0.81; 95% CI:0.80-0.82), breast cancer (aOR 0.80; 95% CI:0.80-0.81), colorectal cancer (aOR 0.90; 95% CI:0.89-0.91), or prostate cancer (aOR 0.85; 95% CI:0.85-0.87). During the qualitative interviews, PCPs and psychiatrists identified potential barriers to cancer screening including access to care, physical accessibility to services, available support, follow-up, communication, comorbidity, and patient concerns. While respondents felt these barriers were not specific to those with SMI, they expressed concern that they presented a disproportionate burden for individuals with SMI. Additional barriers that were specific for the SMI population included mental health symptoms, concerns over capacity to engage in shared-decision making, and provider-bias.

CONCLUSIONS: People with SMI were less likely to receive recommended cervical, breast, colorectal, and prostate cancer screening. Improving cancer screening rates in the SMI population will likely require a multi-disciplinary approach to overcome the multiple barriers that providers report.

ANALGESIC SAFETY RISKS IN OLDER VETERANS - TRUE VS. ANALYTIC RISK

Tessa Runels[1]; Jessica Lum[7]; Mark Trentalange[3]; Abraham A. Brody[4,5]; Matthew J. Bair[6,8]; Robert D. Kerns[9,10]; Cynthia Brandt[9,11]; Melissa Garrido[7,12]; Ula Hwang[1,2]. [1]GRECC, James J Peters VA Medical Center, Bronx, NY; [2]Emergency Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; [3]Anesthesiology, James J. Peters VA Medical Center, Bronx, NY; [4]GRECC, James J Peters Bronx VAMC, New York, NY; [5]Hartford Institute for Geriatric Nursing, New York University College of Nursing, New York, NY; [6]Medicine, Indiana University School of Medicine, Indianapolis, IN; [7]Partnered Evidenced-Based Policy Resource Center (PEPReC), VA Boston Healthcare System, Boston, MA; [8]Center for Health Information and Communication, Roudebush VA Medical Center, Indianapolis, IN; [9]PRIME Center, VA Connecticut, West Haven, CT; [10]Psychiatry, Neurology, and Psychology, Yale University, New Haven, CT; [11]Emergency Medicine, Yale University, New Haven, CT; [12]Health Law, Policy and Management, Boston University School of Public Health, Boston, MA. (Control ID #3390600)

BACKGROUND: Previous studies have compared the safety profiles of alternative analgesics, yet the conclusions vary greatly.

METHODS: Observational, national cohort of US Veterans (≥50 years) with osteoarthritis receiving an outpatient analgesic prescription (acetaminophen, NSAIDs, opioid, or topical analgesic) after being 180+ days analgesic naïve according to VHA pharmacy records. Inverse probability of treatment weights (IPTW) were used to adjust for selection bias. We used survival analyses to assess the risk of composite safety events (cardiovascular, gastrointestinal, fracture, hepatotoxicity, respiratory) across medication groups 365 days post-analgesic receipt, with subsequent analgesic prescriptions and death as competing risks.

RESULTS: From 2010-2018, 271,505 Veterans (mean age=64.3 years; 93.5% male) were balanced across 47 confounders (max absolute mean standardized difference=0.09). Veterans prescribed acetaminophen and opioids had an increased risk of cardiovascular (HR 1.32 and 1.23; p<0.001), gastrointestinal (HR 1.51 and 1.52; p<0.001), fracture (HR 1.86 and 1.57; p<0.001), and respiratory events (HR 1.51 and 1.39; p<0.001) compared to those prescribed NSAIDs. Hepatotoxicity risk was greatest with opioids and topicals (HR 1.77 and 1.49; p<0.001) compared to NSAIDs.

CONCLUSIONS: Early findings show the comparative safety of analgesics varies depending on the outcome event in question. The estimated effects of acetaminophen with this analytic approach indicate higher risks for certain safety events relative to other analgesic types, counter to presumed clinical practice. Caution should be taken when interpreting these results as residual, unobserved confounding across groups likely remains.

ANALYSIS OF PRIMARY CARE PROVIDER ELECTRONIC HEALTH RECORD NOTES FOR DISCUSSIONS OF PREDIABETES USING NATURAL LANGUAGE PROCESSING METHODS

Eva Tseng[1]; Jessica L. Schwartz[1]; Masoud Rouhizadeh[2]; Nisa Maruthur[3,1]. [1]General Internal Medicine, Johns Hopkins University SOM, Baltimore, MD; [2]Johns Hopkins University, Baltimore, MD; [3]Medicine, Johns Hopkins University School of Medicine, Baltimore, MD. (Control ID #3389605)

BACKGROUND: Prior studies using structured EHR data suggest that patients with prediabetes are not receiving evidence-based care, but prediabetes may be discussed in unstructured data. Natural language processing (NLP) methods can evaluate unstructured data in EHR notes and provide insight into PCP practices. Our objective was to develop and

validate an NLP tool to identify discussions about prediabetes in EHR notes.

METHODS: We included adult patients without diabetes with an in-person office visit at any general medicine clinic at a single academic center and at least one HbA1c 5.7-6.4% between 7/1/2016 and 12/31/2018. In phase 1, the authors devised an initial keyword search strategy based on clinical experience.

We extracted notes matching to at least one of the keywords within the inclusion/exclusion criteria. Two expert annotators manually annotated the notes to determine whether they represented clinical discussions of prediabetes (We did not consider keywords pulled in simply as a diagnosis under past medical history, problem list, or chief complaint without additional discussion). Any disagreements were resolved between annotators. We then used the annotated notes to train and evaluate multiple machine learning (ML) and deep learning classifiers to replicate human annotation. To reduce overfitting and classification bias, we applied 10-fold cross-validation to shuffle the training and test sets. In phase 2, we applied a similar annotation process and machine learning method on notes from a different group of clinic practices.

We analyzed notes from phase 2 to describe the content of prediabetes discussions: labs ordered or reviewed (HbA1c or fasting glucose); lifestyle counseling; diabetes prevention program (DPP) discussion/referral; nutrition referral/discussion; and metformin discussion or ordering/continuation. Our denominator was the number of patients with a documented discussion about prediabetes. Our numerator was the number of patients with a documented discussion about prediabetes who had each outcome above.

RESULTS: We identified 269 patients with prediabetes discussions in phase 2. Most commonly, PCPs provided lifestyle counseling (80%), reviewed current labs (63%) and ordered follow-up labs (60%). PCPs discussed/referred to a nutritionist infrequently (4%). We did not find any discussions/referrals to a DPP. Metformin was discussed, ordered or continued in <2% of patients.

NLP and ML classification, including Logistic Regression and Bi- directional Recurrent Neural Network, provided promising results, close to human performance.

CONCLUSIONS: We developed and validated an NLP tool that identifies clinical discussions about prediabetes in the EHR. PCPs most commonly provided lifestyle counseling in the office and infrequently placed referrals to nutrition or DPPs, which have strong evidence for preventing progression to diabetes.

AN AMBULATORY INTENSIVE CARE UNIT ("A-ICU") FOR PATIENTS IMPACTED BY SOCIAL DETERMINANTS OF HEALTH IMPROVED MENTAL HEALTH FUNCTIONING, PATIENT WELL-BEING, AND OUTPATIENT ENGAGEMENT AT 6-MONTHS: INTERIM RESULTS OF SUMMIT RANDOMIZED CONTROLLED TRIAL

Brian Chan[2,1]; Samuel T. Edwards[7,2]; Matthew Mitchell[3]; Devan Kansagara[4]; Christina Nicolaidis[5,2]; Philip T. Korthuis[6]; Somnath Saha[7,2]. [1]Central City Concern, Portland, OR; [2]Division of General Internal Medicine, Oregon Health & Science University, Portland, OR; [3]Quality Management, Central City Concern, Portland, OR; [4]General Internal Medicine, Portland VA Medical Center, Portland, OR; [5]Social Work, Portland State University, Portland, OR; [6]Medicine, Oregon Health & Science University, Portland, OR; [7]Section of General Internal Medicine, Portland VA Medical Center, Portland, OR. (Control ID #3392280)

BACKGROUND: People experiencing homelessness, co-morbid chronic medical conditions, and substance use disorder (SUD) make up a disproportionate number of high-cost, high-need patients at risk of frequent acute care utilization. Intensive ambulatory care unit ("A-ICU") interventions aim to improve patient engagement, quality of care, and reduce excess hospitalizations.

METHODS: This is an updated analysis of a randomized trial of SUMMIT, an A-ICU for high-utilizers at a federally qualified health center that serves patients with high rates of homelessness and poverty. SUMMIT is a stand-alone team consisting of care coordinators, an addictions-boarded physician, social workers, complex care nurse, pharmacist, and team manager, with a low staff-to-patient ratio and increased appointment flexibility. Patients were eligible to be referred to SUMMIT if they had 1+ hospitalizations in the prior six months, or had 2+ chronic medical conditions and/or active substance use or a mental health condition. Patients were randomized to enroll in SUMMIT immediately or to remain in a treatment as usual patient centered medical home model. We assessed functional status using the 12-item short form survey (SF-12) at six months, and wellbeing question from the Edmonton Symptom Assessment System (ESAS). We also examined primary care visits (PCP), mental health visits (MH), and hospital admissions at 6 months.

RESULTS: Of 139 patients enrolled, 52% (n=73) were randomized to SUMMIT immediately. Average age was 54.7 years (+/-10.1), with the majority male (62.6%) and Caucasian (77.7%); a majority (60.4%) had high school education or less, 84.2% had very low income (<$1000/month), 27.3% reported having an opioid use disorder, and 51.1% reported being homeless within the past year. In the six months prior to enrollment, participants averaged 7.3 (+/-1.2) PCP visits and 2.6 (+/-1.7) hospitalizations. At six month follow up, SUMMIT patients had higher SF-12 Mental Health scores (46.5 vs 42.0, P<0.01), and higher self-reported wellness rating (ESAS 6.3 vs 4.9, P<0.01); while SUMMIT patients had higher number of PCP visits (12.3 vs 4.9, P<0.01) and MH visits (7.8 vs 6.4, P<0.01), hospital admissions did not differ between the groups at six month follow-up (1.94 vs 1.91, P=0.72).

CONCLUSIONS: Patients referred to the SUMMIT A-ICU are adversely impacted by social determinants of health including poverty, homelessness, and SUD. SUMMIT improved mental health functional status and well-being, perhaps mediated through increased engagement in outpatient primary and behavioral health care. Though we did not see differences in hospitalizations at follow-up, six months may be too soon for the intervention to have an impact. Both groups experienced decreases in hospitalizations, suggesting evidence of regression to the mean. These findings suggest A-ICUs may improve key patient-reported health outcomes.

A NATIONAL EVALUATION OF RACIAL/ETHNIC INEQUITIES IN INTERHOSPITAL TRANSFER

Evan Shannon[1]; E. John Orav[1]; Jie Zheng[2]; Jeffrey L. Schnipper[1]; Stephanie Mueller[1]. [1]Division of General Internal Medicine, Brigham and Women's Hospital, Boston, MA; [2]Harvard Chan School of Public Health, Boston, MA. (Control ID #3387247)

BACKGROUND: While there are numerous examples of racial/ethnic health inequities in our healthcare system, their presence in interhospital transfer (IHT) has not been well-characterized. We sought to determine if there are racial/ethnic inequities in IHT among patients with select medical conditions previously associated with mortality benefit from transfer.

METHODS: We performed a cross-sectional analysis of 2013 Center for Medicare and Medicare Services (CMS) 100% Master Beneficiary Summary and Inpatient claims merged with 2013 American Hospital Association data. Patients with age ≥ 65 and a primary diagnosis of acute myocardial infarction, stroke, sepsis or respiratory disease who were continuously enrolled in Medicare A/B and had an acute care hospitalization claim in 2013 were included. The outcome was IHT, as previously defined by having corresponding transfer and admission/discharge claims in two different acute care hospitals. The primary predictor was race, as

categorized in the CMS dataset (White, Black, Hispanic, Other). We examined patient and hospital characteristics by race, then calculated crude and adjusted odds of transfer by race using univariable then multivariable logistic regression models adjusting for patient age, sex, Medicaid co- insurance, median income for zip-code, diagnosis-related group weight, hierarchical conditional category (HCC) comorbidity score, admissions in previous year, season of admission, and accounting for fixed-effects by hospital.

RESULTS: Of the 899,557 unique hospital admissions included in the cohort, 20,171 (2.7%) of White, 1,913 (2.3%) of Black and 1,062 (2.2%) of Hispanic patients underwent IHT. Patient characteristics differed by race; most notably, compared to White patients, Black and Hispanic patients had a high frequency of Medicaid co-insurance (17.9% vs. 47.1% and 62.1%, respectively). In unadjusted analyses, Black patients had lower odds of transfer to compared to White patients (OR 0.92, 95% CI 0.89-0.95); there was no difference for Hispanic patients. After adjusting for patient characteristics and hospital fixed effects, compared to white patients, Black patients had lower adjusted odds of transfer (aOR 0.87, 95% CI 0.81-0.92) while Hispanic patients had higher adjusted odds of transfer (aOR 1.14, 95% CI 1.05-1.24).

CONCLUSIONS: In this nationally representative study of hospitalized Medicare patients, we found that Black patients had lower odds and Hispanic patients had higher odds of transfer for diseases associated with mortality benefit from transfer, after accounting for patient and hospital characteristics. There are several potential explanations for these findings, including provider bias (implicit or explicit), different likelihood of request for transfer among minority patients, or unmeasured confounding. Given these results, more research into transfer decision-making and transfer processes is necessary to further understand these observed inequities in IHT.

A NATIONAL SURVEY ON SERIOUS ILLNESS CONVERSATIONS DURING MEDICINE RESIDENCY: WHERE DO WE STAND AND WHERE DO WE GO NEXT?

Caroline Cubbison[1]; Salma Batool-Anwar[2]; Elizabeth Stevenson[3]. [1]Internal Medicine, North Shore Medical Center, Salem, MA; [2]Brigham and Women's Hospital, Boston, MA; [3]North Shore Medical Center, Salem, MA. (Control ID #3372608)

BACKGROUND: While formal serious illness conversation (SIC) and palliative care (PC) training have become routine in some graduate medical education (GME) programs, they have yet to become standard. A national shortage of PC specialists underscores the importance that all clinicians feel comfortable having SICs. We aimed to better understand the current attitudes, comfort levels and interest experienced by medicine residents towards SIC and PC training, to identify areas that may be worthwhile addressing when implementing PC curricula during residency.

METHODS: Eligible participants were current internal medicine residents in a US-based ACGME accredited program. A twelve-item online survey that encompassed different aspects of SICs was administered after a demographic questionnaire that explored the subjects' prior medical and SIC training. Subjects were asked to rank their answers on a five-point "strongly disagree" to "strongly agree" scale. Chi- square analysis was performed and p-values <0.05 were considered significant.

RESULTS: Data from 158 surveys represented a mixed group of US and international medical graduates (IMG) training in 23 different US states from 28 different originating countries. Sixty-five percent of subjects had not received SIC or PC training in medical school. More than a third of respondents felt uncomfortable having SICs with emotional patients and families. When discussing code status, US-trained females had the highest comfort levels (p=0.004) as did those training in an urban setting (p=0.003 for males; p=0.04 for females). Allopathically trained females also identified as more confident (p=0.004). When delivering serious news, however, community trained residents were more comfortable (0.004 for males, 0.03 for females) as were men who had received prior PC training (p=0.018). Surprisingly, nearly 20% of respondents did not feel supported by their senior residents and attendings to hold SICs. Eighty-five percent of respondents agreed that they would want formal PC training integrated into their program, yet less than half (40%) already have it included.

CONCLUSIONS: Amongst US medicine residents, integrating SIC training into GME would be well received and address gaps in medical school training. Focusing on emotional response training may further prepare residents. Males self-identify as less confident in these skills overall, but our data suggests that when exposed to formalized training this improves significantly, underscoring the importance of male engagement in curricula. Both urban and community training settings have their strengths and gaps in SIC preparation. Support surrounding SICs from senior residents and attendings should be more demonstrative to encourage junior house staff. A limitation of our study is its low survey response rate, though it is the first survey of its class to collect data from such a diverse pool of subjects.

AN EFFECTIVE WEIGHT LOSS INTERVENTION FOR INDIVIDUALS WITH FOOD INSECURITY AND DIABETES: RESULTS FROM THE REAL HEALTH RANDOMIZED CLINICAL TRIAL

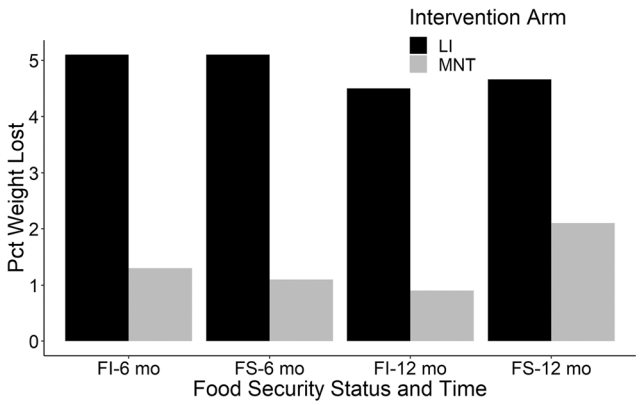
Seth A. Berkowitz[1]; Deborah Wexler[2]; Yuchiao Chang[2]; Bianca Porneala[3]; Linda Delahanty[2]. [1]Division of General Medicine & Clinical Epidemiology, UNC School of Medicine, Chapel Hill, NC; [2]Massachusetts General Hospital, Boston, MA; [3]MGH, Boston, MA. (Control ID #3386718)

BACKGROUND: Food insecurity (limited access to nutritious food owing to cost) is associated with increased risk for type 2 diabetes (T2D) complications. Lifestyle interventions (LI) are recommended for management of T2D. However, LI may be ineffective for individuals with food insecurity, as food insecurity could impede weight loss. In a pre-planned subgroup analysis of the REAL HEALTH-Diabetes randomized clinical trial (NCT02320253), we tested the effectiveness of LI for individuals with food insecurity and T2D.

METHODS: The study included adults (age ≥ 18 years) with T2D, body mass index ≥ 25 kg/m^2 (or ≥ 23 kg/m^2 if of self-reported Asian ancestry), hemoglobin A1c of 6.5 to 11.5%, blood pressure < 160/100 mm Hg, and who were willing to lose 5-7% body weight. We assessed food insecurity with the 6-item USDA Food Security Survey Module (≥2 affirmative responses indicated food insecurity). Participants were randomized to medical nutrition therapy (MNT), the standard of care, or a pragmatic group LI delivered in- person or by telephone. The outcome was percentage weight change from baseline. We tested, using linear mixed effects models, whether the intervention effect varied by food security status using an interaction term, adjusting for age, gender, race/ethnicity, education, language, income, and health insurance.

RESULTS: Of 208 participants, 13% were food insecure. Those with food insecurity were more likely to be racial/ethnic minorities (p<0.001) and have lower education (p<0.001). LI, versus MNT, led to greater weight loss at 6 months (5.1% lost vs. 1.1% lost, p<.0001) and 12 months (4.7% lost vs. 2.0% lost, p=0.0005). The intervention effect was similar regardless of food security status (5.1% bodyweight lost vs. 1.1% in food secure participants and 5.1% bodyweight lost vs. 1.3% in food insecure participants at 6 months; 4.7% bodyweight lost vs. 2.1% in food secure participants and 4.5% bodyweight lost vs. 0.9% in food insecure participants at 12 months, p-for-interaction = 0.99) (*Figure*).

CONCLUSIONS: The REAL HEALTH-Diabetes lifestyle intervention led to meaningful weight loss at 6 and 12 months for individuals with food insecurity and T2D.



ANEMIA AT DISCHARGE AND RISK OF READMISSIONS IN ELDERLY PATIENTS

Niraj Patel, Yeshanew Teklie, Bahaa Amer, Victoria Campdesuner, Kayla Marini, Yorlenis Rodriguez, Karen Hamad, Mary Geary, Wilhelmine Wiese-Rometsch. Internal Medicine Residency, Florida State University at Sarasota Memorial Health Care System, Sarasota, FL. (Control ID #3391875)

BACKGROUND: Anemia is defined by the World Health Organization (WHO) as hemoglobin (Hb) concentration less than 12.0 gm/dL for females and less than 13.0 gm/dL for males. Objective of this quality improvement initiative was to test if anemia independently is associated with readmission in elderly patients discharged from the medicine service of a community teaching hospital.

METHODS: We conducted a retrospective cohort study declared exempt by our Institutional Review Board involving electronic medical record data from patients at least 65 years old hospitalized between September 2009 and June 2019 discharged not to hospice care. Severity of anemia classified by the WHO was applied for Hb concentrations obtained at hospital discharge for females as mild (11.0 – 11.9 gm/dL), moderate (8.0 –10.9 gm/dL), severe (<8.0 gm/dL); and males as mild (11.0 - 12.9 gm/dL), moderate (8.0 - 10.9 gm/dL), severe (<8.0 gm/dL). Time to readmission after index hospitalization within 30d, 90d, and 180d with mild, moderate, severe, or no anemia were compared using Kaplan Meier survival curves with covariates (age; sex; multiple chronic conditions; length of stay; APR-DRG Severity of Illness and Risk of Mortality; and discharge destination) controlled using Cox regression. Readmission after 180d was considered a new index hospitalization. Continuous variables are summarized using median (interquartile range) contrasted using Kruskal-Wallis analysis of variance. Categorical variables are summarized as proportions compared using chi square or Fisher exact test. Statistical tests were two-tailed with $p<.05$ considered significant.

RESULTS: Among 13,526 inpatients with 18,793 discharges median age was 78 (14) years statistically similar by sex (49% females) exhibiting an anemia distribution of no (31.0%), mild (20.5%), moderate (47.1%) and severe (1.4%). Race distributed as 89.9% white; 5.9% African American or Black; and 4.2% Other. Females differentiated distribution across anemia spectrum at no (95.7%) ($p<0.001$), mild (26.4%) ($p<0.001$), moderate (51.0%) and severe (43.5%). No, mild, moderate and severe anemia corrected for putative confounders impacted ($p<0.001$) respectively cumulative risk of readmission at 30d (7.0%, 7.9%, 17.2%, 21.3%), 90d (12.0%, 15.3%, 28.1%, 34.8%) and 180d (16.4%, 20.7%, 34.4%, 42.6%).

CONCLUSIONS: An essential patient-centric question is whether anemia in elderly inpatients affects poor outcomes and/or whether anemia is a surrogate marker for underlying overt and/or subclinical disease(s). Although present quality improvement initiative was not designed to unravel mechanisms of anemia, we controlled for putative severity of illness confounders while demonstrating readmission risk escalating with severity of anemia. Moreover, our findings herald readmission risk associated with "no anemia" as defined by the WHO. Tailored anemia care could offer clinical advantages to mitigate risk for readmission.

AN EVIDENCE MAP OF GENETIC THERAPIES

Eric A. Apaydin[1,2]; Andrea S. Richardson[3]; Sangita Baxi[1]; Jerry Vockley[4]; Olamigoke Akinniranye[1]; Rachel Ross[1]; Jody Larkin[1]; Aneesa Motala[1]; Gulrez Azhar[1]; Susanne Hempel[1,5]. [1]Southern California Evidenced- based Practice Center, RAND Corporation, Santa Monica, CA; [2]Health Services Research & Development, VA Greater Los Angeles Healthcare System, Los Angeles, CA; [3]Health Care, RAND Corporation, Pittsburgh, PA; [4]Medical Genetics, Children's Hospital of Pittsburgh, Pittsburgh, PA; [5]Keck School of Medicine, University of Southern California, Los Angeles, CA. (Control ID #3341287)

BACKGROUND: Genetic therapies replace or inactivate disease-causing genes or introduce new or modified genes. These therapies have the potential to cure in a single application rather than treating symptoms through repeated administrations. This evidence map provides a broad overview of the genetic therapies that have been evaluated in randomized controlled trials (RCTs) for efficacy and safety.

METHODS: We searched PubMed, EMBASE, Web of Science, clinicaltrials.gov, and grey literature to November 2018. Two independent reviewers screened publications using predetermined eligibility criteria. Study details and data on safety and efficacy were abstracted from included trials. Results were visualized in an evidence map.

RESULTS: We identified 119 RCTs evaluating genetic therapies for a variety of clinical conditions. On average, samples included 107 participants (range: 1-1,022), and were followed for 15 months (range: 0-124). Interventions using adenoviruses (40%) to treat cardiovascular diseases (29%) were most common. In RCTs reporting safety and efficacy outcomes, most genetic therapies (60%) were associated with improved symptoms but in nearly half (45%) serious adverse events (SAEs) were also reported. Improvement was reported in trials treating cancer, cardiovascular, ocular, and muscular diseases. However, only 19 trials reported symptom improvement for at least one year. SAEs reported in intervention and control groups included death, stroke, myocardial infarction, and infections. The evidence map shows the distribution of evidence to date.

CONCLUSIONS: This evidence map provides a broad overview of research studies that allow strong evidence statements regarding the safety and efficacy of genetic therapies. Most interventions improve symptoms, but serious adverse events are also common. More research is needed to evaluate genetic therapies with regard to the potential to cure diseases.

AN INNOVATIVE APPROACH TO IMPROVING IN-TRAINING EXAMINATION SCORES THROUGH THE UTILIZATION OF AN ADAPTIVE LEARNING QUESTION BANK

Bryan Haimes[1]; Justin Glasgow[2]; Jennifer N. Goldstein[3]; Allen Friedland[4]; Gretchen Rickards[3]; John Donnelly[5]; Himani Divatia[3]. [1]Internal Medicine-Pediatrics, Christiana Care Health System, Wilmington, DE; [2]Hospital Medicine, UAB, Birmingham, AL; [3]Medicine, Christiana Care Health System, Newark, DE; [4]Department of Internal Medicine and Department of Pediatrics, Christiana Care Health System, Newark, DE;

[5]Internal Medicine / Pediatrics, Christiana Care Health System, Newark, DE. (Control ID #3392046)

BACKGROUND: Internal Medicine (IM) In-Training Exams (ITEs) are annual markers of resident progress and strong predictors of passing the American Board of Internal Medicine (ABIM) certification exams. While low standardized ITE percentiles correlate with increased risk of board failure, literature is limited with regards to specific tools that can be utilized to enhance ITE scores and increase the likelihood of passing the ABIM exam.

Identifying innovative strategies IM programs can employ to improve annual ITE scores is critical for optimizing ABIM exam pass rates. With evolving technology, learners are utilizing multiple platforms for preferred study techniques, including mobile applications. Additionally, question banks are increasingly utilizing adaptive learning as an interactive model of spaced repetition theory for long term retention of material. However, the effectiveness of these new technologies is poorly understood.

This study evaluated the effectiveness of a novel board review question bank in improving resident performance in annual ITE scores and ABIM examination performance.

METHODS: A novel board review question bank that utilizes adaptive learning was provided to IM residents, including combined IM-Pediatrics and Emergency Medicine-IM programs (N=85) for three academic years to enhance ITE preparation in addition to standard study materials. Residents were encouraged to complete a minimum of 50 questions per 2 week elective rotation, and 100 questions per 4 week elective rotation. The number of questions completed was tracked at time intervals prior to each ITE. Multiple regression analysis evaluated how resident question completion predicted ITE scores and ABIM scores controlling for baseline ITE scores from year one of residency.

RESULTS: Number of questions completed during the first year of product use showed improvement in scores; for every 200 questions completed during that academic year, there was a predicted one percent increase in ITE score (p=.014). During the second year of utilizing the product, there was no effect of number of questions completed with overall score improvement of the ITE. ITE score data from the third year of product use is still pending. There was no significant relationship between questions completed and improvement in ABIM 3-digit scores (p=.855), although these data were only available for a small subset of residents (n=47).

CONCLUSIONS: Residents who utilized this novel question bank during the first year that it was available demonstrated improvement in ITE scores. As ITE scores are predictive of passing the ABIM examination, this new question bank could help improve residency program pass rates. Further research can focus on use of the metacognitive aspect of the adaptive learning tool to develop tailored individualized learning plans or referrals for psychodiagnostic testing for residents at risk of failing the ABIM certification exam.

AN INTENSIVE HIGH UTILIZER INTERVENTION DOES NOT REDUCE HOSPITAL READMISSIONS: THE CHAMP RANDOMIZED CONTROLLED TRIAL

Bruce L. Henschen[3]; Maria Theodorou[1]; Margaret Chapman[2]; Kenzie A. Cameron[3]; Kevin O'leary[1]. [1]Hospital Medicine, Northwestern Memorial Hospital, Chicago, IL; [2]Hospital Medicine Unit/Division of General Internal Medicine, Massachusetts General Hospital, Ipswich, MA; [3]Medicine/General Internal Medicine and Geriatrics, Northwestern University, Chicago, IL. (Control ID #3392110)

BACKGROUND: A small number of patients account for a disproportionate number of hospital readmissions. The Complex High Admission Management Program (CHAMP) is designed to improve care and reduce hospitalizations for frequently readmitted patients. Non-randomized studies of CHAMP found reductions in readmission but may be subject to regression to the mean. We conducted a randomized trial of CHAMP compared with usual care to accurately assess the program's effect on hospital readmissions.

METHODS: The CHAMP team consists of 2.0 FTE social workers, 0.6 FTE physicians, 0.1 FTE program administrator, and support from pharmacy residents, a psychologist, and a pre-existing transitional care clinic. The study had three inclusion criteria: A) 3 or more 30-day inpatient readmissions to Northwestern Memorial Hospital in a 12-month period, B) 2 or more readmissions plus referral from a care team member, or C) 2 readmissions plus 3 observation stays. Patients already followed by a multidisciplinary team (i.e. oncology, transplant) were excluded. Eligible patients were randomized to CHAMP or control (delayed-enrollment, eligible for CHAMP in 18 months). The primary outcome was number of inpatient 30-day readmissions at 180 days after enrollment; secondary outcomes included number of inpatient 30-day readmissions at 30 and 90 days, total hospital admissions, and time to third inpatient 30-day readmission. Results were stratified by presence of sickle cell disease.

RESULTS: We randomized 75 eligible patients to CHAMP and 76 to control. CHAMP and control patients were similar in age, sex, demographics; 7 CHAMP and 6 control patients had sickle cell disease. Both groups had fewer readmissions at 180 days after enrollment compared to 180 days prior to enrollment [baseline CHAMP mean 2.7 (95% CI 2.3-3.0) vs. control 2.7 (95% CI 2.4-3.1), p=0.87]. However, CHAMP-enrolled patients had more inpatient 30-day readmissions at 180 days [CHAMP mean 1.3 (95% CI 0.9-1.8) vs. control 0.8 (95% CI 0.5-1.1), p=0.04]. Readmissions were concentrated among patients with sickle cell disease [CHAMP mean 4.8 (95% CI 2.4-9.5) vs. control 1.7 (95% CI 0.4-6.4), p=0.17]; there were no differences in readmissions among patients without sickle cell disease [CHAMP mean 0.9 (95% CI 0.6-1.2) vs. control 0.7 (95% CI 0.5-1.0), p=0.31]. There were no differences in number of 30-day readmissions at 30 and 90 days, total hospital admissions, or in time to third inpatient readmission between the groups.

CONCLUSIONS: In a randomized study, frequently hospitalized patients enrolled in CHAMP experienced reductions in utilization over time, similar to observational studies. However, CHAMP did not reduce readmissions compared to a control group. Though CHAMP may affect other critical aspects of patient care, such as patient-reported outcomes, interventions targeting specific medical or social needs may be more successful in reducing hospital readmissions

AN OUNCE OF PREVENTION: IMPROVING MEDICAL STUDENT EDUCATION IN PREVENTIVE CARE THROUGH AN INTEGRATIVE APPROACH

Sneha Shrivastava[1]; Lauren Block[2]. [1]General Internal Medicine, Northwell Health, Westbury, NY; [2]Medicine, Northwell Health, Lake Success, NY. (Control ID #3385738)

BACKGROUND: Preventive care training is important in undergraduate medical education. Our medical school has an integrated curriculum where 1st and 2nd-year students are exposed to ambulatory care concurrently with basic science education. To improve students' preventive care experience, we conducted a quality improvement project to assess gaps in our 1st and 2nd-year curriculum and identify opportunities to integrate prevention across the curriculum. We involved key stakeholders, including students, faculty, community preceptors, and curricular subcommittees.

METHODS: We conducted a needs assessment survey of third-year medical students (MS3) and ambulatory clinic preceptors. We asked MS3 how often they performed preventive care tasks at their ambulatory

clinics and how knowledgeable and important they felt about 15 preventive care topics on a 3-point Likert care scale (very, somewhat, none). We asked the preceptors how often prevention was discussed and students' performance on 15 preventive care topics on a 5-point Likert scale (5=strongly agree). Preventive care topics were selected based on clinical learning objectives set by the medical school.

RESULTS: The response rate for the MS3 survey was 41.0%(41/100). Students most often performed both obesity counseling and screening for metabolic conditions (Avg=69.7%). They felt all topics were important to their training, and reported feeling very knowledgeable in screening for substance misuse, depression, and metabolic conditions. Students least performed smoking cessation counseling (43.4%) and included smoking cessation in their patient presentations (Avg=36.8%). They felt least knowledgeable in post-partum depression and lung cancer screening. The response rate for the preceptor survey was 44.8%(13/29). The majority of preceptors discussed preventive care at every clinical session (61.5%) and expected students to include prevention in their patient presentations (Mean=3.7 on a 5-point Likert scale). They felt the students performed well on screening for nicotine use (M=4.1,SD=0.8), obesity (M=4,SD=0.9), and complications of diabetes (M=4,SD=0.8), but did not perform well on nutritional assessment (M=3.1,SD=1.1), screening for domestic violence (M=3.2,SD=1.2) and assessing patients for safety (M=3.2,SD=1.2).

CONCLUSIONS: Medical students and preceptors identified gaps in the preventive care curriculum. Based on discussions with curricular subcommittees, the next steps to improve preventive care education are adding prevention-focused learning objectives to existing didactics, integrating prevention with problem- based learning and clinical reasoning sessions, adding new topics on human trafficking, trauma-informed care, and nutrition based on students' requests, and introducing a new case-based preventive care session during medicine clerkship. An integrative approach can be helpful in learning prevention and a multiple stakeholder approach can identify unique opportunities to integrate and improve preventive care education effectively.

AN RCT TO INCREASE MOBILITY AND FUNCTION AFTER HOSPITAL DISCHARGE – THE MOVE IT STUDY

Scott R. Greysen[1,4]; Dylan Small[2]; Catherine Reale[3]; Charles Rareshide[3]; Mitesh S. Patel[1,3]. [1]DGIM, University of Pennsylvania, Philadelphia, PA; [2]Statistics, University of Pennsylvania, Philadelphia, PA; [3]Nudge Unit, University of Pennsylvania School of Medicine, Philadelphia, PA; [4]-Section of Hospital Medicine, University of Pennsylvania, Philadelphia, PA. (Control ID #3392397)

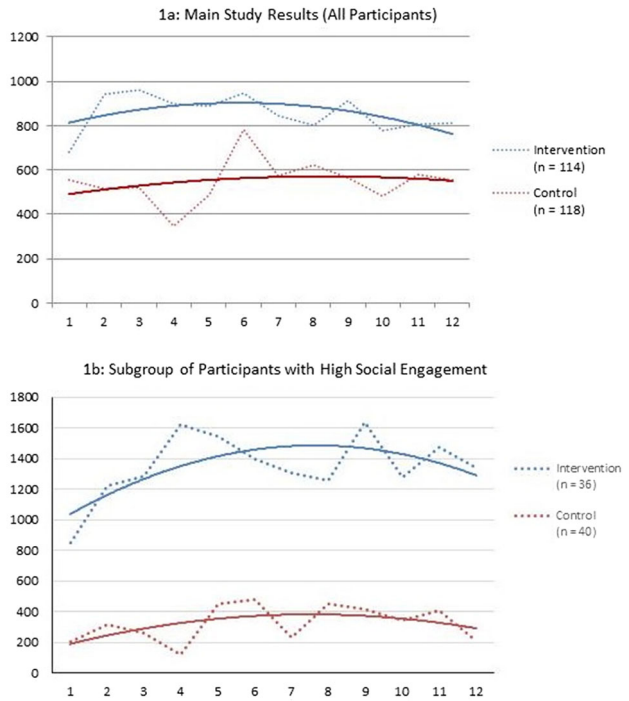
BACKGROUND: Gamification and social incentives, such as family/peer engagement in goal-setting and feedback, are increasingly used by health plans to promote physical activity in community settings but have not been used to improve mobility and reduce functional decline after hospitalization.

METHODS: 12-wk RCT of gamification with social incentives for general medicine/oncology patients at academic medical center. All participants recieved wearable device to track daily steps. Control group (n=118) received feedback from device only; intervention group (n=114) entered into a 12-week game with points/levels for achieving step goals reinforced by social incentives from a support partner (family/peer) who provided encouragement. Primary outcome was mean change in daily steps from baseline. Secondary outcomes were change in functional status (difficulty with ADL/IADLs and walking) and acute care utilization (ED visits and readmissions). Covariates were patient-reported characteristics such as sleep, quality of life, and social network size/strength (social engagement).

RESULTS: We recruited a diverse sample (N=232): 57% non-White; 61% female; 44% annual income <$50k; mean age, 40. Intervention arm had greater change in mean daily step count which did not reach statistical significance (adjusted difference, 270; 95% CI, -214, 754; p=0.27); however, subgroup analyses of participants with higher social engagement showed marked improvement in step counts (adjusted difference, 1,124; 95% CI, 409, 1841; p=0.002) – FIGURE 1. Participants in this subgroup also had less functional decline (4% compared to 12% control) and fewer 30-day readmissions (8.3% vs. 15% control). Intervention participants age 50-65 also had less functional decline (16% vs. 19% control).

CONCLUSIONS: Gamification with social incentives was effective in promoting higher mobility and reducing functional decline in patients with higher social engagement. Patients with lower social engagement may need additional support to benefit from such interventions.

Figure 1: Primary Outcome: Mean Step Increase above Baseline by Week after Discharge



ANTIMICROBIAL DE-ESCALATION PRACTICES ACROSS HOSPITALS FOLLOWING NEGATIVE CULTURES IN PATIENTS WITH PNEUMONIA

Abhishek Deshpande[1]; Sandra Richter[2]; Sarah Haessler[3]; Peter K. Lindenauer[4]; Pei-Chun Yu[5]; Marya Zilberberg[8]; Peter B. Imrey[5]; Thomas Higgins[6]; Michael B. Rothberg[7]. [1]Medicine, Cleveland Clinic, Cleveland, OH; [2]Pathology, Cleveland Clinic, Cleveland, OH; [3]Department of Medicine, Baystate Medical Center, Springfield, MA; [4]Institute for Healthcare Delivery and Populatin Science, University of Massachusetts medical School - Baystate, Springfield, MA; [5]Quantitative Health Sciences, Cleveland Clinic, Cleveland, OH; [6]Medicine, Baystate Medical Center, Springfield, MA; [7]Internal Medicine, Cleveland Clinic, Cleveland, OH; [8]University of Massachusetts, Amherst, MA. (Control ID #3391617)

BACKGROUND: For patients at risk for multidrug-resistant organisms, IDSA/ATS guidelines recommend empiric therapy against methicillin-resistant *Staphylococcus aureus* (MRSA) and *Pseudomonas*. Following negative cultures, the guidelines recommend antimicrobial de-escalation. We assessed antibiotic de-escalation practices across hospitals and their

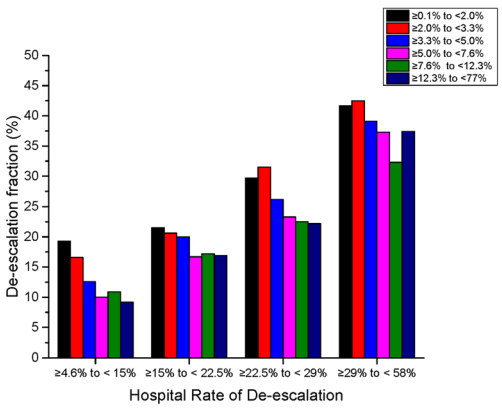
associations with outcomes in hospitalized pneumonia patients with negative cultures.

METHODS: We included adults admitted with pneumonia in 2010-2015 to 164 US hospitals if they had negative blood and/or respiratory cultures and received both anti-MRSA and antipseudomonal agents other than quinolones. De-escalation was defined as stopping both empiric drugs by day 4 while continuing another antibiotic. We compared adjusted outcomes (in-hospital 14-day mortality, late deterioration [ICU transfer], length-of-stay and costs) across hospital de-escalation rate quartiles. We also examined the likelihood of de- escalation based on the patient's predicted mortality risk across hospital de-escalation quartile.

RESULTS: Of 14,170 patients, 1924 (13%) had both initial empiric drugs stopped by hospital day 4. Hospital de-escalation rates ranged from 2%-35% with a median of 13%. De-escalation was more common in hospitals with >400 beds compared to hospitals with <200 beds (9.7% vs. 5.9%); in teaching institutions compared to others (9.7% vs. 6.3%); and in urban compared to rural hospitals (8.2% vs. 6.9%). There were no discernible trends in 14-day mortality, late ICU transfer or median length of stay across the quartiles of de- escalation. Within each quartile of hospital de-escalation rate, patients at higher predicted risk for mortality were less likely to be de-escalated. At hospitals in the top quartile of de-escalation, even among patients at lowest risk for mortality, the de-escalation rates were < 50% (Figure).

CONCLUSIONS: A minority of eligible pneumonia patients had antibiotics de-escalated by hospital day 4 following negative cultures and de-escalation rates varied widely among hospitals. The decision to de-escalate therapy was more strongly related to local practice than to patient predicted mortality. No hospital de-escalated even 50% of low risk patients. To adhere to recent guidelines will require substantial changes in practice.

Bar chart of hospital rates of day 4 de-escalation (y-axis), grouped by hospital de-escalation quartile and further stratified by sextiles of predicted mortality (x-axis).



APPROPRIATENESS OF ANTICOAGULATION THERAPY FOR PRIMARY CARE PATIENTS WITH ATRIAL FIBRILLATION

Kathryn A. Martinez[1]; Mark H. Eckman[2]; Michael B. Rothberg[1]. [1]Center for Value-Based Care Research, Cleveland Clinic, Cleveland, OH; [2]University of Cincinnati College of Medicine, Cincinnati, OH. (Control ID #3387472)

BACKGROUND: When making decisions about oral anticoagulation for patients with atrial fibrillation, physicians must weigh stroke risk reduction against bleeding risk. The Atrial Fibrillation Decision Support Tool (AFDST) is a decision analytic model that predicts the optimal anticoagulation strategy for specific individuals. Our objective was to describe the appropriateness of anticoagulant therapy (as judged by the AFDST) in a large primary care population.

METHODS: This retrospective cohort study used data from the Cleveland Clinic Health System. Primary care patients were included if they had a diagnosis of atrial fibrillation or flutter between 2015 and 2018. Patients co-managed by cardiologists were excluded. The AFDST model uses CHA2DS2-VASc and HAS- BLED to estimate the optimal anticoagulation strategy for each patient. We compared AFDST model-recommended anticoagulation to each patient's actual anticoagulation. Using mixed effects logistic regression, accounting for clustering by primary care physician, we estimated the adjusted odds of 1) receiving any oral anticoagulation if the AFDST model recommended anticoagulation, and 2) being on the model's optimal drug. Regression models adjusted for patient race, marital status, and insurance type. The first model also adjusted for estimated benefit of optimal anticoagulation versus nothing, as measured in quality adjusted life years. We assessed anticoagulation rates for individual physicians with at least 10 patients recommended to receive it.

RESULTS: The sample included 12,308 patients and 3,894 physicians. The median CHA2DS2-VASc score was 4 (Interquartile Range (IQR):2-5); the median HAS-BLED was 2 (IQR:1-3). The AFDST recommended anticoagulation for 93% of patients, most frequently with apixaban (85%) or dabigatran (9%). Of patients recommended to receive anticoagulation, 41% did, and of these, 29% were receiving the model- recommended drug. Of 804 patients recommended not to receive anticoagulation, 44% were anticoagulated, most commonly with warfarin (43%). Anticoagulation was largely insensitive to CHAD2DS2-VASc scores; anticoagulation was given to 38% of patients with a score of 2, 42% with a score of 5 and 33% with a score of 8. In adjusted analyses, relative to white patients, black patients were less likely to receive any anticoagulant (aOR:0.68; 95%CI:0.57-0.81). Patients with greater predicted benefit of anticoagulation were not more likely to receive it. For individual physicians, the proportion of patients expected to benefit who received anticoagulation ranged from 25-71%.

CONCLUSIONS: In this primary care population, less than half of patients predicted to benefit from oral anticoagulation were receiving it, and less than a third were receiving the specifically recommended agent. Anticoagulation was unrelated to predicted stroke risk, and optimal use of anticoagulation varied widely among individual physicians.

A PRAGMATIC RANDOMIZED CONTROLLED TRIAL TO EXAMINE THE EFFECTS OF A PREDIABETES DIAGNOSIS AND BRIEF COUNSELING ON PATIENT ENGAGEMENT IN STRATEGIES TO PREVENT DIABETES

Jeffrey T. Kullgren[1]; Angie Fagerlin[2,3]; Caroline R. Richardson[4]; Bradley Youles[5]; Dina H. Griauzde[6]; Michele Heisler[7]. [1]VA Center for Clinical Management Research and Department of Internal Medicine, Ann Arbor VA Healthcare System and University of Michigan, Ann Arbor, MI; [2]Salt Lake City VA Medical Center, Salt Lake City, UT; [3]University of Utah, Salt Lake City, UT; [4]Family Medicine, University Of Michigan, Ann Arbor, MI; [5]Health Services Research & Development, Department of Veterans Affairs, Ann Arbor, MI; [6]Internal Medicine, University of Michigan, Ann Arbor, MI; [7]Ann Arbor VA/University of Michigan, Ann Arbor, MI. (Control ID #3391669)

BACKGROUND: A potentially important opportunity to engage patients in strategies to prevent type 2 diabetes mellitus (T2DM) is when they are screened for T2DM and found to have prediabetes. Yet, little is known about the effects of a prediabetes diagnosis and brief counseling on patient engagement in evidence- based strategies to prevent T2DM (e.g., participation in a weight management program like the Diabetes Prevention Program or use of metformin).

METHODS: In a 12-month pragmatic randomized controlled trial, 315 non-diabetic patients from the Ann Arbor Veterans Affairs Medical

Center (AAVA) who had a major risk factor for T2DM, no hemoglobin A1c (HbA1c) test to screen for T2DM in the previous 12 months, and an upcoming primary care appointment at the AAVA were randomly assigned to one of two treatments at that primary care visit: (1) undergo an HbA1c test to screen for T2DM and receive brief standardized telephone and written counseling about their HbA1c results based on VA and American Diabetes Association guidelines; or (2) review a VA brochure about recommended screening tests and immunizations (attention control). The primary outcome was weight change after 12 months, measured using VA administrative data. Secondary outcomes included reported participation in a weight management program, use of metformin, attempted weight loss, change in physical activity, and level of motivation to prevent T2DM. Data for secondary outcomes were collected from surveys administered before randomization and at 2 weeks, 3 months, and 12 months after the baseline primary care appointment. Difference-in-differences analyses compared changes in outcomes between participants in the HbA1c test arm found to have prediabetes and participants in the brochure arm.

RESULTS: The 106 participants in the Hb1Ac test arm who were found to have prediabetes (out of the 252 participants in that arm) had no greater change in weight, participation in a weight management program, use of metformin, weight loss attempts, or physical activity after 12 months than the 63 participants in the brochure arm. Participants with prediabetes had a greater increase in their level of motivation to prevent T2DM (measured on a 0-10 scale) at 2 weeks (mean 1.0; $P < 0.001$) and 3 months (mean 0.8; $P = 0.004$), but not at 12 months, than participants in the brochure arm.

CONCLUSIONS: Using an HbA1c test to identify patients with prediabetes and providing them with brief standardized counseling increased their short-term level of motivation to prevent T2DM. However, this increased motivation was not sustained and, in the absence of longitudinal supports, did not translate into more engagement in evidence-based strategies to prevent T2DM. New approaches are needed in primary care to help patients who are diagnosed with prediabetes translate their short-term heightened motivation to prevent T2DM into effective engagement in preventive strategies.

A PREDICTION MODEL TO GUIDE LEGIONELLA TESTING FOR PATIENTS HOSPITALIZED WITH COMMUNITY-ACQUIRED PNEUMONIA

Michael B. Rothberg[1]; Abhishek Deshpande[1]; Peter B. Imrey[2]; Ning Guo[2]; Peter K. Lindenauer[3]; Sarah Haessler[4]; Tara Lagu[3]. [1]Internal Medicine, Cleveland Clinic, Cleveland, OH; [2]Quantitative Health Sciences, Cleveland Clinic, Cleveland, OH; [3]Institute for Healthcare Delivery and Population Science, University of Massachusetts medical School - Baystate, Springfield, MA; [4]Department of Medicine, Baystate Medical Center, Springfield, MA. (Control ID #3392101)

BACKGROUND: *Legionella pneumophila* is a rare cause of community acquired pneumonia. Thus, routine testing of all patients is not cost-effective. Guidelines recommend that Legionella testing should be reserved for severe pneumonia, and in cases associated with an outbreak or recent travel. We sought to develop a predictive model for Legionella infection to aid in diagnostic testing.

METHODS: We conducted a large retrospective cohort analysis using the Premier Hospital Database from 2010-2015. We included adults who had an ICD-9 code for pneumonia as principal diagnosis (or as a secondary diagnosis paired with a principal diagnosis of respiratory failure or sepsis), received antibiotic treatment for pneumonia by hospital day 1, and had any test for Legionella. We used multivariable logistic regression group LASSO variable selection to identify characteristics associated with a positive test from candidate patient demographics, co-morbid conditions present on admission, markers of disease severity, season (June-Oct vs. Nov-May), US census region, and presence of a local outbreak (2 or more cases in the current month or at least one case in the previous month). The model was developed using a random 80% of hospitalizations and validated on the remaining 20%.

RESULTS: Of 166,689 eligible patients, 43,070 (25.8%) were tested for Legionella at 165 hospitals, and 642 (1.5%) tested positive. Compared to negative tests, positive tests were more likely to occur during a local outbreak (50% vs. 18%, p<0.001), from June-Oct vs. Nov-May (70% vs. 35%, p<0.001), and to be accompanied by hyponatremia (36% vs. 14%, p<0.001). In the logistic regression model, a positive test was linked most strongly to a local outbreak (OR 3.0), summer months (OR 2.4), hyponatremia (OR 2.6), diarrhea (OR 1.4), and smoking (OR 1.6). Patients with risk factors for other causes of pneumonia were at decreased risk, including those with chronic lung disease (OR 0.8) and admission in the past 6 months (OR 0.8). Admission to intensive care and other markers of severe pneumonia were not selected for inclusion in the model, which had a c-statistic of 0.78 in the validation set. Predicted risk ranged from 0.3% to 21%, and 82% of patients with a positive test were in the top 3 deciles of predicted risk. In the dataset, physicians tested 21% of patients in the lowest risk decile and 37% of patients in the highest risk decile. In contrast, testing the 20% of patients at highest risk in the entire sample would be expected to identify 1143 cases, using only 33,338 tests (3.4% positivity rate).

CONCLUSIONS: Although incidence of Legionella in this pneumonia cohort was low, information available at the time of admission could be used to predict infection with reasonably high discrimination. Risk varied by 70-fold. Use of a predictive model to guide testing should allow clinicians to detect more cases while ordering fewer tests.

A QUALITATIVE ANALYSIS OF PRIMARY CARE CLINICIANS' JUSTIFICATIONS FOR ORDERING OPIOIDS

Tiffany Brown[1]; Ji Young Lee[1]; Stephen Persell[1]; Daniella Meeker[2]; Tara Knight[3]; Jason N. Doctor[3]; Jeffrey A. Linder[1]. [1]Department of Medicine; Division of General Internal Medicine and Geriatrics, Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Preventive Medicine, Pediatrics, University of Southern California Keck School of Medicine, Los Angeles, CA; [3]University of Southern California, Los Angeles, CA. (Control ID #3391923)

BACKGROUND: The CDC has issued guidelines to improve opioid use by using non-opioid alternatives, avoiding transitioning to chronic opioid use, and reducing chronic, high-dose opioid use. In this pilot, we deployed electronic health record (EHR) nudges informed by behavioral economic principles to improve primary care clinicians' guideline adherence. One part of the intervention was to require a justification for prescribing an opioid medication at the time of ordering. Our objective was to qualitatively describe these clinician justifications.

METHODS: For 41 primary care clinicians at three primary care clinics at one academic medical center, three different clinical decision support (CDS) alerts were triggered within the EHR when clinicians opened an opioid order that was for a) an opioid-naïve patient, b) a second opioid prescription within 90 days, or c) a chronic, high-dose opioid renewal. These CDS reminded clinicians that safer alternatives or doses should be prescribed and encouraged the clinician to change or cancel the order. If the clinician persisted with the order, a "justification alert" appeared that asked the clinician to enter a free-text rationale for the order and informed them if the text field was left blank, "No justification was given for ordering an opioid" would be entered in the encounter report visible to other clinicians. We reviewed all clinician justifications that were captured within the EHR and organized them into major themes. The pilot study ran from March-November 2019.

RESULTS: During the pilot, the justification alert fired 388 times. Clinicians usually entered a unique justification as opposed to the default language (347/388; 89%). There were seven major themes to documented justifications: 1) description of patients' acute or chronic pain (e.g., "Intractable back pain" and "Pain for zoster"); 2) post-operative pain; 3) prolonged cough; 4) failure of alternative treatments (e.g., "Persisting pain, alternatives not helpful" and "Have exhausted alternatives"); 5) balancing risks and benefits (e.g., "Acceptable risk"); 6) mentioning a short term supply (e.g., "Short term, acute pain"); or 7) including details that another approach to pain management was pending (e.g., "Bridging pain control until sees Spine" and "To see pain specialist in August").

CONCLUSIONS: When asked to provide a justification for ordering opioids, most clinicians added unique entries to patients' charts. These entries provided contextual details and often reflected that the clinician was aware of the risks of opioids and despite this felt the prescription was necessary. Additional studies are needed to understand if displaying clinicians' justifications to patients will influence prescribing.

A QUALITATIVE STUDY OF VIOLENT POLITICAL RHETORIC AND HEALTH IMPLICATIONS FOR SPANISH AND CHINESE SPEAKING IMMIGRANTS

Itzel J. Lopez-Hinojosa[2]; James Zhang[2]; Katherine M. Lopez[4]; Aresha Martinez-Cardoso[5]; Arshiya A. Baig[3]; Elizabeth L. Tung[1]. [1]Section of General Internal Medicine, University of Chicago, Chicago, IL; [2]Pritzker School of Medicine, University of Chicago, Chicago, IL; [3]General Internal Medicine, University of Chicago, Chicago, IL; [4]Washington University in St. Louis, St Louis, MO; [5]Department of Public Health Sciences, University of Chicago, Chicago, IL. (Control ID #3387522)

BACKGROUND: Violent political rhetoric regarding immigrant populations in the U.S. often incites the discriminatory treatment of immigrants at both interpersonal and institutional levels, shaping both their health and healthcare experiences. Given the rise in anti-immigrant rhetoric since 2016, this qualitative study explores and compares how Spanish- and Chinese-speaking immigrant populations in Chicago make sense of violent political rhetoric, utilize coping strategies to maintain their sense of belonging, and experience downstream health consequences.

METHODS: In 2019, we conducted, recorded, and transcribed 14 semi-structured focus groups with adults (N=80), ages ≥ 35 years, who immigrated to the U.S. Participants were recruited from four community sites in either predominantly Hispanic/Latino or Chinese neighborhoods in Chicago. Focus groups were conducted by racially- and linguistically-concordant interviewers in Spanish, Mandarin, or Cantonese. The research team developed a codebook iteratively and analyzed transcripts using grounded theory and the constant comparison method. Each transcript was coded by two research members; discrepancies were resolved using a standard of intercoder agreement.

RESULTS: The mean age of participants was 61.4±13.1 years; the majority were female (62%), unemployed (68%), and attained less than a high school diploma (53%). Almost two-thirds (61%) were Chinese-speaking and one-third (39%) were Spanish-speaking. While most Spanish-speaking participants (93%) indicated some level of stress due to rhetoric against immigrants, less than half of Chinese-speaking participants (39.6%) reported some stress due to rhetoric. Approximately one-third (32%) of Spanish-speaking participants screened positive for PTSD, compared to only 4% among Chinese-speaking participants. Participants described several ways by which violent political rhetoric increased discrimination against immigrants: "They think we're fifth class citizens, not second or third, but fifth." Another woman said: "They've always got a foot against our necks, you know? The police just antagonize the worker." Many participants responded to these experiences by using coping strategies like self-blame, helplessness, and propagating model minority expectations: "We should look to integrate into society, speaking like society, getting educated like society, being useful." Downstream consequences included impacts on mental health ("I would like to be at peace, without the fear of always thinking what's going to happen tomorrow") and physical health ("There are people who don't sleep. Maybe at the beginning, they're able to deal with it. But with time, they lose a lot of sleep and they wind up sick.")

CONCLUSIONS: Participants often described experiences of violent political rhetoric toward immigrants in the U.S. and formulated coping mechanisms to maintain a sense of self. These experiences were often linked to increased experiences as victims of acts of hate, with impacts on mental and physical heath.

A QUANTITATIVE ANALYSIS OF PATIENT RISK FACTORS FOR GUN POSSESSION IN CHICAGO

Nichole Smith[1]; Madison Wilson[1]; Monica E. Peek[3]; Elizabeth L. Tung[2]. [1]Pritzker School of Medicine, University of Chicago, Chicago, IL; [2]-Section of General Internal Medicine, University of Chicago, Chicago, IL; [3]Medicine, The University of Chicagoa, Chicago, IL. (Control ID #3384845)

BACKGROUND: Recent growth in gun violence and high-profile mass shootings have elevated discussions about gun possession to the forefront of national debate. While gun possession may enhance feelings of safety and protection from harm, it may also increase risk of suicide or interpersonal violence. Some advocates have called for healthcare professionals to screen and intervene on high-risk patients. However, few studies have examined the patient characteristics and types of neighborhood violence exposures associated with gun possession, and patients' self-described reasons for gun possession.

METHODS: A sample of 504 adult patients were recruited from primary care clinics in two epicenters of violent crime in Chicago. Surveys were administered by trained research assistants using computer-assisted personal interviewing software. Patients anonymously self-reported gun possession status through a series of validated items. Lifetime exposure to neighborhood violence was measured using the Brief Trauma Questionnaire (BTQ), which included items for being a victim of violence, or being the witness, close friend, or relative of someone who died violently. BTQ items were also adapted to assess exposure to police violence as a victim, witness, or close friend/relative. Logistic regression models were used to examine gun possession as a function of patient characteristics and violence exposures, adjusting for age, gender, race/ethnicity, education, insurance status, and employment status.

RESULTS: The majority of patients were aged >50 years (77%), female (71%), and non-Hispanic Black (75%). Of the 454 patients who responded to the gun possession items, 83 (18%) reported possession of any firearm and 54 (12%) reported carrying a gun outside the home. The majority (78%) of those who disclosed carrying a gun reported "protection" as the primary reason for doing so. Male gender (AOR=2.47, 95% CI, 1.51-4.05), exposure to community violence (AOR=1.83, 95% CI, 1.02-3.26) and exposure to police violence (AOR=2.11, 95% CI, 1.22-3.64) were associated with higher adjusted odds of gun possession. Hispanic/Latino race/ethnicity (AOR=0.24, 95% CI, 0.07-0.78), uninsured status (AOR=0.11, 95% CI, 0.01-0.84), and living alone (AOR=0.45, 95% CI, 0.25-0.84) were associated with lower adjusted odds of gun possession. There were no significant differences in gun possession between non-Hispanic white and non-Hispanic black patients, or among those diagnosed with mental health conditions.

CONCLUSIONS: Prior exposure to neighborhood violence, especially police violence, had strong associations with gun possession in this sample of urban-dwelling adults in high-crime areas. There was no difference in gun possession between black and white patients. Self-

protection was overwhelmingly reported as the primary reason for carrying a gun. It is imperative for healthcare professionals to understand and address prior experiences with violence when screening patients for gun possession and assessing for safety in clinical settings.

A RANDOMIZED CONTROLLED TRIAL FOR MEDICATION RECONCILIATION VIA SECURE MESSAGING TO REDUCE MEDICATION DISCREPANCIES AFTER HOSPITAL DISCHARGE

Steven R. Simon[3,5]; Alissa L. Russ-Jara[2]; Alan Zillich[2]; Amy W. Baughman[3]; Amy Rubin[4]; Erin Beilstein- Wedel[4]; Jonathan Moyer[6]; Gary L. Smith[4]; Laura K. Triantafylidis[4]; Megan Nowak[4]; Julianne Brady[4]; Catherine Yeksigian[4]; Amy Linsky[4,1]. [1]Medicine, VA Boston Healthcare System, Boston, MA; [2]Pharmacy Practice, Purdue University College of Pharmacy, Indianaolis, IN; [3]Geriatrics and Extended Care, VA Boston Healthcare System, Cambridge, MA; [4]Center for Healthcare Organization and Implementation Research, VA Boston Healthcare System, Boston, MA; [5]VA Greater Los Angeles Healthcare System, Los Angeles, CA; [6]Biostatistics and Epidemiology, University of Massachusetts, Amherst, Amherst, MA. (Control ID #3391458)

BACKGROUND: Medication discrepancies, defined as unintentional differences found between patients' medical records and patients' reports of medications they are taking, occur frequently after hospital discharge, predisposing patients to adverse drug events, emergency department (ED) visits, and readmissions. Medication reconciliation is a Joint Commission National Patient Safety Goal and is required at every care transition. However, high discrepancy rates suggest the need to develop strategies to improve medication reconciliation after discharge. One potential solution is to leverage online patient portals that allow interactive, asynchronous electronic communication for review of medications. The objective of this study was to test the effect of an electronic tool we previously developed for medication review, known as the Secure Messaging for Medication Reconciliation Tool (SMMRT), which we hypothesized would reduce medication discrepancies (primary outcome measure) and the combined outcome of ED visits plus readmissions, compared to usual care.

METHODS: In a randomized controlled trial at one Veterans Affairs Medical Center, we enrolled 240 Veterans hospitalized in the acute inpatient and sub-acute rehabilitation units. Participants were randomized to receive the SMMRT intervention (n=118) or usual care (UC; n=122). Veterans in the SMMRT group were enrolled in the patient portal, trained to use both secure messaging and the SMMRT tool, and contacted by a clinical pharmacist to review medications and reconcile discrepancies in the 2-week period following hospital discharge. Contact with the participant occurred preferentially by secure messaging via SMMRT but also by telephone if necessary. We used telephone interviews and medical records to ascertain the presence of each outcome measures within 30 days of hospital discharge. We used linear regression to compare mean discrepancies and chi-square tests to compare rates of ED visits and admissions (combined) in the two groups.

RESULTS: At baseline, SMMRT and UC groups were similar with respect to patients' demographic and clinical characteristics, although the mean age in the SMMRT group (63 years) was slightly younger than in the UC group (66 years; p=0.07). Thirty days after discharge, there were fewer medication discrepancies in the SMMRT group (4.4 per person) than in the UC group (6.4 per person; p<0.001), a 34% reduction. There was no difference in the rates of the combined endpoint of 30-day readmissions and ED visits between the SMMRT group (30%) and the UC group (34%; p=0.51).

CONCLUSIONS: An intervention to promote asynchronous medication review after hospital discharge reduced medication discrepancies by 34% but did not appear to reduce ED visits and readmissions. This approach may be incorporated in post-discharge communication to improve patient safety. Future study should explore additional methods of asynchronous medication review after hospital discharge, such as through mobile apps and text-messaging.

A RAPID NATIONAL NEEDS ASSESSMENT OF VA OPIOID DISPOSAL PROCESSES AND INFRASTRUCTURE

Cati Brown-Johnson[1]; Matthew McCaa[2]; Peter Glassman[3]; Jesse Holliday[4]; Molly Schnell[5]; lorenz Karl[6]; Jeremiah McKelvey[4]; Karleen Giannitrapani[7]. [1]Evaluation Sciences Unit, Stanford School of Medicine, Stanford, CA; [2]Health Services Research & Development, U.S. Department of Veterans Affairs, Menlo Park, CA; [3]Medicine, VA Greater Los Angeles HCS, Los Angeles, CA; [4]VA Palo Alto Health Care System, Menlo Park, CA; [5]Northwestern University, Evanston, IL; [6]pcph, stanford, Stanford, CA; [7]Center for Innovation to Implementation, Veterans Health Administration, Menlo Park, CA. (Control ID #3390513)

BACKGROUND: Opioid diversion, referring to opioids diverted from legitimate prescriptions to illegal circulation was 5x higher in 2017 compared to 2002 (Kurtz 2019). In partnership with the VA pain program office, we undertook a rapid national needs assessment to understand how sites handle proper disposal of unused opioid medications and identify opportunities for intervention.

METHODS: We interviewed key stakeholders on perceptions of VA opioid disposal programs, including communication with providers and patients, law-enforcement-run disposal days, mail-back envelops, secure bins located at VA and other pharmacies, and buy-back programs. We utilized a combination of snowball and purposive sampling to connect with geographically dispersed stakeholders. Interviews were conducted Nov- Dec 2019 with 12 VA stakeholders (8 sites; representation from surgery, pain, ambulatory care, pharmacy, and VA police). We employed Stanford lightning report rapid qualitative analytic techniques.

RESULTS: Theme 1: There is limited VA standardization of opioid disposal advice and practices. Many providers are unaware of best practices or even current options locally. Providers do not routinely discuss opioid disposal, and documentation provided with prescriptions does not necessarily include disposal information. One exception is long-term opioid therapy where the patient consent does include generic information about disposal.

Theme 2: Providers identified three ideal patient types/situations for opioid disposal intervention: acute situations (post-surgery), tapering or changing prescriptions (long-term pain patients), and bereaved families (post-palliative care). One post-operative buy-back program was locally successful in a rural setting. Other providers were open to implementing buy-back at their locations, but named barriers related to cost, resources (pharmacy FTE), and complexity/location (eg. distance to pharmacies for patients).

Theme 3: Frequently implemented interventions included blue bins located by pharmacies for secure disposal of medications, and mail-back envelopes given to patients by physicians or pharmacists. There were barriers to implementing these interventions, namely cost perceptions (e.g. pre-marked postage to facilitate use could incur significant costs with larger volume).

CONCLUSIONS: Opioid disposal efforts are underway across the nation's VA. Buy-back programs, secure disposal (bins and mail-back envelops), and potential policies are three promising avenues for future intervention. Overall, providers were motivated to address this issue of removing unused opioids from circulation, but acknowledged barriers of cost, resources, and competing priorities. Future efforts should coalesce disparate interventions into a centralized program that includes

communication to patients/providers, interventions tailored to specific settings/populations, and layered interventions so that every veteran can access disposal.

A RARE CASE OF EOSINOPHILIC MYOCARDITIS IN A PATIENT WITH HYPEREOSINOPHILIC SYNDROME

Daniel Rodriguez. Internal Medicine, USF, Tampa, FL. (Control ID #3392422)

BACKGROUND: Hypereosinophilic Syndrome (HES) is a disorder marked by sustained eosinophilia in which infiltration of eosinophils cause damage to multiple organs. Presentation varies widely, but dermatologic and pulmonary clinical manifestations are among the most common presenting symptoms. Cardiac involvement (i.e. eosinophilic endocarditis/myocarditis), while rare, is among one of the major causes of morbidity and mortality among HES patients.

METHODS: We present the case of a 38 year old female who initially presented with severe dyspnea on exertion and petechial rash. Patient found to be thrombocytopenic on admission with elevated absolute eosinophil count (present on prior admissions and persistently elevated on subsequent admissions as well). CT chest revealed diffuse bilateral infiltrates. TTE performed due to concerns for heart failure revealed right sided cardiac strain with apical thrombus concerning for Eosinophilic Myocarditis (Loeffler's Endocarditis). Patient was started on IVIG for thrombocytopenia, with improvement in platelet count. After normalization of platelets, patient was also initiated on anticoagulation and high dose steroids for Eosinophilic Myocarditis.

Subsequent admissions revealed patient had developed diffuse lymphadenopathy. IgE was found to be significantly elevated. Genetic testing revealed the patient to be FIP1L1-PDGFRA negative; a tyrosine kinase mutation associated with myeloproliferative variant of HES. Patient was scheduled for follow up with Hematology/Oncology for biopsy and further management.

RESULTS: In the setting of diffuse lymphadenopathy, elevated IgE, along with dermatologic and pulmonary findings, it was suspected that our patient had a Lymphocytic or Myeloproliferative variant of HES. One study found that therapy with Imatinib in patients with myeloproliferative features of HES variants had a 54% response rate, even in FIP1L1-PDGFRA negative patients.

CONCLUSIONS: Despite extensive evaluation, as many as 75 percent of cases of HES reveal no identifiable etiology. Guidelines for the identification and treatment of such patients has not been well established in the literature, and the wide variety of clinical presentations often results in delayed diagnosis.

HES is a rare condition with incidence rate of 0.35 cases per 1,000,000 individuals per year. Cardiac involvement in HES was first described by Loeffler in 1936. Since then, numerous case reports have documented cardiac involvement in both children and adults. Treatment for Loffler's Endocarditis typically involves high dose steroids, +/- anticoagulation and treatment of the underlying cause if identified.

AREA DEPRIVATION INDEX PREDICTS 10-YEAR ALL-CAUSE MORTALITY FOLLOWING CABG SURGERY

Sarah O. Crowe, Scott D. Rothenberger, Kaleab Abebe, Amy M. Anderson, Bruce L. Rollman. Department of Medicine, University of Pittsburgh, Pittsburgh, PA. (Control ID #3391401)

BACKGROUND: Living in a disadvantaged neighborhood can impact a patient's long-term health. Area Deprivation Index (ADI) is a comprehensive measure of neighborhood socioeconomic status that includes such indicators as median income, employment status, housing, English language proficiency, and poverty rate. While living in more disadvantaged neighborhoods has been associated with higher rates of diabetes and early death, few studies have examined the relationship between ADI and mortality among patients with cardiovascular conditions. We addressed this question among a cohort of patients who enrolled in a NIH- funded trial to treat depression following coronary artery bypass graft (CABG) surgery.

METHODS: Between 3/04 and 9/07, we enrolled 453 post-CABG patients from eight Pittsburgh-area hospitals (302 depressed (inpatient PHQ-2(+)/2-week outpatient PHQ-9 ≥10) and 151 non-depressed control subjects (PHQ-2 (-)/PHQ-9 <5). We used the University of Wisconsin's Neighborhood Atlas (www.neighborhoodatlas.medicine.wisc.edu) to determine ADI for each patient's home address at the time of surgery and then classified ADI into four categories: Very Advantaged (ADI: 1-25); Advantaged (26-50); Disadvantaged (51-75); and Very Disadvantaged (76-100). We then confirmed patient vital status as of 12/31/2018, and used Kaplan-Meier analyses to determine 10-year mortality incidence with cox proportional hazards models to assess statistical significance.

RESULTS: We were able to determine ADI for 446 (98%) patients, including 297 (67%) who met the criteria for post-CABG depression. Their mean age was 65 (SD:11), 60% were male, 88% were White, 83% had hypertension, and 41% had diabetes. Patient distribution by ADI category was as follows: 8% Very Advantaged, 22% Advantaged, 40% Disadvantaged, and 30% Very Disadvantaged. This distribution did not differ by baseline depression status. The 10-year incidence of all cause mortality was 37%, and compared to Very Advantaged (reference group), the mortality hazard ratio was 1.26 (95% CI: 0.60-2.64) for Advantaged, 1.27 (0.63-2.57) for Disadvantaged, and 1.98 (0.98-3.99) for Very Disadvantaged (P=0.04).

CONCLUSIONS: ADI is predictive of 10-year all-cause mortality following CABG surgery. While our findings need to be confirmed for other cardiovascular conditions and in other communities, we strongly encourage policymakers and elected officials to consider neighborhood ADIs when making allocation decisions for limited public and private resources to address the social determinants for better health.

ARE AGE AND RACE ASSOCIATED WITH PRESCRIPTION OF SMOKING CESSATION PHARMACOTHERAPY IN HOSPITALIZED VETERANS?

David A. Katz[1,2]; Steven Fu[3]; Kathleen M. Grant[6,7]; Allan V. Prochazka[4,5]; Catherine Battaglia[4,5]; John Holman[1]; Mary Vaugha Sarrazin[1,2]; Mark Vander Weg[1,2]. [1]Center for Access & Delivery Research and Evaluation (CADRE), Iowa City VA Health Care System, Iowa City, IA; [2]Department of Medicine, University of Iowa, Iowa City, IA; [3]Center for Chronic Disease Outcomes Research (CCDOR), Minneapolis VA Health Care System, Minneapolis, MN; [4]Department of Medicine, VA Eastern Colorado Health Care System, Denver, CO; [5]The Denver Seattle Center for Veteran-centric Value-based Research (DiSCoVVR), Denver, CO; [6]Mental Health and Behavioral Sciences Department, VA Nebraska-Western Iowa Health Care System, Omaha, NE; [7]The Department of Internal Medicine, University of Nebraska Medical Center, Omaha, NE. (Control ID #3391658)

BACKGROUND: A minority of hospitalized smokers are prescribed nicotine replacement therapy (NRT) or other FDA-approved medications for smoking cessation in Veterans Health Administration (VHA) hospitals. Disparities in cessation pharmacotherapy may be especially salient in older and nonwhite inpatients (inpts), possibly related to patients'

misconceptions about cessation medication, level of nicotine dependence, and physicians' concerns regarding competing comorbid conditions. The aim of this study is to determine the association between patient age, race, and prescription of cessation pharmacotherapy in hospitalized veterans who smoke.

METHODS: We conducted a secondary analysis of data from a guideline implementation trial involving 849 hospitalized smokers (>1 cigarette/day) on the medicine inpatient wards at four University-affiliated VHA medical centers. We identified all inpt orders for cessation medications and used medical record review and face-to-face interviews to collect data on potential confounders of cessation medication prescribing, including age, race, educational attainment, primary admission diagnosis (by ICD-9 category), presence of a smoking- related condition, cigarettes per day (cpd), readiness to quit (Contemplation Ladder), and withdrawal symptoms (Minnesota Nicotine Withdrawal Scale). As the % of inpts for whom cessation medication had been prescribed was similar before and after the study intervention, data from both periods were combined. Multivariable risk adjusted logistic regression models were created using generalized estimating equations to assess the association between age, race, and any prescription of cessation pharmacotherapy, with adjustment for patient covariates, intervention period, hospital, and clustering by inpatient physician.

RESULTS: Mean age of inpts was 59 years and 12% were nonwhite; 68% had a smoking-related condition and 44% were admitted with a primary cardiopulmonary diagnosis. Median cpd was 15 (interquartile range 10-20), and 55% were ready to quit. Cessation pharmacotherapy was ordered for 36% of inpts (92% were prescriptions for NRT). Bivariable analysis showed that 42, 39, and 29% of patients aged <50, 50-64, >65 were prescribed cessation pharmacotherapy, respectively (p=.003 by Score test for trend). Compared to inpts <50 years, elderly inpts (>65 years) were significantly less likely to be prescribed cessation medication (aOR=0.40, 95% CI= 0.23, 0.70). Compared to Caucasian inpts, cessation medication was less likely to be prescribed for nonwhites (aOR=0.49, 95% CI=0.29, 0.81).

CONCLUSIONS: There is a significant opportunity to provide more hospitalized veterans with cessation pharmacotherapy, as recommended by The Joint Commission. Further research is needed to explore patients' treatment preferences and health beliefs, clinicians' prescribing attitudes, and system-related factors that may explain age- and race-related disparities in prescription of tobacco treatments.

ARE ALL NON-RESOLVING LACTATES THE SAME IN SEPSIS? THE ASSOCIATION BETWEEN LACTATE TRAJECTORY AND OUTCOMES AMONG SEPTIC PATIENTS WITH ELEVATED LACTATE AFTER 24 HOURS

Nick Flores[1]; Alexander J. Beagle[1]; Priya A. Prasad[2]; Kirsten Kangelaris[3]. [1]School of Medicine, University of California, San Francisco, San Francisco, CA; [2]Division of General Internal Medicine, Department of Epidemiology and Biostatistics, UCSF, San Francisco, CA; [3]Department of Medicine, UCSF, San Francisco, CA. (Control ID #3392279)

BACKGROUND: Serum lactate is a common prognostic marker incorporated into treatment guidelines for fluid administration in sepsis. Little is known about the clinical characteristics and outcomes of patients with non-resolving lactate. We sought to determine differences in characteristics and outcomes of sepsis patients according to relative changes in lactate between 24-48 hours after presentation.

METHODS: Electronic medical record data from adults presenting to a large urban academic emergency department between 2012-2018 that met sepsis-III criteria and had a lactate level >2 in the first 24 hours were included. Lactate trajectory was defined as ($lactate^{peak\ 0\text{-}24h}$-$lactate^{peak\ 24\text{-}48h}$)/$lactate^{peak\ 0\text{-}24h}$. Patients were divided into three groups based on lactate trajectory: "resolvers" had a trajectory of ≥0.25, "nonresolvers" had a trajectory of >-0.24 and <0.24, and "worseners" had a trajectory of ≤-0.25. Using bivariate tests, we compared clinical characteristics and outcomes between groups.

RESULTS: Of 5,446 patients, 5,027 (92.3%) were resolvers, 315 (5.8%) were nonresolvers, and 104 (1.2%) were worseners. The groups had similar triage vitals, demographics and received similar amounts of fluid within the first 24 hours (Table). Cancer and liver disease were increased among nonresolvers and heart failure was increased among worseners. Mortality was 16% in resolvers, compared to 27% in nonresponders and 49% in the worseners (p<0.001). A similar pattern was observed for mechanical ventilation, ICU admission rates, and vasopressor requirement (Table).

CONCLUSIONS: Lactate trajectory after presentation is associated with differences in clinical characteristics and outcomes in sepsis. While patients with nonresolving and worsening lactate after 24 hours had worse clinical outcomes, underlying differences in comorbidities may explain some of the differences in lactate metabolism and adverse sepsis outcomes. More work is needed to determine whether additional fluids would be of benefit in these patients.

Table. ASA Scores Assigned by Internal Medicine and Anesthesiology Physicians

Anesthesiology ASA Scores	Internal Medicine ASA Scores: 1	2	3	4	Total

2	6	10	2	0	18
3	9	73	50	0	132
4	0	2	11	0	13
Total	15	85	63	0	163

ARE CLINICIANS ADHERING TO THE 2018 USPHTF PSA SHARED DECISION-MAKING GUIDELINES? CHART REVIEW OF PSA DISCUSSION DOCUMENTATION

Jason Ramos, Maria Mirica, Gordon D. Schiff. Center for Patient Safety Research and Practice, Brigham and Women's Hospital, Boston, MA. (Control ID #3391559)

BACKGROUND: Although the prostate-specific antigen (PSA) test is widely used to screen for prostate cancer, USPSTF recommendations have historically advised against routine screening, and the most recent guidelines issued in 2018 emphasize the importance of shared decision making (SDM) between the patient and the clinician. The aim of this study was to describe the frequency and ways SDM making is currently being documented in the charts of age-appropriate males.

METHODS: This was a retrospective medical record review of a random sample of 100 male patients. A Brigham and Women's Hospital (BWH) electronic data repository was queried to find males aged 55-70 years who had made a routine office visit to one of the primary care clinics at or affiliated with BWH between 6/1/18-5/31/19, a one-year period following the release of the 2018 USPSTF guidelines. Patients diagnosed with prostate cancer prior to 6/1/18 and those who had a PSA test completed during the specified timeframe were excluded from the sample. Charts from the routine visits were reviewed for evidence of SDM regarding PSA in primary care visit notes. We considered SDM documentation present

when the note contained some language indicating a PSA relevant discussion occurred.

RESULTS: Of the 100 charts reviewed, 33% had documentation of PSA-related SDM. Language used to document decision making varied and included 1) a standardized 3-sentence institutional macro-smart phrase (N=6, 18% of the shared decision-making notations) stating the patient understood testing implications, a discussion of benefits and risks, and a patient's final decision, 2) provider templated text (N=7, 21%) containing other descriptive language related to risks and benefits and 3) a free text (N=20, 61%) description of a SDM discussion. In an additional 23 charts there was some reference to either a prior PSA test result (free text or templated lab results) or a plan to discuss PSA in the future, but none mentioned any SDM conversation during the visit.

CONCLUSIONS: Findings from this study suggest that, despite recent recommendations from the USPSTF to conduct patient-clinician discussions regarding PSA testing, documentation of SDM occurred with only 33% of eligible patients. Given that prostate cancer is the leading (non-skin) cancer and 2nd leading cause of cancer death in men, failure to document such shared decision making poses both clinical and malpractice risks. Our study is limited by a small sample size and a somewhat broad definition of the SDM documentation (making our conclusions conservative). Further research is needed to investigate the scope of the problem across clinical settings and reasons for poor SDM documentation. Understanding how and when PSA-related SDM is being documented can help inform development of tools and strategies that improve adherence to guidelines, simplify the workflow, and enhance proper documentation.

A REMOTE DIGITAL TRIAL FOR INSIGHTS ON NOVEL CONTEXTS OF AMBULATORY BLOOD PRESSURE MEASUREMENTS

Francis Allinson[1]; Nolan Mejia[2]; Lauren Ariniello[2]; Andrew LeBlanc[2]; Giorgio Quer[2]; Evan Muse[2,3]. [1]Scripps Green Internal Medicine Residency, Scripps Green / Scripps Clinic, San Diego, CA; [2]Scripps Research Translational Institute, La Jolla, CA; [3]Scripps Clinic, La Jolla, CA. (Control ID #3391769)

BACKGROUND: Outpatient blood pressure (BP) monitoring is key in the diagnosis and management of hypertension. With advances in wearable BP devices and technologies the ability to gain insight into BP in novel contexts has expanded greatly. Here we wanted to explore the usability of a novel wrist-worn BP cuff monitor for outpatient data collection with participants following digital cues rather than in person instruction. Transmitted measurements were subsequently used to evaluate BP variation with the time of day and day of week, BP variation with mood, and orthostatic measurements.

METHODS: After virtual informed consent participants were supplied with the BP monitor and asked to download a customized study application to their smartphone. They were instructed to wear the wrist cuff and take BP measurements for at least two days per week for a 4-week monitoring period, capture orthostatic BP at least twice during the trial, and record at least two BP readings each week associated with the extremes of emotional state - calm and stressed.

RESULTS: Fifty participants, 25 women and 25 men, with a mean age of 44.5 years were enrolled and received the BP monitor. 82% of the participants transmitted data via the study app. The median wear time of the device during the study was 11 days (IQR 8-17). Wednesday was associated with the highest average systolic BP (133 mmHg, SEM 1.3) and Saturday was associated with the lowest average systolic BP (129 mmHg, SEM 1.8). 32 participants attempted orthostatic measurements, with 78% successfully measuring at least one set of orthostatic vitals according to study guidelines with only 2 individuals recording positive orthostatic vital signs. 24 participants measured BP in association with mood at least once during the study. The difference between the average calm and stressed BP was statistically significant ($p<0.005$) with a corresponding 5 mmHg increase in systolic BP associated with stress when compared to daily average BP, and a 5 mmHg decrease in systolic BP associated with calm when compared to daily average BP.

CONCLUSIONS: This prospective digital study showed that wearable BP technology combined with an easy to use smartphone application is an attractive option when monitoring BP in the outpatient setting. This is one of the first studies to evaluate the usability of digital cues to perform orthostatic measurements, with the results showing that the majority of those who attempted orthostatic BP following cues on their smartphone did so correctly. The statistically significant change in BP between calm and stressed emotional states underscores the role of mindfulness and stress relief when targeting BP control. When sequentially monitored in the outpatient setting, BP varies based on a number of different potentially modifiable factors and continued efforts to improve BP monitoring strategies using novel devices should be explored.

A RESIDENT-LED INTERDISCIPLINARY QUALITY IMPROVEMENT INITIATIVE TO INCREASE OSTEOPOROSIS SCREENING IN AN URBAN CLINIC

Catherine Teskin[2]; Hiba Sayed[1]; Patrick Ho[1]; Nikita Donti[2]; Melissa Morgan-Gouveia[3]. [1]Internal Medicine, Christiana Care, Wilmington, DE; [2]Internal Medicine, Christiana Care Health Systems, Wilmington, DE; [3]Medicine, Christiana Care Health System, Wilmington, DE. (Control ID #3367851)

BACKGROUND: Osteoporosis is a major cause of morbidity and mortality in the United States. The USPSTF recommends screening all women age 65 and older or younger women with risk factors for osteoporosis.[2] Unfortunately, osteoporosis screening rates remain low nationwide.[3] In our residency clinic, the baseline screening rate for women age 65 and older was 47%. We aimed to increase this rate by 10% over a three month period.

METHODS: Our root cause analysis identified provider, patient, and system level barriers to osteoporosis screening. Plan-Do-Study-Act (PSDA) cycle 1 targeted provider knowledge through didactic education and posters in the clinic space. PDSA cycle 2 identified patient barriers. We collaborated with an institutional nurse-led program called "Strong Bones" that has existing initiatives in place to detect and treat osteoporosis. We used a health registry embedded within our electronic medical record to identify patients from our clinic who were eligible for osteoporosis screening. A Strong Bones nurse then reached out to each patient to explain the need for screening and to help navigate barriers. We then tracked the rate of osteoporosis screening between PDSA cycles through the health registry and manually reviewed patient level data during a three month patient outreach period.

RESULTS: After PDSA cycle 1, we saw a slight increase in our screening rate from a baseline of 46% (101/216) to 49% (106/216). During PDSA cycle 2, we identified and chose 138 patients eligible for osteoporosis screening to be contacted. 71 of these patients were called during the outreach period, and 11 scans were completed. Our screening rate at the beginning of cycle 2 was 34% (111/322) and increased to 36% (122/338). The most common barrier identified during this period was patient disinterest, though many were unreachable.

CONCLUSIONS: Results from PDSA-1 showed that resident education alone increased the number of DEXA scans ordered, but did not substantially increase completed screenings due to patient barriers. Furthermore, relying on "inreach" interventions targeting only the patients present at the office visit missed a large proportion the patient panel. PDSA cycle 2 addressed both of these issues. There was a substantial increase in DEXA

completion and we were also able to quantify the barriers our patients faced in the process. Limitations included difficulty in obtaining reliable data. Additionally, ongoing changes to the health registry's patient attribution characteristics led to a lower rate of completed screening even though the total number of screenings increased. Although our intervention led to more patients having their screening completed, it was very time-intensive and would be difficult to sustain moving forward. Next steps consist of identifying ways to decrease system level barriers, such as through streamlined scheduling and same day appointments.

ARE SOCIAL NETWORK CHARACTERISTICS OF PEOPLE WITH SERIOUS MENTAL ILLNESS ASSOCIATED WITH QUANTITY OF CIGARETTES SMOKED OR READINESS TO QUIT?

Benjamin Meza[1]; Gail L. Daumit[1]; Craig E. Pollack[1]; Faith B. Dickerson[3]; Corinne Cather[2]; Anne E. Evins[2]; Kimberly Gudzune[1]. [1]School of Medicine, Johns Hopkins, Baltimore, MD; [2]Psychiatry, Massachusetts General Hospital, Boston, MA; [3]Sheppard Pratt Health System, Baltimore, MD. (Control ID #3391398)

BACKGROUND: Nationally, 53% of adults with serious mental illness (SMI) are estimated to smoke cigarettes, which contributes to reduced life expectancy. In general populations, social networks influence smoking habits through behavior modeling and social norms, yet the networks of people with SMI differ in ways that may affect network influence on smoking (e.g., predominantly family). Our objective was to 1) characterize the social networks of people with SMI who smoke, and 2) identify whether network-level factors were associated with quantity of cigarettes smoked and readiness to quit.

METHODS: We performed a secondary analysis of baseline data collected as part of the TRIUMPH randomized controlled trial, which assessed the effectiveness of a smoking cessation intervention for people with SMI who receive care at community mental health centers. A subsample (n=75; 34.1%) reported characteristics of 10 social network members, including gender, relationship type, and smoking status. Network variables are represented as the median [IQR] proportion of a participant's network members perceived to have a given attribute. We also determined connections between network members to calculate network density – a property associated with behaviors. We conducted bivariate analyses examining the association between number of cigarettes smoked (dichotomized to ≤10 cigarettes/day versus >10 cigarettes/day) or readiness to quit smoking in the next month (dichotomous) and social network characteristics using Wilcoxon-Mann-Whitney non-parametric tests.

RESULTS: Participants' mean age was 50 years (SD 11), 52% male, 48% Black, and 49% White. Social network members were 53% [40%, 70%] women, 50% [28%, 70%] friends, and 40% [10%, 60%] family. Nearly half of network members were active smokers (40% [20%, 50%]). Structurally, the average network had a density of 61.9% (SD 25.7%). Participants reported smoking regularly for an average of 32 years (SD 12), and we found that 53% reported smoking ≤10 cigarettes/day and 68% were ready to quit smoking in the next month. In bivariate analyses, no social network characteristics were significantly associated with baseline number of cigarettes smoked or readiness to quit.

CONCLUSIONS: Interestingly, the network characteristics of this subsample of adults with SMI from community mental health centers were different than other studies in this population – participants reported networks compromised with a higher proportion of friends than family, which may related to social connections formed at the community centers. We did not find an association between network characteristics and baseline cigarettes smoked or readiness to quit, possibly due to the RCT study design; however, given social networks' importance in smoking cessation interventions in general populations, future research should explore whether baseline network factors influence cessation among adults with SMI.

ARE SPECIFIC ELEMENTS OF ELECTRONIC HEALTH RECORD USE ASSOCIATED WITH CLINICIAN BURNOUT MORE THAN OTHERS?

Rebekah Gardner[2]; Ross W. Hilliard[1]; Jacqueline Haskell[3]. [1]Medicine, Alpert Medical School of Brown University, Providence, RI; [2]Department of Medicine, Alpert Medical School of Brown University, Providence, RI; [3]Healthcentric Advisors, Providence, RI. (Control ID #3375439)

BACKGROUND: Over the past decade, researchers, physicians, and, increasingly, the public have focused their attention on burnout among healthcare workers. Stress related to health information technology is both measurable and common, with two-thirds of physicians and half of advance practice providers reporting in one survey that electronic health records (EHRs) add to the frustration of their workday. In a large national study, investigators found low satisfaction with EHRs generally and computerized physician order entry in particular; use of computerized physician order entry was associated with a 30% increase in the risk of burnout among survey respondents. In light of the evidence demonstrating that clerical and administrative tasks and inbox management consume a substantial proportion of clinicians' total EHR time, we set out to identify whether certain components of work within the EHR contribute more to burnout than others, with particular attention to measures of workload and efficiency within the EHR system itself. Specifically, the aim of this study is to examine the association between clinician burnout and measures of EHR workload and efficiency, using EHR user action log data. We hope that by identifying individual EHR work elements that are associated with burnout, we can then more effectively direct interventions to improve well-being among physicians and other providers.

METHODS: We merged data from a statewide clinician survey on burnout with Epic EHR data from the ambulatory sites of two large health systems; the combined dataset included 422 clinicians. We examined whether specific EHR workload and efficiency measures were independently associated with burnout symptoms, using multivariable logistic regression and controlling for clinician characteristics.

RESULTS: Clinicians with the highest volume of patient call messages had almost four times the odds of burnout compared to clinicians with the fewest (adjusted OR 3.81, CI 1.44-10.14, p=0.007). No other workload measures were significantly associated with burnout. Among the efficiency variables, none were significantly associated with burnout in the main analysis; however, in a subset of clinicians for whom note entry data were available, clinicians in the top quartile of copy and paste use were significantly less likely to report burnout, with an adjusted OR of 0.22 (CI 0.05-0.93, p=0.039).

CONCLUSIONS: We found that high volumes of patient call messages were significantly associated with clinician burnout, even when accounting for other measures of workload and efficiency. In the EHR, "patient calls" encompass many of the tasks occurring outside of face-to-face visits and likely represent an important target for those seeking to improve clinician well-being. Our results suggest that increased workload is associated with burnout and that EHR efficiency tools are not likely to reduce burnout symptoms, with the possible exception of copy and paste.

ARE THERE RACIAL/ETHNIC DIFFERENCES IN THE EFFECTS OF PHYSICIAN RECOMMENDATION TO EXERCISE ON PHYSICAL ACTIVITY LEVELS OF U.S. ADULTS WITH ARTHRITIS? AN ANALYSIS OF THE NATIONAL HEALTH INTERVIEW SURVEY, 2002, 2006, 2009, AND 2014

Jeremy Huckleby[1,2]; Rose Ramos[1]; Anna Napoles[1]. [1]National Institute on Minority Health and Health Disparities, National Institutes of Health, Betesda, MD; [2]Medical Research Scholar Program, National Institutes of Health, Betesda, MD. (Control ID #3373668)

BACKGROUND: Although the prevalence of arthritis is similar among Whites and African Americans (AAs) and lower among Hispanics, arthritis-associated symptoms are more severe among AAs and Hispanics, compared to Whites. Exercise is recommended for persons with arthritis to reduce symptoms, and physician recommendation to exercise may increase patients' exercise levels. This study examined the effects of receipt of physician recommendation on physical activity (PA) levels, and whether these effects differ by race/ethnicity.

METHODS: This was a retrospective, cross-sectional analysis focused on U.S. adults ages ≥18 with self- reported doctor-diagnosed arthritis, using data from the National Health Interview Survey, waves 2002, 2006, 2009 and 2014. The two outcomes were met aerobic or strengthening PA guidelines (yes vs. no) based on the 2008 Physical Activity Guidelines for Americans. Predictors included self-reported race/ethnicity (AA, Asian, Hispanic, or White), ever receiving a physician recommendation to exercise to relieve arthritis symptoms (yes vs. no), and a race/ethnicity x receipt of exercise recommendation interaction term. Covariates included age, gender, marital status, education, smoking status, body mass index, self-reported health status, number of comorbid conditions, having a usual source of care, psychological distress level, employment status, income and region of the country. Multivariate logistic regression models, applying NHIS sampling weights, assessed the independent association of race/ethnicity and physician recommendation on the odds of meeting aerobic and strengthening PA guidelines.

RESULTS: Total sample was 27,887 (72.4% White, 15.4% AA, 10.1% Hispanic and 2.2% Asian). Mean age was 60.9 years (SD=15.1). AA (62.0%), Hispanics (61.3%) and Asians (60.4%) were slightly more likely than Whites (55.1%) to report receipt of physician recommendation to exercise ($p<0.001$). AA (73.8%) and Hispanics (73.9%) were more likely than Whites (63.5%) to meet PA guidelines for aerobic activity ($p<0.001$). AA (86.5%) and Hispanics (88.8%) were slightly more likely than Whites (82.5%) to meet PA guidelines for strengthening activity ($p<0.001$). Controlling for covariates, receipt of recommendation to exercise was associated independently with meeting aerobic (OR=1.12; 95% CI 1.04, 1.22) and strengthening (OR=1.15, 95% CI 1.05, 1.27) guidelines, regardless of race/ethnicity. Compared to Whites, Asians had lower odds of meeting aerobic (OR=0.80; 95% CI 0.64, 0.99) and strengthening activity guidelines (OR=0.77; 95% CI 0.61, 0.99), and AA had greater odds of meeting strengthening activity guidelines (OR=1.21; 95% CI 1.05, 1.39).

CONCLUSIONS: AAs, Hispanics and Asians with arthritis were slightly more likely than whites to receive a physician recommendation to exercise to relieve arthritis symptoms. Receiving a physician recommendation to exercise to relieve arthritis symptoms can improve physical activity levels in all racial/ethnic groups.

A RISK-STRATIFIED APPROACH TO CREATING A SAFE AND EFFECTIVE LOW-TOUCH INTERVENTION TO CONTACT PRIMARY CARE PATIENTS AFTER VISITS TO THE EMERGENCY DEPARTMENT

Anna U. Morgan[1]; Susan H. Regli[3]; Asaf Hanish[3]; Nancy Mcglaughlin[2]; Susan C. Day[1]. [1]Internal Medicine, University of Pennsylvania, Philadelphia, PA; [2]Primary Care Service Line, University of Pennsylvania, Philadelphia, PA; [3]Data Science, University of Pennsylvania, Philadelphia, PA. (Control ID #3391847)

BACKGROUND: Timely follow-up by a patient's primary care office after discharge from the Emergency Department is believed to improve patient outcomes and is required by the CMS Comprehensive Primary Care Plus (CPC+) program. Prior to the rollout of this initiative, post-ED outreach varied across the University of Pennsylvania Health System's (UPHS) Primary Care Service Line (PCSL) practices based on available resources. Patients were contacted as staffing allowed by a nurse care manager or via the EHR patient portal. The goals of this initiative included: 1) developing a standardized and equitable workflow to reach out to all patients after ED discharge 2) testing the ability of a UPHS risk score to guide the level of post-ED contact, 3) testing the safety and efficiency of portal messages and non-RN staff for ED outreach.

METHODS: First, a standardized workflow was developed to contact patients after ED discharge, escalate their care to clinical staff when necessary, and capture data about the outcome of the outreach in our EHR. Next, low risk patients (risk score <6) enrolled in the portal were contacted using bulk messaging. Finally, high risk patients (risk score ≥ 6) OR who were not enrolled in the portal were called by non-clinical staff. All patients with clinical questions were referred to an RN and/or offered an appointment. A pilot project was completed in three practices (two academic, one community).

RESULTS: The pre-period (10/1/2018 - 3/1/2019) included 2,124 discharges (1,764 unique patients). The post-period (4/2/2019-9/1/2019) included 2,281 discharges (1,832 unique patients). Patients were much more likely to be contacted within 7 days of ED discharge (56% vs. 79%), and the mean time to contact decreased (3.8 vs. 2.6 days, $p =<0.001$). Patients were more likely to open a message than respond to a phone call (69% vs. 41%, $p =<0.001$). Of the 683 discharges with a response, 69 (10%) required an escalation to a clinical staff member. We did not see a significant increase in 30-day returns to the Emergency Department, hospital admissions, or readmissions.

CONCLUSIONS: We developed a standardized workflow that met the needs of multiple practices, and found improvements in patient safety, quality, and resource management. The relatively low proportion of patients who required escalation to a clinical staff member reassures us that use of non-clinical staff and electronic communication can safely be the first point of contact for patients. Moreover, lack of significant change in returns to the ED or inpatient settings suggests that this lower touch strategy did not have a negative impact on patient care. The project was deemed successful: the new workflow is resource-saving for the PCSL while simultaneously improving our communication with patients. It was rolled out across the PCSL in July 2019.

ASA PHYSICAL STATUS DETERMINATION BY INTERNAL MEDICINE PHYSICIANS AND IMPLICATIONS FOR CARDIAC RISK ASSESSMENT

Kevin R. Riggs[1,4]; Terry Shaneyfelt[4]; Jeffrey Simmons[2]; Melanie Morris[3,4]; Stefan Kertesz[5,1]; Joshua Richman[3,4]. [1]Division of Preventive Medicine, University of Alabama at Birmingham, Birmingham, AL; [2]Department of Anesthesiology and Perioperative Medicine, University of Alabama at Birmingham, Birmingham, AL; [3]Department of Surgery, University of Alabama at Birmingham, Birmingham, AL; [4]Birmingham VA Medical Center, Birmingham, AL; [5]Medicine, Birmingham VA Medical Center & U. Alabama Birmingham, Homewood, AL. (Control ID #3391143)

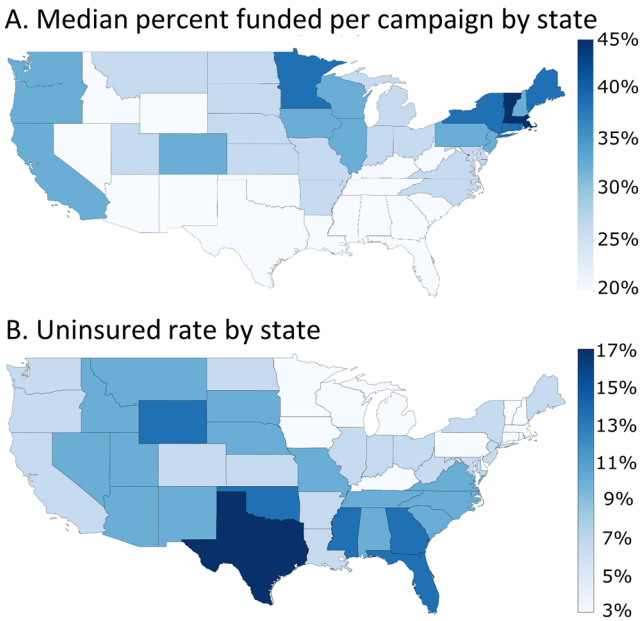
BACKGROUND: Estimating cardiac risk is an important aspect of preoperative evaluation. Several widely used risk calculators incorporate

the American Society of Anesthesiologists (ASA) performance status score. However, internists are not typically trained in determining ASA scores, and how well they make that determination is uncertain. The aim of this study was to compare ASA scores assigned by internal medicine physicians and anesthesiologists, and determine the implications of discrepancies on cardiac risk predictions.

METHODS: This was an observational cohort study of Veterans being evaluated in a preoperative evaluation clinic at a single center. ASA scores were recorded by internal medicine physicians performing preoperative medical consultations between April 2017 and April 2018 as part of a quality improvement initiative. For patients who went on to have surgery in the proceeding 90 days, ASA scores assigned by anesthesiology on the day of surgery were retrieved from the medical record. We compared mean ASA scores between the two groups using a paired t-test, and assessed interrater agreement using a weighted kappa. Gupta (also known as MICA) cardiac risk scores incorporating alternative ASA scores were calculated. Analyses were performed using STATA 15.

RESULTS: Data was collected on 216 patients, of whom 163 had surgery in the next 90 days. Among included patients, mean age was 67, 94% were male, 63% underwent orthopedic operations, and 23% underwent urologic operations. ASA scores assigned by anesthesiology and internal medicine are shown in the Table. ASA scores were concordant in 60 cases (36.8%). ASA scores by internal medicine were lower in 101 cases (62.0%) and higher in 2 cases (1.2%). The mean ASA scores were 2.97 by anesthesiology and 2.29 by internal medicine ($p < 0.0001$). The weighted kappa was 0.08. Gupta cardiac risk score was able to be calculated in 160 patients, and was >1% in 14 patients using the anesthesiology ASA score, compared to 5 patients using the internal medicine score.

CONCLUSIONS: ASA scores assigned by internal medicine physicians were systematically lower than those assigned by anesthesiologists. These differences are important because current guidelines recommend consideration of preoperative cardiac testing when the predicted cardiac risk is >1%. Anesthesiologists should be aware of these differences when preoperative evaluations are performed by internal medicine physicians.



A SEAT AT THE TABLE FOR COMMUNITY SOCIAL SERVICE AGENCIES: PERSPECTIVES ON IMPROVING THE PARTNERSHIPS WITH THE HEALTHCARE SYSTEM IN THE WHOLE PERSON CARE-LOS ANGELES (WPC-LA) PROGRAM

Etsemaye P. Agonafer[1]; Vanessa Nunez[4]; Maria Morales[1]; Jessica Jara[3]; Sarmen Hakopian[3]; Kelli Poole[2]; Clemens S. Hong[3]; Tiffany Kenison[1]; Ish Bhalla[1]; Francesca Cameron[1,2]; Savanna Carson[1]; Stefanie D. Vassar[5]; Arleen F. Brown[6,2]. [1]Department of Medicine, UCLA, Los Angeles, CA; [2]Los County Department of Health Services, Los Angeles, CA; [3]Department of Health Services, Los Angeles County, Los Angeles, CA; [4]PRIME Program, David Geffen School of Medicine at UCLA, Los Angeles, CA; [5]Division of Internal Medicine & Health Service Research, UCLA, Los Angeles, CA; [6]Division of General Internal Medicine and Health Service Research, UCLA, Los Angeles, CA. (Control ID #3341856)

BACKGROUND: Whole Person Care-Los Angeles (WPC-LA) is a 5-year California Section 1115 Medicaid Waiver implemented by the Los Angeles County Department of Health Services (LAC DHS) to address the unmet health and social needs of high-risk populations experiencing homelessness, justice involvement, substance use disorder, complex mental health, medical conditions and/or pregnancy. WPC-LA initiated cross-sector community social service partnerships to integrate services. Although health and social service collaborations are increasingly common, there is limited evidence on effective management of partnerships and their implementation seldomly incorporates perspectives of social service organizations. To address this gap we aimed to solicit community social service perspectives.

METHODS: Using a partnered approach, we conducted a brief survey and in-depth semi-structured interview with employees of community social service agencies partnered with WPC-LA. We used purposive, snowball, and diversity sampling to recruit participants. Surveys solicited demographic characteristics about the respondent and agency. Interviews elicited perspectives about the agency's clients, care delivery process, and impact of WPC-LA. Surveys were analyzed using descriptive statistics. Interviews were analyzed using the Rapid Assessment Process, a qualitative inquiry that incorporates the Consolidated Frameworks for Implementation Research, triangulation, and iterative data analysis. Preliminary results were disseminated to participants through voluntary in-person and virtual conferences for verification of themes.

RESULTS: We conducted 65 interviews with key informants from 36 community social service agencies collectively serving all regions of LAC and high-risk WPC-LA populations. Key informants, on average, had 12.4 years (SD 9.5) of social services experience and 35.4% had a shared-lived experience with their clients. We categorized their perspectives into themes: 1) holistic understanding of their clients' circumstances (*"[clients have] the ability to take nothing and make it something, even if it's just surving in hostile environments"*); 2) relational client-centered care delivery process dependent on partnerships with other agencies; 3) appreciation for WPC-LA's work across silos despite various implementation challenges; and 4) recognition that their expertise should be incorporated into evolving health and social service partnerships (*"we need dialogue, inclusion… a seat at the table…to share a prespective from the frontlines"*).

CONCLUSIONS: Community social service agencies bring important expertise to providing integrated clinical and social care through their understanding of high-risk populations, their ability to meet individuals *"where they are"*, and connection with varied service networks. Our findings suggest opportunities and strategies to develop policies that build more effective and sustained linkages between healthcare systems and social service agencies that care for vulnerable populations.

A SPATIAL EXPLORATION BETWEEN HEALTHCARE COVERAGE AND MEDICAL CROWDFUNDING IN THE UNITED STATES

Sameh Saleh[1]; Richard Medford[1,2]. [1]Internal Medicine, UT Southwestern Medical Center, Dallas, TX; [2]Clinical Informatics, UT Southwestern Medical Center, Dallas, TX. (Control ID #3392171)

BACKGROUND: Americans have increasingly turned to medical crowdfunding to finance rising personal healthcare-related costs. This growing reliance is primarily attributed to the lack of a publicly funded healthcare system and resultant gaps in healthcare access and coverage. We explore the effect of healthcare coverage on medical crowdfunding in the United States.

METHODS: We conducted a cross-sectional spatial analysis of all active medical GoFundMe (the largest charitable crowdfunding platform globally) campaigns in the United States between September 1, 2018 and August 30, 2019. Through web scraping, we extracted all text available from each campaign's webpage and used the location of the campaign to label state-level characteristics including Medicaid expansion status and uninsured rate. We explored descriptive statistics for numerical variables extracted and evaluated spatial representations of medical crowdfunding by state.

RESULTS: We studied 120,310 campaigns, which raised more than $2.4 billion over the course of the last year. Yet, only 11.3% of all campaigns met their funding goal. While 36.1% of the American population resides in non-Medicaid expansion states, 39.1% of campaigns were in non-Medicaid expansion states (p<0.001). However, campaigns in non-Medicaid expansion states raised substantially less (median, $1,325; interquartile range [IQR], $565 to $3,310) than those in Medicaid expansion states (median, $1,636; IQR, $655 to $3,895) (p<0.001). They also met less of their funding goal (median 24.4%; IQR, 9.5% to 55.7% vs. median 30.2%; IQR, 11.5% to 67.0%) (p<0.001). States with higher uninsured rate tended to meet less of their funding goal as well (Figure 1).

CONCLUSIONS: These findings support concerns that medical crowdfunding does not adequately bridge gaps in healthcare coverage, but rather, further maligns those with less socioeconomic privilege. Further research is needed to understand the social, ethical, and economic implications of medical crowdfunding in the United States.

Characteristics of 5,446 patients stratified by lactate clearance

	Responders (n=5027)	Nonresponders (n=315)	Worseners (n=104)	*P* value
Demographic characteristics				
Age, years	66.1 (18.0)	66.8 (16.8)	62.8 (18.6)	0.15
Female gender	2160 (43.0%)	132 (41.9%)	44 (42.3%)	0.93

ASSESSING APPROPRIATE ASPIRIN (ASA) USAGE IN ELDERLY PATIENTS: A QUALITY IMPROVEMENT INITIATIVE

Lauren Block[1]; Nancy A. LaVine[1]; Jennifer Verbsky[1]; Victoria Zhao[2]; Daniel J. Coletti[1]. [1]General Internal Medicine, Northwell Health, New Hyde Park, NY; [2]Zucker School of Medicine, Hempstead, NY. (Control ID #3390531)

BACKGROUND: A recent study indicated nearly 25% of patients aged > 40 without CVD take daily aspirin (ASA) for primary prevention, and almost half of adults in the US over age 70 take low dose ASA daily. However, recent publications on the risks/benefits of low-dose ASA to prevent cardiovascular events led the AHA/ACC to recommend against routine ASA use in persons > 70 or increased bleeding risk. We aimed to describe the use of ASA in our elderly patients, and deprescribe when appropriate.

METHODS: This quality improvement project was conducted in our interprofessional (IP) training clinic. We sought to identify scheduled patients > 65 taking ASA in a preclinical huddle, review ASA indications, discuss ASA risks/benefits and conduct shared decision making with the patient. Members of our IP team (physician assistant, pharmacy, and medical students) reviewed the EMR indications for daily ASA: diabetes mellitus (DM), stent placement/coronary artery bypass grafting (CABG), myocardial ischemia (MI), stroke/transient ischemic attack (TIA), acute coronary syndrome (ACS), and peripheral artery disease (PAD). ASCVD score was also reviewed. The student determined if the patient had significant risk of fall or bleeding. Indications, risk factors, and adherence to daily ASA were confirmed during a discussion with the patient. We recorded overall patterns of ASA use in our elderly patients and tracked the number of patients de-prescribed ASA from March through August of 2019.

RESULTS: 44 patients >65 years were seen during the project period. 17 (39%) were found to have ASA on their medication list. Of 17 patients taking ASA 9 had risk factors (DM, stent placement or CABG, MI, TIA or stroke, ACS, or PAD). One patient was prescribed ASA by oncology to prevent cancer recurrence. The remaining 7 patients (41%) did not have an evidence-based indication for ASA. Aspirin was deprescribed in these patients via shared decision making. Of the 7 deprescribed, 1 patient restarted ASA in the follow up period. Of note, 2 of 44 (7%) patients not on ASA had cardiovascular risk factors and were prescribed ASA.

CONCLUSIONS: 41% of patients > 65 in our sample taking ASA did not have an evidence-based indication and were receptive to discontinuing ASA after risks and benefits were discussed. Unexpectedly, review of cardiovascular risk led to *initiating* ASA in 2 patients. This highlights the importance of medicine reconciliation and focused patient education on ASA risks/benefits. Team discussions of the risks and benefits of daily ASA underscored the complexity of applying new treatment guidelines, particularly in patients with diabetes and higher ASCVD scores. Our project was limited by a small cohort of elderly patients, with a low percentage of ASA use (38%) compared with recent data, possibly due to the unique patient population in our IP clinic. Additional, longitudinal, research using larger samples is needed to refine recommendations for "right-prescribing" daily aspirin regimens in primary care.

ASSESSING CLINICIAN EDUCATOR PROFESSIONAL IDENTITY AT AN ACADEMIC MEDICAL CENTER

Anne Dembitzer[2,3]; Penelope Lusk[1]; Neil Shapiro[3,1]; Kevin Hauck[1]; Verity E. Schaye[1]; Michael Janjigian[4]; Khemraj Hardowar[5]; Stefanie Reiff[6]; Sondra Zabar[4]. [1]Medicine, New York University-Langone Health, New York, NY; [2]Internal Medicine, NYU School of Medicine, New York, NY; [3]Medicine, Dept. Of Veterans Affairs, New York, NY; [4]Medicine, NYU School of Medicine, New York, NY; [5]PRMEIR, New York University, South Ozone Park, NY; [6]Internal Medicine, NYU Langone Hospital - Brooklyn, Brooklyn, NY. (Control ID #3391496)

BACKGROUND: Professional Identity (PI) is a dynamic construct that relates to how individuals perceive and conceptualize their professional roles. A strong PI is associated with improved motivation, job satisfaction, and academic productivity. Understanding the PI of clinician-educators (CE) is challenging because most have a variety of roles. But academic centers tend to prioritize clinical and research roles over educational responsibilities. We sought to understand the CE of PI specifically in their educator role. To assess and conceptualize PI we used the Professional Identity Essay (PIE), a writing framework based on Kegan's stage theory of identity development that has previously been used to assess PI in lawyers, dentists, and medical students.

METHODS: Study subjects were all participants in the Education for Educators (E4E) program, a yearlong faculty development program offered within the Department of Medicine that is available to all physicians who self-identify as a CE. At the first session all participants completed the PIE, a series of nine narrative prompts focusing on CE personal and professional expectations as educators, their response to failure, and their professional role models. Two faculty (MD and graduate student) reviewed all submissions and completed an initial content analysis of the PIE to assess themes and qualities of CE PI.

RESULTS: Twenty-four CEs completed the baseline PIE, 43% were women. Participants included 14 hospitalists and 9 subspecialists in practice an average of 3 years (range 1-17 years). Four themes were identified: (1) Understanding their role as an educator. Roles described ranged from simply imparting clinical knowledge and running teaching sessions, to the belief that being an educator was a vital role central to being a physician. (2) Experiencing conflicts between teaching and other professional and personal roles. All reported struggling with finding time to teach. Many reported taking time away from family to prepare for teaching. (3) Feeling misunderstood at institutional and societal levels. Many felt that their teaching efforts were not valued and their struggles not addressed. (4) Differences between the descriptions of professional exemplars and CE expectations for themselves. Descriptions of exemplars emphasized acceptance, availability, support and sponsorship. In contrast, many participants described their own roles simply as distributors of knowledge without mentioning the traits of exemplars.

CONCLUSIONS: This group of mostly junior CE had wide variability in their descriptions of their roles as educators and in their view of exemplary educators. However, they shared similar struggles regarding time, inter-role conflicts, and many expressed a sense of feeling misunderstood or undervalued. Understanding the PI of CE may help us support educator development, mitigate burnout, further the mission of faculty development and ultimately enhance medical education.

ASSESSING FOOD INSECURITY IN ADULT PATIENTS WITH DIABETES

Cody Moore[1]; Amanda Miller[2]; Nancy T. Kubiak[1]; Diane Chlebowy[2]; Kaitlin Gordon[1]; Jennifer Olges[1]. [1]Internal Medicine, University of Louisville, Louisville, KY; [2]School of Nursing, University of Louisville, Louisville, KY. (Control ID #3392055)

BACKGROUND: Food insecurity, the lack of consistent access to enough food for a healthy, active life, affected 12.9% of U.S. and 15.5% of Kentucky households in 2016. A 2018 pilot survey of patients in the internal medicine resident clinic (IMRC) demonstrated that 39% of patients were food insecure.

Medical literature shows an association between food insecurity and many chronic medical conditions, including diabetes mellitus (diabetes). To determine the next steps, we explored perceptions of health and biometric data in patients with diabetes and food insecurity in our IMRC.

METHODS: A convenience sample of IMRC patients (N=32) with diabetes were invited to participate while at their appointment. Patients consenting to the study completed the 2-question hunger vital signs survey, a brief quality of life questionnaire, 2 questions about the use of the food pantry, and demographic information. Patient chart review collected biometric data including body mass index (BMI), weight, hemoglobin A1C (A1C), and blood pressure (systolic-SBP and diastolic-DBP).

RESULTS: The mean age of the study population was 57.8 (SD = 12.7), 59% were male, 40% divorced, 63% had a high school degree or less, and 50% lived in a house. A majority were unemployed (62.5%), and 47% reported a monthly family income of $1,000 or less. Overall, 50% (n=16) were food insecure. In the past 12 months. 43.8% (n=14) worried whether the food would run out before they got money to buy more, and 43.8% (n=14) worried that the food they bought just didn't last and they didn't have money to get more. Patients had a mean of 9.8 days a month where their physical health was not good and a mean of 5.8 days monthly where their mental health was not good. The mean A1C, BMI, SBP, and DBP results were 7.9 (SD = 2.01), 33.5 (SD = 8.2), 132.3 (SD = 20.1), 77.1 (SD = 9.1), respectively.

CONCLUSIONS: In a convenience sample of patients with diabetes in an IMRC, 50% were food insecure, and patients indicated significant numbers of days with poor physical and mental health. These results stress that further enrollment and analyses are important to better understand the extent that food insecurity has on quality of life, diabetes biomarkers, BMI, and blood pressure in adults with diabetes over time. Future research studies can evaluate the effectiveness of interventions to address food insecurity and improve health outcomes in this population.

ASSESSING MENTAL HEALTH DIAGNOSES AND MENTAL HEALTH SERVICE UTILIZATION AMONG HIGH-RISK WOMEN VETERANS

Taona P. Haderlein[1]; Elizabeth M. Yano[3]; Alison B. Hamilton[4]; Evelyn T. Chang[2]. [1]Center for the Study of Health Innovation, Implementation, and Policy, Department of Veterans Affairs, Los Angeles, CA; [2]General Internal Medicine, VA- Greater Los Angeles, Los Angeles, CA; [3]Center for the Study of Healthcare Innovation, Implementation & Policy, VA Greater Los Angeles Healthcare System, Sepulveda, CA; [4]Center for the Study of Healthcare Innovation, Implementation and Policy, VA Greater Los Angeles Healthcare System, Los Angeles, CA. (Control ID #3387377)

BACKGROUND: Women veterans (WVs) exhibit higher mental healthcare utilization than male veterans, suggesting high care needs. To address the unique needs of WVs, the Veterans Health Administration (VHA) implemented women's health primary care. Characteristics of women's health primary care clinics (WH- PACT) include designated women's health providers, chaperoned gender-specific exams, secure treatment areas, and access to mental health care. While preliminary evidence suggests positive impacts of WH-PACT, no known work examines how WH-PACT affects mental health treatment seeking. Using data from a high- risk sample, the current study aims to a) describe gender differences in mental health diagnosis and care utilization, and b) assess the effects of WH-PACT on VHA mental health clinic utilization.

METHODS: We used data from participants in the PACT Intensive Management (PIM) demonstration, a pilot intensive outpatient management program for high-risk patients. We used administrative data to extract mental health conditions, history of military sexual trauma (MST) diagnosis, and mental health utilization during the 12 months prior to study assignment.

We used chi-squared analyses to compare rates of mental health diagnoses between men and women veterans. We conducted negative binomial

regression analyses with mental health clinic visit counts during the 24-month study period as dependent variables. We used past-year WH-PACT attendance (0=no,1=yes) as the independent variable. Age, ethnicity, and Gagne Comorbidity Index scores were included as covariates.

RESULTS: The sample included 3,995 PIM participants from five geographically diverse sites (*M* age=66.58, 10% female). Eligibility requirements included 1) a risk score in the 90th percentile for 90-day hospitalization as determined by a validated algorithm and 2) a recent hospitalization or emergency department visit.

WVs showed higher rates of PTSD (p<.01), depression (*p*<.01), psychoses (*p*<.01), anxiety (*p*<.01), and bipolar disorder (*p*<.01) than men. Thirty percent of women reported MST, compared to 3% of men (*p*<.01). Fifty-seven percent of the sample visited a VHA mental health clinic during the study period. A higher proportion of women (79%) than men (56%; *p*<.01) visited a VHA mental health clinic. Regarding specific clinics, WVs showed higher rates of individual (*p*<.01), group (*p*<.01), primary care-mental health integration (PC-MHI; *p*<.01), and telephone mental health (*p*<.01) utilization than men.

Sixty-five percent of women in the sample (n=399) utilized WH-PACT during the previous year. WH-PACT attendance was associated with higher VHA mental health visit counts. Regarding specific clinics, PC-MHI visit counts were higher among women who utilized WH-PACT.

CONCLUSIONS: Effective healthcare for high-risk WVs requires prioritization of mental health service availability. This study provides preliminary evidence in support of WH-PACT as a strategy for improving mental health care access.

ASSESSING PROFESSIONAL IDENTITY FORMATION AND REFLECTIVE CAPACITY IN MEDICAL STUDENTS: CORRELATED, BUT NOT THE SAME

Lisa Altshuler[2]; Penelope Lusk[1]; Verna Monson[3]; Aja King[3]; Adina Kalet[4]. [1]Medicine, New York University-Langone Health, New York, NY; [2]General Internal Medicine, NYU School of Medicine, New York, NY; [3]Consultant, Minneapolis, MN; [4]Medical College of Wisconsin, Milwaukee, WI. (Control ID #3391575)

BACKGROUND: A mature medical professional identity (PI) is a fundamental outcome of medical education (Irby and Hamstra, 2016) and medical schools across the country are developing approaches to support professional identity formation (PIF) in students. Reflective capacity, not just in the moment but as a broad skill, is key to core professional competency and may underlie PIF (Wald, 2015). Yet the relationship between reflective capacity and PIF is not well understood. Do these two concepts assess the same developmental capacity? Is reflective capacity a prerequisite for professional identity development? This pilot study is an initial attempt to explore this issue and to examine the relationship between written reflective capacity and professional identity development.

METHODS: As part of a professionalism curriculum medical students complete the Professional Identity Essay (PIE) at three time points: upon entrance to the school, after basic science courses, and after clinical rotations. The PIE (Bebeau and Lewis 2004), based on Kegan's developmental model (1982), requires responses to 9 prompts which elicit conceptions of the professional role. It is scored on a 5-point scale reflecting Kegan's 5 stages, with transitional stages captured by half-points.

For this study, we randomly selected 20 PIE protocols from the 100 completed by the Class of 2020 after their basic science curriculum. These were scored by three raters (VM, AK, LA). Interrater reliability was established by reaching 100% agreement within one half stage on the PIE. The same raters scored the PIE protocols with the Reflection Evaluation for Learners' Enhanced Competencies Tool (REFLECT), following the scoring criteria (Wald 2010, Wald 2012). For both the PIE and REFLECT we averaged the three raters into a single score. A Pearson two-tailed correlation was then computed between the two scales.

RESULTS: Completed scores on both measures were available for 19 of the 20 PIES. The range of PIE scores was 2.5-4, as would be expected of students at this point in their careers (Kalet 2018). REFLECT scores ranged 2-4. There was a statistically significant moderate positive correlation between the PIE and REFLECT (r=.628, *p*=.004), with REFLECT scores explaining 39% of the variance of PIE scores.

CONCLUSIONS: The correlation between PIE scores and REFLECT ratings suggests that the PIE captures and reflects some elements of learners' reflective capacity. However there remains a large component of the PIE score not explained by reflective capacity, which suggests that the PIE, as a standalone measure of PIF, demonstrates qualities beyond reflective capacity. Further investigation is warranted in order to tease out the interplay between these two concepts. Understanding the relationship between PIF and reflective capacity can inform educators in promoting a more nuanced and sophisticated PI development in students.

ASSESSING THE IMPACT OF TIME OF COMPLETION ON EVALUATION RESULTS IN GRADUATE MEDICAL EDUCATION

Joshua Cutler, Robin Klein. Internal Medicine, Emory, Atlanta, GA. (Control ID #3390746)

BACKGROUND: Competency based medical education as implemented in the Next Accreditation System (NAS) of the Accreditation Council for Graduate Medical Education (ACGME) relies upon frequent, criterion based assessments of resident performance (Holmboe 2010). It is unclear how the variable of timing that evaluations are completed influence rating patterns. We aim to assess the influence of timing of evaluations on rating score patterns.

METHODS: This is a retrospective review of faculty evaluations of Internal Medicine resident performance from inpatient general medicine rotations from 2013-2017. Evaluations were collected from the residency management system and de-identified with respect to faculty and trainees. Quantitative analysis, including regression modeling, was conducted with the assistance of a statistician.

RESULTS: Data included 3,777 evaluations of 436 residents by 235 faculty. Of these evaluations, 436 (11.5%) were submitted more than 90 days after rotation end, termed Late Evaluations, with a mean time to submission of 217.2 days. The mean time to submission in the on time group was 23.7 days. Of the 235 faculty, 70 (28.8%) submitted at least one late evaluation with a mean 6.2 late submissions among this group. Using 1 to 5 scale, the composite competency score was similar for on-time evaluations and late evaluations (mean [SD] 4.58 [0.45] vs. 4.65 [0.39]) for late evaluations. Controlling for resident's baseline, using IM - In Training Examination Score, we found that late evaluation status was not a significant variable in terms of rating score variability (composite competency score p = 0.42). Similar findings were seen in the six core competency scores.

CONCLUSIONS: The NAS framework requires frequent, direct-observation based assessments of resident performance by faculty. We found that 28% of faculty were responsible for the late evaluations in our study suggesting the practice of late evaluations is a faculty-specific trait.

We found that competency rating patterns were similar for on-time evaluations and late evaluations. Our findings suggest that once an evaluators' perception of a resident is formed, it is stable and consistent, even with significant delays in reporting those impressions.

Reasons for our findings are unclear as it stands to reason that delays in completing evaluations would influence rating patterns. One possible

explanation for this phenomenon is that faculty impressions of residents may be informed by encounters outside of the residents' performance on the ward rotation. In addition, clustering around the mean and ceiling effect of ratings may limit the ability to detect differences in ratings.

This is the first study to assess impact of the timing of evaluation completion on evaluation results. Future study in competency based medical education in graduate medical education should consider the influence of key variables such as timing of evaluation completion and its impact on the validity of evaluation results.

ASSESSING THE READINESS OF PEDIATRIC HEMATOLOGY CLINICS TO IMPLEMENT A SOCIAL NEEDS SCREENING AND REFERRAL INTERVENTION PROGRAM FOR PATIENTS WITH SICKLE CELL ANEMIA

Stephanie Loo[1]; Annelise Brochier[2]; Mikayla Gordon Wexler[2]; Kristin Long[3]; Patricia Kavanagh[2,4]; Mari- Lynn Drainoni[5]; Arvin Garg[2,4]. [1]Department of Health Law, Policy, and Management, Boston University School of Public Health, Somerville, MA; [2]Department of Pediatrics, Boston Medical Center, Boston, MA; [3]Department of Psychological and Brain Sciences, Boston University, Boston, MA; [4]Boston University School of Medicine, Boston, MA; [5]School of Public Health, Boston University, Boston, MA. (Control ID #3389511)

BACKGROUND: WE CARE is a screening and referral intervention assessing and providing resources for families with unmet social needs that has been successfully demonstrated in the pediatric primary care setting to connect families in need with resources and is now being tested in specialty settings. This aim of this study was to assess pediatric hematology clinics' receptiveness and readiness to implement a social needs screening and referral program for patients with sickle cell anemia (SCA).

METHODS: Six focus groups were held at four pediatric hematology clinics in New England in late 2019. The WE CARE screening domains were discussed: childcare, food insecurity, housing, parental employment and high school education status, and utilities. Discussion questions were designed around the revised Promoting Action of Research Implementation in Health Services implementation science framework. Participants represented all members of the SCA clinical team including from providers to front-desk staff.

RESULTS: Participants reported that the majority of their patients and families have unmet social needs. While there is no standard screening for social needs, SCA clinic staff described that needs often come up during visits given the longitudinal relationships established between families and team members. Participants reported that established workflows existed to address social needs, oftentimes led by a social worker that is shared within joint hematology-oncology clinics. They expressed frustration with the limited availability of clinic resources to address needs for their SCA patients, particularly noting the disparity compared to their pediatric oncology patients. Participants felt that WE CARE could be an acceptable intervention to apply within this clinic setting, particularly in assessing needs on a routine basis. However, they cautioned against assessing parent education and employment, as they felt that their priorities were to address needs directly affecting the child rather than the parent. They also emphasized that assisting with patients' school medical exemptions was a necessary but missing social need domain for the SCA patient population. Finally, participants readily identified places within existing workflows to implement WE CARE, mostly via handing paper screens to parents upon check-in with social workers assigned to review responses and distribute resources for identified needs.

CONCLUSIONS: Pediatric hematology clinic staff acknowledged the prevalence of unmet social needs for their SCA patients and disparity in available clinic resources compared to oncology patients. They were receptive to implementing a social needs intervention like WE CARE in their practice setting and highlighted key areas of expansion relative to the unique needs of children with SCA.

ASSESSING THE RISK OF OPIOID OVERDOSE AFTER OPIOID TAPER: A RETROSPECTIVE COHORT STUDY

Hector R. Perez[1]; Matthew Gosen[2]; Michele Buonora[3]; Chinazo Cunningham[4]; Joanna L. Starrels[5]. [1]Division of General Internal Medicine, Albert Einstein College of Medicine, Bronx, NY; [2]Albert Einstein College of Medicine, Bronx, NY; [3]Internal Medicine, Montefiore Medical Center, Bronx, NY; [4]Medicine, Albert Einstein College of Medicine & Montefiore Medical Center, Bronx, NY; [5]General Internal Medicine, Albert Einstein College of Medicine & Montefiore Medical Center, Bronx, NY. (Control ID #3391463)

BACKGROUND: Evidence of risks after an opioid taper, including potential opioid overdose, is emerging. Currently, limited evidence exists to ascertain prevalence of opioid overdose after tapering. We sought to evaluate whether a taper was associated with increased risk of opioid overdose in a retrospective study of patients on chronic opioid therapy (COT) who did and did not undergo a taper.

METHODS: We conducted a retrospective cohort study of patients on COT at the major university health system in the Bronx, New York between 2008 and 2014. Adult patients on COT with a stable dose of at least 25 daily morphine milligram equivalents (MME) over a baseline year were included. Patients with any history of cancer before the baseline year were excluded. Patients were considered to have experienced an opioid taper if they had a reduction of at least 30% from their baseline dose throughout the year after the baseline year (the exposure year). Patients who had a stable dose or increased dose were controls. The primary outcome was opioid overdose after the exposure year, ascertained from the hospital electronic health record by ICD-9 codes (965.00-965.02, 965.09, E850.0-E850.2). Descriptor statistics were tabulated, and, where feasible, t-tests, median tests, or chi-square tests were used to measure differences between tapered and control groups. Multivariate analyses were not conducted due to small cell sizes.

RESULTS: Of 1,338 patients on COT, 207 (15.5%) experienced opioid tapers and 1,131 (84.5%) did not. Average age was 51.6 years, 54.6% were female, 83.5% were non-White, and 13.3% had a diagnosis of opioid use disorder at baseline. Median follow-up time was 4.4 years. There were 4 tapered patients with opioid overdoses (1.9%) and 36 non-tapered patients with opioid overdoses (3.2%), which did not reach statistical significance (OR 0.60, 95% CI 0.21-1.70). One overdose in the non-tapered group was fatal. Median dose change in the taper group was -73.6% versus +9.1% in the non-taper group; these were not significantly different in patients who experienced overdoses compared to those who did not.

CONCLUSIONS: In this sample of patients on COT, we found no statistical difference in opioid overdose over the course of 4 years of follow-up. However, the number of events detected was small and limited by ascertainment in only our hospital system. Nonetheless, our results are among the first to attempt to quantify the risk of opioid overdose after a taper. Further research should be conducted with larger sample sizes to ascertain a more accurate measure of prevalence of opioid overdose after a taper.

ASSESSMENT OF PATIENT NAVIGATION PROGRAMS ACROSS AN ENTIRE CITY

Amy LeClair[1]; Oluwabunmi Emidio[4]; Tracy A. Battaglia[2]; Nicole Casanova[2]; Jennifer Haas[3]; Karen Freund[1]; Stephenie Lemon[4]. [1]Department of Medicine, Tufts Medical Center, Boston, MA; [2]Medicine, Boston University Medical Center, Boston, MA; [3]Medicine, MGH, Boston, MA; [4]U Mass Medical School, Worcester, MA. (Control ID #3390623)

BACKGROUND: In Boston, Massachusetts, as in most other US cities, inequities in breast cancer mortality have persisted and increased among Black, non-Hispanic women compared to women of other racial/ethnic groups. Well documented systems issues contribute to disparities in breast cancer outcomes, including fragmented access, insurance coverage, and competing social barriers to care. Patient navigation is a widely cited systems-based approach to improving outcomes among under-served populations. Despite such programs existing in all major Boston hospitals, disparities have not been reduced. The objective of this study was to conduct a baseline assessment of navigation processes in six hospitals in preparation for a city-wide implementation trial of standardized navigation.

METHODS: A mixed methods approach was used to capture information from stakeholders who were directly involved in the oversight and/or implementation of breast cancer treatment-focused navigation programs in the six hospitals that provide the majority of treatment to breast cancer patients in Boston. These included patient navigators, their supervisors, and clinicians providing oncology care. Workflow assessments guided by a semi-structured interview guide were conducted in-person to understand site-specific implementation processes.

Interviews assessed dimensions such a staffing and administrative infrastructures and funding, navigation processes across treatment phases, navigation workflow, and barriers to the implementation of patient navigation programs. This project targeted providers from the six hospitals identified as providing treatment to the vast majority of patients with breast cancer in the City of Boston.

RESULTS: All of the hospitals offer patient navigation services to their patients undergoing treatment for breast cancer. Results indicate that the navigation programs at each hospital are heterogeneous in terms of who delivers navigation services, the type of services provided, and the timing of those services relative the patient's cancer treatment. There is heterogeneity across the sites with respect to phases of treatment during which navigation services are provided – with some starting at diagnosis, while others beginning only with chemotherapy, and different navigators for diagnostic care, surgical care and oncology care – and patients for whom these services are offered, with differing algorithms to identify women at risk of delays in care. Sites utilize both lay and/or professional navigators, who contact patients primarily through telephone at some sites versus in person at clinic visits at others. Navigators are funded through grants and/or hospital operating budgets.

CONCLUSIONS: While all hospitals offer navigation programs, services provided to patients varies widely within and across sites, with internal fragmentation of navigation services in each hospital. This may account for the lack of impact of navigation on breast cancer disparities.

ASSOCIATION BETWEEN ACUTE INPATIENT BED AVAILABILITY AND RISK OF SUICIDE FOR PSYCHIATRIC PATIENTS

Peter J. Kaboli[1]; Bjarni Haraldsson[1]; Joseph A. Simonetti[2]; M. Bryant Howren[3]; Michael Jones[4]; Nicholas Mohr[5]; Matthew R. Augustine[6]; Ranak Trivedi[7]. [1]Internal Medicine, Iowa City VA and University of Iowa, Iowa City, IA; [2]Hospital Medicine Program, VA Denver Medical Center, Denver, CO; [3]Center for Rural Health Research and Policy, Florida State University, Tallahassee, FL; [4]Biostatistics, University of Iowa College of Public Health, Iowa City, IA; [5]Emergency Medicine, Iowa City VA and University of Iowa, IOWA CITY, IA; [6]Internal Medicine, James J. Peters VA Medical Center, Bronx, NY, Bronx, NY; [7]Center for Innovation to Implementation/Psychiatry and Behavioral Sciences, VA Palo Alto Health Care System/Stanford University, Menlo Park, CA. (Control ID #3392670)

BACKGROUND: Lack of acute medical services (e.g., emergency department, intensive care unit) has been associated with adverse clinical outcomes, including mortality. The association between acute psychiatric inpatient beds and suicide has not been well described. In the Veterans Health Administration (VHA), suicide rates among veterans have increased despite mental health care investments. Our objective was to examine the relationship between veteran suicide risk and availability of acute inpatient psychiatric beds in VHA and the community, as well as other community and patient-level factors.

METHODS: Retrospective cohort study using VHA administrative data and publicly available data sources for Veterans enrolled in VHA primary care between Jan 2003 and Dec 2016. Data sources included the VHA Support Service Center (VHA inpatient psychiatric beds and occupancy rates), VHA Clinical Data Warehouse (patient-level factors), Area Health Resources Files (civilian inpatient psychiatric beds), State Mental Health Agency (county-level data on mental health spending), and the National Death Index Suicide Registry. Community-level analyses, including the hospital and surrounding area, were conducted using generalized linear mixed models with random intercepts for hospital, modeling number of suicides per quarter. VHA bed availability was categorized into quintiles from lowest to highest occupancy.

RESULTS: Of 10,119,845 Veterans identified, 26,105 (0.26%) died by suicide. From 2003 to 2016, the rate of veteran suicide increased while the number of acute mental health beds in VHA hospitals decreased, per 100,000. Compared to hospitals in the lowest occupancy quintile, rate ratio (RR) of suicide increased in quintile 2 (RR=1.13; 95% confidence interval [CI] 1.01-1.27), quintile 3 (RR=1.19; 95%CI 1.05-1.34), quintile 4 (RR=1.20; 95%CI 1.06-1.35), and quintile 5 (RR=1.24; 95%CI 1.10-1.41). Of the community-level contextual variables, lower suicide risk was observed for each additional 25 community psychiatric beds/100,000 population (RR=0.89; 95%CI 0.85-0.94) and each additional $50 spent on mental health per capita (RR=0.95; 95%CI 0.93-0.97).

CONCLUSIONS: Lack of acute inpatient psychiatric bed availability in VHA hospitals was associated with higher suicide risk, while additional community mental health investment was associated with lower suicide risk. This novel study used occupancy data and not just numbers of beds to assess the potential risk of bed availability and suicide. Future work should clarify optimal levels of bed availability and mental health spending to reduce suicide rates. Hospital occupancy, as a measure of access, should be considered with other performance metrics to ensure adequate access to acute care.

ASSOCIATION BETWEEN ACUTE KIDNEY INJURY AND SERUM PROCALCITONIN LEVEL

Mariam Charkviani[1]; Sumit Sohal[1]; Maria A. Yanez Bello[1]; Daniela P. Trelles[1]; Alisha Sharma[1]; Natia Murvelashvili[1]; Harvey J. Friedman[2]. [1]Internal Medicine, Amita Saint Francis Hospital, Evanston, IL; [2]Amita Saint Francis Hospital, Evanston, IL. (Control ID #3378776)

BACKGROUND: Bacterial infections are associated with increased morbidity and mortality in patients with renal failure. PCT can be used as a helpful adjunct to clinical judgment for resolving diagnostic uncertainty in patients with known or suspected bacterial infections. PCT is

barely detectable in serum under normal conditions, however, during systemic inflammatory response or bacterial infection, it is produced by various organs and released into the blood. Studies have shown that PCT levels are higher in patients with various degrees of kidney disease compared to a patient with no signs of renal impairment. Only limited data is available about the diagnostic value of serum PCT during bacterial infection in patients with acute kidney injury (AKI). This study aimed to assess the diagnostic usefulness of serum PCT as a marker of bacterial infection in patients with AKI and to assess the correlation of serum creatinine to serum PCT level.

METHODS: This retrospective case-control observational study involved all patients admitted to the hospital and had PCT checked during admission. Patients were categorized into three groups, patients with proven bacterial infection, no bacterial infection and possible bacterial infection. Proven bacterial infection was defined by positive blood, urine culture or PCR/cultures of respiratory tract secretion, no infection was defined by negative blood culture and no clinical suspicion of bacterial infection and possible infection was defined as negative cultures but clinical suspicion of bacterial infection based on clinical signs and radiologic studies. We compared serum PCT in patients with AKI and proven bacterial infection to patients with AKI and no bacterial infection and calculated the correlation between creatinine and PCT level. Patients with end- stage kidney disease and other causes of elevated PCT (pancreatitis, cancer, severe burns), were excluded from the study.

RESULTS: 197 were analyzed in the study, of which 152 patients met the inclusion criteria. 38 patients could be classified into "The AKI group" and 87 into the "non-AKI group"(n=125). There were 35 patients in the proven bacterial infection group. Patients with proven bacterial infections were found to have significantly higher mean serum PCT level 5.49±8.75 compared to patients with non-confirmed bacterial infection (1.79±4.88, $p<0.001$). PCT levels were significantly higher in the AKI group (10.99 ±12.24) than in the non-AKI group (2.39±2.93, $p>0.001$) in patients with a proven bacterial infection. Patients with no infection had much higher PCT levels in the AKI group as compared to the non-AKI group (5.76 ±14.67 vs 0.7±1.39, $p=0.003$). The study also showed that there is a weak positive correlation between creatinine and serum PCT level(0.125, $p=0.15$)

CONCLUSIONS: Higher cutoff levels of PCT are needed in patients with AKI to use it as a marker of infection. Specificity of PCT may decrease in patients in AKI if current reference cutoff values are used to guide clinical decisions

ASSOCIATION BETWEEN DIETARY QUALITY AND HOSPITAL UTILIZATION IN FOOD- INSECURE INDIVIDUALS

Jenny Jia[1]; Vicki Fung[2]; Anne N. Thorndike[1]. [1]General Medicine Division, Massachusetts General Hospital, Boston, MA; [2]Mongan Institute Health Policy Center, Massachusetts General Hospital, Boston, MA. (Control ID #3390544)

BACKGROUND: Food insecurity is linked to increased acute care utilization, but the role that dietary quality plays in the connection between food insecurity and adverse health outcomes is unclear. Using data on low-income participants of the National Health and Nutrition Examination Survey (NHANES), we studied whether food insecurity was associated with hospitalization and whether lower dietary quality was associated with increased hospital utilization in food-insecure individuals.

METHODS: We included non-pregnant adults (age≥18) with family income below 300% of the federal poverty level from NHANES 2009-2014. Participants in NHANES were assigned one of four household food security levels using the US Food Security Survey Module, which we recategorized as food-secure, marginally food-secure, and food-insecure. We examined whether food insecurity was associated with any self-reported hospitalization over the past 12 months using multiple logistic regression. Among food-insecure individuals, we assessed dietary quality using quartiles of participants' Healthy Eating Index-2015 (HEI) scores (Q1<38, Q2=38-46, Q3=47-55, Q4>55) calculated from 24-hour dietary recall data. We assessed whether HEI quartile was associated with hospital utilization using multiple logistic regression. Analyses were adjusted for age, sex, race/ethnicity, education level, health insurance, and family income and accounted for the complex survey design of NHANES.

RESULTS: The study sample included 11,707 adults, of whom 3,291 (weighted percentage, 24.8%) were food-insecure and 1,713 (13.6%) were marginally food-secure. In the past 12 months, 13.8% of food-insecure, 11.7% of marginally food-secure, and 11.5% of food-secure participants had been hospitalized. In multivariable analyses, food-insecure participants had higher odds of hospitalization (aOR=1.32, 95% CI: 1.09, 1.60) compared to food-secure participants. In the food-insecure group, individuals with the least healthy diets were more likely to be younger, non-Hispanic white, and have at least some high school education. Food-insecure participants with the least healthy diets (HEI Q1) had significantly higher odds of being hospitalized in the past 12 months (aOR=1.58, 95% CI: 1.07, 2.35) compared to those with the healthiest diets (HEI Q4). Individuals with intermediate dietary quality did not have significantly increased odds of hospitalization compared to those with the healthiest diets (HEI Q2 aOR=1.22, 95% CI: 0.81, 1.82; HEI Q3 aOR=1.21, 95% CI: 0.83, 1.77).

CONCLUSIONS: Food insecurity was associated with inpatient hospitalization among low-income NHANES participants. Among the food-insecure group, those with the least healthy diets were more likely to be hospitalized than those with the healthiest diets. Despite the limitations of cross-sectional data, these results suggest that community and healthcare efforts to improve health outcomes by addressing food insecurity should integrate education and resources to improve dietary quality.

ASSOCIATION BETWEEN EMERGENCY DEPARTMENT CROWDING AND PATIENT PERCEPTIONS OF INTERPERSONAL CARE

Nadia Liyanage-Don[1,2]; David S. Edelman[3,5]; Bernard Chang[4,2]; Katharina Schultebraucks[4,2]; Anusorn Thanataveerat[2]; Donald Edmondson[2]; Ian M. Kronish[1,2]. [1]General Internal Medicine, Columbia University Irving Medical Center, New York, NY; [2]Center for Behavioral Cardiovascular Health, Columbia University Irving Medical Center, New York, NY; [3]Vagelos College of Physicians and Surgeons, Columbia University, New York, NY; [4]Emergency Medicine, Columbia University Irving Medical Center, New York, NY; [5]Mailman School of Public Health, Columbia University, New York, NY. (Control ID #3387915)

BACKGROUND: Emergency department (ED) crowding has been associated with numerous healthcare issues, including treatment delays, medication errors, increased morbidity and mortality, and higher costs of care. Less is known about the impact of ED crowding on the psychosocial aspects of patient-physician interactions, or "interpersonal care". This includes clear and effective communication, responsiveness to patient needs, emotional support, and cultural sensitivity. We examined whether ED crowding as measured by the Emergency Department Work Index (EDWIN score) was associated with patient perceptions of interpersonal care among those presenting to the ED with suspected acute coronary syndrome (ACS).

METHODS: We enrolled a cohort of English- and Spanish-speaking patients presenting to an urban academic medical center ED with suspected ACS from 2014-2016. ED crowding was measured using the EDWIN score, a validated method that incorporates patient volume, triage category, physician staffing, and bed availability. Scores <1.5 indicate an active but manageable ED, 1.5-2 a busy ED, and >2 an overcrowded ED.

EDWIN score was calculated at the time of presentation and every hour thereafter to produce an "admission EDWIN score" and an "average EDWIN score" over the duration of a patient's ED visit. During the index admission, patients completed the 18-item short form Interpersonal Processes of Care (IPC) survey, which measures sub-domains of patient-physician communication, shared decision-making, and interpersonal style. IPC questions were asked in reference to patients' emergency care and answered on a 5-point Likert scale, with total scores <72 considered suboptimal. Linear regression was used to examine the association between EDWIN score and IPC score, adjusting for age, sex, race, ethnicity, education, health insurance status, depression, primary language, and patient-physician language concordance.

RESULTS: The 933 included subjects had a mean age of 60 (SD 13) years, 46% were women, 56% were Hispanic, and 48% were Spanish speakers. Mean EDWIN score at the time of admission was 1.37 (SD 0.51), while mean EDWIN score averaged over the entire ED visit was 1.50 (SD 0.39). Mean IPC score was 76.01 (SD 11.6, range 18-90). In linear regression models, higher EDWIN score on admission was associated with lower mean IPC score, even after adjusting for covariates (β = -1.58, p = 0.03). No significant associations were found between EDWIN score averaged over the entire ED visit and IPC score.

CONCLUSIONS: Our findings show that increased ED crowding at the time of presentation is associated with poorer patient perceptions of interpersonal care received in the ED. Ineffective patient-physician interactions often lead to decreased patient satisfaction with care, lower adherence to recommended therapy, and worse physical and psychological outcomes. In the hectic ED environment, improving both crowding and communication between patients and physicians may be effective strategies to address these quality issues.

ASSOCIATION BETWEEN LINGUISTIC ACCULTURATION AND CARDIOVASCULAR MEDICATION ADHERENCE AMONG HISPANICS

Nadia Liyanage-Don[1,2]; Talea Cornelius[2]; Emily Romero[2]; Carmela Alcantara[3]; Redeana Umland[2]; Siqin Ye[4,2]; Ian M. Kronish[1,2]. [1]General Internal Medicine, Columbia University Irving Medical Center, New York, NY; [2]Center for Behavioral Cardiovascular Health, Columbia University Irving Medical Center, New York, NY; [3]School of Social Work, Columbia University, New York, NY; [4]Cardiology, Columbia University Irving Medical Center, New York, NY. (Control ID #3375637)

BACKGROUND: Despite having a higher prevalence of cardiovascular disease (CVD) risk factors, Hispanics have lower rates of CVD-related and all-cause mortality as well as higher life expectancy compared to non-Hispanic whites – a phenomenon known as the "Hispanic health paradox." However, this survival benefit attenuates as Hispanics become increasingly acculturated to Western lifestyles, potentially due to the adoption of unhealthy behaviors. In this study, we examined whether greater linguistic acculturation as assessed by English proficiency was associated with lower electronically-measured adherence to cardiovascular medications among Hispanic patients presenting with suspected acute coronary syndrome (ACS).

METHODS: We enrolled a cohort of English- or Spanish-speaking patients presenting to an urban academic medical center emergency department with suspected ACS from 2014-2016. Patient ethnicity and native language were assessed through self-report. English proficiency was determined by asking those whose native language was Spanish to rate how well they spoke English on a 5-point Likert scale (from 1 = "very well" to 5 = "not at all"). Patients who were discharged on at least one CVD-related medication were asked to take that medication for one month post-hospitalization using an electronic pill bottle that recorded the date and time of each bottle opening. Medication adherence was defined as the percentage of monitored days with the correct number of bottle openings. Binary generalized estimating equations with a logit link were used to examine the association between Hispanic ethnicity, English proficiency, and odds of adherence to daily CVD medication, adjusting for age, sex, Charlson comorbidity index, discharge diagnosis (ACS or other), and dosing frequency of the monitored medication.

RESULTS: The 332 included subjects had a mean age of 62 (SD 12) years, 43% were women, and 63% were Hispanic. Among Hispanics, 80% identified Spanish as their native language. Mean English proficiency score among native Spanish-speakers was 3.79 (SD 1.25, range 1-5 with higher numbers indicating lower English proficiency). Overall, patients took their cardiovascular medications as prescribed on 75% of monitored days. Hispanics had significantly higher odds of medication adherence than non-Hispanics (adjusted OR 1.28, 95% CI 1.06-1.56, p = 0.01). Among native Spanish-speakers, increasing English proficiency was associated with lower odds of medication adherence (adjusted OR 0.81 per 1-point increase in English proficiency, 95% CI 0.76-0.87, p < 0.001).

CONCLUSIONS: While Hispanics generally had higher rates of medication adherence than non-Hispanics, among native Spanish-speakers, greater linguistic acculturation was associated with lower medication adherence. Non-adherence to recommended medical therapy is therefore one plausible mechanism that may help to explain the observed worsening of cardiovascular outcomes among Hispanics as they become increasingly acculturated to living in the United States.

ASSOCIATION BETWEEN MILD COGNITIVE IMPAIRMENT AND SELF-REPORTED MEDICATION ADHERENCE AMONG BLACK BELT AFRICAN AMERICANS WITH PERSISTENTLY UNCONTROLLED HYPERTENSION

Sunidhi Singh[1]; Joanna Bryan[2]; Elizabeth Baquero[2]; Monika M. Safford[2]. [1]Weill Medical College, New York, NJ; [2]Department of Medicine, Weill Cornell Medical College, New York, NY. (Control ID #3391599)

BACKGROUND: The southeastern US includes predominately African American communities with high prevalence of hypertension (HTN), contributing to cognitive impairment and dementia. Even mild cognitive impairment (MCI) may increase risk for medication nonadherence, which requires numerous cognitive processes. We investigated the relationship between MCI and self-reported barriers to medication adherence among enrollees in the NHLBI-funded *Southeastern Collaboration to Improve Blood Pressure (BP) Control (SEC) Trial* in an effort to understand the complexity behind persistently uncontrolled HTN.

METHODS: The ongoing SEC Trial is enrolling African American Black Belt residents with persistently elevated HTN to test two strategies to improve BP control - practice facilitation and peer coaching. Patients with diagnosed dementia are excluded. In this observational cross-sectional analysis, the exposure was MCI (missing 3+ questions on the validated Six Item Screener). [MMS1] Candidate outcomes were 15 self-reported barriers to medication adherence; sometimes, often, or very often reporting trouble indicated the presence of a barrier. Barriers associated with MCI with bivariate p<0.10 were included in a count variable.

The association between the count and MCI was examined using ordinal logistic regression, adjusting for sociodemographics, mental and physical functioning, social isolation, and total number of medications. Limitations: This is a sample from a trial population in a rural Southeastern US region, possibly impacting generalizability. The study was underpowered to detect potentially important differences in SBP.

RESULTS: We studied 1,061 patients; 51 (5%) had MCI. Mean age was 58 years and 60% were women. Patients with MCI were more likely to be

older, male, less educated, impoverished, socially isolated, have lower mental functioning, and have nonsignificantly higher mean SBP (159 mm Hg) compared with participants without MCI (156 mm Hg, p=0.26). Overall, 64% reported 1+ barrier to medication adherence, and 22% reported 3+. The most common barriers were forgetting to fill prescriptions on time (33%) and not being able to afford medications (26%). For barriers included in the count variable, patients with MCI reported on average 2.0 barriers and those without MCI reported 1.2 (p<0.01). After full adjustment, compared to the odds of having a given number of barriers among those without MCI, MCI was associated with 273% greater odds of reporting more medication adherence barriers (proportional OR 2.73, 95% CI 1.54-4.87).

CONCLUSIONS: MCI was an independent risk factor for reporting more barriers to medication adherence in this sample. Since none of these patients carried a diagnosis of dementia, systematic screening using the Six Item Screener in primary care could identify hypertensive individuals in need of additional assistance with medication adherence to help them achieve lower BP levels, thereby decreasing their risk for progression to dementia.

ASSOCIATION BETWEEN NON-VITAMIN K ORAL ANTICOAGULANT COPAYMENT AND ADHERENCE IN ATRIAL FIBRILLATION: A REAL-WORLD COHORT STUDY

Benjamin N. Rome[1,2]; Joshua J. Gagne[1,2]; Jerry Avorn[1,2]; Aaron S. Kesselheim[1,2]. [1]Program On Regulation, Therapeutics, And Law, Division of Pharmacoepidemiology and Pharmacoeconomics, Department of Medicine, Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA. (Control ID #3387104)

BACKGROUND: Among patients with atrial fibrillation, adherence to non-vitamin K oral anticoagulants (NOACs) is suboptimal, leading to increased risk of stroke. NOACs are expensive, and high out-of-pocket costs have been associated with lower adherence in other conditions. We evaluated whether higher copayments are associated with lower NOAC adherence.

METHODS: Using claims data from a large national insurer of commercial and Medicare Advantage patients (Optum Clinformatics DataMart), we performed a cohort study of patients with atrial fibrillation (and no other indication for anticoagulation) who newly initiated a NOAC in 2012–2017. Patients were required to have ≥6 months of available data prior to NOAC initiation to assess exclusion criteria and covariates. Medicare patients with a low-income subsidy were excluded. The exposure studied was the level of copayment for the first NOAC prescription, standardized to a 30-day supply. Patients were divided at the median into low (≤$45) versus high (>$45) copayments, and groups were 1:1 propensity-score matched based on demographics, insurance characteristics, comorbidities, prior health care utilization, calendar year, and which NOAC patients received. Patients were followed for one year, or until switching to a different anticoagulant, undergoing an ablation procedure, disenrolling from the insurance plan, or death. The primary outcome was adherence, measured by proportion of days covered (PDC). Secondary outcomes included NOAC discontinuation (no refill for 30 days) and switching anticoagulants (prescription for a different NOAC, warfarin, or low-molecular-weight heparin). In the matched cohort, we compared PDC using Wilcoxon rank-sum test and rates of discontinuation and switching using Cox proportional hazards regression.

RESULTS: We matched 63,574 patients between the two copayment groups, achieving balance across 50 clinical and demographic covariates (standardized differences <0.1). Apixaban (54%) and rivaroxaban (33%) were the most commonly used NOACs, and 71% of patients were in Medicare Advantage plans. Adherence was lower in patients who had high copayments (median PDC 0.81, interquartile range [IQR] 0.44-0.97) than in those with low copayments (median 0.87, IQR 0.52-0.98; p <0.001). Patients with high copayments also had higher rates of discontinuation (hazard ratio [HR] 1.23, 95% confidence interval [CI] 1.20-1.25) and switching to a different anticoagulant (HR 1.21, 95% CI 1.15-1.28). Results were similar among Medicare and commercially-insured patients.

CONCLUSIONS: Higher copayments were associated with lower NOAC adherence and higher rates of discontinuation. Patients with atrial fibrillation who do not adhere to oral anticoagulation are at higher risk of stroke. Policies to lower or cap cost-sharing of important medications may lead to improved adherence and better patient outcomes.

ASSOCIATION BETWEEN POST-HOSPITAL FOLLOW-UP VISITS WITH A PRIMARY CARE PROVIDER AND 30- AND 90-DAY HOSPITAL READMISSIONS

Noah Kojima[1]; Marielle Bolano[2]; Andrea Sorensen[1]; Chad Villaflores[1]; Keara Darragh[1]; Catherine Sarkisian[3]. [1]Medicine, David Geffen School of Medicine at University of California Los Angeles, Los Angeles, CA; [2]Internal Medicine, University of California, Los Angeles, Los Angeles, CA; [3]Medicine, UCLA and Greater Los Angeles VA, Los Angeles, CA. (Control ID #3392222)

BACKGROUND: Hospital readmissions are a major source of national healthcare expenditures. Many health systems encourage post-hospital primary care provider (PCP) visits, but the literature is mixed as to whether this reduces hospital readmissions. Our study evaluated the association between 7- and 14-day PCP visits and 30- and 90-day hospital readmissions in adult patients within a health system.

METHODS: We performed a retrospective cohort study of patients in a healthcare system located in Los Angeles, CA. Electronic health records of patients hospitalized from January 2016 to November 2019 were evaluated. Adults (age ≥ 18 years) who were discharged home were included. Demographic and clinical characteristics were compiled. Logistic regression models were used to estimate odds ratios (OR) with 95% confidence intervals [95%CI] for readmissions within 30- and 90-days of discharge. The primary predictors were a PCP visit within 7- and 14-days of discharge. In both models we adjusted for sex, age, and number of chronic conditions.

RESULTS: We identified 10,038 patients who met the study inclusion criteria. The median patient age was 70 years (interquartile range: 57, 81);5,806 (57.8%) patients were female, and 8,209 (81.9%) were Caucasian. Overall, 1,922 (18.6%) had a 7-day PCP visit, 2,776 (40.8%) had a 14-day PCP visit, and 7,262 (72.4%) did not see a PCP within 14 days of discharge. The unadjusted OR of readmission for patients with a 7-day PCP visit, versus no 7-day PCP visit, was 0.69, 95%CI: 0.60-0.79, within 30 days of discharge, and 0.67, 95%CI: 0.60-0.76, within 90 days of discharge. The unadjusted OR of hospital readmission for patients with a 14-day PCP visit, versus no 14-day PCP visit, was 0.67, 95%CI: 0.60-0.76, within 30 days of discharge, and 0.70, 95%CI: 0.63-0.77, within 90 days of discharge. The adjusted OR of hospital readmission for patients with a 7-day PCP visit, versus no 7-day PCP visit, was 0.72, 95%CI: 0.63-0.83, within 30 days of discharge, and 0.74, 95%CI: 0.67-0.82, within 90 days of discharge. The adjusted OR of hospital readmission for patients with a 14-day PCP visit, versus no 14-day PCP visit, was 0.70, 95%CI: 0.62-0.79, within 30 days of discharge and 0.76, 95%CI: 0.69-0.83, at 90 days of discharge.

CONCLUSIONS: Most patients in this study did not follow-up with a PCP within 14 days after hospital discharge. Post-discharge PCP visits within 7- and 14-days were associated with a lower likelihood readmission within 30- or 90-days of discharge. Limitations of this study include unmeasured potentially confounding variables such as markers of sickness preventing ability to get to a PCP visit. Despite this limitation, with low rates of PCP visits observed within 7- and 14-days of discharge, a

large cohort of patients might benefit from efforts to increase early post-discharge PCP visits. Randomized trials should be conducted to determine whether patient utilization of early post-discharge PCP visits might benefit patients and reduce healthcare expenditure.

ASSOCIATION BETWEEN POST-SKILLED NURSING HOME STAY FOLLOW-UP VISITS WITH A PRIMARY CARE PROVIDER AND 30 DAY HOSPITAL READMISSIONS

Marielle Bolano[1]; Noah Kojima[1]; Andrea Sorensen[2]; Chad Villaflores[2]; Catherine Sarkisian[3]. [1]Internal Medicine, University of California, Los Angeles, Los Angeles, CA; [2]Medicine, University of California, Los Angeles, Los Angeles, CA; [3]Medicine, UCLA and Greater Los Angeles VA, Los Angeles, CA. (Control ID #3390722)

BACKGROUND: Previous research suggests that timely post-discharge follow-up with a primary care provider (PCP) after a hospital admission may reduce readmission risk. Hypothesized reasons include improving transition of care by reconciling medications and reviewing discharge plans. Patients who were discharged to skilled nursing facilities (SNFs) are largely excluded from these studies.

Patients discharged to a SNF are typically more vulnerable, exhibit greater medical complexity, and thus may be at heightened risk for readmission. If PCP follow up after discharge from a SNF also mitigates risk reduction for readmissions, this could be a powerful mechanism for preventing readmissions.

This study examines demographic, clinical characteristics and 30-day readmission rates for patients successfully connected with a PCP within 7 and 14 days of discharge from a SNF compared to patients who did not.

METHODS: This is a retrospective cohort study of hospital readmissions following discharge from SNFs affiliated with an academic center in Los Angeles between January 2016 and November 2019. We examined unadjusted correlations between having a PCP visit and 30-day readmission rate. We used a multivariate logistic regression model to estimate the adjusted odds ratio of a patient experiencing a 30-day hospital readmission for patients who did and did not have a PCP visit following their SNF discharge. Our covariates included age, sex, and number of chronic conditions (as defined by Centers for Medicare and Medicaid Chronic Conditions Data Warehouse).

RESULTS: There were 1,648 patients discharged during the study period. Of these, 1,083 (65%) were female and the median age was 88 (IQR 73,88). With respect to our main outcome of interest, 183 (11%) had a primary care visit within 7 days and 309 (19%) had a primary care visit within 14 days. Overall rates of hospital readmission were 28% for those who did not see a PCP and 13% for those who saw a PCP within 14 days. Compared to those who did not see a PCP, the adjusted odds ratio of hospital readmission within 30 days of discharge were lower for patients who saw a PCP within 7 days of discharge from SNF (OR 0.55, 95% CI 0.36-0.85, p=0.01) as well as patients who saw a PCP within 14 days of discharge from SNF (OR 0.39, 95% CI 0.27-0.56, p< 0.01).

CONCLUSIONS: We found that patients discharged from SNFs who see a PCP within 7 or 14 days of discharge have lower likelihood of experiencing a 30-day hospital readmission compared with similar patients who do not. Though we adjusted for patient demographics and comorbidities in our models, it is possible that coming to a PCP visit is a proxy for better health status. It is also possible that when a PCP sees a patient soon after a SNF visit, the PCP provides important care that prevents readmission. Many health systems have institutional mechanisms to identify patients with recent hospital discharges and connect them with PCPs; this study suggests such interventions could be beneficial for patients leaving SNFs.

ASSOCIATION OF A SHARED MEDICAL APPOINTMENT PROGRAM FOCUSED ON NUTRITION AND LIFESTYLE INTERVENTIONS WITH PATIENT-REPORTED HEALTH- RELATED QUALITY OF LIFE AND BIOMETRIC OUTCOMES

Michelle Beidelschies[1]; Marilyn Alejandro-Rodriguez[1]; Ning Guo[3]; Alex Milinovich[3]; Anna Postan[1]; Michael B. Rothberg[2]. [1]Center for Functional Medicine, Cleveland Clinic, Medina, OH; [2]Internal Medicine, Cleveland Clinic, Cleveland, OH; [3]Quantitative Health Services, Cleveland Clinic, Cleveland, OH. (Control ID #3389437)

BACKGROUND: A growing number of Americans has one or more chronic conditions associated with lifestyle. Shared medical appointments (SMAs) offer a promising strategy to deliver sustainable care and education needed to regress or prevent chronic disease. Functioning for Life (FFL) is a 10-week SMA program focused on providing nutrition, lifestyle and behavioral health education and interventions to patients with various chronic conditions, and is led by a multi-disciplinary team of caregivers (a medical provider (MD/DO/PA/NP), dietitian and health coach). Our objective was to investigate the association of the FFL program with changes in health-related quality of life (HRQoL) and biometrics.

METHODS: A single-center, retrospective study was conducted to evaluate changes in HRQoL and biometrics for patients participating in the FFL program. HRQoL was measured using PROMIS Scale v1.2 Global Health (PROMIS GH), a set of self-administered, psychometrically validated questions that measure physical, mental, and social health. Patients were eligible if they were ≥18 years-old and participated in the FFL program between September, 2017 and February, 2019. Patients also had to have a baseline PROMIS Global Physical Health (GPH) score and a follow-up score at 10 weeks (±1 week). PROMIS T-scores have a mean of 50 and standard deviation of 10; changes of 5 points suggest a clinically important change. The primary outcome was change in PROMIS GPH scores from baseline to 10 weeks. Secondary outcomes included change in PROMIS Global Mental Health (GMH) scores, weight, systolic and diastolic blood pressure. Baseline and 10-week PROMIS GH scores, weight, BMI, systolic and diastolic blood pressure were compared using paired t-test.

RESULTS: In total, 284 patients were included. Mean age was 49.4±12.8, 83.0% were female and 85.2% were Caucasian. About 98% of patients attended more than half of the weekly sessions, 88% attended 7, and 35% attended all 10. At 10 weeks, patients had a significant improvement in their PROMIS GPH scores (from 45.6±7.3 at baseline to 49.3±7.0, p<0.001) with 38.7% improving their score by 5+ points or more. Similarly, patients experienced a significant improvement in their PROMIS GMH scores (from 45.6 ±8.5 at baseline to 49.1±7.8, p<0.001) with 36.6% improving their score by 5+ points or more. Patients also experienced a mean weight loss of 7.8 pounds (p<0.001 vs. baseline) and systolic blood pressure change of 6.1 points (p<0.001 vs. baseline).

CONCLUSIONS: The FFL program offers a promising strategy to deliver sustainable lifestyle intervention for patients with chronic disease, and could serve as a solution for the delivery of nutrition and lifestyle recommendations which are notoriously difficult to integrate into standard primary care. Future studies are currently underway to examine longitudinal changes in HRQoL, biometrics and cost.

ASSOCIATION OF FLUOROQUINOLONES OR CEPHALOSPORINS WITH CLOSTRIDIOIDES DIFFICILE INFECTION AFTER EMPIRIC TREATMENT FOR COMMUNITY-ACQUIRED PNEUMONIA

Abhishek Deshpande[1]; Preethi Patel[2]; Pei-Chun Yu[4]; Peter B. Imrey[4]; Michael B. Rothberg[3]. [1]Medicine, Cleveland Clinic, Cleveland, OH; [2]Hospital Medicine, Cleveland Clinic, Cleveland, OH; [3]Internal Medicine, Cleveland Clinic, Cleveland, OH; [4]Quantitative Health Sciences, Cleveland Clinic, Cleveland, OH. (Control ID #3391677)

BACKGROUND: *Clostridioides difficile* infection (CDI) is the most common cause of antibiotic-associated diarrhea and its incidence has increased exponentially in the last decade. Treatment with certain antibiotics has been identified as an important risk factor for CDI, and community-acquired pneumonia (CAP) is the most commonly treated infection in the hospital setting. Current Infectious Diseases Society of America (IDSA) guidelines recommend empiric antibiotic therapy with either a respiratory fluoroquinolone or a combination of a beta lactam with a macrolide, but the comparative risk of CDI with either regimen is unknown. The aim of this study was to compare the incidence of CDI in patients treated with either of these two empiric regimens.

METHODS: We conducted a large retrospective cohort analysis using the Premier Healthcare Database from 2010 – 2015 at 175 hospitals in the United States. We included adults who had both an ICD-9 diagnosis code for pneumonia as principal diagnosis (or as a secondary diagnosis paired with a principal diagnosis of respiratory failure or sepsis), and received at least 3 days of either empiric therapy. Patients receiving other antibiotics in the first 3 days were excluded. Hospital-acquired CDI was defined as a presence of a diagnosis billing code not present on admission and a positive laboratory test for CDI at or after hospital day 4. Multivariate logistic regression analysis was conducted to determine the association between antibiotic regimen in the first 3 hospital days and CDI, adjusted for known CDI risk factors (age, immunosuppression, hospitalization in the past 3 months, NSAIDS and acid-suppressive therapy, ICU admission, on dialysis and combined comorbidity score). Sensitivity analysis (fluoroquinolones vs. cephalosporins plus macrolides) was also performed with CDI being defined either by the presence of a diagnosis billing code not present on admission or a positive laboratory test for CDI at or after hospital day 4.

RESULTS: Our sample included 58,884 eligible patients treated with either cephalosporin plus macrolide (37,358 patients) or a quinolone (21,526 patients). A total of 136 patients (0.23%) developed hospital-acquired CDI, 93 (0.25 %) patients who received cephalosporin plus macrolide and 43 (0.20%) patients who received a fluoroquinolone. After adjustment for patient demographics, co-morbidities and risk factors, the risk of CDI was similar for fluoroquinolones vs. cephalosporins plus macrolides (Odds ratio [OR] =0.81, 95% CI 0.56-1.16). The risk for CDI was also similar for fluoroquinolones vs. cephalosporins plus macrolides on sensitivity analysis (OR=0.86, 95% CI 0.64-1.15).

CONCLUSIONS: Among patients with CAP at US hospitals, CDI occurred in approximately 0.25% of patients, a relatively uncommon complication. Risk of CDI was unaffected by choice of the initial guideline recommended therapy for CAP.

ASSOCIATION OF HIGH-DEDUCTIBLE HEALTH PLAN ENROLLMENT WITH ADVANCED BREAST CANCER PRESENTATION

James F. Wharam[1]; Fang Zhang[2]; Craig C. Earle[3]; Christine Lu[4]; Larissa Nekhlyudov[5]; Stephen B. Soumerai[6]; Hefei Wen[4]; Anita Wagner[4]; Dennis Ross-Degnan[7]. [1]Population Medicine, Harvard Medical School and Harvard Pilgrim Healthcare, Boston, MA; [2]Department of Population Medicine, Harvard Pilgrim Health care Institute, Boston, MA; [3]Medicine, University of Toronto, Toronto, ON, Canada; [4]Department of Population Medicine, Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, MA; [5]Internal Medicine, Brigham & Women's Hospital, Boston, MA; [6]Department of Population Medicine, Harvard Medical School, Boston, MA; [7]Population Medicine, Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, MA. (Control ID #3379406)

BACKGROUND: High-deductible health plans (HDHP) require large out-of-pocket payments, including for cancer diagnosis and treatment. HDHPs are associated with delays in breast cancer diagnosis of up to 8 months, but effects on cancer outcomes are unknown. We hypothesized that, compared with women in generous health plans, HDHP members would present with more advanced breast cancer and experience higher total costs in the 90 days after incident diagnosis.

METHODS: We studied 2004-2014 data in a large commercial and Medicare Advantage claims database. We included women aged 50-64 who were in traditional low-deductible (≤$500) health plans for 1 baseline year and then experienced either an employer-mandated switch to HDHPs (≥$1000) or an employer- mandated continuation in low-deductible plans. The index date was the HDHP switch date or, among potential controls, a randomly chosen "anniversary date" (annual insurance renewal date). We then restricted the study sample to women who developed incident breast cancer up to 10 years after the index date and classified them as low or high income based on neighborhood poverty level. Using baseline characteristics and stratifying by low- and high-income, we closely matched HDHP members to contemporaneous low- deductible members. Outcomes included (1) the percentage of women with incident breast cancer who had *de novo* metastatic disease and (2) total health care costs in the 90 days after incident diagnosis (a proxy for intensity of services in the post-diagnosis period). The cost variable was standardized across time and geography. To estimate differences between HDHP and control members, we used logistic regression to model the percentage with *de novo* metastatic disease and negative binomial regression to model 90-day total costs, adjusting for multiple baseline characteristics.

RESULTS: Our study sample included 751 HDHP members and 2777 matched controls. 4.4% of low- income HDHP members presented with *de novo* metastatic breast cancer versus 1.8% of low-income controls, an absolute difference of 2.6% (p=0.035). Total 90-day costs after incident breast cancer diagnosis were $42,883 among low-income HDHP members and $37,869 among low-income controls, an absolute difference of $5,014 (p=0.013). We did not detect statistically significant differences in study outcomes between high-income HDHP and high-income control members.

CONCLUSIONS: Low-income HDHP members had a substantially higher risk of presenting with advanced-stage breast cancer than similar members in low-deductible plans, and higher post-diagnosis total health care costs. Reducing financial barriers to breast cancer diagnosis among low-income HDHP members might improve breast cancer outcomes and costs.

ASSOCIATION OF MARIJUANA USE WITH RECEIPT OF PREVENTIVE CARE AND HEALTH BEHAVIORS

Emily Lum[1]; Sri Lekha Tummalapalli[2]; Meena Khare[1]; Salomeh Keyhani[2]. [1]Population Health and Policy Research Group, Northern California Institute for Research and Education, San Francisco, CA; [2]Medicine, University of California at San Francisco, San Francisco, CA. (Control ID #3391671)

BACKGROUND: There are conflicting reports on the effects of marijuana use on health behaviors with some studies suggesting that marijuana

use was associated with decreased use of other substances and other studies suggesting increased use. In addition, it is unknown whether receipt of preventive care delivery among users is different from non-users.

METHODS: Using the Behavioral Risk Factor Surveillance System, an annual telephone survey administered to over 500,000 US adults, we identified individuals who were eligible to receive 13 different preventive services including influenza, pneumonia, tetanus, and HPV vaccinations, serum cholesterol and blood glucose screening, alcohol use and HIV screening, as well as HbA1c screening and foot and eye examinations among respondents with diabetes. Using logistic regression, we examined whether users were less likely to receive preventive care services after adjusting for age, sex, race/ethnicity, employment, education, and marital status. We also examined the association of current marijuana use with other health behaviors including tobacco and alcohol use after adjusting for baseline characteristics.

RESULTS: Among 45,655,241 participants in 2017, 10.7% reported marijuana use in the past 30 days with 69.3% of current users, using it daily. Smoking was the most common method of use (90.4%). Compared to non-users, users were more often younger, male, high school graduates, and employed. After adjusting for baseline characteristics, users were less likely than non-users to have received an influenza vaccine in the past year (AOR=0.65, 95% CI=0.53-0.81) or to be screened for diabetes in the past 5 years (AOR=0.82, 95% CI=0.69-0.99). Users were more likely to be screened for alcohol use (AOR=1.6, 95% CI=1.1-2.5) and HIV (AOR=2.7, 95% CI=1.7-4.3) than non-users. There was no difference between marijuana users and non-users in the receipt of other services. After adjusting for baseline characteristics, compared to non-users, marijuana users were significantly more likely to currently smoke tobacco (AOR=3.1, 95% CI=2.5-3.9), use electronic nicotine vaping products (AOR=2.8, 95% CI 2.0-3.8), or use smokeless tobacco (4.6% vs 2.8%, p<0.008). Respondents who used marijuana were more likely to have had at least 1 alcoholic beverage in the past month (AOR=3.6, 95% CI=2.9-4.5) compared to non-users. Furthermore, risk adjusted analysis demonstrated that users were almost three times (AOR=2.9, 95% CI=2.4-3.6) as likely to binge drink in the past month compared to respondents who did not use marijuana.

CONCLUSIONS: Marijuana users were less likely to receive preventive services, such as influenza vaccination and diabetic screening but were more likely to be screened for high risk behaviors. Users were more likely to use other substances, such as tobacco and alcohol and engage in binge drinking. Current users may need more targeted care to ensure they receive needed preventive services and substance cessation counseling.

ASSOCIATION OF PATIENT ACTIVATION WITH BLOOD PRESSURE CONTROL IN AFRICAN AMERICAN PATIENTS

Courtney R. Lee, Carol Horowitz. Internal Medicine, Icahn School of Medicine at Mount Sinai Hospital, New York, NY. (Control ID #3371261)

BACKGROUND: To assess whether patient activation is associated with blood pressure control amongst participants of African ancestry.

METHODS: A secondary analysis of prospectively collected data from the Genetic testing to Understand and Address Renal Disease Disparities (GUARDD) Trial. Study included 2,050 hypertensive patients of African ancestry receiving primary care in 15 academic, community, and safety-net practices in New York City. Patients were eligible if they self-identified as having African ancestry, age 18-70 years, received primary care from a participating clinic site, and had hypertension defined as two of three criteria: an ICD-9 diagnosis of hypertension, taking anti-hypertensive medications, or two systolic blood pressure (BP) readings >140mmHg at least six months apart. Exclusion criteria included diabetes, chronic kidney disease pregnancy, non-English speaking, presence of cognitive impairment, and not community dwelling. The primary outcome was systolic BP control (<140mmHg). Logistic regression evaluated the association between the patient activation measure (PAM) and BP control after controlling for selected characteristics.

RESULTS: The mean age was 53 years (SD±10); 66% were female, the mean systolic BP was 134 mmHg (SD±20) and the mean diastolic BP was 85mmHg (SD±12). The mean PAM score was 68 (SD±83). Low patient activation (PAM level 1 and 2) was associated with lower odds of blood pressure control (unadjusted odd ratio [OR], 0.81 [95% CI, 0.67-0.98]; p=0.02). After adjusting for gender, education, and income, there was no significant association between low PAM and odds of BP control (adjusted OR, 0.84, [95% CI 0.68-1.02]; p=0.08). When assessing for a dose-dependent association, the odds of blood pressure control did not increase with higher patient activation levels (Table1).

CONCLUSIONS: Among patients of African ancestry, patient activation was not associated with better blood pressure control after adjusting for selected patient characteristics. Further research would be needed to assess whether patient engagement is an effective strategy to improve hypertension in this patient population.

ASSOCIATION OF PATTERNS OF MULTIMORBIDITY WITH LENGTH OF STAY: A MULTINATIONAL OBSERVATIONAL STUDY

(Control ID #3385983)

BACKGROUND: Multimorbidity is very prevalent and associated with length of stay (LOS). However, we lack data on which combinations of chronic comorbidities are associated with LOS. Since interventions could shorten LOS, it is important to better understand the associated risk factors.

METHODS: We used a multinational retrospective cohort of 126828 medical inpatients with multimorbidity (i.e. ≥2 chronic diseases). We classified the chronic diseases into categories of comorbidities using the Clinical Classification Software. We described the combinations of co-morbidities most strongly associated with prolonged LOS (≥ country-specific average LOS) and reported the difference in median LOS for

those combinations. We also assessed the association between number of chronic diseases or of body systems and prolonged LOS.

RESULTS: The strongest association with LOS (OR 7.25, 95%CI 6.64-7.91) and the highest difference in median LOS (13 days, 95%CI 12.8-13.2) were found for diseases of white blood cells combined with hematological malignancy (Table). Other comorbidities in the top combinations included mostly neurological disorders and chronic ulcer of skin with ORs between 2.37 and 3.65 and a difference in median LOS of 2-5 days ($p < 0.001$ for all). LOS was associated with the number of chronic diseases and of body systems (≥7 body systems (N=11,423): OR 21.50, 95%CI 19.94-23.18).

CONCLUSIONS: LOS was strongly associated with specific combinations of comorbidities and particularly with the number of body systems. Describing patterns of multimorbidity associated with LOS may help hospitals anticipate resource utilization and judiciously allocate services.

Comorbidity 1	Comorbidity 2	OR (95%CI)	Difference in median LOS (days) (95%CI)	Attributable LOS (days)
Diseases of white blood cells	Hematological malignancy	7.25 (6.64-7.81)	13.0 (12.8-13.2)	29,744
Diseases of white blood cells	Other nervous system disorders	3.65 (3.22-4.15)	4.0 (3.6-4.4)	3,764
Paralysis	Other nervous system disorders	3.28 (2.89-3.72)	4.0 (3.6-4.4)	3,832
paralysis	Cerebrovascular disease	3.08 (2.80-34.0)	5.0 (4.7-5.3)	8,450
Cerebrovascular disease	Other nervous system disorders	2.99 (2.68-3.34)	3.0 (2.7-3.3)	3,681
Paralysis	Chronic heart disease	2.92 (264-3.23)	4.0 (3.7-4.3)	5,864
Diseases of white blood cells	Chronic heart disease	2.91 (2.67-3,17)	3.0 (2.8-3.3)	6,108
Diseases of white blood cells	Esophageal disorders	2.84 (2.52-3.20)	3.0 (2.6-3.4)	3,033
Chronic ulcer of skin	Chronic heart disease	2.74 (2.55-2.93)	3.0 (2.9-3.2)	10,248
Chronic ulcer of Skin	Chronic kidney disease	2.62 (2.39-2.87)	3.0 (2.8-3.3)	5,564
Chronic ulcer of skin	Arthropathy and arthritis	2.62 (2.38-2.88)	3.0 (2.7-3.3)	4,986
Hematological malignancy	Chronic heart disease	2.57 (2.37-2.79)	2.0 (1.8-2.2)	4,636
Diseases of white blood cells	Mood disorders	2.54 (2.25-2.86)	2.0 (1.6-2.4)	1,948
Chronic ulcer of skin	Paralysis	2.54 (2.20-2.92)	3.0 (2.6-3.4)	2,118
Chronic ulcer of skin	Solid malignancy	2.51 (2.17-2.90)	3.0 (2.6-3.4)	1,986
Diseases of white blood cells	Chronic kidney disease	2.47 (2.15-2.85)	2.0 (1.6-2.4)	1,424
Chronic ulcer of skin	Other nervous system disorders	2.46 (2.22-2.71)	3.0 (2.7-3.3)	4,866
Chronic ulcer of skin	Chronic obstructive pulmonary disease and bronchiectasis	2.43 (2.15-2.74)	2.0 (1.6-2.4)	1,906
Chronic ulcer of skin	Peripheral and visceral atherosclerosis	2.41 (2.17-2.79)	2.0 (1.6-2.4)	1,280
Chronic kidney disease	Cerebrovascular disease	2.37 (2.07-2.72)	3.0 (2.6-3.4)	2,592

ASSOCIATION OF PROVIDER SPECIALTY WITH PROCEDURAL-RELATED MORBIDITY AND ADVERSE EVENTS AMONG PATIENTS UNDERGOING SURGICAL AND MEDICATION ABORTIONS

Dolly Patel[1]; Sarah Roberts[2]; Doug Leslie[1]; Guodong Liu[1]; Carol Weisman[1]; Cynthia Chuang[1]. [1]Pennsylvania State College of Medicine, Hershey, PA; [2]University of California San Francisco School of Medicine, San Francisco, CA. (Control ID #3378082)

BACKGROUND: Since *Roe v. Wade* legalized abortion in the U.S. in 1973, states have passed numerous restrictive abortion policies. In Mississippi, state law requires all abortions be performed exclusively by obstetrician-gynecologists (OBGYNs). In South Carolina, OBGYNs are required to perform all abortions after 14 weeks gestation. One rationale for such policies is to ensure the safety of abortion care, however there are no current data comparing abortion outcomes by physician specialty. To further understand if abortion safety differs by physician specialty, we used a large, national claims database to compare abortion- related morbidities and adverse events in abortions performed by OBGYNs vs. physicians of other specialties.

METHODS: Using the Truven Health MarketScan claims database, we identified privately insured women who had an induced abortion between January 1, 2011 and December 31, 2014. The sample was limited to abortions provided by OBGYNs and physicians of other specialties. The primary outcome was abortion-related morbidity and adverse events occurring within 6 weeks of the abortion, including retained products of conception, abortion-related infection, hemorrhage, and uterine perforation. Control variables included patient age, abortion type (medication, first trimester aspiration, second trimester or later), Elixhauser Comorbidity Index, U.S. census region, and year.

RESULTS: There were 42,770 abortions completed during the study timeframe; 30,564 (71.5%) abortions were provided by OBGYNs and 12,206 (28.5%) abortions were provided by physicians of other specialties. In unadjusted analyses, abortion-related morbidity or adverse events occurred in 3.6% of abortions provided by OBGYNs compared with 3.2% of abortions provided by physicians of other specialties. In adjusted analyses, there was no statistically significant difference in abortion-related morbidity or adverse events comparing physicians of other specialties vs. OBGYNs (adjusted OR 0.89, 95% CI 0.78-1.01).

CONCLUSIONS: Among privately insured women having abortions, there was no statistically significant difference in morbidity or adverse events when provided by OBGYN vs. physicians of other specialties. Our findings do not support state laws that have prohibited physicians of other specialties from performing abortions.

ASSOCIATION OF TIME OF DAY WITH DELAYS IN ANTIBIOTIC INITIATION AMONG WARD PATIENTS WITH HOSPITAL-ACQUIRED SEPSIS

Rachel Kohn[1,2]; Jennifer C. Ginestra[1,2]; Rebecca A. Hubbard[3]; Catherine L. Auriemma[1,2]; Mitesh S. Patel[1,4]; Jeff I. Rohrbach[5]; Paul Junker[5]; Neil Fishman[1]; Meeta P. Kerlin[1,2]; Scott D. Halpern[1,2]; Gary E. Weissman[1,2]. [1]Medicine, University of Pennsylvania, Philadelphia, PA; [2]Palliative and Advanced Illness Research (PAIR) Center, University of Pennsylvania, Philadelphia, PA; [3]Biostatistics, Epidemiology and Informatics, University of Pennsylvania, Philadelphia, PA; [4]Wharton School and Penn Medicine Nudge Unit, University of Pennsylvania, Philadelphia, PA; [5]Clinical Effectiveness and Quality Improvement, Hospital of the University of Pennsylvania, Philadelphia, PA. (Control ID #3342972)

BACKGROUND: As the day progresses, clinicians may experience impaired clinical reasoning. This may exert its greatest effects on identifying and treating heterogeneous, diagnostically uncertain clinical syndromes, including sepsis. We examined the association of time of day with antibiotic initiation among ward patients with hospital-acquired sepsis.

METHODS: In 4 hospitals, we conducted a retrospective cohort study of index hospital-acquired sepsis episodes for ward patients 7/2017-6/2019. Sepsis onset was defined using Sepsis-3 criteria. The exposure was hours from 7AM (work day start). We fit a discrete-time time-to-event model with hours from sepsis onset as the time axis, to assess the association between hour relative to 7AM and probability of antibiotic initiation. We used logistic regression to assess the association between time of sepsis onset and odds of antibiotic initiation within 3 hours (CMS SEP-1 quality measure). We adjusted for hospital, admit year, age, gender, race, ethnicity, admit diagnosis, and service type.

RESULTS: Among 156,399 visits, 7,569 (5%) had sepsis. Visits were median 62 years (IQR 51-71), 53% male, and 79% on medicine services. Median time to antibiotic initiation was 10 hours (IQR 3-48) after sepsis onset and 2,057 (27%) patients received antibiotics within 3 hours.

Relative to 7AM, the probability of antibiotic initiation at each hour differed significantly, ranging from 0.8% (95% CI 0.6-1.0%) at 7AM to 8.7% (95% CI 8.1-9.4%) at 9PM (all p<0.001) (Figure). Relative to sepsis onset at 7AM, odds of antibiotic initiation within 3 hours also differed significantly (range: 0.5 [95% CI 0.3-0.7] at 4PM to 1.5 [95% CI 1.0-2.1] at 9PM).

CONCLUSIONS: Antibiotic initiation peaks at 9AM/PM, early in clinicians' 12-hour shifts, and declines until shift change with nadirs at 7AM/PM. These findings suggest handoffs and/or decision fatigue cause treatment delays for hospital-acquired sepsis. Confirming these findings and distinguishing between mechanisms may lead to quality-enhancing interventions.

Figure. Conditional adjusted probability per hour from 7AM of antibiotic initiation among ward patients with hospital-acquired sepsis*

ASSOCIATIONS BETWEEN STATE MEDICAID UTILIZATION MANAGEMENT POLICIES FOR BUPRENORPHINE, DRUG OVERDOSE BURDEN, AND OPIOID USE DISORDER TREATMENT AVAILABILITY

Paul Christine[1]; Allison Lin[2]; Renuka Tipirneni[1]. [1]Internal Medicine, University of Michigan, Ann Arbor, MI; [2]Psychiatry, University of Michigan, Ann Arbor, MI. (Control ID #3392244)

BACKGROUND: State Medicaid programs employ a variety of utilization management policies, such as prior authorization (PA), to ensure safe delivery of care while containing costs and minimizing resource misuse. Several such policies have been directed at buprenorphine, a highly effective medication used to treat opioid use disorder (OUD). Given current efforts to increase availability of buprenorphine treatment across states, it is critical to understand whether utilization management policies, including PA and mandatory psychosocial counseling, affect the availability of buprenorphine. Prior work suggests that states that require PA have fewer addiction treatment facilities that offer buprenorphine. We

sought to extend these analyses by examining if state utilization management policies were associated with other buprenorphine treatment resources and drug overdose burden.

METHODS: We compared measures of buprenorphine treatment availability, substance use disorder (SUD) prevalence, overall overdose deaths and opioid overdose deaths across states with and without Medicaid requirements for: PA for buprenorphine; PA for buprenorphine-naloxone; psychosocial counseling. Data included: Medicaid utilization management policies, number of licensed prescribers with waivers to prescribe buprenorphine for OUD; SUD prevalence; overdose deaths; SUD treatment facility data; buprenorphine maintenance prescriptions per 1000 Medicaid enrollees (obtained from 2017-2018 Substance Abuse and Mental Health Service Administration, National Survey on Drug use and Health, CDC, National Survey of Substance Abuse Treatment Services, and Medicaid State Drug Utilization Data). Means and medians were calculated and pairwise comparisons made with t-tests and Wilcoxon rank sum tests as appropriate.

RESULTS: A majority of states required PAs for buprenorphine and buprenorphine-naloxone (39 and 30, respectively), while 17 states required counseling. SUD prevalence, overall overdose deaths, and opioid overdose deaths were similar in states with and without PA and counseling requirements. States requiring PA for buprenorphine had a lower proportion of SUD treatment facilities offering medications for OUD compared to states without prior authorizations (18.8% vs 21.4%, p=0.02). There were no differences in median number of providers licensed to prescribe buprenorphine (25.5 vs 20.2, p=0.27) or buprenorphine prescriptions per 1000 Medicaid enrollees (84.9 vs 58.0, p=0.55) in states with and without PA requirements. Similar results were observed for counseling requirements.

CONCLUSIONS: In this cross-sectional study, state Medicaid policies requiring PA or counseling for buprenorphine were associated with lower availability of OUD medications in SUD treatment facilities but no difference in the number of buprenorphine prescribers or prescriptions for Medicaid enrollees. Prospective research is needed to assess whether removing utilization management requirements is associated with changes in access to buprenorphine.

A SURVEY OF INTERNAL MEDICINE INTERNS REGARDING THE MOST USEFUL TOPICS TO INCLUDE IN AN INTERNAL MEDICINE TRACK OF A "GET READY FOR RESIDENCY BOOT CAMP" COURSE

Rachel Vanderberg[1]; Anna K. Donovan[2]. [1]Internal Medicine, UPMC, Pittsburgh, PA; [2]Medicine, Division of General Internal Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA. (Control ID #3387832)

BACKGROUND: Several studies suggest that incoming interns frequently lack clinical and professional skills that residency program directors expect interns to have mastered during medical school. Various curricular efforts have attempted to remedy this discrepancy including residency preparatory "boot camps." We are currently developing a preparatory course for fourth year medical student entitled "Get Ready for Residency Boot Camp" that will entail a general curriculum for all fourth-year students as well as an Internal Medicine (IM) track for students planning a career in IM. The general curriculum is largely simulation based including standardized patient cases (i.e. breaking bad news) and management of acute clinical scenarios (i.e. myocardial infarction) with some didactics (i.e. capacity evaluation, wellness). We performed a needs assessment survey of current IM interns at our institution, who come from 44 accredited U.S. medical schools, about the content areas they would have found most useful in the IM track of the boot camp course.

METHODS: We surveyed a convenience sample of IM interns in October of 2019 regarding high yield topics to include in the IM track of the boot camp course. Prior to the survey, the interns received a brief introduction to the curricular project and an overview of topics included in the general curriculum. The survey asked interns to examine a list of clinical (medical knowledge) topics and a list of "non-clinical" (communication, professionalism, patient care, and system-based practice) topics. They were instructed to select the three most useful topics from both lists for the IM track of the boot camp course. The survey also had a free response section that asked them to write in one additional clinical and "non-clinical" topic. The list of topics presented to the interns was developed through literature review and local expert clinician educator input. We excluded topics already included in the general curriculum.

RESULTS: There was a 79% response rate (64/81). The most frequently identified useful clinical topics included: rational approach to antibiotics (27/64, 42%); electrolyte management (26/64, 41%); inpatient diabetes management (25/64, 39%); and acid-base disorders (24/64, 38%). "Write in" topics included acute pain, altered mental status, and critical care topics (i.e. respiratory failure and septic shock). The most frequently identified useful "non-clinical" topics included: cross-cover (44/64, 69%); responding to difficult or "offensive" patients (31/64, 48%); giving and receiving feedback (24/64, 38%); and adult learning theory (23/64, 36%). "Write in" topics included time management/organization tips and disposition/discharge options.

CONCLUSIONS: We have incorporated 12/13 (92%) of the most useful topics identified by IM interns into the IM track of the boot camp course, which is offered as two separate four-week blocks in March and April of 2020.

A TRAUMA EDUCATION PILOT CURRICULUM FOR PATIENTS IN URBAN PRIMARY CARE

V. Laavanya Divakaruni[1]; Regina A. Jacob[2]. [1]School of Medicine, Lewis Katz School of Medicine at Temple University, Philadelphia, PA; [2]General Internal Medicine, Temple University, Philadelphia, PA. (Control ID #3390632)

BACKGROUND: Posttraumatic stress disorder (PTSD) is prevalent in low-income communities and is often a missed diagnosis that contributes heavily to medical and psychological co-morbidity. Current treatment standard for PTSD is cognitive behavioral therapy and psychotherapy usually provided by a mental health professional. However, many individuals in low-income communities do not have regular access to behavioral health. There is some evidence to support the use of trauma education as an initial treatment for PTSD, particularly in those with multiple traumatic exposures as seen in urban patient populations. Furthermore, trauma education discussions do not require behavioral health expertise and can be performed by primary care providers in clinics without co-located behavioral health.

METHODS: Urban primary care participants with significant PTSD and moderate depression were selected from a larger cross-sectional study and randomized into two groups. The control group received an educational curriculum in various primary care diseases and the intervention group received an educational curriculum in PTSD. Each group met for 60-90 minutes weekly for 6 weeks. Symptoms of PTSD and depression were measured at the beginning of each session and semi-structured focus group discussions comprised the remainder of each session. Interviews were audiotaped, transcribed, and analyzed using Grounded Theory Methodology.

RESULTS: Six participants completed the curriculum, and three were randomized to each group. Average age was 54.15 ± 13.29 years, 5 (83.33%) were female, 3 (50%) completed some college, and average

Adverse Childhood Experience score=5. Two-sample *t*-tests showed no difference between the control group and the intervention group with regards to PTSD or depression symptoms during the 6-week course. Qualitative analysis generated the following themes in the intervention group 1) childhood events: perceptions of safety and trust; 2) support system: defining and identifying support; 3) internal processing: understanding reactions and recognizing coping mechanisms; 4) acceptance: acknowledging the past and its impact; 5) future planning: finding joy and purpose.

Exit-surveys completed by participants demonstrated that the curriculum was well-received. Both groups reported an improvement in knowledge and would recommend the course to a friend or loved one. When asked if the course helped understand how disease might impact life, the intervention group valued the course slightly higher compared to the control group. Participants in the intervention group successfully created individual toolkits of healthy coping strategies to use in times of stress.

CONCLUSIONS: Trauma education is a reasonable initial treatment intervention in urban primary care where the prevalence of PTSD is elevated and the access to behavioral health is limited. Future studies will need to follow larger cohorts over a longer period in order to truly assess the impact of trauma education on symptoms of PTSD and depression.

ATTITUDES AND PERCEIVED CONFIDENCE IN IDENTIFYING AND ADDRESSING PATIENTS' SOCIAL NEEDS AMONG SURGERY AND PRIMARY CARE RESIDENTS

Raquel C. Greer[1,2]; Jessica Bienstock[1]; Eric B. Bass[1,2]; Leonard S. Feldman[1]; Pamela Lipsett[1]; Monica Mix[1]; Katherine Shaw[1]; Michael Brady[1]; Afroza Gillani[1]; Gail Berkenblit[1]; Tanjala S. Purnell[1,2]; Fabian Johnston[1]; Alejandra Ellison-Barnes[1]; Chidinma Ibe[1,2]; Panagis Galiatsatos[1]; Erica N. Johnson[1]; Rachel Kruzan[1]; Helen Hughes[1]; Mindi B. Levin[1,2]; Tony Bridges[2]; Lisa A. Cooper[1,2]. [1]Johns Hopkins School of Medicine, Baltimore, MD; [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD. (Control ID #3390267)

BACKGROUND: Health care professionals' understanding of adverse social determinants of health (SDOH) and their ability to address them is essential to delivery of comprehensive care of diverse populations. However, residents' perceived competency in integrating patients' social needs into routine care is unclear.

METHODS: As part of a larger project to develop and pilot a community engagement and SDOH curriculum for Johns Hopkins residency programs, we conducted a mid-year survey of general surgery interns and primary care (internal medicine and medicine-pediatric) residents (post-graduate year 1-4) to assess their attitudes and perceived confidence in identifying and addressing patients' social needs. We used descriptive statistics to describe questionnaire responses.

RESULTS: Twenty surgical interns and 17 primary care residents completed the survey (86% response rate). Nearly all residents reported frequently encountering patients with unmet social needs and agreed addressing patients' social needs is as important as addressing their medical conditions (97% and 100% respectively). However, fewer surgery residents reported receiving training or having access to good role models for identifying and addressing patients' social needs compared to primary care residents. Overall, most residents felt confident in identifying patients' unmet social needs, however fewer residents felt confident in addressing them once they were identified. (p=0.001)

CONCLUSIONS: Although all residents agreed addressing patients' social needs was important, less than half felt confident in addressing them. Access to SDOH training also varied between programs. Meaningful curricula tailored to meet the differing needs of individual residency programs is needed to enhance residents' capacity to effectively address the health care needs of vulnerable populations, with a particular emphasis on integration into programs where training is currently lacking. Health system efforts to link community resources may also enhance residents' capacity to effectively address patients' social needs.

Table. Residents' Attitudes and Self-rated Confidence in Identifying and Addressing Patients' Social Needs	% of Residents	
	Surgery (n=20)	Primary Care (n=17)
Received training in identifying and addressing SDOH*†	35	100
Had good role models to identifying and addressing SDOH*†	53	100
Agreed well-informed about most available resources to address patients' social needs**	25	88
Confident in identifying unmet social needs‡	68	88
Confident in addressing unmet social needs‡	40	25

†Surgery vs. primary care residents. p<0.01

AUGMENTING PREDICTIVE MODELING OF HOSPITAL READMISSIONS WITH SOCIAL DETERMINANTS OF HEALTH

Patrick Ryan[1,2]; John Rice[3,4]; Anna Furniss[4]. [1]General Internal Medicine, Denver Health and Hospital Authority, Denver, CO; [2]School of Medicine, University of Colorado, Aurora, CO; [3]Biostatistics, Colorado School of Public Health, Aurora, CO; [4]ACCORDS, University of Colorado, Aurora, CO. (Control ID #3372801)

BACKGROUND: Identifying patients at high risk of readmission through predictive modeling is one strategy to reduce unnecessary readmissions, a significant source of patient morbidity and healthcare costs. However, the performance of predictive models in urban safety-net populations who suffer disproportionately from socioeconomic disparities is not known. We sought to assess how validated predictive models of readmission perform in an urban safety-net population and if augmenting them with variables addressing social determinants of health may improve prediction of urgent rehospitalization within 30 days of discharge.

METHODS: We performed a retrospective cohort analysis of patients ≥ 18 years old admitted (16,540) to Denver Health (DH), a tertiary care urban safety-net hospital that includes 9 Federally Qualified Health Centers, between July 1, 2016 and June 30, 2018, tracking readmissions through July 31, 2018. Emergent hemodialysis, obstetric and psychiatric admissions were excluded. We applied the LACE, LACE+ and Epic predictive models of urgent readmission to the cohort to determine how well they performed in the DH population compared to the original populations used in their development. We developed a new predictive model using the variables in the LACE model, augmented with the following variables: Area Deprivation Index, patient language, housing, healthcare utilization, patient identified barriers to learning, mental health and substance abuse diagnoses, and discharge location. In model development, we randomized 50% of the cohort into a training set to perform logistic regression with stepwise selection based upon AIC criteria to control for confounding. We tested the final model on the remaining 50% of the cohort in our validation set. We compared the predictive models' performance with the C-statistic. We had 80% power to detect a difference 0.039 in the C-statistics of the models tested.

RESULTS: The predictive model with the best performance was the Epic model with a C-statistic of 0.71 compared to LACE (0.65) and LACE+ (0.61). Our augmented model had a C-statistic of 0.66. In comparing the C-statistics, the Epic model was significantly higher than the other models ($p < 0.05$). The variables most associated with readmissions in urban safety-net patients were (OR): AMA discharge (3.19), mental health diagnosis (2.06) and healthcare utilization (1.94).

CONCLUSIONS: Our new predictive model with non-traditional covariates performed better in our cohort than the LACE and LACE+ predictive models. While the Epic model performed the best in an urban safety- net population, it requires the most covariates, including lab value data. Our results demonstrate the value of accounting for socioeconomic status and mental health in assessing the risk of readmission in urban safety- net patients. More importantly, some of these variables are potentially modifiable, and if properly addressed can help reduce the risk of readmission in this vulnerable population.

AVAILABILITY OF SEXUALLY TRANSMITTED INFECTION SCREENING SERVICES AND IMPLICATIONS FOR PREP DELIVERY IN COLLEGE AND UNIVERSITY STUDENT HEALTH SERVICES

Alyse Wheelock[1]; Samantha Rawlins-Pilgrim[2]; Carl G. Streed[3]; Margaret Higham[5]; Jessica Taylor[4]. [1]Internal Medicine, Boston Medical Center, Arlington, MA; [2]Internal Medicine, Boston Medical Center, Dorchester, MA; [3]Medicine, Section of General Internal Medicine, Boston Medical Center, Boston, MA; [4]General Internal Medicine, Boston University/ Boston Medical Center, Boston, MA; [5]Tufts University Health Service, Medford, MA. (Control ID #3391935)

BACKGROUND: Sexually transmitted infections (STIs) are increasingly prevalent among college-aged individuals in the US. The Centers for Disease Control and Prevention (CDC) recommend comprehensive screening and treatment for STIs, including three-site testing (i.e. urinary/vaginal, throat, and rectal swab specimens) for gonorrhea and chlamydia (GC/CT) among people at risk. College and university student health services are uniquely positioned to deliver sexual health services to young people. However, published data on STI testing and treatment on college campuses are limited.

METHODS: Questions about STI testing and treatment services were included as part of a larger study of HIV pre-exposure prophylaxis (PrEP) availability at undergraduate student health services (SHS) in New England. Electronic surveys were distributed to 143 SHS directors between April – October 2019. Chi- squared statistics were used to evaluate associations.

RESULTS: Fifty-six SHS directors (39%) responded to the survey. The majority of institutions represented were four-year (n=52, 93%) and private (n=42, 75%). Fifty respondents completed questions related to STI testing and PrEP. STI testing of any kind was offered at 48 SHS (96%). Forty-one SHS (82%) offered HIV testing, most commonly as fourth generation laboratory testing (n=36, 88%). Syphilis testing was available at 45 (90%) SHS. Urine GC/CT testing was available at 47 (94%) SHS and vaginal GC/CT testing was offered at 44 (88%); a full complement of three-site GC/CT testing was offered at 40 (80%). Among SHS with any STI testing, 13 (27%) offered intra-muscular penicillin, 34 (71%) offered intra-muscular ceftriaxone, and 35 (73%) offered oral azithromycin for on-site STI treatment. Thirty-two institutions (64%) reported offering PrEP, some through a formal program. Among 18 SHS without PrEP, 12 respondents (67%) reported that clinical and laboratory monitoring posed a significant barrier to implementation (rated 3-4 on a scale from 1-4). Compared to SHS that did not offer three-site GC/CT testing, those that did were more likely to offer PrEP (20% vs. 75%, $p<0.001$).

CONCLUSIONS: Although many college and university SHS in New England offer STI testing, 20% did not offer three-site GC/CT testing. This represents a gap in screening, as studies have demonstrated that up to 77% of CT and 95% of GC infections are missed by urine GC/CT screening alone in high risk populations. Increasing access to comprehensive STI screening for college students is an important priority. STI service limitations may also pose a barrier to implementation and expansion of PrEP programs on college campuses, as three-site testing is critical to high-quality PrEP care. Interventions to increase PrEP availability at SHS should incorporate expansion of STI screening access. Additional work is necessary to understand and address barriers faced by SHS to providing comprehensive STI screening and treatment.

A VALIDATED ALGORITHM TO IDENTIFY OPIOID AND CANNABIS USERS USING URINE TOXICOLOGY RESULTS

Peggy Wong[1]; Samuel Leonard[1]; Rachel Maas[1]; Salomeh Keyhani[2]. [1]NCIRE, SF VA, San Francisco, CA; [2]Medicine, University of California at San Francisco, San Francisco, CA. (Control ID #3391475)

BACKGROUND: Given the wide spread use of prescription opioids and the legalization of cannabis in over 33 states, the use of both substances is increasingly common. However, the health effects of combined cannabis and opioid use is unknown. Urine toxicology data can be potentially used to identify users and assess the health effects of use. We developed and validated an algorithm that combines text and numerical processing to map drug screening data to one of four results: positive, negative, test not given/canceled, or unknown.

METHODS: Urine drug screening results are recorded in the VA's Corporate Data Warehouse. However, no standard name for drug screenings exists; laboratory results are reported as numeric measurements, text, or some combination of the two; and the units of measurement are often missing. We identified all urine opioid drug screens and urine cannabis drug screens using LOINC Codes, text mining on the laboratory test name, and text mining on the laboratory result value. Drug screenings were limited to those given in primary care in the VA between January 1, 2012 and December 31, 2018. The resulting datasets consisted of 10,739,412 opioid drug screenings and 4,027,551 cannabis drug screenings. We first grouped drug screening data by similar result values and units. We then iteratively compared random samples of 20 cases from each category to the text relevant to the drug screening in each patient's chart. Once the proportion of unclassifiable tests were less than .5%, we assessed the strength of the urine toxicity exposure categorization approach by obtaining a sample of 75 Veterans (25 Veterans who had both opioids and cannabis in the urine toxicology data, 25 Veterans who only had evidence of opioid in the urine toxicology data, and 25 Veterans showing no evidence of either substance in their urine toxicology data), and reviewed their respective charts using national CAPRI. We then assessed the positive predictive value of the final algorithm against chart review.

RESULTS: Among a sample of 10,739,412 opioid urine screenings given in the VA, 7,986,231 tests were negative, 2,372,317 were positive, and 354,600 tests not given or canceled. We were unable to classify 26,264 tests (.24%). Among 4,027,551 cannabis urine drug screenings, 3,493,543 were negative, 455,315 were positive, 72,091 not given or canceled. We were unable to classify 6,602 cannabis tests (.16%). The unclassifiable tests were characterized by the result field containing incomprehensible text or the result field containing a numeric measurement with no accompanying units specified. The PPV of the algorithm against chart review was 1.00 among the classifiable tests.

CONCLUSIONS: We developed an approach to identify positive and negative urine drug screens. The algorithm can be used to assesses the health effects of cannabis use among long-term opioid users in the VA.

BACK SO SOON?

Mohammed Abozenah[1]; Adam Dossaji[2]; Kirti Joshi[3]; Christine L. Bryson[1]; Ryan Quarles[1]. [1]Internal Medicine, Baystate Medical Center, Springfield, MA; [2]Internal Medicine, Baystate Medical Center, Springfield, MA; [3]Hospital Medicine, Baystate Health, Springfield, MA. (Control ID #3391095)

BACKGROUND: Hospital readmissions are a commonly identified issue affecting many healthcare organizations in the US. As Jencks et al outlined in his study of Medicare beneficiaries between 2003 and 2004, almost 20% of patients are re-hospitalized within 30 days of discharge, and more than a third within 90 days. This carries major implications from healthcare cost to increased morbidity. As of the early 21st century, a combined staggering 59.3% of medical and surgical patients discharged from hospitals in the US either were readmitted or deceased at 12 months post-discharge. We attempt to identify patterns in 7-day readmissions within our institution, with hopes to be able to prevent them in the future.

METHODS: Patients who were discharged from the hospitalist service and readmitted to the hospital within 7 days were identified. The discharging hospitalist performed the first review on the reason for readmission with the help of a standardized form we created. They were asked to rate the readmission as preventable or not preventable. If preventable, they were then asked to classify the reason for readmission in broad categories. A two-physician reviewer process was used to reduce any bias. This involved a bi-monthly meeting of a group of interested hospitalists and residents, to perform a second review of the initial readmission forms. Deep dives were utilized in instances when there was a clear discrepancy between the initial and second review. The preventable cases were then classified into sub-categories in an attempt to identify patterns amenable to systems provisions with the goal of reducing preventable readmissions.

RESULTS: Of the 171 patient charts reviewed to date, 110 (64.33%) were unavoidable. Various causes were identified in the 61 (35.67%) readmissions that were avoidable, with non-adherence and social issues being the most commonly implicated (25%). Other causes included patients leaving against medical advice (AMA), premature discharges, substance dependence issues, and incomplete discharges or medical errors.

CONCLUSIONS: Hospitalists are interested and willing to examine their seven day readmissions for possible errors and learn from them. A well-validated system to identify early readmissions can aid in addressing implicated issues and reducing their prevalence. A multidisciplinary approach is necessary, and we aim to explore various measures in an attempt to reduce these readmissions. This includes systems-based interventions to control diagnostic and medication errors, patient education, early involvement of social work and case management, identifying and controlling factors leading to AMA, and employing discharge checklists that serve as reminders to reduce discharge errors.

BARRIERS TO BEDSIDE TEACHING AND GIVING FEEDBACK IDENTIFIED BY EARLY- CAREER ACADEMIC HOSPITALISTS

Shradha Kulkarni[1]; Margaret Fang[1]; Jeffrey Glasheen[2]; Vikas Parekh[3]; Julie Machulsky[4]; Jade Myers[5]; Brad Sharpe[1]. [1]Department of Medicine, University of California, San Francisco, San Francisco, CA; [2]University of Colorado, Aurora, CO; [3]University of Michigan, Ann Arbor, MI; [4]Community, SGIM, Alexandria, VA; [5]Society of Hospital Medicine, Philadelphia, PA. (Control ID #3389477)

BACKGROUND: Academic hospitalists have identified teaching learners as the most fulfilling aspect of their jobs. Components of effective clinical education include teaching at the bedside and giving feedback. To enhance and develop the teaching and professional developmental skills of early-career hospitalists, the Society of Hospital Medicine (SHM), the Society of General Internal Medicine (SGIM), and the Association of Chiefs and Leaders of General Internal Medicine (ACLGIM) created the Academic Hospitalist Academy (AHA), an annual conference of lectures and workshops. Our study aims to identify the barriers to teaching effectively at the bedside and providing feedback to learners as identified by academic hospitalists attending AHA.

METHODS: As part of AHA enrollment, all attendees are asked to complete an anonymized, voluntary survey prior to the start of the conference. The survey includes questions about participant demographics, barriers to teaching at the bedside, and barriers to providing feedback to learners. We collected the survey responses from all 11 years of the AHA (2009 to 2019) and coded and categorized the free-response answers.

RESULTS: The average age of AHA attendees was 34 years, and attendees have an average 3.2 years of hospitalist experience. Of the 812 hospitalists who completed the survey, 702 (86.4%) identified barriers to bedside teaching and 685 (84.4%) identified barriers to providing feedback. Lack of time was the most commonly reported barrier to bedside teaching, reported by 86.8% of hospitalists, and named as the leading barrier by the majority of hospitalists (53.7%). Lack of confidence in bedside teaching skills was also named as a barrier by a majority of hospitalists (74.6%). Barriers to providing feedback included a lack of confidence in individual skills, listed as a barrier by 80.2% of hospitalists, followed by difficulty giving negative feedback (43.9%) and lack of time (38.1%).

CONCLUSIONS: Time constraints and lack of confidence in individual skills are the most common barriers to bedside teaching and providing feedback reported by academic hospitalists. With these data, AHA and other groups engaged in hospitalist career development and clinical education can better tailor their training to the needs of academic hospitalists.

BASELINE KNOWLEDGE AND ATTITUDES ABOUT HPV VACCINES IN EAST AFRICAN IMMIGRANT MOTHERS AND THEIR ADOLESCENT CHILDREN

Megha Shankar[1,2]; Linda Ko[3,5]; Anisa Ibrahim[4,6]; Farah Bille Mohamed[7]; John Lin[7]; Fanaye Gebeyaw[7]; Isabelle Celentano[3]; Ahmed Ali[6]; Victoria M. Taylor[5]; Rachel L. Winer[7]. [1]Health Services Research and Development, VA Palo Alto Health Care System, Menlo Park, CA; [2]Center for Primary Care and Outcomes Research, Stanford University, Stanford, CA; [3]Department of Health Services, University of Washington School of Public Health, Seattle, WA; [4]Department of Pediatrics, University of Washington, Harborview Medical Center, Seattle, WA; [5]Division of Public Health Sciences, Fred Hutchinson Cancer Research Center, Seattle, WA; [6]Somali Health Board, Seattle, WA; [7]Department of Epidemiology, University of Washington, Seattle, WA. (Control ID #3386149)

BACKGROUND: HPV vaccine uptake is low among East African adolescents in the U.S. Providers, parents, and adolescents are stakeholders in vaccination, and there are social, cultural, and religious factors that influence vaccination decisions. This presentation will describe baseline demographics and HPV vaccine knowledge and attitudes of mothers and adolescents who participated in an educational intervention to promote HPV vaccination.

METHODS: We recruited East African mothers and their 14-17 year old adolescent children to participate in an educational intervention to promote HPV vaccination. The educational intervention was delivered via 10

dinners held in East African community centers in the Seattle metropolitan area; 8 with the Somali community and 2 with the Ethiopian community. Mothers were administered face-to-face interviews in their native language, and adolescents self-completed paper surveys. Surveys assessed demographics and baseline knowledge and attitudes about HPV vaccines. Survey measures included true/false statements to assess HPV- related knowledge and social norms. Self-efficacy (e.g., 'You have enough information to make a decision about vaccination') was measured with agree/disagree statements. Willingness to vaccinate was measured as yes/no/undecided. All questions included a 'not sure' response option.

RESULTS: 120 mothers participated in the dinners with 136 of their 14-17 year old adolescent children. Most (85%) mothers were Somali, and 58% were <40 years of age. Mothers' reported a median of 8 (interquartile range 1-12) years of formal education, and 61% reported a median annual household income <$25,000. Mothers' baseline knowledge of HPV and HPV vaccines was very low, with correct responses ranging from 3% to 38% of participants (not sure responses ranged from 61% to 90%). Pre-intervention, only 12% of mothers felt they had enough information to make a decision about HPV vaccination (76% were not sure) and only 9% of mothers felt they wanted their children to get the HPV vaccine (91% were undecided). Adolescents' baseline knowledge of HPV and HPV vaccines was higher, with correct responses ranging from 27% to 67%, and 38% of adolescents indicating willingness to get the HPV vaccine (23% were not willing, and 39% were not sure).

CONCLUSIONS: Baseline results confirm key knowledge gaps about HPV vaccines and low intention to vaccinate, particularly among mothers, with higher levels of knowledge in their adolescent children. This gap suggests there is room for improvement through an intervention. The majority of mothers responded "not sure" to many of the questions about HPV vaccination, suggesting that there are knowledge gaps that can be targeted, rather than just attitude-behavior gaps. Interventions that target low HPV vaccine awareness may increase HPV vaccine uptake in high priority communities.

BEDSIDE ROUNDS OBSERVATION: PATIENT-CENTEREDNESS OF COMMUNICATION

Michelle Sharp[1]; Nicole Williams[1]; Laura Hanyok[2]; Janet Record[1]. [1]Medicine, Johns Hopkins University School of Medicine, Baltimore, MD; [2]Medicine, Johns Hopkins University, Baltimore, MD. (Control ID #3384747)

BACKGROUND: Patient-centered communication is associated with improved patient understanding and adherence to therapy. At our hospital, 1 of 4 general medicine services utilizes a specific curriculum to teach patient-centered care (PCC) and communication. We did not provide scripting on how to conduct bedside rounds, but we hypothesized that communication would be more patient-centered on PCC team rounds than on standard teams.

METHODS: We designed an observation checklist of 8 behaviors for inpatient bedside rounds covering domains of etiquette-based behaviors, patient-centered communication, and shared decision-making. 3 items were designated Always Behaviors: knocking before entering, articulating the medical plan for the day, and asking if the patient had any questions.

RESULTS: Between August 2018 and May 2019 a trained observer completed 448 observations of bedside rounds. Always Behaviors were performed in 39.0% vs. 14.9% of encounters on PCC vs. standard teams ($p<0.001$). Performance of patient-centered behaviors are shown in the Table. Team census was not different between PCC and standard teams (mean 10.0 vs. 10.2 patients, $p=0.75$). Mean time spent discussing each patient was not different between groups (PCC 18.1 vs. standard 18.2 minutes, $p=0.73$). The subset of time spent at the bedside per patient was greater on the PCC team (8.5 vs. 7.1 minutes, $p<0.001$).

CONCLUSIONS: Performance of Always Behaviors during inpatient team rounds was more frequent on a team with a PCC curriculum than on standard teaching teams. However, the performance rate was lower than anticipated. Our checklist facilitates objective evaluation of PCC and could guide efforts to improve PCC during bedside rounds. Next steps will include sharing checklist performance with PCC team attendings and assessing the degree of correlation between patients' perspectives on communication and results of checklist observations.

BEHAVIORAL ECONOMICS INFORMED DECISION SUPPORT TO IMPROVE CHOOSING WISELY ADHERENCE WHEN ORDERING TESTS AND TREATMENTS FOR GERIATRIC PATIENTS: A PILOT STUDY

Theresa A. Rowe[1]; Ji Young Lee[1]; Tiffany Brown[1]; Yaw A. Peprah[1]; Jeffrey A. Linder[1]; Mark W. Friedberg[2]; Stephen Persell[1]. [1]Department of Medicine; Division of General Internal Medicine and Geriatrics, Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Blue Cross Blue Shield of Massachusetts, Boston, MA. (Control ID #3392462)

BACKGROUND: Our objective was to pilot test the implementation and effect of three electronic health record (EHR) clinical decision support (CDS) tools to reduce (1) prostate specific antigen (PSA) screening in men aged ≥ 75 years old (2) ordering of urine studies for non-specific reasons in women ≥ 65 years old, and (3) failure to de-intensify diabetes treatment in older adults with a HbA1c of <7.0 (DM) treated with insulin or sufonylureas.

METHODS: This pilot study occurred January through July 2019 within an academic health system with an enterprise wide EHR (Epic). We enrolled consenting physicians from three primary care practices to receive CDS alerts when conditions within the patient's chart met triggering criteria. CDS alerts, pops-up that included language to increase the salience of potential harms, used social norms to remind clinicians that their peers were not routinely using the test/treatment for similar patients (PSA), and recommended that clinicians consider canceling the order (PSA and urine studies) or de-intensifying diabetes treatment (DM). It also informed clinicians that if they proceeded to sign the order they would be asked to enter a justification that would be included in the chart (PSA/urine studies). Data regarding CDS exposure and resulting actions taken by clinicians were extracted from the EHR. We performed manual chart review for all cases where DM CDS fired to determine if treatment was de-intensified. We compared performance data for participating and non-participating primary care physicians across the health system for the six months prior to the pilot and after completion of the pilot.

RESULTS: Pilot clinicians (n=14) were 79% female and had an average of 21 (standard deviation, 6) years in practice. Among the 73 patients for which the DM CDS was triggered 128 times, physicians reduced the intensity of diabetes treatment in 22 (30%). For urine studies, the test was not ordered at 60% of encounters where the CDS activated. The proportion of urine tests done for non-specific reasons fell to 6.7% (5/75) during the pilot from 13.0% (10/77) in the six months before the pilot among the test physicians, and the difference in differences in rates between test physicians and non-test physicians was -8.9%. PSA screening was low at baseline for test physicians. In 4 of 19 (21%) encounters with PSA CDS, the physician did not order the test.

CONCLUSIONS: In this pilot study, behavioral economics informed clinical decision support aimed at curbing several clinical practices identified in the Choosing Wisely guidance statement from the American Geriatrics Society affected clinician behavior. We are currently investigating the effect of these alerts in a larger randomized controlled trial.

BEST INTENTIONS: MEDICATION NON-DISPENSING AFTER HOSPITAL DISCHARGE

Ravi Budhan[2]; William B. Preston[1]; Ching C. Reisig[3]; Jay Naik[4]; Julie Kanevsky[3]; William Southern[5]. [1]Internal Medicine, Montefiore Medical Center, New york, NY; [2]Internal Medicine, Montefiore Medical Center - Albert Einstein College of Medicine, Bronx, NY; [3]Internal Medicine, Montefiore Medical Center, Bronx, NY; [4]Internal Medicine, Robert Wood Johnson Univeristy Hospital, New Brunswick, NJ; [5]Medicine, Montefiore, Bronx, NY. (Control ID #3391322)

BACKGROUND: There are over 36 million hospital admissions in the U.S. each year with a median of 4 medications prescribed to each patient discharged, contributing in part to the over 4 billion prescriptions dispensed annually in the United States. Non-dispensing of discharge medications is associated with hospital readmission and increased mortality. Factors such as patient age, changed or new medication, medication type, hospital duration, lack of teaching, and cost have been identified as playing significant roles in medication non-dispensing following discharge. We sought to determine how frequently medications were not dispensed after discharge at an urban academic medical center.

METHODS: All patients discharged from the teaching service at Montefiore Moses Medical Center over a one-month period were eligible. From these, a random number generator was used to select a sample of patients. For each patient, demographic characteristics and all newly prescribed medications were abstracted from the electronic medical record (EMR). Patients were excluded if they were not on the teaching service or if they were discharged to a facility. Medications were excluded if they were not newly prescribed. The primary outcome, dispensing of medication, was assessed by information in the EMR and by calling pharmacies. We examined the proportion of patients who filled all new prescriptions. Predictors of non- dispensing including patient gender, language, and weekend vs. weekday discharge were examined using chi- square tests.

RESULTS: Of 442 eligible patients, 305 were reviewed and 166 met criteria for inclusion. Of these patients, 52 (31.3%) had at least one medication not dispensed following discharge. Of the total 408 new medications prescribed, 104 (25.5%) were not dispensed. Analysis by medication type showed the two medications least likely to be completely dispensed were as follows: of 11 patients prescribed any insulin, 4 (36.3%) were not dispensed at least one of the insulin prescriptions and of 12 patients prescribed inhalers, 4 (33.0%) were not dispensed at least one of the inhalers. The two medications most likely to be completely dispensed were anticoagulants 14/14 (100%), followed by antihypertensives 26/28 (93%). Patient gender, language, and weekend vs. weekday discharge were not associated with non-dispensing.

CONCLUSIONS: We found 31% of patients had at least one newly prescribed medication not dispensed after discharge. The medications most likely to be dispensed were anticoagulants, while the least likely was insulin. It is unclear why anticoagulants were more reliably filled, but it may involve the severity of illness requiring anticoagulants and the way doctors communicate about these medications, which if true, could represent an intervention for improving dispensing. The medication most likely to be non-dispensed was insulin, which may have to do with relative difficulty of use. These data suggest insulin and inhalers may represent the best targets for intervention.

BEYOND PROXIMITY AND TOWARDS EQUITY: A MULTIDIMENSIONAL VIEW OF URBAN GREEN SPACE ACCESS

Daniel J. Hindman[1]; Craig E. Pollack[2]. [1]Department of Medicine, Division of GIM, Johns Hopkins University School of Medicine, Baltimore, MD; [2]Health, Policy, and Management, Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD. (Control ID #3381943)

BACKGROUND: Green spaces have been associated with increased physical activity and a wide range of improved health outcomes, including better mental health, decreased rates of low-weight births, lower blood pressure, decreased cardiovascular mortality, and lower all-cause mortality. However, disparities in access to green space limit these potential public health benefits. Current concepts of access are focused on physical proximity. In order to capture additional relevant factors that impact access, we created and evaluated a multidimensional tool to describe green space access across diverse communities.

METHODS: We conducted a cross-sectional study in two historically disinvested communities bordering a large urban park in Baltimore City, Maryland. We randomly selected 175 households in the two neighborhoods for an in-person survey conducted between April to September 2019. Our primary outcome was self-reported number of visits to the park over the last 30 days. Our main independent variables conceptualized park access based on Penchansky and Thomas' healthcare theory of access with its five domains: Availability, Accessibility, Accommodation, Affordability, and Acceptability. We ran negative binomial regression models to test whether measures of access were associated with park use, adjusting for a range of covariates (age, education, car-ownership, children in the household, and physical activity).

RESULTS: Among the 87 respondents (response rate 50%), the mean age was 49.0 years old, 72% were African American, and 32% reported children in the household. The median number of park visits over the prior 30 days was 2 (IQR 0-5). 30% of respondents had not visited the park over the prior 30 days. Frequency of park use over the prior 30 days had statistically significant associations with age, education, car- ownership, and presence of children in the household. Physical proximity (≤10-minute walking distance) was not associated with increased frequency of park use. Frequency of park use was associated with the perception that there were events in the park that individuals could participate in (adjusted Incidence Rate Ratio [IRR] 7.44 [95% CI 3.03, 18.3]) and feeling safe in the park during the day (adjusted IRR 7.35 [95% CI 2.60, 20.7]). Those who reported that living near the park was affordable reported fewer park visits (adjusted IRR 0.53 [95% CI 0.32, 0.86]).

CONCLUSIONS: In two historically disinvested urban communities, physical proximity was not associated with green space use. However, multiple dimensions of a broad conceptual theory of access were significantly associated with green space use. Our findings suggest the need to focus beyond physical proximity as policymakers and practitioners work to increase equity in access to green space and improve health.

BLOOD PRESSURE MEDICATION PATTERNS OF USE IN OHIO MEDICAID BENEFICIARIES WITH UNCONTROLLED HYPERTENSION

Shari Bolen[8]; Suparna Navale[1]; Lillian Prince[2]; Siran Koroukian[1]; Michelle Menegay[3]; Douglas Einstadter[8]; Jackson Wright[4]; Randall D. Cebul[1]; Adam T. Perzynski[8]; Catherine Sullivan[5]; Jonathan Lever[6]; Michael Konstan[1]; Dushka A. Crane[3]; Allison Lorenz[3]; Doug Spence[3]; Arun RajanBabu[3]; Tonni Oberly[3]; Melissa Nance[7]; Stephen Albanese[7]; Donald P. Wharton[7]; Mary S. Applegate[7]. [1]Case Western Reserve University, Cleveland, OH; [2]Kent State University, Kent, OH; [3]The Ohio Colleges of Medicine Government Resource Center, Columbus, OH; [4]Case Western Reserve University, University Hospitals Cleveland Medical Center, Cleveland, OH; [5]The MetroHealth System, Cleveland, OH; [6]Better Health Partnership, Cleveland, OH; [7]Ohio Department of Medicaid, Columbus, OH; [8]Center for Health Care Research and Policy, Case Western Reserve University at The MetroHealth System, Cleveland, OH. (Control ID #3387878)

BACKGROUND: Little is known regarding current-day blood pressure (BP) medication patterns of use by Medicaid patients within primary care

practices. Understanding BP medication patterns of use in primary care practices provides opportunities to improve BP control in this population.

METHODS: Using a unique data resource comprised of electronic health records (EHRs) from practices in an Ohio Department of Medicaid funded statewide hypertension quality improvement (QI) project linked with Medicaid pharmacy claims data, this study aimed to: 1) describe BP medication types, dosages and adherence in patients with uncontrolled BP; and 2) determine changes in filled BP medications after an uncontrolled BP visit. We included 3,828 individuals on Medicaid with a diagnosis of hypertension and at least one visit at one of 8 practice sites participating in a statewide hypertension QI project with linked claims data between 01/2017 through 12/2018. Visit dates and BP measurements were obtained from EHR data, while data on patient demographics and BP medications were retrieved from Medicaid enrollment and claims data. Medication intensification was defined as the addition of a new BP medication to the existing regimen, and/or an increase in the dosage. Medication adherence was defined as medication possession ratio of ≥80%.

RESULTS: In the overall sample, mean age was 50 years (SD 10); 57% were women; 40% were non- Hispanic white; 58% were non-Hispanic black; and 19% had diabetes. Half (50%) had good medication adherence (MPR>80%). Of the 1,549 (40%) patients with uncontrolled BP and linked claims data, the top 4 BP medication classes used were calcium channel blockers (54%), thiazide and thiazide-like diuretics (44%), angiotensin converting enzyme inhibitors (43%), and beta blockers (28%). Only 10% were on chlorthalidone and 6% were on spironolactone. Of those with uncontrolled BP, 24% were on hydrochlorothiazide 12.5 mg, 36% were on hydrochlorothiazide 25 mg, and 30% were on amlodipine 5 mg (all lower than optimal dosing) indicating an opportunity for medication intensification. For those with good medication adherence (MPR>80%) and on only 2 BP medications (N=451), only 47% had BP medication intensified within one month of a visit with uncontrolled BP; 42% had no BP medication change; 8% were de-escalated/stopped therapy; and 3% switched therapy. In the less adherent subgroup (MPR<80%), 53% had medication intensified, 26% had no change, 19% de-escalated/stopped therapy, and 2% switched therapy within one month.

CONCLUSIONS: Among patients with poorly controlled BP, medication adherence and medication intensification (two key drivers of BP control) remain suboptimal. These data also identify opportunities for greater use of higher doses of diuretics and calcium channel blockers. Increased efforts to implement existing hypertension best practices which include providing feedback to sites on medication patterns of use are needed to achieve better BP control among Medicaid populations in primary care.

BREMELANOTIDE TREATMENT PROVIDED CLINICALLY MEANINGFUL BENEFITS IN PREMENOPAUSAL WOMEN WITH HYPOACTIVE SEXUAL DESIRE DISORDER

Sheryl Kingsberg[1]; Anita Clayton[2]; David Portman[3]; Robert Jordan[4]; Dennis Revicki[5]; Laura Williams[6]; Julie Krop[6]. [1]University Hospitals Cleveland Medical Center, Cleveland, OH; [2]University of Virginia, Charlottesville, VA; [3]Sermonix Pharmaceuticals, Columbus, OH; [4]Palatin Technologies, Cranbury, NJ; [5]Evidera, Bethesda, MD; [6]AMAG Pharmaceuticals, Waltham, MA. (Control ID #3370504)

BACKGROUND: Hypoactive sexual desire disorder (HSDD) is the most common sexual dysfunction in women, and is characterized by an absence or deficiency of sexual desire accompanied by distress. Bremelanotide, a melanocortin receptor agonist, is approved for the treatment of acquired, generalized HSDD in premenopausal women. The RECONNECT studies (Studies 301 and 302), which comprised two identically designed, double-blind, randomized, placebo-controlled studies, demonstrated that subcutaneous self-administration of bremelanotide, as needed, significantly improved sexual desire and decreased related personal distress in premenopausal women with HSDD. The objective of this study is to determine whether bremelanotide treatment provided clinically meaningful benefits.

METHODS: The co-primary endpoints were change from baseline to end-of-study (EOS) for Female Sexual Function Index–desire domain (FSFI-D) and Female Sexual Distress Scale–Desire/Arousal/Orgasm (FSDS- DAO) Item 13 scores. Clinically meaningful significance was evaluated using General Assessment Questionnaire Question 3 (GAQ Q3), which evaluated patients' perceived benefit of the drug ("Compared to the start of the study [prior to taking the study drug], to what degree do you think you benefitted from taking the study drug?"). GAQ Q3 scores ranged from 1 (very much worse) to 7 (very much better); responders were defined as score ≥5. Additionally, a cumulative distribution analysis was performed to determine the percentage of patients whose changes in the co-primary endpoints from baseline to EOS achieved predefined clinically meaningful thresholds (FSFI-D ≥0.6, FSDS-DAO Item 13 ≤-1). Finally, a receiver operating characteristics (ROC) analysis was performed to determine how predictive the co-primary endpoints were of patient perceived benefit by measuring the area under the time-concentration curve (AUC), with AUC >0.5 indicating discrimination between a nonresponder and a responder.

RESULTS: Responses to GAQ Q3 demonstrated clinically meaningful and statistically significant (P<0.0001) differences between the treatment groups in each study, with 58.3% and 58.2% responder rates for bremelanotide and 36.1% and 35.4% for placebo in Studies 301 and 302, respectively. The cumulative distribution for the co-primary endpoints showed highly statistically significant differences (FSFI-D: P<0.0001; FSDS-DAO Item 13: P=0.0002) for both studies. Good discrimination was computed for the co- primary endpoints, with AUCs of 0.715 and 0.714 for FSFI-D and 0.666 and 0.651 for FSDS-DAO Item 13 in Studies 301 and 302, respectively.

CONCLUSIONS: An independently predefined threshold for dynamic anchor assessment of GAQ Q3, as well as cumulative distribution analysis, ROC analysis, and prespecified responder rates for the co-primary endpoints on desire and distress all confirmed clinically meaningful and statistically significant differences between bremelanotide and placebo in both studies.

BUNDLED PAYMENTS FOR MEDICAL CONDITIONS DEMONSTRATE SAVINGS AT 3 YEARS AFTER ACCOUNTING FOR EPISODE PRECEDENCE

Joshua Rolnick[2,3]; Joshua M. Liao[5,6]; Ezekiel J. Emanuel[7]; Xinshuo Ma[8]; Eric Z. Shan[7]; Claire T. Dinh[8]; Jingsan Zhu[8]; Erkuan Wang[8]; Qian Huang[8]; Deborah Cousins[8]; Amol S. Navathe[1,4]. [1]Corporal Michael J. Crescenz VA Medical Center, Philadelphia, PA; [2]Department of Medicine, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [3]National Clinician Scholar Program, University of Pennsylvania, Philadelphia, PA; [4]Department of Medical Ethics and Health Policy, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [5]Department of Medicine, University of Washington, Seattle, WA; [6]Leonard Davis Institute of Health Economics, Philadelphia, PA; [7]Department of Medical Ethics & Health Policy, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [8]Department of Medical Ethics and Health Policy, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA. (Control ID #3391294)

BACKGROUND: Published studies of medical bundles have not found evidence of savings. Defining medical episodes is methodologically complex because patients experience frequent hospitalizations, and programs

include "episode precedence" rules to determine how overlapping episodes are assigned to hospitals. Both the Bundled Payments for Care Improvement (BPCI) program and its ongoing successor, BPCI-Advanced, use precedence rules. Yet the impact of these rules on measured performance is unknown. We compared hospital performance for four high-volume medical bundles using two precedence methodologies.

METHODS: We performed a difference-in-differences analysis of episodes in Medicare claims 2011–2016 for congestive heart failure, pneumonia, acute myocardial infarction, and chronic obstructive pulmonary disorder. In prior work, episodes were constructed with BPCI precedence, preferentially assigning overlapping episodes in the performance period to BPCI hospitals. We reconstructed episodes using a "naturally occurring" method that always assigned episodes to the earlier hospitalization. BPCI hospitals were compared with matched non-BPCI hospitals using identical propensity-score matching and statistical models. The primary outcome was standardized total episode spending. Secondary outcomes included spending by category, readmission rates, and mortality. Generalized linear models clustered at the hospital level were adjusted for patient characteristics, time-varying market characteristics, and hospital and quarter fixed effects.

RESULTS: In original results with precedence, BPCI participation was not associated with a change in total spending. Skilled nursing facility (SNF) spending decreased (-5.6%, 95% CI -9.4% to -1.6%, p=0.01), and home health (HHA) spending increased (+5.2%, 95% CI 2.3% to 8.3%, p<0.001). BPCI participation was also associated with increases in readmissions spending (+3.6%, 95% CI 0.9% to 6.3%, p=0.01) and the 90- day readmission rate (+1.4 pp, 95% CI 0.9 pp to 2.0 pp, p<0.001). In contrast, with "naturally occurring" episodes, BPCI participation was associated with a *decrease* in total spending (-1.2%, 95% CI -2.3% to -0.2%, p=0.02). SNF spending still decreased (-6.3%, 95% CI -10.0% to -2.5%, p=0.001), while HHA spending increased (+4.4%, 95% CI 1.4% to 7.5%, p=0.004). However, readmissions spending and the readmission rate no longer increased.

CONCLUSIONS: BPCI participation in 4 common medical conditions was associated with savings at 3 years after removing apparent bias against participants from precedence. A spurious finding of increased readmissions was corrected by removing precedence. Medical bundles may lead to practice changes that reduce Medicare spending and reduce institutional post-acute care without unintended effects on quality. Policymakers should recognize the impact of methodological issues in program design such as episode precedence, which can lead to bias in measured performance.

BURDEN OF ACUTE ISCHEMIC STROKE AFTER PERCUTANEOUS CORONARY INTERVENTION IN THE ELDERLY: AN ANALYSIS OF THE NATION INPATIENT SAMPLE

Shivaraj Patil[1]; Karthik Gonuguntala[1]; Manish Kumar[2]; Chaitanya Rojulpote[3]. [1]Internal Medicine, University of Connecticut, FARMINGTON, CT; [2]Geriatrics, University of Connecticut, FARMINGTON, CT; [3]University of Pennsylvania, Philadelphia, PA. (Control ID #3362017)

BACKGROUND: Ischemic stroke is an uncommon complication after per-cutaneous coronary intervention (PCI). Data on the outcomes of post-PCI ischemic stroke complicating acute myocardial infarction (AMI) in elderly patients is limited.

METHODS: We used the National Inpatient Sample from 2010 to 2014 to identify elderly patients (age≥65 years) with AMI (ICD code 410.xx) who underwent PCI. In this retrospective cohort, we compared in- hospital outcomes of patients with and those without post-PCI ischemic stroke. The effect of post-PCI ischemic stroke on in-hospital mortality, length of stay and cost of hospitalization was assessed using multivariate logistic and linear regression models.

RESULTS: A total of 545,187 elderly patients with AMI underwent PCI. Overall prevalence of post- PCI ischemic stroke was 0.6% (Mean age (SD) 75.6± 7.2 years, 50.6% women, 69.9% Caucasian) and increased with advancing age (0.6% in age 65-74 years, 0.7% in age 75-84 years and 0.9% in ≥85 years; p <0.001). In hospital mortality (overall 33% vs. 4.8%; aOR = 6.06, 95% CI = 5.43-6.77; 26.3% vs. 3.3% in age 65-74 years, 35.3% vs. 5.4% in age 75-84 years and 48.5% vs. 10.4% in ≥85 years; p <0.001), length of stay (Median 6 vs. 3 days; aOR =1.69,95% CI= 1.64 -1.71; p<0.001) and cost of hospitalization ($105,880 vs. $67,314; aOR = 1.35, 95% CI =1.32 -1.37;p<0.001) in post-PCI ischemic stroke group were significantly higher.

CONCLUSIONS: In our study, the prevalence of post-PCI ischemic stroke among elderly patients increased with advancing age and was independently associated with higher fatality, longer hospitalization and increased costs. Our study highlights the poor prognosis associated with stroke after PCI, thereby allowing physicians to counsel patients and families around outcomes if such an event were to occur.

BURDEN OF PRESCRIPTION MEDICATION USE AMONG THE ELDERLY WITH TYPE 2 DIABETES IN THE US

Phuc H. Le[1]; Anita D. Misra-Hebert[2]; Nazleen Bharmal[2]; Michael B. Rothberg[2]. [1]Center for Value-based Care Research, Medicine Institute, Cleveland Clinic, Cleveland, OH; [2]Internal Medicine, Cleveland Clinic, Cleveland, OH. (Control ID #3392102)

BACKGROUND: Type 2 Diabetes (T2D) affects 1 in 4 US adults aged ≥65 years. In addition to diabetes complications, these patients often have high prevalence of chronic comorbiditiesand therefore are at risk of harm from polypharmacy. To understand the burden of polypharmacy in this vulnerable population, we examined trends in prescription drug use.

METHODS: This is a retrospective analysis of 2001-2016 National Health and Nutrition Examination Survey. We included people aged ≥65 years who had ever been told they had diabetes, had an HbA1C >6.4%, or fasting plasma glucose >125 mg/dL. Trends were estimated for the mean number of prescription drugs per patient and prevalence of reported use of ≥5 drugs, ≥10 drugs, and any of 13 different drug classes. We also examined change in patient characteristics and burden of comorbidities. Trends were examined across 3 periods (2001-2006, 2007-2012, 2013-2016) using logistic or linear regression. Finally, we compared prescription drug use between patients with vs. without diabetes and those taking insulin vs not aggregately for 2001-2016. We used Stata 14.2 and accounted for survey weights.

RESULTS: The final sample included 11,159 patients, 3,178 of whom had T2D. Across the 3 study periods, mean age slightly decreased while mean BMI and the percentage of male, non-White, with high-school or higher education, and no insurance increased. Number of comorbidities also increased, driven by hypercholesterolemia and obesity; cardiovascular disease decreased. The average number of drugs per patient increased from 5.6 in 2001-2006 to 6.4 in 2013-2016 (Table). Compared to the elderly without diabetes, those with T2D had more comorbidities (5.4 vs 3.5), used more drugs (6.2 vs 4), had two and three times more the prevalence of using ≥5 drugs (65% vs 35%) and ≥10 drugs (14% vs 4%). Patients taking insulin had the most comorbidities (6.0), took the most drugs (8.1), and were most likely to use ≥5 drugs (85%) or ≥10 drugs (28%).

CONCLUSIONS: Over 15 years, use of prescription drugs has increased significantly in the elderly with T2D. Patients with T2D, especially those who use insulin, are a particularly vulnerable group with a high burden of co-morbidities and likely to experience polypharmacy. Future work should explore opportunities to decrease polypharmacy in this group.

BURNOUT AMONG VA PROVIDERS EXPERIENCING CHALLENGES IN MANAGEMENT OF VA AND NON-VA CARE

Eric A. Apaydin[1]; Danielle Rose[2]; Michael McClean[3]; Susan E. Stockdale[3]. [1]Health Services Research & Development, VA Greater Los Angeles Healthcare System, Los Angeles, CA; [2]VA HSR&D Center for the Study of Healthcare Provider Behavior, VA GLA Healthcare System, Sepulveda, CA; [3]HSR&D Center of Excellence, Greater Los Angeles VA Healthcare System, Sepulveda, CA. (Control ID #3392662)

BACKGROUND: Care management is a key component of managing complex patients in the patient centered medical home model of primary care. However, care management can overburden already busy providers with additional administrative tasks, contributing to provider burnout. Congress recently increased the scope of care management in VA primary care with the introduction of non-VA Community Care through the Choice and MISSION Act(s). VA primary care providers (PCPs) must now manage care in the VA, and coordinate externally with non-VA Community Care providers.

Internally, VA PCPs are burdened with tasks like receiving patient messages on a timely basis, helping patients when they can't reach VA specialists, or assessing whether face-to-face appointments are needed (vs. care by telephone call or e-mail). External care management requires that VA PCPs must assist patients unable to schedule routine tests with Community Care providers or manage prescriptions from non-VA providers, particularly for pain management (e.g., opioids). To understand the role of these changes in care management, we analyzed challenges with internal and external care management and their relationships with VA provider burnout.

METHODS: Population: 1547 PCPs in 540 VA facilities nationwide responded to our survey (14% response rate).

Our cross-sectional survey contained 9 questions about challenges with care management (response range: 0-4, not at all challenging to extremely challenging), and through factor analysis, we created two indices of care management challenges: one internal (k=4, range 0-4, Cronbach's alpha 0.76) and external (k=5, range 0-4, Cronbach's alpha 0.84). On average, respondents found both internal (mean [M] 2.27, standard deviation [SD] 0.97) and external (M 2.41, SD 1.02) care management at least somewhat challenging.

We assess whether care management challenges were associated with two measures of provider burnout (any burnout vs. none; burnout a few times a week or more vs. a few times a month or less), adjusted for provider gender, age, race, ethnicity, VA tenure, PACT tenure, and supervisor status. Models were also adjusted for survey nonresponse.

RESULTS: Fifty-one percent of our sample reported some level of burnout overall, and 47% reported feeling burned out at least once a week. PCPs were more likely to be burned out overall if they reported more than average challenges with internal (odds ratio [OR] 1.86, linearized standard error [SE] 0.16) or external (OR 1.21, SE 0.09) care management. PCPs who reported more than average internal (OR 1.91, SE 0.15) or external (OR 1.09, SE 0.09) care management challenges were also more likely to be burned out at least once a week.

CONCLUSIONS: VA primary care providers who reported greater than average internal or external care management challenges were more likely to be burned out. Burnout among VA PCPs is linked to internal and external care management challenges. Improving internal and external care management could help improve provider experience.

CANCER-RELATED THEMES PRESENTED AT SGIM: ARE WE KEEPING UP WITH POPULATION TRENDS AND RESEARCH INNOVATION?

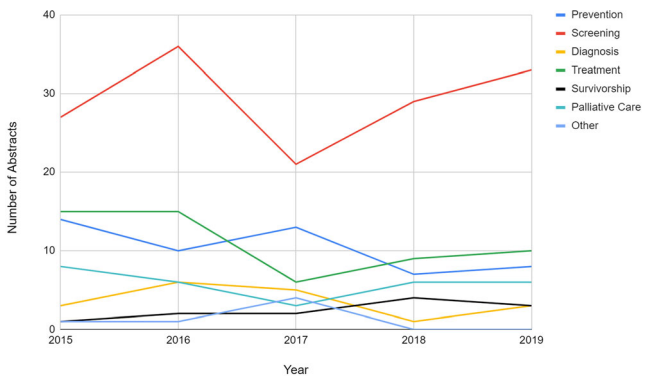
Danielle Amundsen[1]; Youngjee Choi[1]; Larissa Nekhlyudov[2]. [1]Johns Hopkins School of Medicine, Baltimore, MD; [2]Internal Medicine, Brigham & Women's Hospital, Boston, MA. (Control ID #3381007)

BACKGROUND: In 2019, an estimated 1.7 million new cancer diagnoses occurred in the U.S. The population of cancer survivors grew to 16.9 million and will rise to 22.1 million by 2030. Primary care physicians (PCPs) care for patients across the cancer continuum and must have core competencies to attend to the needs of this growing population. National conferences are an important venue for medical education and dissemination of innovative research findings. We assessed the trends in cancer-related abstracts presented at SGIM annual meetings.

METHODS: All abstracts from the 2015-2019 annual SGIM conferences (n=3437) were reviewed for content areas across the cancer continuum: prevention, screening, diagnosis, treatment, survivorship and palliative/end of life care (P/EOL). A one-tailed unpaired t-test compared abstracts addressing primary/secondary prevention (prevention and diagnosis) to tertiary prevention (all others) per year.

RESULTS: We found n=304 (8.8% of total) abstracts related to cancer presented. Prevention, screening, diagnosis, treatment, survivorship and P/EOL were addressed in 52 (17.1%), 146 (48.0%), 18 (5.9%), 55 (18.0%), 12 (4.0%) and 29 (9.5%), respectively. Some addressed multiple categories, and 6 were classified as "other". (Figure 1). Per year, significantly more abstracts addressed primary and secondary (mean=39.60, SD=4.72) than tertiary prevention (mean=22.80, SD=5.26), $t(8)=5.31$, $p<0.001$. Breast (mean =18.2, SD=4.66), colon (mean=12.8, SD=3.11) and lung (mean=8.2, SD=2.29) cancers were most commonly presented.

CONCLUSIONS: Cancer-related topics accounted for 8.8% of the research presented at the 2015-2019 SGIM annual meetings, with main focus on primary and secondary prevention. With the cancer survivorship population growing and reaching levels comparable to common chronic diseases, PCPs must be adequately prepared to care for patients across the cancer continuum. Content presented at national meetings should reflect the population trends, raise awareness of core competencies and promote innovative research.



CANNABIS AND HIGH DOSE PRESCRIPTION OPIOID USE AMONG ADULTS WITH SICKLE CELL DISEASE

Ling Huang[1]; Yuting Deng[2]; Caterina P. Minniti[3]; Joanna L. Starrels[2]. [1]Albert Einstein College of Medicine, Bronx, NY; [2]General Internal Medicine, Albert Einstein College of Medicine & Montefiore Medical Center, Bronx, NY; [3]Hematology, Albert Einstein College of Medicine & Montefiore Medical Center, New York, NY. (Control ID #3389623)

BACKGROUND: Opioids have been the mainstay of treatment for sickle cell disease (SCD) pain since the 1960s. Up to 40% of patients with chronic SCD pain take daily opioid analgesics, often at high doses that increase the risk of opioid use disorder or overdose. We previously found that among adults with SCD engaged in outpatient care, self-reported cannabis use was common and positively associated with being prescribed opioids. Using a more rigorous method, this study aims to investigate the relationship between cannabis use and high dose opioid prescription in a sample of adults with SCD, and our hypothesis is that patients who test positive for tetrahydrocannabinol (THC) are less likely to be on high dose chronic opioid therapy (COT), driven by cannabis' potential analgesic effect.

METHODS: Using electronic medical record data from large urban medical center, we identified patients aged 18 and older who had a visit to the outpatient SCD clinic, an emergency department (ED), or an inpatient encounter for SCD, based on ICD-10-CM codes, between July 1, 2018 and June 30, 2019. Sociodemographic and clinical data were extracted, including age, gender, race, ethnicity, SCD genotype, presence of avascular necrosis, urine toxicology tests for THC, and opioid prescriptions. COT was defined by 3 or more prescriptions within 6 months, and considered to be "high dose" if the morphine milligram equivalent per day was 90 or greater. We first determined whether the sociodemographic and clinical factors were associated with high dose COT with $p<0.25$ on univariate analyses, then using the associated sociodemographic and clinical factors as covariates, we conducted a multivariate logistic regression model to determine the relationship between urine toxicology test positive for THC and high dose COT.

RESULTS: Among 1,054 patients meeting inclusion criteria, there were 2894 outpatient SCD clinic visits (2.7±5.7 per patient), 2684 ED encounters (2.5±10.2 per patient), and 1153 inpatient encounters (1.1±2.1 per patient). Among 145 patients who were prescribed COT from the health system, 64 (44%) were prescribed high dose opioids, and 94 (65%) had at least one urine toxicology test; among these, 33 (35%) were positive for THC. In univariate analyses, the following variables were associated with high dose COT: older age (p=0.07), female gender (p=0.08), Hispanic race (p=0.007), SCD genotype (p=0.07), ≥4 ED visits (p=0.09), ≥4 hospitalizations (p=0.15) and no SCD clinic visit (p=0.05). In a multivariate analysis controlling for these factors, urine toxicology test positive for THC was not associated with high dose COT (AOR=0.35, 95% CI: 0.12-1.06, p=0.06).

CONCLUSIONS: In this cohort of adults with SCD, having a urine toxicology test positive for THC was not associated with being prescribed high dose COT, though sample size was limited. These findings highlight the need for further research to understand potential therapeutic benefit of cannabis and its relationship with opioid use in adults with SCD.

CAN REGIONALIZATION OF CARE REDUCE SOCIOECONOMIC DISPARITIES IN BREAST CANCER SURVIVAL?

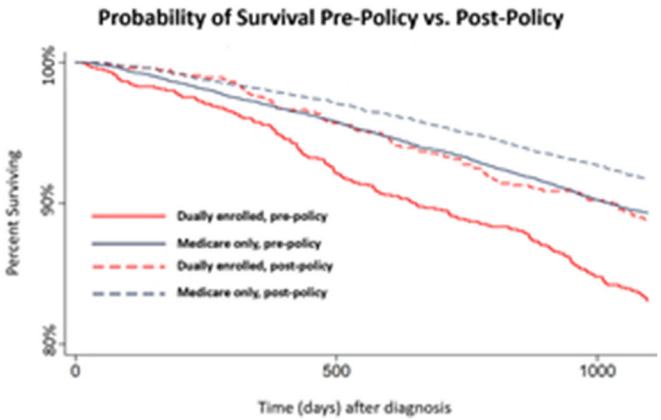
Nicole Rademacher[1]; Liliana E. Pezzin[1]; Emily L. McGinley[1]; Nina A. Bickell[2]; Ann Nattinger[1]. [1]Medicine, Medical College of Wisconsin, Milwaukee, WI; [2]Population Health Science & Policy, Icahn School of Medicine at Mount Sinai, New York, NY. (Control ID #3391246)

BACKGROUND: Breast cancer patients of low socioeconomic status (SES) have worse 5-year survival than more affluent women and are more likely to undergo surgery in low-volume facilities. Since breast cancer patients treated in high-volume facilities have better survival, regionalizing care of low SES patients toward high-volume facilities may reduce SES disparities in survival. Under a policy enacted in 2009 by New York state (NY), NY Medicaid does not pay for initial breast cancer surgery in low-volume facilities. Our objective was to determine if NY's policy reduced SES disparities in survival among breast cancer survivors diagnosed in 2006-2008 vs. 2014-2015.

METHODS: We contrasted 3-year all-cause mortality, the primary study outcome, for two cohorts: patients enrolled in Medicare and Medicaid (dual enrollment, indicates low SES) and patients enrolled only in Medicare (unaffected by the policy). Difference-in-differences methods estimated the impact of NY's policy on survival of dually enrolled beneficiaries. The models controlled for age at diagnosis, race, comorbidities, and temporal trends.

RESULTS: Unadjusted survival curves (Figure 1) and multivariate estimates both demonstrated improvement in survival over time among both low and higher SES groups, although the higher SES group had better survival at both time periods ($p<0.001$ for both SES group and time period). The disparity between low and high SES declined over time. The difference-in-difference interaction term yielded a coefficient of -0.13 (95% CI -0.30, 0.03) with p=0.12.

CONCLUSIONS: NY's policy was associated with a trend toward a reduction in SES disparities in breast cancer survival at 3-years after diagnosis. Although p=0.12, literature suggests that a 95% confidence limit may be too restrictive for interpretation of such social experiments. Given this, we interpret these data as suggestive of a beneficial effect of the regionalization policy for reducing disparities in breast cancer survival. This finding provides evidence to support additional exploration of regionalization policies on disparities.



CAN RESEARCH ASSISTANTS CLASSIFY MEDICATION DISCREPANCIES AS ACCURATELY AS PHARMACISTS?

Megan Nowak[1]; Steven R. Simon[3,4]; Alissa L. Russ-Jara[2]; Alan Zillich[2]; Amy Rubin[5]; Julianne Brady[5]; Catherine Yeksigian[5]; Jonathan Moyer[6]; Amy Linsky[5,1]. [1]Medicine, VA Boston Healthcare System, Boston, MA; [2]Pharmacy Practice, Purdue University College of Pharmacy, Indianaolis, IN; [3]Geriatrics and Extended Care Service, VA Boston Healthcare System, Boston, MA; [4]VA Greater Los Angeles Healthcare System, Los Angeles, CA; [5]Center for Healthcare Organization and Implementation Research, VA Boston Healthcare System, Boston, MA; [6]Biostatistics and Epidemiology, University of Massachusetts, Amherst, Amherst, MA. (Control ID #3391701)

BACKGROUND: Medication discrepancies are associated with adverse drug events, emergency department visits, and hospitalizations. A validated taxonomy, MedTax, is comprised of 12 primary and 28 secondary classifications for medication discrepancies. MedTax was designed for use by a pharmacist; however, in the context of clinical research, pharmacists' time is limited. Therefore, we sought to determine whether research assistants (RAs) could classify discrepancies using MedTax as accurately as a pharmacist.

METHODS: We evaluated medication discrepancies assessed 30 days post-hospital discharge at one Veterans Affairs Medical Center. We modified MedTax to include the eight most expected types of discrepancies: omission; commission; duplication; discrepancy in strength, frequency, number of units or total daily dosage; discrepancy in dosage form or route of administration; computer system expiration; other; and no discrepancy. Next, we trained a pharmacist (PharmD) and two RAs (each with a master's degree) to use the modified MedTax. Under the supervision of two physicians, six training sessions were performed using 79 discrepancies identified from a clinical trial. In the first session, the pharmacist and RAs collaboratively classified 25 discrepancies. In the subsequent five rounds, the pharmacist and RAs independently classified the remaining discrepancies, continuing until the raters reached >90% agreement.

Finally, to assess agreement among coders, 945 discrepancies were independently classified and comprise the sample for this analysis. The pharmacist reviewed all discrepancies while the RAs divided them evenly for independent review. Our primary analysis compared the pharmacist's classifications to the combined effort of the RAs, and our secondary analyses compared the pharmacist's classifications to each individual RA. Krippendorff's alpha was used to assess concordance between all three coders, while Cohen's kappa coefficient was used to assess concordance between each pharmacist-RA pair.

RESULTS: In our primary analysis, RAs classified discrepancies with comparable accuracy as a pharmacist (Krippendorff's α=0.81, 95% confidence interval [CI] 0.78-0.84). Secondary analyses revealed similar findings, with each individual RA performing at a comparable level as the pharmacist (RA-1: Cohen's κ=0.85, 95% CI 0.77-0.92; RA-2: Cohen's κ=0.79, 95% CI 0.73-0.85).

CONCLUSIONS: Individuals without medical training were able to be trained to use the modified MedTax taxonomy to classify medication discrepancies as well as a pharmacist. Implementing standardized taxonomies into research and clinical practice enables comparison of findings across studies and settings. By demonstrating that individuals without a clinical education were capable of being trained to accurately apply the modified MedTax taxonomy, our results support the use of such individuals for classifications tasks, potentially saving costs and time-based resources in future research studies.

CAPTURING IMPACT ON EMPLOYEE EXPERIENCE THROUGH NETWORK ANALYSIS OF THE VHA INNOVATORS NETWORK

Anais Tuepker[1,2]; Dylan E. Waller[1]; Elizabeth Orvek[3,4]; George L. Jackson[5,6]; Anita A. Vashi[7,8]; Allen L. Gifford[9,10]; Allison Amrhein[11]; Brynn Cole[11]; Sarah L. Cutrona[3,12]. [1]Center to Improve Veteran Involvement in Care (CIVIC), VA Portland Health Care System, Portland, OR; [2]Department of General Internal Medicine and Geriatrics, Oregon Health & Science University, Portland, OR; [3]Center for Healthcare Organization and Implementation Research, Edith Nourse Rogers Memorial Veterans Hospital, Bedford, MA; [4]Quantitative Methods Core, Department of Population and Quantitative Health Sciences, University of Massachusetts Medical School, Worcester, MA; [5]Center of Innovation to Accelerate Discovery and Practice Transformation (ADAPT), Durham Veterans Affairs Health Care System, Durham, NC; [6]Department of Population Health Sciences, Duke University School of Medicine, Durham, NC; [7]Center for Innovation to Implementation, VA Palo Alto Health Care System, San Francisco, CA; [8]Department of Emergency Medicine, University of California, San Francisco, CA; [9]Center for Healthcare Organization and Implementation Research, VA Boston Healthcare System, Boston, MA; [10]Boston University, Boston, MA; [11]Veterans Health Administration Innovators Network, Department of Veterans Affairs, Washington DC, DC; [12]Division of Health Informatics and Implementation Science, Department of Population and Quantitative Health Sciences, University of Massachusetts Medical School, Worcester, MA. (Control ID #3387541)

BACKGROUND: The Veterans Health Administration Innovators Network (iNET) trains diverse frontline employees in developing health care delivery innovations, with the twin goals of improved employee experience alongside improved care quality. Prior interviews found iNET was highly valued "as a network." To investigate characteristics of the network created and sustained through iNET participation, our evaluation team used network analysis to: 1) quantify connections, known as "edges," in network analysis, created through national and local iNET activities; 2) identify patterns of network growth and engagement associated with participant characteristics (network group, professional role, location); and 3) explore which edges were sustained and why.

METHODS: Initial (T1) data collection used checklists to identify connections created during a national in- person training. At 5 months (T2) and 9 months (T3), tailored emails asked follow-up questions about which connections were sustained through further contact, whether new connections had been created through iNET-related work, and which connections had been most useful and why. We used Gephi network visualization and analysis software to examine density of sustained connections from T1 to T3, density within iNET participant groups, and patterns across roles (MD, non-MD clinical, administrative) and geographic locations. Participants groups were Innovation Specialists (new or established iNET site leads), Innovation Project Investees (leaders of funded innovation projects, most of whom were new to iNET at T1), Finalists (innovation leads from non-iNET VA facilities), and iNET staff/consultants.

RESULTS: 94 iNET participants from 38 VA facilities nationally provided data at T1; T2 response rate was 73% (n=69) and T3 rate was 63% (n=60). Over 9 months in 2019, the network grew from interactions among 162 to 247 individuals, with 44% of T1 edges sustained at T3 (see Image). Edges sustained from T1 (n=524) outnumbered all subsequent edges created (n=126). Edges between investees were infrequently sustained (89/383, or 23%); edges between Innovation Specialists were sustained at a higher rate (137/167, or 82%). Edge creation across roles and locations was common. Innovation specialists were highly valued for instrumental and motivational support; edges resulting from common innovation project interests were also highly valued.

CONCLUSIONS: Network analysis identified overall network growth, frequent edge sustainment, and growth across professional and regional boundaries. The visualization capacity of network analysis aided discussion and actionable feedback to program partners. Network patterns and qualitative data suggest Innovation Specialists provided ongoing support for investees and each other. Connections among investees were less likely to be sustained, with unclear implications. Innovation training programs like iNET may effectively dismantle silos and address other barriers to employee engagement and innovation within healthcare.

CAPTURING THE REST: INPATIENT INTERVENTION STUDIES FOR NON-ADHERENT HOSPITALIZED WOMEN TO IMPROVE BREAST CANCER SCREENING ADHERENCE

Waseem Khaliq[1]; Regina Landis[2]; Colleen Siferd[5]; Lisa Jacobs[1]; Melinda Kantsiper[1]; Eric Howell[3]; Scott Wright[4]. [1]Medicine, Johns Hopkins University School of Medicine, Ellicott city, MD; [2]Medicine, CIMS Division, Johns Hopkins, Baltimore, MD; [3]Johns Hopkins, Baltimore, MD; [4]medicine, jhusom, Baltimore, MD; [5]Howard County General Hospital, Columbia, MD. (Control ID #3346167)

BACKGROUND: More than a third of hospitalized women are overdue for breast cancer screening and at high risk for developing breast cancer. We evaluated the feasibility of two separate interventions for non- adherent hospitalized women to improve their adherence to breast cancer screening recommendation. First intervention consisted of inpatient breast cancer screening education, scheduling an outpatient mammography prior to hospital discharge, a reminder phone call and a small monetary incentive for screening test. The second intervention consisted of inpatient breast cancer screening education and offering inpatient screening mammography.

METHODS: For both intervention studies women aged 50-75 years who were hospitalized to a general medicine service and were non-adherent to breast cancer screening were approached for enrollment. Socio- demographic, reproductive history, family history for breast cancer, and medical comorbidities data was collected for all patients. Chi square and unpaired t-tests were utilized to compare characteristics among women who did and did not get screening.

RESULTS: First intervention was conducted among 30 hospitalized women who were non-adherent to breast cancer screening at Johns Hopkins Bayview Medical Center, the mean age for study population was 57. 8 years, mean 5-year Gail risk score was 1. 68, and 57% of women were African American. Only one third of the enrolled women (n=10) went to their pre-arranged appointments for screening mammography. Not feeling well enough after the hospitalization and not having insurance were reported as main reasons for missing the appointments. Second intervention was conducted among 101 hospitalized women non-adherent to breast cancer screening at Howard County General Hospital, the mean age for this study population was 59. 2 years, mean 5-year Gail risk score was 1.63, and 29% of women were African American. More than two-third of the enrolled women (n=79) under went in-patient screening mammography. All women who underwent screening mammography during inpatient stay were extremely satisfied. Neither the ordering hospitalists nor the nurses taking care of these women reported any concerns or misgiving. Convenience of having a screening mammography while in-patient stay was reported to be a facilitator of completing the screening test.

CONCLUSIONS: Although both interventions were successful in improving awareness and adherence to breast cancer screening, inpatient mammography intervention had much higher impact on breast cancer screening adherence. Because hospitalization creates the scenario wherein patients are in close proximity to healthcare resources, at the same time that they are reflecting upon their health status, strategies could be employed to counsel, educate, and motivate these patients towards health maintenance. Future studies need to evaluate the inpatient feasibility of other common cancer-screening tests to overcome the significant barriers to compliance with cancer screening for hospitalized population.

CARDIOVASCULAR DISEASE GUIDELINES AND THE ART OF MEDICINE: COMPARING GUIDELINES AND PRIMARY CARE PROVIDERS' APPROACH TO CVD TREATMENT

Jeremy Sussman[1,2]; Jane Forman[3]; Laura Damschroder[4]; Kunal Mathur[1]; Bradley Youles[5]; Linda Takamine[6]. [1]Internal Medicine, University of MIchigan, Ann Arbor, MI; [2]VA Ann Arbor Healthcare System, Ann Arbor, MI; [3]HSR&D, VA Center for Clinical Management Research, Ann Arbor, MI; [4]Ann Arbor VA Center for Clinical Management Research, Ann Arbor, MI; [5]Health Services Research & Development, Department of Veterans Affairs, Ann Arbor, MI; [6]Health Services Research & Development, VA, Ann Arbor, MI. (Control ID #3392586)

BACKGROUND: Clinical practice guidelines have been accused of emphasizing strong dichotomies such as treatment thresholds and being insufficiently attentive to patient values and context. To understand potential misalignment between published guidelines and the information providers need to provide patient care, we performed a qualitative analysis of interviews with primary care providers about their practice and guidelines for prevention of cardiovascular disease (CVD).

METHODS: This was a qualitative study comparing 9 CVD prevention guidelines with primary care providers' approach to CVD treatment, as described in 30 to 60-minute semi-structured interviews in which they formulated treatment plans for four patient scenarios. Interviews were conducted in person and by phone. Using a content analysis approach, we developed coding categories encompassing pharmacologic and nonpharmacologic factors based on clinical experience and inductively from the interview data. We applied these codes to the interview transcripts and to the text in the CVD treatment guidelines from the American Heart Association, the US Preventive Services Task Force, and the National Institutes of Health, then compared findings across the two types of data sources.

RESULTS: Guidelines consistently provide detailed instructions for *pharmacologic* treatment decisions. In interviews, providers cited and attempted to follow these guidelines with relatively little variation. In contrast, providers showed much greater variation in the degree to which they focused on *nonpharmacologic* factors, and in their methods of addressing them. Further, for nonpharmacologic factors, there was a notable divergence between providers' accounts of treatment decision-making and the guidelines. Providers regularly demonstrated that these aspects of care – patient lifestyle and behavior, shared decision-making (SDM), social determinants of health (SDOH), medication adherence, and team-based care – were as critical to treatment decisions as pharmacologic options. Though guidelines do urge *assessment* of these nonpharmacologic factors, they are dramatically less emphasized and often lack *actionable strategies* to address them, such as details on how to perform SDM or how to access resources to improve lifestyle behavior for individual patients. Providers expressed clear barriers to addressing nonpharmacologic factors, including: insufficient time; that SDOHs may be unactionable (e.g., solving a patient's lack of access to fresh food); and the difficulty of performing true shared decision-making and of improving adherence. Guidelines rarely guided providers in how to overcome these barriers.

CONCLUSIONS: Providers approached CVD treatment at a greater level of nuance and with different priorities than are captured by guidelines. Guidelines, performance measures, and other tools that guide clinical care must recognize the breadth of factors in clinical decision-making and provide better support to providers for addressing them.

CBD OR CBT: WHAT TYPES OF TREATMENT DO PAIN MANAGEMENT SPECIALISTS PROVIDE?

Pooja Lagisetty[1]; Stephanie Slat[1]; Goodarz Golmirzaie[2]; Jennifer Thomas[1]; Amy Bohnert[2]. [1]Internal Medicine, University of Michigan, Ann Arbor, MI; [2]Anesthesiology, University of Michigan, Ann Arbor, MI. (Control ID #3390382)

BACKGROUND: An estimated 50 million Americans experience chronic pain. To minimize risks associated with opioid treatment for chronic pain, governmental agencies recommend a multimodal approach, combining medications, restorative therapies, procedures (e.g. joint injections) and behavioral therapy with "timely, early consultation with pain specialists" for complex pain. This study sought to quantify access to pain clinics and the services they offer.

METHODS: The study used "secret shopper" audit methodology during July 2019-September 2019.3 The pain clinics were sampled from IQVIA OneKey, a frequently updated healthcare database listing over 9.6 million practitioners, and were drawn from 9 states. Research Assistants (RAs) called clinics posing as a patient on long-term opioid therapy (LTOT)

seeking care. RAs asked about clinic size, providers available, treatments offered, insurances accepted, referral requirements, wait time for a new patient appointment, and providers' willingness to prescribe opioids, assist with opioid tapering, and/or use buprenorphine to manage pain. Descriptive analysis was performed to summarize findings.

RESULTS: Of these 366 clinics in the sample, 48.1% were unwilling to accept patients with Medicaid. Additionally, 54.9% required a referral before accepting patients, and another 23.2% reported that referral requirements varied by insurance. The median wait time for a new appointment was 9 [IQR 4-17] days. Nearly all clinics (97.0%) performed interventional procedures and 77.3% managed pain medications; over a third (36.3%) offered only one or both of these services. Physical therapy was offered by 38.3%. A quarter (25.1%) offered cannabidiol (CBD) products in the 8 states where they were legal (n=355). Opioid tapering was offered at 246 clinics (67.2%); 105 (42.7%) of those reported having a buprenorphine provider on staff. Only 12.8% offered behavioral therapy. Multimodal treatment combining procedures, medication management, and behavioral therapy was rare (10.4%).

CONCLUSIONS: This study indicates many gaps in access to care at pain clinics, especially to multimodal care. Almost half of pain clinics did not accept Medicaid, and many required primary care physician (PCP) referrals, which may be difficult for patients on LTOT to obtain. Few pain clinics offered behavioral therapy, which can address factors such as pain catastrophizing that are commonly associated with pain-related disability. Interestingly, more clinics offered CBD products than behavioral therapy, despite evidence for CBD being less robust than that for behavioral therapy. The focus on procedural pain relief may be particularly limiting in patients who have chronic pain with co-morbid substance use disorders. Thus, while timely multimodal specialty care may be the ideal pain treatment model, it is currently unavailable to most patients.

CHALLENGES AND BARRIERS IN MODERN DAY CARE COORDINATION

Yousaf Ali[1,2]. [1]Medicine, University of Rochester, Rochester, NY; [2]School of Medicine and Dentistry, Rochester, NY. (Control ID #3386530)

BACKGROUND: The care of hospitalized patients have become increasingly complex. Inpatient care coordinators (CC) play an integral role in helping care teams with this transition of care and provide valuable guidance and support for patients as they navigate the transition from the hospital to home or other care setting. Additionally, they establish a reliable link between hospitalists and primary care physicians. Hospitals face pressure to perform well on outcomes such as length of stay, patient flow, and readmissions which places additional pressures on CC roles and responsibilities.

We conducted a survey to determine the role and function of inpatient CC, highlight some of the challenges and barriers faced by hospital based CC, and outline potential ways in which care teams can assist CC.

METHODS: Design/setting: Survey based study of inpatient CC across academic, private, and VA Medical Centers. Subjects: Hospital based CC, social workers, and case managers.

A survey monkey link with a ten-question survey was emailed to 156 inpatient CC from five teaching hospitals. Survey questions were developed and analyzed by the study investigators. 85 subjects completed the survey between October and December 2019 with a response rate of 54.4%. Majority of the questions were closed ended with one open comment question.

RESULTS: Most CC described their responsibilities as arranging home health services and equipment, follow up appointments and transportation. 60% of the survey participants develop patient care plans based upon the physician management plans. CC identified contacting family members and obtaining primary care appointments as a major barrier. 36% described constant interruptions in workflow as a consistent challenge and 34% note challenges with understanding the medical providers' follow up plans. Significant barriers with negative impact on CC workflow include extended hold time when making appointments and communication with providers. 70% felt that lack of patient engagement was a significant barrier. 89% of CC reported that a major cause of patient dissatisfaction at discharge related to patients not feeling ready for discharge followed by insurance non-coverage of home equipment and transport. CC suggested improving communication for discharge planning, changes, and/or consistency in the discharge plan, timely completion of discharge paperwork with advanced notice, seeking improved communication from travel and medical services, increase responsiveness and accountability from physicians and consultants, and to have a trusting, collaborative relationship.

CONCLUSIONS: CC care for an increasingly complex group of hospitalized patients with a variety of roles and responsibilities. This study identifies some issues that lead to patient dissatisfaction at discharge, identifies barriers that impact the work of CC, and offers suggestions for improving the work of CC through closer collaboration, trust, improved communication, and institutional support.

CHALLENGES THAT OCCUR WHEN ATTEMPTING TO DE-IMPLEMENT POTENTIALLY HARMFUL CARE: THE ROLE OF OTHER PROVIDERS AND INHERITED PRESCRIPTIONS

Toral J. Parikh[1,5]; Chris Gillespie[3]; Krysttel Stryczek[2]; George Sayre[1,6]; Barbara Majerczyk[1]; Christine Hartmann[1,6]; Megan B. McCullough[3]; Steven Zeliadt[1,6]; David Au[1,7]; Christian D. Helfrich[4,6]. [1]Health Services Research and Development, Puget Sound VA Healthcare System, Seattle, WA; [2]Research & Development, VA Northeast Ohio Healthcare System, Mentor, OH; [3]Center for Healthcare Organization and Implementation Research, VA Health Services Research & Development, Bedford, MA; [4]Health Service Research and Development, VA Puget Sound Healthcare System, Seattle, WA; [5]Division of Gerontology and Geriatric Medicne, University of Washington, Seattle, WA; [6]School of Public Health, University of Washington, Seattle, WA; [7]Division of Pulmonary, Critical Care, and Sleep Medicine, University of Washington, Seattle, WA. (Control ID #3390923)

BACKGROUND: Despite knowing the futility or the potential harms of certain clinical practices, providers struggle to successfully de-implement them. While the literature offers examples of barriers and promoters of de-implementation, the context is limited to qualitative data from hypothetical scenarios or generalized concepts. There are few reports from specific interventions to reduce low-value practices and even fewer on patterns across multiple de-implementation projects. Our aim was to assess factors influencing the provision of and the challenges to de-implementing specific low-value practices across three de-implementation projects.

METHODS: Semi-structured qualitative interviews with primary care providers (PCPs), specialists, and clinical staff were conducted as part of three distinct quality improvement clinical de-implementation projects at Veterans Health Administration (VHA) medical facilities. The projects focused on reducing (1) unnecessary follow-up imaging for lung nodule surveillance, (2) use of inhaled corticosteroids (ICS) for mild- to moderate COPD, and (3) use of antipsychotic medications to address disruptive behavior in dementia. Forty-nine providers and clinical staff were interviewed about their experiences with the low-value practice and de-implementation efforts at their sites. We conducted a cross-project inductive thematic analysis of factors influencing the decision to deprescribe in these three areas. We focus on one emergent and particularly salient theme, the role of other providers who interact with patient care prior to or during the intervention but not specifically targeted by it.

RESULTS: In all three studies, participants reported that other providers both facilitate and complicate their decision to deprescribe low-value care. Facilitators included providers identifying their colleagues and specialists as resources for guideline updates and discontinuation of low-value practices. For example, PCPs reported reaching out to colleagues or specialists with specific questions or referred their patients to specialists. One barrier was that PCPs and specialists reported feeling hesitant to discontinue a practice, even if considered an overtreatment, that was prescribed by another provide. Likewise, clinical staff reported additional challenges to discontinuing a low-value practice if the patient enrolled in their care with an inherited prescription or recommendation from a previous provider.

CONCLUSIONS: Other providers involved in patient's care, either previously or in real time, could hold a major influence on providers' and staff's ability and willingness to de-implement low-value practices. Successful interventions might target the strength of a specialist's influence, empowering PCPs to take ownership of prescriptions they may have not initiated, and encouraging clinical staff to play a more dynamic role in deprescribing potentially harmful practices that have become status-quo for the patient.

CHANGE IN ATTITUDES OF INTERNAL MEDICINE INTERNS TOWARDS COMMUNITY- ORIENTED PRIMARY CARE EDUCATION AT AN URBAN, ACADEMIC RESIDENCY PROGRAM FROM 1998-2018

Stephanie Nothelle[2]; Manasa Ayyala[3]; Rebeca Rios[5]; Belinda Chen[4]; Erica N. Johnson[1]. [1]Department of Medicine, Division of Infectious Diseases, Johns Hopkins School of Medicine, Baltimore, MD; [2]Medicine, Johns Hopkins Bayview Medical Center, Baltimore, MD; [3]Medicine, Rutgers New Jersey Medical School, Newark, NJ; [4]Medicine, Johns Hopkins, Baltimore, MD; [5]Family Medicine, Georgetown University School of Medicine, Washington, DC. (Control ID #3392400)

BACKGROUND: Despite a growing interest in focusing on social context, it is unclear how exposure to these concepts prior to residency and the value residents place on these experiences have changed over time. We aim to describe how residents' prior exposure to community-oriented primary care (COPC) and attitudes towards the importance of an experience in COPC changed in our residency program over 20 years.

METHODS: We used survey data from Internal Medicine residents who attended an urban, academic residency program from 1998-2018. The voluntary survey was administered to interns prior to completion of a mandatory COPC curriculum to assess their baseline knowledge and experiences with COPC. We grouped responses into three time points (1998-2008, 2009-2012, 2015-2018) that reflect the addition of a patient-centered curriculum and a social determinants of health curriculum that may have affected who selected our program. Gaps in time reflect missing data. Our primary outcome was change over time in the response to: "Rate how important an education experience on community health is to your professional values?" We hypothesized that the numerical rating would increase over time, reflecting changing attitudes of our residents. As secondary objectives, we examined how rating of the importance of an educational experience in community health was to future career plans and how previous involvement in community health changed over time. We used descriptive statistics to determine proportions of responses in each time period and Pearson's chi-squared testing to calculate p-values.

RESULTS: We reviewed data from 182 available surveys. Most (n=104) completed the survey between 1998-2008, with fewer in 2009-2012 (n-27) and 2015-2018 (n=51). The demographics of each cohort are as follows: 1998-2008 (n=137, 53% women, 22% underrepresented in medicine [UIM], 45% in the Primary Care Track [PCT]); 2009-2012 (n=45, 53% women, 20% UIM, 40% PCT); and 2015-2018 (n=48, 48% women, 35% UIM, 35% PCT). Across all cohorts, 87% of residents rated an experience in community health as very important or essential to their professional values and 37% rated an experience in community health as very important or essential to their career plans. There was a statistically significant increase in previous experience with community health over time, with 52% of residents reporting no experience in community health from 1998-2008, 40% from 2009-2012 and 26% from 2015-2018 (p=0.04).

CONCLUSIONS: Although ratings of the importance of an experience in community health for professional values or career goals did not change over time, residents entering the program were significantly more likely to report previous experience in community health. This may reflect changes in medical school curricula or changes to the applicant pool to our program in response to an increase in community-oriented curricular offerings. Residency training is another opportunity to create learning experiences that may influence learners to focus on COPC.

CHANGES IN BREAST CANCER SCREENING COSTS AFTER THE INTRODUCTION OF DIGITAL BREAST TOMOSYNTHESIS

Ilana B. Richman[1]; Jessica Long[1]; Natalia Kunst[5,1]; Jessica Hoag[1]; Xiao Xu[2]; Kelly A. Kyanko[3]; Jenerius Aminawung[1]; Susan Busch[4]; Cary Gross[1]. [1]Division of General Internal Medicine, Yale School of Medicine, New Haven, CT; [2]Department of Obstetrics, Gynecology and Reproductive Sciences, Yale University School of Medicine, New Haven, CT; [3]Population Health, NYU School of Medicine, New York, NY; [4]Health Policy and Management, Yale University, New Haven, CT; [5]Department of Health Management and Health Economics, University of Oslo, Oslo, Norway. (Control ID #3390569)

BACKGROUND: Previous studies have estimated that breast cancer screening costs more than 7 billion dollars annually in the US. However, in recent years, screening technology has changed considerably with the introduction of digital breast tomosynthesis (DBT). DBT is more expensive than 2D mammography but may produce fewer false positives requiring costly follow up. The impact of DBT on screening costs has not been well characterized. The goal of this study was to characterize changes in screening costs associated with the introduction of DBT in a privately insured population, and to estimate corresponding changes in total national expenditures.

METHODS: We conducted a longitudinal study of screening costs from 2012-2018, using the Blue Cross Blue Shield Axis, a large database of commercial claims. We identified screening 2D mammograms and DBT among women 40-59 in each calendar year. We calculated the cost of the screening test as well as the screening episode. Episodes included the initial screen plus any follow up tests (diagnostic mammography with or without DBT, ultrasound, MRI, and biopsy) performed within 4 months. DBT costs were calculated for 2015 onward, as DBT was not reimbursed prior to 2015. All costs were inflation-adjusted to 2017 dollars. Pairwise comparisons of median costs used the Wilcoxon rank-sum test. We also used Census and CDC data to estimate screening costs among privately insured women in this age group nationally.

RESULTS: Our study included 14,027,791 women screened between 2012-2018. The median cost of a 2D mammogram fell from $223 in 2012 to $216 in 2015 (p=<0.001), to $196 by 2018 (p<0.001 for 2015 vs 2018). By contrast, between 2015 and 2018, the cost of DBT rose from $274 to $285 per test (p<0.001). The proportion of women screened with DBT also rose during this period from 12% to 58%. As a result, the median cost of a screening exam increased from $223 to $237 (p<0.001), a 6% increase overall, despite a 12% decline in the cost of a 2D mammogram. Between 2012-2018, the median episode cost among all screened women rose from $233 to $261 (p<0.001). Median episode costs among women

screened with 2D were steady 2012-2015 at $233 then declined to $210 in 2018 (p<0.001 for 2015 vs 2018). Episode costs for women screened with DBT were higher overall, and rose from $294 to $309 between 2015-2018 (p<0.001). During this period, rates of follow up among screened women were stable at 12-13%. Given national mammography rates in this age group, we estimate that the introduction of DBT was associated with an additional $769 million in health care expenditures since 2015.

CONCLUSIONS: The introduction of DBT has contributed to rising breast cancer screening costs. Although changes in unit costs for screening are relative small, mammography is widely used and these small changes translate into large national expenditures. Whether this additional expenditure on screening has contributed to improved health is not known.

CHANGES IN FINANCIAL MARGINS AND QUALITY AMONG CRITICAL ACCESS HOSPITALS AFTER THE AFFORDABLE CARE ACT

Paula Chatterjee[1]; Rachel M. Werner[2]; Mingyu Qi[3]; Karen E. Joynt Maddox[4]. [1]General Internal Medicine, University of Pennsylvania, Philadelphia, PA; [2]Medicine, University of Pennsylvania and Philadelphia VA, Philadelphia, PA; [3]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; [4]Medicine/Cardiology, Washington University School of Medicine, Saint Louis, MO. (Control ID #3390547)

BACKGROUND: Critical access hospitals (CAHs) are safety-net institutions that serve rural and underserved areas. Often located in areas with high rates of poverty and low population density, they struggle financially and have had challenges providing high-quality care. Medicaid expansion under the Affordable Care Act (ACA) broadened insurance coverage and reduced hospitals' financial burden of uncompensated care in states that elected to expand, which could be highly beneficial for CAHs. However, whether the financial circumstances or quality of care at CAHs changed after the ACA remains unknown.

METHODS: Difference-in-differences (DID) linear regression comparing changes over time in financial parameters, patient experience, and clinical outcomes between CAHs in states that expanded Medicaid in 2014 compared to those that did not.

RESULTS: From 2011 to 2016, we identified 543 CAHs in states that expanded Medicaid and 661 in states that did not. CAHs in expansion states were more likely to be in the West (28.4% in expansion states vs. 13.2% in non-expansion states, p<0.001) and Midwest (49.8% vs. 44.5%, p<0.001), and were more likely to be non-profit (41.5% vs. 37.9%, p<0.001). There was no difference in average baseline percent of uncompensated care between CAHs in expansion and non-expansion states (0.09 vs. 0.09, p=0.11). Uncompensated care declined more among CAHs in expansion states compared to those in non-expansion states (difference-in-differences DID=-0.37, p=0.02). While the magnitude of differential changes in net hospital operating revenues (DID= $1,795,434, p=0.16) and operating margins (DID=3.2, p=0.11) was large, estimates were imprecise. There was a small reduction in 30-day readmissions for acute myocardial infarction among CAHs in expansion states as compared to those in non-expansion states (DID=-0.62%, p=0.009). However, there were no other significant differential changes in quality between CAHs in expansion vs. non-expansion states (1.16% change in overall patient experience ratings, p=0.16; -0.03% change in all-cause 30-day readmissions, p=0.74; 0.01% change in 30-day heart failure readmissions, p=0.97; -0.03% change in 30-day pneumonia readmissions, p=0.86; -0.12% change in 30-day heart failure mortality, p=0.43; 0.60% change in 30-day acute myocardial infarction mortality, p=0.48; 0.40% change in 30-day pneumonia mortality, p=0.09).

CONCLUSIONS: The ACA was associated with reductions in uncompensated care at CAHs in states that adopted Medicaid expansion, however there was limited evidence that quality improved among CAHs in expansion states, apart from a small decrease in readmission rates from acute myocardial infarction. CAHs continue to face important financial challenges despite recent reductions in uncompensated care associated with expansions of insurance coverage. Whether improving financial margins among these safety-net providers leads to better quality remains an important focus for policymakers.

CHANGES IN HEALTH CARE SPENDING, UTILIZATION, AND MORBIDITY AFTER FIREARM INJURIES

Zirui Song[1,2]; Erica Paulos[1]. [1]Department of Health Care Policy, Harvard Medical School, Boston, MA; [2]Department of Medicine, Massachusetts General Hospital, Boston, MA. (Control ID #3392062)

BACKGROUND: While deaths from firearms has garnered increasing public attention, relatively little is known about the impact of firearm injuries on survivors and their families. We examined economic and clinical consequences of firearm injuries among survivors and family members.

METHODS: Using 2007-2017 commercial insurer and Medicare claims, we analyzed spending, cost- sharing, utilization, and diagnoses before and after firearm injuries among survivors (treatment group), all of whom were continuously enrolled for at least 3 years. Counterfactuals (control group) were constructed using claims history. In addition to unadjusted analyses, we estimated the treatment effect of firearm injury by comparing treatment and control group outcomes in a difference-in-differences analysis using an event study framework, with individual fixed effects and standard errors clustered by individual. Family members were studied analogously.

RESULTS: There were 4,051 survivors of firearm injury, averaging 33.2 years old with 84.3% male. Unadjusted total spending increased from $1,014 per month prior to firearm injury, to $64,208 during the month of firearm injury, then $1,910 per month afterwards. Unadjusted cost-sharing similarly rose from $83 per month before, to $2,007 during, and to $111 after firearm injury. In adjusted analysis, firearm injury was associated with increases of $62,860 (p<0.001), $4,093 (p<0.001), $1,755 (p<0.001), $702 (p=0.048), and $683 (p=0.03) in total spending over the first 5 months, respectively, relative to control. Sharp increases in tests and treatments explained these findings. Findings were similar among subgroups of survivors of assault, self-harm, and other causes. Spending and cost-sharing rose to a lesser degree among family members after firearm injury in the survivor, driven by increased use of psychotherapy services.

Following firearm injury, the prevalence of mental health conditions among survivors increased 5.4-fold, driven by diagnoses of anxiety, mood disorders, and adjustment disorders. Prevalence of pain diagnoses increased 3.9-fold, driven by muscle, limb, and generalized pain. Prevalence of substance abuse diagnoses increased 10.0-fold, driven by non-dependent drug abuse and alcohol. Rates of these diagnoses reverted toward baseline in the months subsequent to injury. Family members exhibited a smaller increase in mental health diagnoses compared to that among survivors.

CONCLUSIONS: Among survivors of firearm injuries, health care spending and cost-sharing increased sharply after the injury. Survivors also experienced a discontinuous rise in mental health disorders, pain, and substance abuse, with subsequent return of these diagnoses toward preinjury rates potentially due to treatment or recovery. Family members were also affected, experiencing an increase in spending largely due to mental health services. While public attention is drawn toward firearm deaths, nonfatal firearm injuries exhibit economic and clinical consequences for survivors and their families.

CHANGES IN OUT-OF-NETWORK LABORATORY TEST SPENDING AND VOLUME IN THE UNITED STATES

Zirui Song[1,2]; Timothy Lillehaugen[1]; Jacob Wallace[3]. [1]Department of Health Care Policy, Harvard Medical School, Boston, MA; [2]Department of Medicine, Massachusetts General Hospital, Boston, MA; [3]Health Policy and Management, Yale School of Public Health, New Haven, CT. (Control ID #3392275)

BACKGROUND: Out-of-network costs are concerning to patients and policymakers. Lab tests - the highest volume health care service in the US - are more expensive out-of-network than in-network. To date, little is known about spending and volume of lab tests out-of-network. We examined out-of-network lab test in a nationwide population with employer-sponsored insurance.

METHODS: Using 2008-2016 claims, we evaluated changes in the share of spending and volume of lab tests that occurred out-of-network, adjusted for age, sex, risk, and insurance plan among 27,833,040 unique individuals whose employers continuously contributed data. We decomposed lab tests into sentinel categories. We also studied prices (allowed amount) per lab test out-of-network and in-network. We tested the model in sensitivity analyses.

RESULTS: Subjects averaged 33.8 years of age, 52% female, with a DxCG risk score of 0.9. The share of lab test spending that occurred out-of-network was 5.2% in 2008-2010 and 11.5% in 2014-2016, an increase of 0.8 percentage-points per year ($p<0.001$). This was driven by toxicology tests, for which the share of spending out-of-network rose from 11.9% to 48.2%—an adjusted 2.9% per year increase ($p<0.001$). Out-of- network tests overall increased from 55 tests per thousand people per year in 2008-2010 to 139 per thousand per year in 2014-2016, similarly driven by out-of-network toxicology testing which rose sharply from 38 to 93 tests per thousand per year ($p<0.001$). The average price per out-of-network test increased from $54 in 2008-2010 to $67 in 2014-2016; that for out-of-network toxicology tests increased from $46 to $88 during this period.

We noted a positive correlation between changes in toxicology spending out-of-network and changes in state- level drug overdose mortality. An OLS model at the state-by-year level from 2008-2016, with state fixed effects and standard errors clustered by state, demonstrated that a 1 percentage-point increase in drug-related mortality was associated with a 2.1 percentage-point increase in the share of toxicology test spending out-of- network (95% C.I., 1.5 to 2.8 percentage points, $p<0.001$). This relationship should not be interpreted as causal.

CONCLUSIONS: The share of lab spending out-of-network rose sharply in the past decade. Increased use of out-of-network lab tests and their prices, relative to in-network lab tests, explained the growing share of lab spending out-of-network. This was driven by toxicology lab tests, which are plausibly related to the opioid epidemic given their use in the diagnosis and monitoring of patients with substance use disorders. To our knowledge, this is one of the first nationwide reports of an upward trend in the share of lab spending out- of-network.

In 2018, the Protecting Access to Medicare Act began paying for lab tests in Medicare using commercial prices. Although the price of each test may be modest, toxicology tests billed out-of-network may reflect an economic opportunity from the opioid epidemic, deserving policy attention.

CHANGES IN OUTPATIENT CARE PATTERNS IN MEDICARE AND THEIR IMPLICATIONS FOR PRIMARY CARE FROM 2000-2017

Michael L. Barnett[1]; Asaf Bitton[3]; Jeffrey Souza[2]; Bruce E. Landon[2]. [1]Health Policy and Management, Harvard T.H. Chan School of Public Health, Boston, MA; [2]Health Care Policy, Harvard Medical School, Boston, MA; [3]Ariadne Labs, Brigham and Women's Hospital, Boston, MA. (Control ID #3391135)

BACKGROUND: The US health care system emphasizes use of specialists which can lead to more fragmented and costly care compared to most other health systems. There is little evidence that this emphasis is decreasing. In 2000, 59% of all office visits in the US were with primary care physicians, which decreased to 49% by 2013, while from 1999-2009, referral rates from primary care physicians (PCPs) nearly doubled. These trends raise renewed questions about the capacity for PCPs to coordinate the care of their patients. However, there is little empirical data on specialist use since 2001 or how this translates to the care received across a PCP's patient panel.

METHODS: We analyzed a 20% national sample of claims for fee-for-service Medicare from 2000-2017. We examined outpatient visits to all office-based physicians, divided into PCPs and specialists. In each calendar year, we attributed patients to the PCP with the plurality of their outpatient visits, or to a specialist if no PCP could be assigned. Our main outcomes included annual beneficiary-level counts of visits to PCPs and specialists, the number of distinct PCP or specialist physicians seen, and the percent of all visits with attributed PCPs. We also counted the number of other physicians who had a visit with each PCPs attributed panel each year. We adjusted for demographic trends using beneficiary-level linear regression controlling for age, sex, race/ethnicity and Medicaid eligibility (We did not adjust for comorbidities because of the drift in "upcoding" over this period).

RESULTS: From 2000-2017, the average unadjusted number of annual outpatient visits per Medicare beneficiary increased 14% from 7.19 to 8.19. This was driven almost entirely by a 22% increase in annual specialist visits from 4.14 to 5.07 per beneficiary, while PCP visits increased marginally from 3.04 to 3.11 visits over the same period. However, there were similar increases for in the number of distinct specialists (1.68 to 2.23, 33% increase) and PCPs (0.91 to 1.18, 30% increase) seen annually. At the PCP level, in 2000 the average PCP's attributed patient panel received outpatient care from 93 other physicians, which increased 62% by 2017 to a median of 151 other physicians. Over the same period, the average number of patients shared between PCPs and physicians caring for their patients decreased 31% from 1.7 to 1.3.

CONCLUSIONS: Since 2000, Medicare beneficiaries are having more outpatient encounters with a greater number of physicians, driven by increasing contact with specialty care. Meanwhile, contact with primary care has remained largely stable. These changes translated into a substantial increase in the span of physicians seen annually in a PCP's attributed panel and were also manifested in weaker connections to other physicians over time. To accommodate the increasingly complex task of care coordination, interventions may be necessary to increase PCPs' capacity to care for complex populations spread over many more physicians (i.e. smaller panels).

CHANGES IN PATIENT REPORTED OUTCOMES FROM A DIABETES GROUP VISIT CLUSTER RANDOMIZED INTERVENTION TRIAL AMONG MIDWESTERN HEALTH CENTERS

Arshiya A. Baig[1]; Erin M. Staab[2]; Jefferine LI[5]; Viridiana Luna[5]; Mengqi Zhu[5]; Wen Wan[5]; Amanda Campbell[4]; Cynthia T. Schaefer[3]; Michael T. Quinn[6]. [1]General Internal Medicine, University of Chicago, Chicago, IL; [2]Department of Medicine, University of Chicago, Chicago, IL; [3]Dunigan Family Department of Nuring and Health Sciences, University of Evansville, Evansville, IN; [4]none, Midwest Clinicians' Network, East Lansing, MI; [5]Section of General Internal Medicine, University of Chicago, Chicago, IL; [6]Medicine, University of Chicago, Chicago, IL. (Control ID #3391679)

BACKGROUND: Diabetes group visits (GVs), shared medical appointments in which patients receive self- management education in a group setting, have been shown to improve clinical outcomes. However, few studies have assessed patient-reported outcomes from diabetes group visits, especially in the health center (HC) setting.

METHODS: In our ongoing cluster randomized controlled trial, we assigned 14 Midwestern HCs to a GV intervention arm or waitlist control. Sixty-eight adult patients with A1C ≥ 8% were enrolled in GVs at seven HC intervention sites. GV patients completed surveys at baseline and 6-months (immediately post- intervention.) Patient-reported outcomes included diabetes self-care behaviors, diabetes self-efficacy, diabetes knowledge, satisfaction with current diabetes treatment, diabetes distress (1=not a problem to 6=a very serious problem), diabetes social support (12 domains, 1=strongly disagree to 5=strongly agree), self-report of mental health problems, and satisfaction with GVs. Generalized linear mixed models (for binary or count outcomes) and linear mixed models (for continuous outcomes) were used to test the effect of GVs, and HCs were considered as random intercept effect.

RESULTS: Fifty-seven patients completed baseline surveys (mean age 52 ± 13 years, 70% female, 11% American Indian, 17% Black, 28% Latino, 42% White, 2% Asian; 80% with mean income <$30,000; 22% preferred to speak in Spanish; mean baseline A1C 9.71% ± 1.43%). We found no significant difference in baseline to 6-months in self-care activities. There was a trend towards improvement in self-efficacy in two domains: confidence in exercising at least 30 minutes on 5 or more days in a week (p= 0.09) and in talking to health care provider regarding concerns related to diabetes (p=0.12). Patient's knowledge increased regarding prevention and treatment of high (p=0.01) and low blood sugar (p=0.01); their satisfaction with current diabetes treatment (p=0.01) also increased. There was a trend towards less overall diabetes distress (3.13 ± 1.21 vs. 2.64 ± 1.31, p=0.08). Overall diabetes social support showed a trend towards improvement (3.51 ±0.73 vs. 3.84 ± 0.79, p=0.07). Diabetes social support showed significant improvements in four domains and trends towards improvement in two domains. Among those who reported a mental health problem in the past six months (62% of patients), there was an increase in the percentage of patients who reported being prescribed a medication from baseline to 6-months (50% vs. 94%, p=0.01). Patients were highly satisfied with the GVs.

CONCLUSIONS: Adults with uncontrolled diabetes who received care in GVs in HCs had improvements in diabetes self-efficacy, diabetes knowledge, diabetes distress, satisfaction with their diabetes treatment, diabetes social support, improvement in treatment of mental health problems, and high satisfaction with the GV program. Future analyses of our ongoing trial will provide assessment of changes in clinical outcomes and long-term patient reported outcomes.

CHANGES IN PRESCRIPTION DRUG SPENDING AND UTILIZATION 8 YEARS INTO GLOBAL PAYMENT

Zirui Song[1,2]; Jose Zubizarreta[1]; Yunan Ji[3]; Dana Safran[4]; Michael E. Chernew[1]. [1]Department of Health Care Policy, Harvard Medical School, Boston, MA; [2]Department of Medicine, Massachusetts General Hospital, Boston, MA; [3]PhD Program in Health Policy, Harvard University, Cambridge, MA; [4]Haven, Boston, MA. (Control ID #3390073)

BACKGROUND: The growth of prescription drug spending is a leading concern for policymakers. To date, efforts to tackle prescription drug spending have focused on lowering drug pricing. Alternative payment models in which providers bear risk for population spending may be another strategy for slowing the growth of drug spending, but evidence of their effects is sparse. We examined a large, two-sided global budget payment model, the Alternative Quality Contract (AQC), over its first 8 years and assessed changes in drug spending and utilization associated with this payment model.

METHODS: We used 2006-2016 data from Blue Cross Blue Shield of Massachusetts, which implemented the AQC, and Truven Health Analytics, which provided data for a control group. The intervention group comprised about 700,000 unique enrollees whose providers entered the AQC; the control group comprised roughly 1,040,000 unique enrollees from the 8 other Northeastern states whose providers were not in the AQC. Cardinality matching was used to balance treatment and control groups based on age, sex, and DxCG risk score. Through an intention-to-treat approach, we used a difference-in-differences model at the individual-year level. We decomposed spending by insurer and patient (cost-sharing) portions and by branded and generic drugs. We tested for differences in pre-intervention trends and the robustness of main results.

RESULTS: Over the first 8 years, we found large and statistically significant reductions in prescription drug spending attributable to the AQC. Across the 4 initial cohorts that entered the contract in years 2009-2012, estimated changes in prescription drug spending ranged from -12% to -24% of total prescription drug spending relative to control (p<0.001). Relative reductions of similar magnitude were observed in the insurer portion of spending, while relative reductions in patient out-of-pocket costs (cost-sharing) were generally smaller. Changes in spending and utilization differed among branded and generic segments across the cohorts. Directly analyses of quantity revealed that the number of specialty drug scripts declined by roughly 11% to 24% of pre-intervention levels across the cohorts, though not all estimates were significant.

CONCLUSIONS: Over 8 years in a large two-sided global budget contract, spending on prescription drugs slowed relative to control, driven by savings from branded pharmaceuticals. Reductions in price may be achieved by substitution to generics or other lower-priced alternatives, and reductions in quantity may come from decreased prescribing of drugs in unnecessary or lower-value scenarios. To date, savings on drug spending have not been accompanied by quality deficits or increased ED visits. Population-based prospective payment models with downside risk offers a potential framework to address prescription drug spending. This evaluation offers an initial assessment of longer-run implications under such a global budget model, which resembles other ACO arrangements across the country.

CHANGES IN SAFETY-NET HOSPITAL UTILIZATION ASSOCIATED WITH AFFORDABLE CARE ACT COVERAGE EXPANSION IN 2014

Karen E. Lasser[1]; Meng-Yun Lin[2,3]; Michael Paasche-Orlow[1]; Shuting Wang[1]; Leo Hsia[1]; Amresh D. Hanchate[3,1]. [1]Medicine, Boston Medical Center, Boston, MA; [2]Section of General Internal Medicine, Boston Medical Center, Boston, MA; [3]Social Sciences and Health Policy, Wake Forest School of Medicine, Winston Salem, NC. (Control ID #3382074)

BACKGROUND: Safety-net hospitals (SNHs) often have lower profit margins, with fewer services available. Non-SNHs may thus be more attractive to patients with freedom to choose where they receive care. Medicaid expansion and other provisions of the Affordable Care Act (ACA) increased insurance rates, thus enabling previously uninsured patients the choice to transfer care from SNH to non-SNH. It is unclear how the reduction in uninsurance affected utilization of SNHs overall, or among racial/ethnic minorities.

METHODS: Using 2011-2015 all-payer inpatient discharge data from 12 Medicaid expansion states (AR AZ CA CO IA IL KY MA NJ NY OR PA) and 5 non-expansion states (FL NC TX VA WI), we classified hospitals in the top quartile for the percentage of Medicaid discharges in 2010 in each state as SNHs throughout the study period. Using pre-expansion zip code-level uninsurance rate, we stratified each state into

four quartiles of uninsurance. Using a quasi-experimental difference-in-differences study design and linear regression models with zip code fixed effects, and age, sex and race/ethnicity as covariates, we estimated the post-expansion change in hospitalization rate in higher vs. lowest pre-expansion uninsurance quartiles within states. To assess changes related to ACA reforms overall we estimated separate models for Medicaid expansion and non-expansion states. To assess change from Medicaid expansion alone we compared expansion vs. non-expansion states. We also estimated models for individual states to explore heterogeneous treatment effects. All models examined differences by race/ethnicity.

RESULTS: In analyses of Medicaid expansion states combined, there was no significant change in the proportion of hospitalizations in a SNH in the top three quartiles of uninsurance relative to the lowest uninsurance quartile. In non-expansion states, there was a 1.1% decrease (95% CI -1.8, -0.4) in the proportion of SNH hospitalizations in the highest uninsurance quartile relative to the lowest quartile. There was no change in SNH use associated with Medicaid expansion alone. Across states there was heterogeneity in the direction/magnitude of change. Relative to the lowest uninsurance quartile, the proportion hospitalized in a SNH in the highest quartile decreased significantly in FL (-1.5%), CA (-1.4%), WI (-1.0%), MA (-0.9%), TX (-0.7%), NC (-0.6%), IL (-0.5%), VA (-0.5%) and NJ (-0.3%) and increased significantly in KY (1.4%), NY (1.1%), IA (0.9%), AZ (0.4%). There was heterogeneity in corresponding changes by race/ethnicity with sizable changes among non-Hispanic whites (TX=-6.7%; AR=2.2%), non-Hispanic blacks (CA=-2.8%; TX=1.2%), Hispanics (AR=-7.9%; IL=3.2%) and Asians (NY=-4.9%; MA=2.7%).

CONCLUSIONS: ACA reforms led to heterogeneous changes in SNH use. SNH use decreased in some states and race/ethnic groups (as hypothesized), but increased in others, possibly due to patient preference (e.g., proximity, language services). Further study of underlying factors is warranted.

CHANGES IN THE IMPACT OF THE MEDICARE'S JOINT REPLACEMENT BUNDLED PAYMENT PROGRAM FROM THE SECOND TO THIRD YEAR OF THE PROGRAM

Andrew Wilcock[3]; Michael L. Barnett[1]; J. Michael McWilliams[2]; David Grabowski[2]; Ateev Mehrotra[2]. [1]Health Policy and Management, Harvard T.H. Chan School of Public Health, Boston, MA; [2]Department of Health Care Policy, Harvard Medical School, Boston, MA; [3]University of Vermont, Burlington, VT. (Control ID #3391202)

BACKGROUND: Controversy remains over whether bundled payment models should be voluntary or mandatory and the degree to which providers selectively choose to care for healthier, less costly patients. The Comprehensive Care for Joint Replacement (CJR) model, a randomized, mandatory bundled payment initiative for lower extremity joint replacement (LEJR), provides an opportunity to inform both debates. In 2018, the 3rd year of CJR, Medicare made CJR participation voluntary in half of the participating metropolitan statistical areas (MSAs), enabling a comparison of voluntary vs. mandatory participation. In the third year, Medicare also allowed knee LEJRs to be performed as outpatient procedures, which CJR hospitals have an incentive to avoid to retain more healthier, more profitable patients within bundled payments.

METHODS: Using 2015-8 Medicare claims and difference-in-differences methods, we compared LEJR episodes (admission plus subsequent 90 days) in both the randomly selected 29 MSAs transitioned to voluntary participation vs. their control MSAs and the 38 MSAs where participation remained mandatory vs. control MSAs. Our primary outcomes were institutional spending per episode and predicted spending per episode (measure of patient selection). We also examined characteristics of hospitals in voluntary MSAs who dropped vs. stayed and the percent of inpatient vs. outpatient billed knee LEJR episodes in mandatory vs. voluntary MSAs. Our models adjusted for beneficiary and procedure characteristics as well as hospital and MSA-level random effects to account for clustering of outcomes.

RESULTS: Within voluntary MSAs, the savings from CJR fell by 37%: -$628 (95% CI -1,005,-250) in Year 2 and -$398 (95% CI -856,60) in Year 3. There was no difference in the adoption of outpatient knee billing between intervention vs. control MSAs. In voluntary MSAs, 73% of hospitals performing 62% of episodes dropped out of the CJR program in Year 3. Hospitals that dropped out had higher total spending per episode at baseline vs stayers ($29,215 vs. $27,973). In mandatory MSAs, savings in institutional spending per episode fell by 34%: -$1,273 (95% CI -1,842,-704) in Year 2 and -$838 (95% CI -1,367,-308) in Year 3. This decline was driven by use of outpatient knee procedures. In mandatory MSAs fewer total knee replacements were performed outpatient setting in 2018 (16% vs. 26% in intervention vs. control MSAs).

CONCLUSIONS: By Year 3 of CJR, savings in both voluntary and mandatory MSAs decreased, though by different mechanisms. In voluntary MSAs, the mechanism appears to be differential drop out of higher-cost hospitals that were generating savings. In mandatory MSAs, the mechanism came from risk selection from differential use of outpatient knee procedures. In the current structure of this payment model, higher cost hospitals who may generate the most savings are unlikely to participate. The results also illustrate how providers within such programs can use risk selection to retain healthy, low cost patients.

CHARACTERISTICS OF AMBULATORY VISITS ASSOCIATED WITH SCREENING FOR DIABETES AMONG YOUNG ADULTS: ANALYSIS OF A NATIONALLY-REPRESENTATIVE SAMPLE

Maya S. Venkataramani[1]; Scott J. Pilla[2]; Nisa Maruthur[3]. [1]Division of General Internal Medicine, Johns Hopkins University School of Medicine, Baltimore, MD; [2]General Internal Medicine, Johns Hopkins University, Baltimore, MD; [3]Medicine, Johns Hopkins University School of Medicine, Baltimore, MD. (Control ID #3390496)

BACKGROUND: The prevalence of type 2 diabetes is rising among young adults in the U.S., as are rates of complications among young adults with type 2 diabetes. While early detection is known to be important, diabetes screening among high-risk young adults, for whom screening is recommended, remains sub-optimal. Understanding characteristics of ambulatory visits in which screening occurs is important in identifying opportunities to improve screening practices.

METHODS: We analyzed data from the 2012-2016 National Ambulatory Medical Care Survey, a nationally representative survey of U.S. ambulatory visits. Our analytic sample consisted of visits for adults ages 18-25 who were not currently pregnant and did not carry a diagnosis of diabetes; we also restricted our sample to visits in which patients were seen by a provider (MD, NP, midwife or PA). The primary outcome was prevalence of diabetes screening, defined as having a hemoglobin A1c (HbA1c) or glucose ordered at the visit or drawn on the day of visit. We compared patient (age, race/ethnicity, gender, weight status), provider (e.g., practice specialty) and visit (e.g., type of visit) characteristics between visits with and without diabetes screening using chi-squared tests. All results were weighted yielding nationally representative estimates.

RESULTS: Our analytic sample consisted of 191 million weighted (8,817 unweighted) ambulatory visits over 5 years. Diabetes screening occurred in 2.8% (95% CI 1.8% to 4.2%) of visits. The majority of visits with screening were preventive visits (52.1%), involved female patients (70.4%), and were conducted by general, family or internal medicine providers (74.1%). 34.1% of visits with screening involved Hispanic patients, which was significantly higher than for visits without screening (only 14.2% of visits without screening involved Hispanic patients;

p=0.04). Over 1 in 5 (21.9%) of visits with screening involved patients with obesity, which was also significantly higher than for visits without screening (only 4.4% of visits without screening involved patients with obesity; p<0.01). Visits with screening were also more likely to be preventive care visits than those without screening (52.1% vs 17.5%, p<0.01).

CONCLUSIONS: Diabetes screening with HbA1c or fasting blood glucose was ordered in less than 3% of ambulatory care visits (and overall in only 3.3% of preventive care or regular follow-up visits visits) for 18 to 25 year-olds. Screening was associated with visits involving patients with diabetes risk factors such as Hispanic ethnicity and obesity, and also was more common in preventive visits. Further understanding provider-level factors, such as knowledge of diabetes risk factors, that should prompt diabetes screening in young adults and improving preventive care visit receipt may help enhance screening in this population

CHARACTERISTICS OF EXCESSIVELY PROLONGED HOSPITALIZATIONS IN COLORADO

Sarah A. Stella[1,2]; Mara Prandi-Abrams[3]; Alexandra O. Mannerings[5]; Dominick Kuljis[4]; Sarah J. Cope[1]; Amanda L. Thompson[3]; Joseph W. Keach[1,2]; William J. Burman[6,1]. [1]Department of Medicine, Denver Health, Denver, CO; [2]Department of Medicine, University of Colorado School of Medicine, Denver, CO; [3]Department of Care Management, Denver Health, Denver, CO; [4]Colorado Hospital Association, Denver, CO; [5]Data Prep U, Denver, CO; [6]Denver Public Health, Dever Health, Denver, CO. (Control ID #3390558)

BACKGROUND: Prolonged hospitalizations often do not wholly reflect medical necessity and are instead driven by a variety of non-medical factors. A subset of patients with complex discharge barriers resulting from interactions between their medical and/or psychiatric condition and social circumstances, remain hospitalized long after their acute condition has been resolved. Effectively addressing these excessively prolonged hospitalizations (EPH) requires a better understanding of their characteristics.

METHODS: Denver Health, a safety-net hospital, partnered with the Colorado Hospital Association to conduct an analysis of EPH in the State of Colorado. We utilized the On Demand Hospital Information Network to retrospectively analyze EPH among adult inpatients (18 years or older) between April 1, 2018 and March 31, 2019. We included all urban, rural and critical access hospitals in Colorado, and excluded specialty hospitals (i.e., rehabilitation, long term acute care and psychiatric hospitals). We defined EPH as those with a length of stay (LOS) at least 3 times predicted for that stay's Diagnosis Related Group (DRG) (i.e., LOS-index greater than or equal to 3), excluding stays under 10 days. We assessed the total number of EPH, total excess days (i.e., any inpatient days beyond the national untrimmed arithmetic mean for that DRG), excess costs (i.e., estimated cost of the excess days using a cost-to-charge ratio), patient sociodemographics, and other characteristics of EPH.

RESULTS: During the 1-year study period, there were a total of 6,539 EPH in Colorado representing 1.7% of all hospital discharges, and 11.5% of total inpatient days (163,904 excess days). Average LOS for EPH was 31 days versus 4 days for normal stays. ESH represented 5.8% of total hospital charges. Average charges per EPH were $268,000. Estimated total 1-year cost associated with EPH in Colorado was $89,980,000. The large majority of EPH (89%), excess days (149,945 days) and costs ($83.18M) occurred at urban hospitals. Medicare was the primary payer in 43% of EPH, while Medicaid was the primary payer in 27%, and commercial in 23%. The highest number of EPH and excess days occurred on General Medicine, Behavioral Health, and Neurology services lines. The top 3 DRGs with the highest number of EPH were: Septicemia and Disseminated Infections (430 stays), Other Disorders of Nervous System (393 stays), and Alcohol Abuse and Dependence (337 stays). The top 3 DRGs with the most number of excess days were: Septicemia and Disseminated Infections (11,575 days), Other Disorders of Nervous System (6,977 days), and Schizophrenia (6,931 days).

CONCLUSIONS: Conclusion: Although EPH account for a small proportion of total discharges from Colorado acute care hospitals, they represent a disproportionate share of total inpatient days and costs. This analysis is a crucial first step towards better understanding EPH and may inform the development of meaningful, state-wide policies to deliver better care at lower cost.

CHARACTERIZING GOALS OF CARE MEDICAL RECORD DOCUMENTATION

Neha Reddy[1]; Annapoorna Chirra[2]; Anne M. Walling[2]; Michael A. Pfeffer[2]; Neil Wenger[2]. [1]David Geffen School of Medicine, UCLA, Los Angeles, CA; [2]Medicine, University of California, Los Angeles, Los Angeles, CA. (Control ID #3388758)

BACKGROUND: Mismatch of goals with medical care results in aggressive treatment at the end of life and is related to decreased quality of life and worse caregiver outcomes. Advance care planning (ACP) involves discussions regarding values, prognosis, goals of medical care, treatment preferences, surrogate decision maker, and may yield a completed advance directive (AD) or Physician Orders for Life-Sustaining Treatment (POLST). Goals of Care (GoC) notes in the electronic health record capture these discussions to promote continuity and to inform future care decisions. We characterized the content of GoC notes to understand how ACP is documented.

METHODS: Using grounded theory qualitative methods, we analyzed the content of GoC notes from 2016 at one health system. Every tenth note of 4061 total notes was coded using Atlas.ti until thematic saturation was reached (201 notes coded). Codes were created based upon a preliminary assessment of notes. Further analyses were conducted in Atlas.ti and Excel. C-coefficients were calculated to understand code co- occurrence relationships (c=0 codes never co-occur, c=1 codes always co-occur).

RESULTS: Ninety-one percent of GoC notes contained ACP content (9% other topics such as "healthy baby"). GoC notes contained the following content: 76% treatment preferences (i.e., trial artificial feeding only), 52% prognosis or prognostic awareness, 49% surrogate decision maker, 42% AD, 38% goals of care and future state preferences (i.e., does not want to be kept alive permanently on machines) and 26% POLST. Eighty-nine percent of future state preferences focused on future health states, but 45% of such GoC notes focused on non-health goals. One quarter of GoC notes contained comprehensive ACP documentation of current state/prognosis, future health state/treatment preferences, and decision maker/AD/POLST.

When GoC notes documented family perspectives on treatment preferences, 70% described discussions rather than simply listing preferences, and these discussions more often focused on short-term (days to weeks) rather than long-term (months to years) decisions (c-coefficient=0.59 v 0.07, respectively). In contrast, 64% of GoC notes documenting patient treatment preferences stated the preference without description of discussion.

One quarter of GoC notes used a template and these were tightly linked to documentation of AD (c=0.52), POLST (c=0.44), health care decision maker (c=0.54), and patient opinions on treatment preferences (c=0.59), but tended to contain yes/no data and less detailed documentation of decision making.

CONCLUSIONS: GoC notes are largely used to document family views of real-time end of life treatment plans. Only a minority of GoC notes documented ACP discussions focused on goals of care or future health states. Templates appear to be associated with

breadth, but not depth of documentation. Understanding GoC documentation may inform interventions to improve ACP.

CHARACTERIZING THE RELATIONSHIP BETWEEN VISION AND TECHNOLOGY ACCESS AND USAGE IN ADULT INPATIENTS DIAGNOSED WITH TYPE 2 DIABETES MELLITUS

Juhi Gupta[2]; Vineet M. Arora[1]; Hanna Vollbrecht[2]; Sebastian Otero[1]; Kyle Carey[1]; David Meltzer[1]; Valerie G. Press[1]. [1]Medicine, University of Chicago, Chicago, IL; [2]Pritzker School of Medicine, University of Chicago, Chicago, IL. (Control ID #3391594)

BACKGROUND: Vision is essential for effective disease self-management; however, the role of low vision in self-management has been understudied. One population highly impacted by low vision is persons with diabetes mellitus (DM). DM is the leading cause of new blindness cases in adults and may lead to diabetic retinopathy and glaucoma. The role of vision and self-management is particularly salient with respect to the growing prevalence of Electronic Health (eHealth) interventions for DM self-management. In this study, we assessed differences in access and utilization of technology among adult inpatients with DM and with or without low vision at an academic urban hospital.

METHODS: This is an observational study of hospitalized, adult, general medicine patients who were enrolled in an ongoing quality improvement study (Hospitalist Study), conducted from June through November 2019. Participants who were enrolled in the Hospitalist Study, completed the brief health literacy questionnaire, and met our additional inclusion criteria (i.e. age ≥18 years, English speaking and no need for proxy) were deemed eligible for our sub-study. For our sub-study, patients completed a survey that asked about technology access and use and online capabilities, which was administered at the bedside. Survey responses were stored using REDCap. Visual acuity was assessed using a Snellen Pocket Eye Chart, and DM diagnosis status was determined using the electronic medical record. Descriptive statistics, bivariate chi- squared analyses, and multivariate logistic regression analysis (adjusted for age, race, and gender) were performed using STATA version 15.1 (StataCorp).

RESULTS: Among 49 enrolled participants, the mean age was 52 years, most were black (82%), female (56%), and had at least some college education (60%). Most participants owned technology devices (96%) and had used the internet previously (86%). Participants with low vision (n=27) were less likely to report an ability to perform online tasks without assistance compared to those with normal vision (n=22), including using a search engine (56% vs 91%, p=0.006), opening an attachment (41% vs 86%, p=0.001), and using an online video (56% vs 86%, p=0.02).

CONCLUSIONS: Our study found that technology device ownership and internet usage rates were high in our study population but that participants with low vision reported reduced ability to perform some online tasks as compared to participants with normal vision. This suggests that barriers patients face to using eHealth may be related to online capabilities rather than technology access. To ensure that at-risk populations can effectively utilize these new eHealth technologies, future studies need to be conducted to better understand the relationship between vision level and technology usage.

CHARACTERIZING THE VARIATION OF ALCOHOL CESSATION PHARMACOTHERAPY UTILIZATION IN PRIMARY CARE

Eden Bernstein, Ning Guo, Toyomi Goto, Michael B. Rothberg. Internal Medicine, Cleveland Clinic Foundation, Cleveland, OH. (Control ID #3375203)

BACKGROUND: Excessive alcohol use is linked to 90,000 deaths and more than 250 billion dollars spent in the United States each year. Naltrexone, Acamprosate, and Disulfiram are approved by the Food and Drug Administration (FDA) for the treatment of Alcohol Use Disorder (AUD), but are likely underutilized. Our objective was to describe prescribing trends of these medications by primary care providers (PCPs).

METHODS: We extracted electronic health record (EHR) data of primary care visits in a large healthcare system from 2010 to 2019. Patient inclusion criteria required established care with a PCP, a documented International Classification of Disease (ICD) diagnosis related to AUD, and documented alcohol use in the social history. The resulting data were internally validated to ensure accuracy by manual reference to the EHR. We identified details regarding prescriptions for any of the three FDA approved medications and patient demographics including age, sex, race, median household income, type of insurance coverage, and co-morbidities. We also collected PCP demographics including age, sex, degree, length of practice, and board certification. We compared patient-related factors for those who received a prescription with those who did not using a multivariate analysis. For the provider-level analysis, PCP's with <20 AUD patients were excluded, and prescription rates were analyzed using descriptive statistics.

RESULTS: Of 17,676 patients who met the inclusion criteria, 8.9% received treatment for AUD with one of the FDA approved medications, 3.3% from their PCP. The most commonly prescribed medication was Naltrexone (44.4%) followed by Acamprosate (31.7%) and Disulfiram (23.9%). Patients were on average 53 years old with median household income of $51,770 per year; 65% were male and 46% were Christian; 53% had a co-morbid mood disorder and 56.5% had an anxiety disorder. Patients were less likely to receive treatment if they were Black (aOR 0.71; 95% CI 0.60, 0.85) or older (aOR per decade 0.94; 0.90, 0.98). They were more likely to be treated if they had a higher income (aOR 1.07; 95% CI 1.05, 1.09), a mood disorder (aOR 2.5; 95% CI 2.1, 2.8), or an anxiety disorder (aOR 1.8; 95% CI 1.5, 2.0). Compared to commercial insurance, patients with Medicaid were more likely to be treated (aOR 1.6; 1.3, 1.8), and patients with Medicare (aOR 0.76; 0.64, 0.90) or no insurance (aOR 0.62; 0.48, 0.78) were less likely to be treated. Of 278 PCPs with at least 20 AUD patients, the median rate of initiating treatment was 1.5%; 46.4% did not prescribe medication at all, whereas the top 10% prescribed to 14.3% of their patients.

CONCLUSIONS: Medications for AUD are infrequently prescribed by the vast majority PCP's, particularly for lower income patients, African Americans, older patients, Medicare recipients, and uninsured patients. There is considerable variation in PCP prescriptions with many PCP's not prescribing at all and few high prescribing outliers.

CIVIC ENGAGEMENT AND ADVOCACY: ATTITUDES AND INTENTIONS OF US MEDICAL STUDENTS

Susan Chimonas[2]; Anna Kaltenboeck[2]; Maha Mamoor[2]; Deborah R. Korenstein[1]. [1]Medicine, Memorial Sloan Kettering Cancer Center, New York, NY; [2]Center for Health Policy and outcomes, Memorial Sloan Kettering Cancer Center, Hauppauge, NY. (Control ID #3367770)

BACKGROUND: Civic engagement, particularly regarding just distribution of resources and social determinants of health, is a core component of medical professionalism. Professional organizations frequently emphasize the importance of physician advocacy, but it is unclear how educators can best prepare trainees to meet this professional obligation. We set out to understand medical students' attitudes toward civic engagement, including issues of interest, and to determine congruence with professional obligations.

METHODS: We surveyed a national sample of students from US medical schools. The survey was accessed online through a link from an article posted on the Student Doctor Network (SDN), an on-line student forum; survey completers could enter a lottery to win a $100 gift card. Survey items included questions about demographics and attitudes toward physician advocacy for health issues and involvement in 6 directly medical (e.g. healthcare costs) and 12 related (e.g. immigration) social issues. We used descriptive statistics and chi-square tests to assess associations of attitudes toward advocacy and involvement with sex, political identification, anticipated debt, and intended field. The study was reviewed by our institutional IRB and deemed exempt.

RESULTS: Among 815 viewers of the SDN article, 361 visited the survey and 240 (66%) students representing all US regions completed it. Among the 240 participants, 53% were female; most were white (62%) or Asian (28%) and in MD (82%) or DO (13%) programs. Clinical/non-primary care was the most common intended field (61%). Most agreed that they follow healthcare policy in the news (82%) and plan involvement (80%) and leadership (65%) in healthcare policy issues. Many stated it is very important that physicians encourage medical organizations to advocate for public health (76%), provide health-related expertise to the community (57%), and be politically involved (45%). More participants rated physician advocacy for medical issues as very important (e.g. drug addiction [83%], nutrition [81%], healthcare coverage [81%]) compared to related issues with indirect connections to or implications for health (e.g. national security [22%], transportation [36%], criminal justice [40%]) (p=<0.001). Self-identified liberals were more likely than others to follow health policy in the news (p=0.008) and agree with encouraging medical organizations to advocate for public health (p=<0.001).

CONCLUSIONS: Medical students report political engagement and interest in advocacy, particularly around issues directly tied to healthcare services or health behaviors, which is generally consistent with professional standards. Attitudes remain stable during medical school; few are associated with political affiliation. To optimize physician advocacy, educators should provide opportunities for student engagement in issues of interest.

CLINICAL, DEMOGRAPHIC, PROVIDER AND FORMULARY CHARACTERISTICS ASSOCIATED WITH INITIATION OF A SGLT2 INHIBITOR OR GLP-1 RECEPTOR AGONIST AMONG MEDICARE BENEFICIARIES WITH TYPE 2 DIABETES: A COHORT STUDY

Jing Luo[2]; Inmaculada Hernandez[1]; Nico Gabriel[1]; Walid Gellad[2]. [1]Pharmacy and Therapeutics, University of Pittsburgh, Pittsburgh, PA; [2]Medicine, University of Pittsburgh, Pittsburgh, PA. (Control ID #3386698)

BACKGROUND: Characteristics associated with initiation of newer diabetes medications (e.g. SGLT2 inhibitors and GLP-1 receptor agonists) among older adults with type 2 diabetes (T2D) have not been previously described.

METHODS: Using 2014-2016 claims data from a random 5% sample of Medicare beneficiaries, we sought to describe characteristics associated with initiation of a SLT2i or GLP1-RA, focusing on measures of plan generosity (e.g. the number of drugs covered with no or minimal copays). Our cohort included beneficiaries with T2D who had at least 1 prescription claim for an oral diabetes medication in the 180 days before the start of follow-up (1/1/2015). To identify new initiators, we excluded beneficiaries who filled any insulin, SGLT2i or GLP-1RA prior to the index date or who died before 12/31/16. We developed multivariable logistic regression models controlling a priori for age, race, region, prior medication use, claims-based measures of diabetes severity and clinical comorbidities, provider specialty and measures of formulary generosity.

RESULTS: Of 103,112 eligible beneficiaries (mean age 73, 57% female), 5,076 (4.9%) initiated a SGLT2i or GLP-1RA between 1/1/15-12/31/16. After adjusting for all baseline characteristics, beneficiaries in plans covering 2 or more target drugs in preferred tiers (i.e. 1-3) were more likely (adjusted odds ratio [aOR] 1.18 [95% CI, 1.05 to 1.32]) to initiate one of these medications than patients enrolled in plans covering 0 drugs. Other characteristics associated with higher odds included: age<65 (aOR 1.78 [95% CI, 1.64 to 1.92]), diabetic retinopathy (aOR 1.19 [95% CI, 1.08 to 1.31], obesity (aOR 1.49 [95% CI, 1.38 to 1.62) and having baseline medications prescribed by an endocrinologist (aOR 1.68 [95% CI, 1.49 to 1.89]. Black race (aOR 0.66 [95% CI, 0.60 to 0.73]) and CKD (aOR 0.84 [95% CI, 0.76 to 0.92]) were associated with lower risk of initiation.

CONCLUSIONS: After controlling for a large number of prespecified covariates, Medicare beneficiaries with T2D with more generous prescription drug coverage were more likely to initiate a SGLT2i or GLP-1RA.

CLINICAL FEATURES, RADIOGRAPHIC, AND PATHOLOGIC FINDINGS IN E-CIGARETTE AND VAPING-ASSOCIATED LUNG INJURY

Fionna Feller[1]; Michael Gotway[2]; Prasad Panse[2]; Yasmeen Butt[3]; Maxwell Smith[3]; Brandon Larsen[3]; Henry Tazelaar[3]. [1]Medicine, Mayo Clinic, Scottsdale, AZ; [2]Radiology, Mayo Clinic, Phoenix, AZ; [3]Anatomic Pathology, Laboratory Medicine, Mayo Clinic, Scottsdale, AZ. (Control ID #3390647)

BACKGROUND: New cases of E-cigarettes and vaping associated lung injury (EVALI) continue emerge since the first cases were reported in June 2019. The CDC defines a "confirmed" case of EVALI as using an e-cigarette within 90 days prior to symptom onset with chest CT findings of infiltrates and absence of pulmonary infection. While new data is emerging to define radiographic and pathologic features, the definition of EVALI remains vague. This review aims to further identify the clinical features of these patients along with their radiographic and histopathologic findings.

METHODS: This retrospective study analyzed 24 patients from 19 medical centers in the U.S. who met EVALI criteria according to the CDC. Data on medical history and symptoms were collected. Eight patients were excluded due to minimal data available. All remaining 16 patients received CT chest with images independently reviewed by 2 cardiopulmonary radiologists. Fifteen patients underwent tissue sampling through surgical biopsy, transbronchial biopsy, or cryobiopsy. One patient underwent bronchoscopy with bronchoalveolar lavage only.

RESULTS: Eleven of 16 patients (68%) were male. The average age was 34 years (range: 21 – 67 years). Ten patients (62%) used THC-containing products. All patients presented with cough, 11 with dyspnea (68%), 7 with fever (43%), 4 with chest pain (25%), and 3 with GI symptoms (19%). The most common co-morbidities include chronic lung disease (25%) and obesity (31%). A complete table of all symptoms and co-morbidities will be provided. Three patients had previous occupational exposures. Eight patients (50%) were hypoxic, 3 of which required intubation. The predominant CT chest findings were ground glass opacities (GGO, n=15) and consolidation (n=6). The most common CT pattern was acute lung injury (ALI, 31%) and hypersensitivity pneumonitis (HP, 12%). Fifteen out of 16 patients underwent tissue biopsy, with the most common pathology finding of airway-centered fibrinous and organizing acute lung injury with prominent reactive type 2 pneumocyte hyperplasia.

CONCLUSIONS: There were no significant correlation between pre-existing conditions and severity of respiratory failure. Most common presenting symptoms are cough, dyspnea, fever, and GI symptoms. The main CT patterns observed in our cohort were ALI and hypersensitivity

pneumonitis with GGO and consolidation. The predominant pathology finding was airway-centered acute lung injury with type 2 reactive pneumocyte hyperplasia. Foamy macrophages and inflammatory cells were commonly seen. Our study is limited by incomplete medical records from multiple medical centers. The outcomes of these cases are unknown. Although all cases met CDC criteria for EVALI, it is difficult to completely exclude all other causes of lung injuries. Finally, tissue sampling is not completely precise as the small biopsied area may not accurately represent the overall lung process.

CLINICAL HYPERTENSION GUIDELINES AND SOCIAL DETERMINANTS OF HEALTH

Na'amah Razon[1,2]; Danielle Hessler[1]; Kirsten Bibbins-Domingo[3]; Laura M. Gottlieb[4]. [1]Family and Community Medicine, University of California, San Francisco, San Francisco, CA; [2]Phillip R. Lee Institute for Health Policy Studies, University of California, San Francisco, San Francisco, CA; [3]Medicine, University of California, San Francisco, San Francisco, CA; [4]Family and Community Medicine, UCSF, San Francisco, CA. (Control ID #3391661)

BACKGROUND: One third of U.S adults have hypertension, a major risk factor for mortality from heart disease and stroke. Despite these life-threatening consequences and numerous treatment guidelines, hypertension control is achieved in only half of those diagnosed. Significant inequities in morbidity and mortality persist in minority and low socioeconomic groups. We conducted a scoping review of published hypertension guidelines to explore how they direct clinicians to ask about and address patients' social conditions as part of hypertension management. We defined social conditions based on the Center for Medicare and Medicaid Services initiatives requiring social risk screening. We drew from a National Academy of Medicine's report defining five social care activities foundational to improving care integration at both individual and population levels (5A Framework): *Awareness* of social conditions that influence health; *Adjustments* to clinical decision-making based on contextual data; *Assistance* linking patients to social resources; *Alignment* of resources between health and social services and *Advocacy* to improve community conditions.

METHODS: We reviewed clinical guidelines, protocols, and professional organization statements for hypertension management in adults. Primary outcomes included acknowledgement of social risk on hypertension management or reference to one of the five social care activities.

RESULTS: We found 118 hypertension guidelines using our initial search terms. Forty-three guidelines met all inclusion criteria. 51% (22/43) acknowledged social risk factors as relevant to hypertension management. A partially overlapping 22 guidelines recommended changing care based on social risks. 32% (14/43) of the guidelines did not acknowledge social risk factors or recommend any social care activities as part of hypertension management. When social risk factors were referenced, economic status was the most common social determinant described; one guideline mentioned housing stability and one mentioned utilities security.

CONCLUSIONS: Our analysis highlights important gaps in the translation of social determinants science to clinical practice. Few existing hypertension guidelines acknowledge the impact of social risk factors on hypertension control. Even fewer provide instruction for clinicians on how to screen for or intervene around social risks, including on topics such as food, housing, transportation, and utilities. Findings may reflect gaps in existing evidence on social risk interventions, but also may reveal potential opportunities to identify at-risk individuals who will benefit from tailored hypertension interventions. This review underscores opportunities to elevate research on the intersection of social risk and hypertension. Future guideline developers will need to closely examine emerging evidence on social determinants as a strategy for improving hypertension management.

CLINICALLY MEANINGFUL ANXIETY, COGNITIVE FUNCTION, AND ASSOCIATIONS WITH HEALTH LITERACY AND SELF-MANAGEMENT SKILLS

Rebecca Lovett[1]; Julia Yoshino Benavente[2]; Esther Yoon[1]; Alex Federman[3]; Michael S. Wolf[4]. [1]Department of General Internal Medicine and Geriatrics, Northwestern University, Chicago, IL; [2]General Internal Medicine, Northwestern University, Chicago, IL; [3]Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; [4]Medicine, Northwestern University, Chicago, IL. (Control ID #3387220)

BACKGROUND: High levels of anxiety have been linked to poor medical outcomes, however mechanisms underlying these observed relationships are not entirely clear. The ability to make informed healthcare decisions ('health literacy') and successfully self-manage health may be one pathway linking anxiety to poorer health. We sought to determine the prevalence of clinically meaningful symptoms of anxiety in a cohort of older adults, and to examine associations with health literacy and chronic disease self-management skills.

METHODS: 897 adults aged 55-74 were recruited from diverse primary care settings across Chicago, IL. Clinically meaningful anxiety was defined as a T-score of ≥60 on the Patient-Reported Outcomes Measurement Information System (PROMIS) Anxiety short-form. Health literacy was measured using the Test for Functional Health Literacy in Adults (TOFHLA) and dichotomized into adequate and limited literacy. The Comprehensive Health Activities Scale (CHAS) was used to measure chronic disease self-management skills, such as navigating written materials, recalling instructions presented in oral or technology-based formats, and dosing complex medication regimens. Adjusted logistic and linear regressions were used to assess associations between clinically meaningful anxiety symptoms and outcomes of interest. A factor score representing cognitive function was entered into subsequent models.

RESULTS: 23% percent (n = 208) of the sample endorsed clinically meaningful symptoms of anxiety. These participants were more likely to be only high school educated, earn <$25,000 per year, and self-report a greater number of chronic medical conditions (3.6 vs. 2.4). In adjusted multivariable analyses, clinically meaningful anxiety was significantly associated with poorer overall performance on self-management tasks (B -2.39, 95% CI -4.61, -0.17; p = 0.04). When broken down by skill type, it was associated with poorer recall of spoken instructions (B -3.32, 95% CI -6.42, -0.22; p = 0.04) and recall of information presented in multimedia modalities (B -3.71, 95% CI -7.32, -0.10; p = 0.04), specifically. When entered into models, cognitive function significantly attenuated these associations. All remaining outcomes were found to be non- significant.

CONCLUSIONS: The presence of significant anxiety symptoms may be relatively common yet undetected among older adults in primary care settings, and may interfere with successful management of medical conditions. This may be due to anxiety's negative impact on cognitive processes such as attention and memory, which are involved in many healthcare-related tasks. Routine screening for symptoms of anxiety among patients with medical conditions may help better identify and treat psychological distress that may impact adequate self-management. For patients identified with anxiety, the modality in which important medical information is disseminated should also be considered.

CLINICAL STATUS QUO OF INFECTIVE ENDOCARDITIS IN JAPAN: A SINGLE HOSPITAL- BASED RETROSPECTIVE STUDY

Shun Yamashita[1]; Masaki Tago[1]; Midori Tokushima[2]; Naoko E. Katsuki[1]; Shu-ichi Yamashita[3]. [1]General Medicine, Saga University Hospital, Saga, Japan; [2]General Medicine, saga university, Saga, Japan; [3]General Medicine, Saga medical university, Saga, Japan. (Control ID #3346042)

BACKGROUND: No research on infective endocarditis (IE) of more than 40 patients from all the departments of hospitals they possibly visited in Japan had been conducted since 2000. Imaging modalities such as computed tomography or magnetic resonance imaging are most readily available in clinical practice in Japan of OECD countries. The aim of this study was to clarify the status quo of IE in Japan.

METHODS: The present investigation was a single-hospital-based retrospective study. Inpatients who were diagnosed as having IE or suspected IE in Saga University Hospital from September 2007 to August 2017 were identified by examining hospital data. Two doctors from the Department of General Medicine in our hospital checked the medical charts and collected data on possibly eligible patients. Patients who were subsequently diagnosed as having "definite IE" according to modified Duke's criteria were enrolled. The results were expressed as the median values for quantitative data and as percentages for categorical data.

RESULTS: The study cohort comprised 74 patients of median age 66.5 years, 56.8% of whom were male. Patients were admitted to and treated by 16 departments in our hospital including Cardiovascular Surgery (50.0%), Cardiology (45.9%) or General Medicine (23.0%). Symptoms within 2 months before the first visit to our hospital comprised fever (73.0%), general malaise (33.8%), disturbance of consciousness (24.3%), and dyspnea (24.3%). High-frequency causative microorganisms were *Staphylococcus aureus* (28.4%), followed by *Streptococcus viridans* group (18.9%) and *Enterococcus spp*. (6.8%). High-frequency valves involved were the mitral (48.6%), followed by the aortic valve (25.7%), and multiple valves (14.9%). Patients without cardiac murmurs accounted for 37.8%, without valvular disease 17.6%, and with only mild valvular disease (below grade I) 14.8%. The patients developed various complications including CNS disorders (60.8%) which consisted of embolic stroke (52.7%) and cerebral hemorrhage (31.1%); glomerulonephritis (45.9%); extracranial embolism (36.5%) including splenic infarction (23.0%), renal infarction (12.2%), pulmonary embolism (10.8%), hepatic infarction (2.7%), and superior mesenteric artery embolism (1.4%); disseminated intravascular coagulation (32.4%); disseminated infections (18.9%), including pyogenic spondylitis (9.5%), deep-seated abscess (9.5%), mycotic aneurysm (5.4%), pyogenic arthritis (4.1%), and spinal epidural abscess (1.4%); and acute heart failure (14.9%). The average number of complications per patient was 2.1, with 66.2% of patients having two or more complications.

CONCLUSIONS: Patients with IE could have non-specific symptoms and visit any departments other than cardiovascular departments. When IE is suspected clinically, clinicians must check thoroughly for common complications, even in patients without cardiac murmurs or valvular disease.

CLINICAL TRAINING AND EDUCATION OF PRIMARY CARE INTERNAL MEDICINE RESIDENTS ON OUTPATIENT PROCEDURES A NATIONAL SURVEY OF PRIMARY CARE INTERNAL MEDICINE TRAINING PROGRAM LEADERSHIP

Gabrielle D. Morris[1]; Robin Klein[2]. [1]Internal Medicine, Emory University, Atlanta, GA; [2]Internal Medicine, Emory, Atlanta, GA. (Control ID #3391796)

BACKGROUND: Literature on ambulatory procedure training in Internal Medicine (IM) residency programs and focused Primary Care Internal Medicine (PC IM) residency programs is lacking.

METHODS: We conducted a cross sectional survey of Program Leaders of PC IM training programs or tracks in 2013 identified via the National Resident Matching Program, the American Medical Association's Fellowship and Residency Electronic Interactive Database, and individual program websites.

RESULTS: Forty-five of the 70 programs identified as PC IM training programs or tracks completed the survey (64% response rate). Most PC program directors (89%) reported that their program included ambulatory procedures training.

PC IM program leaders reported training was required or available in pap smear (87%), joint injection and aspiration (82%), incision and drainage (56%), skin biopsy (56%), cryotherapy (47%), suturing (38%), splinting (31%), toenail removal (29%) and IUD placement (16%).

Experience in continuity and subspecialty clinics was the most common means of teaching residents to perform procedures. Additional instructional methods utilized included simulation models (56%), lectures (47%), a procedure clinic (33%), skills lab (29%), media (31%), and standardized patients (11%).

PC IM program leaders described the typical resident graduating from their program as highly competent or competent to perform pap smears (82%), joint injections and aspiration (67%), and incision and drainage (53%). Leaders report the typical graduating resident requires more training or are unable to assess competency to perform splinting (67%), suturing (47%), toenail removal (49%), and IUD placement (67%).

CONCLUSIONS: Currently, there is no standard technique for training and evaluating a resident's ability to perform a procedure. Though programs are incorporating various teaching modalities, many rely on chance patient encounters in subspecialty or continuity clinics with supervising physicians who feel comfortable teaching the procedure.

Though recent graduates recognize the importance in performing common outpatient procedures, many report referring patients to subspecialty clinics due to lack of confidence in independent practice. This equates to fewer internists honing that skillset. Unsurprisingly, general internists in the academic field report less confidence in teaching the procedures, thus creating a cycle where residents have less opportunities to learn and therefore contribute to the growing number of graduates uncomfortable with performing ambulatory procedures.

This study highlights areas for growth in ambulatory training as the only procedure PC program leaders consistently viewed their typical resident as being competent was pap smears. Further, though different training modalities may be utilized to improve competency, ultimately having a workforce of providers more equipped to perform these procedures will enhance education.

CLINICAL UTILITY OF PHARMACOGENETIC DATA COLLECTED BY A HEALTH-SYSTEM BIOBANK

Sonam N. Shah[1,2]; Diane L. Seger[3]; Mary Amato[4,2]; Roseann Gammal[2]; David W. Bates[5]. [1]Department of General Internal Medicine, Brigham and Women's Hospital, Jamaica Plains, MA; [2]Pharmacy Practice, MCPHS University, Boston, MA; [3]IS- Clinical and Quality Analysis, Partners Healthcare System, Wellesley, MA; [4]Division of General Internal Medicine and Primary Care, Brigham and Womens Hosptial/MCPHS, Boston, MA; [5]Medicine, Brigham and Women, Boston, MA. (Control ID #3385797)

BACKGROUND: Use of pharmacogenetic (PGx) data to optimize drug therapy for individual patients has the potential to reduce the incidence of adverse drug reactions (ADRs).[1-3] For example, patients who are positive

for certain human leukocyte antigen (HLA) alleles are at increased risk of severe cutaneous ADRs when given carbamazepine (*HLA-A*31:01* or *HLA-B*15:02*) or oxcarbazepine (*HLA-B*15:02*), and preemptive PGx testing may prevent patients from receiving the drug and experiencing these reactions.[4] A key barrier to the implementation of PGx into clinical practice is the lack of integration of genetic information in the electronic health record (EHR) with clinical decision support (CDS). The aim of this study was to determine the incidence of cutaneous ADRs among patients with positive *HLA-A*31:01* and *HLA- B*15:02* results from Biobank data who received carbamazepine or oxcarbazepine in order to assess the clinical utility of returning these results in the EHR with CDS.

METHODS: We assessed the number of patients over 18 years old who received testing for *HLA-A*31:01* and *HLA-B*15:02* at a Partners-affiliated institution participating in the Partners Biobank Program between 01/01/2016-08/19/2019. Among this group, we determined the number of patients who were positive for *HLA-A*31:01* and received carbamazepine, and we determined the number of patients who were positive for *HLA-B*15:02* and received carbamazepine or oxcarbazepine. Finally, we conducted a chart review to assess whether these patients had a hypersensitivity allergic reaction (HSR) to carbamazepine or oxcarbazepine documented in the allergies section of the EHR that required drug discontinuation.

RESULTS: 36,424 patients received testing for *HLA-A*31:01*; of these, 2,327 patients tested positive (6.4%). Of these patients, 19 (0.82%) received carbamazepine. No patients had a documented HSR to carbamazepine. 36,424 patients received testing for *HLA-B*15:02*; of these, 3,543 patients tested positive (9.7%). Of these patients, 32 (0.90%) received carbamazepine, and two of them (5.3%) had a documented HSR to carbamazepine. In addition, 41 (1.15%) patients received oxcarbazepine, and one of them (2.4%) had a documented HSR to oxcarbazepine. Patients with a documented HSR discontinued the drug that caused it.

CONCLUSIONS: ADRs leading to drug discontinuation were detected among patients who received relevant PGx testing via a health-system Biobank. These reactions may have been preventable if prescribers had access to patients' PGx data in advance of prescribing. Incorporating PGx CDS alerts into the EHR could facilitate the clinical implementation of PGx and decrease incidence of ADRs. Further work includes manual chart review to check for carbamazepine and oxcarbazepine-induced ADRs that may not have been documented in the allergies section; the development of an effective CDS tool to alert prescribers to high-risk PGx results; and the assessment of other PGx data from the Biobank and associated ADRs.

CLINICIANS' EXPERIENCES WITH EVALUATING AND MANAGING CHRONIC COUGH IN ADULT PRIMARY CARE

Tayler Gowan[1]; Monica Huffman[1]; Tasneem Talib[2]; Ashley Griffith[1]; Jessica Weaver[3]; Vishal Bali[3]; Jonathan Schelfhout[3]; Ishita Doshi[3]; Paul Dexter[4,5]; Michael Weiner[4,6]. [1]Regenstrief Institute, Inc., Indianapolis, IN; [2]Indiana University, Indianapolis, IN; [3]Merck & Co., Inc., Kenilworth, NJ; [4]Regenstrief Institute, Inc. and Indiana University, Indianapolis, IN; [5]Eskenazi Health, Indianapolis, IN; [6]U.S. Department of Veterans Affairs, Indianapolis, IN. (Control ID #3379273)

BACKGROUND: Chronic cough (CC), defined by a duration of at least 8 weeks, is one of the most common reasons for primary care visits. Evaluation and treatment may be difficult for primary care providers (PCPs) due to the numerous causes of CC. Since PCPs often serve as the initial assessors and long-term providers of care for patients with CC, we sought to explore their experiences with, and perspectives about, evaluating and managing CC.

METHODS: PCP's treating CC patients were identified from previously published research using natural language processing to identify CC encounters in two healthcare systems. These PCPs were invited to complete an in-depth interview regarding their experiences evaluating and managing CC. Interviews were conducted in person and over the phone, depending on PCP preference. Two researchers analyzed interviews using an iterative inductive and deductive approach. Episode profile summaries and thematic analysis were used to analyze the data.

RESULTS: Three main themes were identified among 8 men and 7 women: defining CC, and identifying its cause; trial and error in evaluation and treatment; and challenges of ongoing management. Our findings revealed significant inconsistencies among PCPs in how they defined CC, which they described as ranging from a minimum of two weeks to six months. PCP's reported that evaluation and treatment for CC can be lengthy and may include multiple visits, diagnostic tests, specialty referrals, and trials of medications. PCPs indicated that the effectiveness of available prescription medications for CC is often insufficient. While confident in their approach to treatment, 13 of 15 PCPs were unaware of clinical guidelines for managing CC.

CONCLUSIONS: PCPs recognized that CC has various causes—and expressed confidence in identifying causes—but conveyed uncertainty or misunderstanding about the definition of CC. Lack of awareness of guidelines for CC likely contributes to inconsistencies in how PCPs define and treat CC. Our findings suggest an opportunity to educate PCPs about evaluation and management of CC to improve care. Better access to, or coordination with, specialists or multi-specialty care for CC may also help. Future research should investigate the alignment of PCPs' management of CC with clinical guidelines.

CLOSING THE GAP: PARTICIPATORY INTERVENTION DEVELOPMENT TO REDUCE CANCER SCREENING DISPARITIES AMONG PATIENTS WITH LIMITED ENGLISH PROFICIENCY

Jane W. Njeru[1]; Mark L. Wieland[1]; Jennifer L. Ridgeway[2]; Ahmed Mohamed[1]; Graciella Porraz-Capetillo[3]; Ahmed Osman[4]; Irene G. Sia[1]. [1]Internal Medicine, Mayo Clinic, Rochester, MN; [2]Health Sciences Research, Mayo Clinic, Rochester, MN; [3]Language Department, Mayo Clinic, Rochester, MN; [4]Intercultural Mutual Assistance Association, Rochester, MN. (Control ID #3383199)

BACKGROUND: In the U.S., adults with limited English proficiency (LEP) have lower rates of recommended cancer screening than the general population. Greater understanding of underlying barriers and stakeholder engagement in intervention development are necessary to increase screening rates. The objectives of this study were: 1) to understand screening barriers from multiple stakeholder perspectives, 2) to identify candidate intervention approaches, and 3) to develop a feasible, acceptable, and theory-based framework for reducing cancer screening disparities among patients with LEP

METHODS: *Setting:* Small metropolitan area of the upper Midwest U.S. *Study Design and Population:* This study employed a three-stage participatory formative evaluation approach. The Social Ecological Model and Health Belief Model served as theoretical frameworks. First, study team members reviewed existing literature on cancer screening interventions with LEP populations. Second, individual interviews were conducted with patients with LEP (women 50-64 and men 50-74 who were eligible for but had not completed recommended screening) (n=9), in-house language interpreters (n=5), primary care providers (n=5), and individuals identified as leaders in the local Cambodian, Hispanic, and Somali communities (n=3). Finally, results of interviews and the literature review were presented at a community summit attended by community members,

representatives from the medical practice, and employees or volunteers of social service organizations serving people with LEP (n=48). Activities engaged attendees in data interpretation and recommendations for intervention development.

Data Analysis: Interviews were analyzed using methods of directed content analysis and parallel-serial memoing. Results of the literature review were summarized by intervention level, population, screening type, study design, and outcome. Results of the community summit activities were discussed by the study team and integrated into the study findings.

RESULTS: Interview findings highlighted multilevel barriers including limited patient understanding of preventive health, time and cost constraints, and variable roles of language interpreters. Interventions in the literature largely focused on single levels and population groups, but community members were able to provide insights on research findings and make suggestions for a two-prong intervention aimed at heterogeneous populations: 1) community-placed, registry-based community health worker education, motivation, and navigation and 2) clinic-based point-of-care medical interpreter education, handoff to provider, and navigation. Pilot testing of these interventions is ongoing.

CONCLUSIONS: This study leveraged multiple data sources to inform understanding of the complex personal, interpersonal, and structural barriers that impede cancer screening among patients with LEP. Participatory methods can further understanding and engage community members in multilevel intervention planning.

CLOSING THE LOOP ON ECONSULTS: WHAT ARE PATIENTS LEARNING ABOUT THEIR HEALTHCARE?

Bennett Wisner[1]; Kimberly Dowdell[2]; Samuel Collins[3]; Megan Leslie[1]. [1]General Internal Medicine, University of Virginia School of Medicine, Charlottesville, VA; [2]Medicine, UVA, Charlottesville, VA; [3]Telemedicine, Univerisity of Virginia, Charlottesville, VA. (Control ID #3390399)

BACKGROUND: As national specialty referral rates climb, patients are subjected to increased wait times and costs. Electronic consultations (eConsults) are formal consultations between primary care providers (PCPs) and specialists, recorded in the electronic medical record (EMR). eConsults have been shown to reduce specialty referrals and healthcare costs, leading to eConsult programs at hospitals across the country. These programs facilitate patient access to specialty care through their PCPs; however, there is little research assessing whether PCPs inform their patients of eConsult responses detailing the specialist's opinion. Our research examines this potential gap in communication to assess whether the eConsult "loop" between the PCP, specialist, and patient is being closed by updating the patient.

METHODS: A retrospective study of eConsults to all participating specialties at a single U.S. tertiary care academic medical center from February 10, 2015 to February 25, 2019. A random sample of all eConsults in this timeframe was chosen by selecting every tenth eConsult, with 60 excluded from analysis. We reviewed patient demographics, type of clinical question, whether the eConsult loop was closed, who closed the loop, how the loop was closed, and loop closure time. Data was collected using a modified version of a previous template.

RESULTS: There was documentation that the loop was closed in 231 of the total 387 eConsults reviewed (59.7%). The average time to close the loop on the eConsult was 9 days, measured from the time the eConsult was ordered to when the patient was informed of the eConsult results as documented in the EMR. eConsults were primarily ordered to assist with the management of patients (62.8%), questions concerning the diagnosis (23.5%) and interpreting labs or imaging (13.7%). The majority of eConsult loops were closed by attending physicians, followed by trainees, nurses, and mid-level providers. Nurses had the shortest average time in closing the eConsult loop at 6 days, followed by mid-level providers, attending physicians, and trainees. When comparing how the eConsult loop was closed, the fastest methods were by using the patient portal (5 days) and making a phone call (6 days). In contrast, closing the eConsult loop at a patient's next appointment had an average loop closure time of 25 days.

CONCLUSIONS: Evaluation of eConsult loop closure demonstrates that although attending physicians close the loop most frequently, the loop closure time was shorter when nurses were involved. The findings also reveal that utilization of patient portal messages and phone contact facilitate earlier patient notification of eConsult results. This study demonstrates room for improvement in conveying specialists' information from eConsults to patients. Overall, 40.3% of eConsults' loop closure remained undocumented. This absence iterates the need for provider specific training to ensure that patients are involved in their healthcare team and that the eConsult loop is closed.

COGNITIVE IMPAIRMENT NO DEMENTIA AND ASSOCIATIONS WITH HEALTH LITERACY, SELF-MANAGEMENT SKILLS, AND HEALTH STATUS

Rebecca Lovett[1]; Laura M. Curtis[2]; Stephen Persell[3]; James W. Griffith[3]; Derin Cobia[4]; Alex Federman[5]; Michael S. Wolf[3]. [1]Department of General Internal Medicine and Geriatrics, Northwestern University, Chicago, IL; [2]General Internal Medicine, Northwestern University, Chicago, IL; [3]Medicine, Northwestern University, Evanston, IL; [4]Psychology, Brigham Young University, Provo, UT; [5]Medicine, Icahn School of Medicine at Mount Sinai, New York, NY. (Control ID #3391495)

BACKGROUND: Cognitive impairment no dementia (CIND) increases as the U.S. ages, and is associated with poor health outcomes. CIND may negatively impact health through the ability to independently self- manage illness, given the cognitive demands associated with many health-related tasks. We sought to determine the prevalence of CIND among a diverse, community-based population, and establish associations between CIND and health literacy, chronic illness self-management and functional health status.

METHODS: Baseline data from the prospective 'LitCog' cohort study was used for this secondary analysis. 863 adults without dementia aged 55-74 were recruited from six socioeconomically diverse primary care clinics in Chicago, IL. CIND was categorized according to severity (None, Mild, Moderate/Severe). Health literacy was measured using the Newest Vital Sign (NVS) and Test of Functional Health Literacy in Adults (TOFHLA). The Comprehensive Health Activities Scale (CHAS) was used to measure self-care performance. Patient-Reported Outcomes Measurement Information System (PROMIS) measures were used to determine physical and mental health status. Multivariable logistic and linear regressions were used to assess adjusted associations between CIND and outcomes of interest.

RESULTS: 36% of the sample exhibited CIND. It was strongly associated with greater likelihood of limited health literacy (NVS: Mild [OR 3.25; 95% CI 1.93, 5.49], Moderate/Severe [OR 6.45; 95% CI 3.16, 13.2]; TOFHLA: Mild [OR 3.46; 95% CI 2.08, 5.75], Moderate/Severe [OR 8.82; 95% CI 4.87, 16.0]; all p's < 0.001) and poor chronic disease self-management (Mild [B = -11.2; 95% CI -13.5, -8.90], Moderate/Severe CI [B = -21.0; 95% CI -23.6, -18.4]; both p's < 0.001). There were no significant associations between CIND and functional health status in adjusted models.

CONCLUSIONS: In this cohort of older adults, CIND was prevalent and strongly associated with requisite skills for managing everyday health needs. Greater attention to subtle declines in chronic disease self-care may

assist with CIND identification and care management within this population.

Conversely, when CIND is observed, clinicians should expect and address difficulties with self-management. Healthcare systems, clinicians, and researchers should also consider ways to best tailor healthcare and support materials for patients with modest impairments in cognition.

COLORBLIND RACIAL IDEOLOGY IS ASSOCIATED WITH AN INCREASE IN THE USE OF RACE IN MEDICAL DECISION-MAKING

Ebiere Okah[1]; Janet Thomas[2]; Andrea Westby[1]; Brooke A. Cunningham[1]. [1]Department of Family Medicine and Community Health, University of Minnesota Medical School, Minneapolis, MN; [2]Division of General Internal Medicine, University of Minnesota, Minneapolis, MN. (Control ID #3377342)

BACKGROUND: Colorblindness is an ideology or worldview that minimizes the role of systemic racism in shaping outcomes for people of color and attributes racial disparities to the bad choices and poor behavior of racial minorities. Physicians who adhere to a color-blind ideology may be less likely to critically interrogate the role of racism in shaping health outcomes, and, therefore, less likely to challenge race-based treatment guidelines. The purpose of this study is to determine if colorblindness is associated with the use race in medical decision-making.

METHODS: We sent 2,039 members of the Minnesota Academy of Family Medicine Physicians (MAFP) an online survey that included demographic questions and two validated surveys: the Color-blind Racial Attitudes Scale (CoBRAS) and the Racial Attributes in Clinical Evaluation (RACE) scale. CoBRAS measures colorblindness using three continuous subscales to measure respondents' unawareness of (1) racial privilege (scored 7-42); (2) institutional discrimination (scored 7-42) and blatant racial issues (scored 7-36). Higher scores indicate a lack of awareness and thus higher levels of colorblindness. The RACE scale (scored 0-28) was used to determine the extent to which physicians used race in medical management, with a higher score indicating a greater use of race. Multivariate regression analyses were used to assess the relationship between a color-blind racial ideology and the use of race in medical decision making.

RESULTS: The response rate was 12% (236/2039). Higher CoBRAS scores were associated with an increased use of race (β=0.05, $p<0.01$), after controlling for age, gender, location of training and practice characteristics. Of the three CoBRAS subscales, only unawareness of institutional discrimination was significantly associated with an increased use of race (β=0.17, p=0.01), after controlling for the aforementioned covariates. Additionally, physicians under 40 years of age, who worked in urban clinics or academic practices, or had a clinic population consisting of at least 70% racial/ethnic minorities were significantly less likely to use race in their treatment decisions than physicians who were 40 years of age and older, worked in non-urban clinics or non-academic practices, or had a clinic a population consisting of less than 70% racial/ethnic minorities, respectively.

CONCLUSIONS: Physicians who adhere to a color-blind racial ideology, particularly those who deny institutional racism, are more likely to use race in their screening and treatment decisions. Because this may be due to a poor understanding of how systemic racism affects health, more physician education about racism as a health risk is needed. Additional research is also needed to evaluate physician motivations and beliefs as it relates to race-based medical guidelines and policies.

COLORECTAL CANCER SCREENING PATIENT NAVIGATION FOR PATIENTS WITH MENTAL ILLNESS AND/OR SUBSTANCE USE DISORDER: RANDOMIZED CONTROLLED TRIAL

Carolina Abuelo[1]; Jeffrey M. Ashburner[1]; Steven J. Atlas[2]; Amy Knudsen[1]; James Morrill[1]; Patricia Corona[4]; Derri Shtasel[3]; Sanja Percac-Lima[1]. [1]Division of General Internal Medicine, Massachusetts General Hospital, Boston, MA; [2]General Internal Medicine, Massachusetts General Hospital, Boston, MA; [3]Psychiatry, Massachusetts General Hospital, Boston, MA; [4]Harvard Medical School, Boston, MA. (Control ID #3378486)

BACKGROUND: Colorectal cancer (CRC) is the second leading cause of cancer death in the US. Screening has been shown to decrease CRC mortality. However, disadvantaged patients such as those with mental illness (MI) or substance use disorder (SUD), are less likely to be screened. Over 43.6 million adult Americans have MI and cancer is the second most common cause of death. Over 20 million American have SUD. In 2017 at Massachusetts General Hospital (MGH) Charlestown Health Center only 30% of primary care patients with SUD or/and MI were screened for CRC compared with a 72% screening rate for all clinic patients. Patient navigation (PN) has been shown to improve CRC screening. The objective of this study was to evaluate the feasibility and effectiveness of PN program on CRC screening in patients with MI and/or SUD.

METHODS: We conducted a 6 month randomized controlled trial at MGH Charlestown Health Center. Of 251 patients aged 50-74 years with MI and/or SUD overdue for CRC screening, 126 were randomized to intervention and 125 to usual care stratified by diagnosis. Patients in the intervention group received a letter followed by a phone call from navigators. Navigators helped patients overcome barriers to CRC screening. The intervention included education, scheduling, explanation of bowel preparation, addressing lack of transportation or accompaniment to appointments. For those refusing colonoscopy, navigators offered fecal occult blood tests. The primary outcome was proportion of patients completing CRC screening in intervention and usual care groups. We used intention to treat analysis for the primary outcome and chi- squared tests to compare the proportion of patients completing screening in the 2 groups.

RESULTS: Navigators contacted 85 patients (67%) in the intervention group and 26 declined to participate. The completion of CRC screening over the 6-month study period was higher in the intervention group, with 25 patients (19.8%) screened, compared to 13 patients (10.4%) in the usual care group (p=0.04). This was mostly due to the colonoscopy screening rate in the intervention group, which was almost double the colonoscopy screening rate in the usual care group (14.3% vs. 7.2%, p=0.07). In our as-treated analyses, among 82 patients in the intervention group who had contact with the navigator and were found to be eligible, 21 completed screening during the study period (25.6% vs 10.4% of controls, p=0.004). Among the 56 patients who agreed to work with the navigator, 19 (33.9%) completed screening during 6 month study.

CONCLUSIONS: The results of this randomized controlled trial showed that a PN is a feasible intervention and can significantly improve CRC screening rates in community health center patients with MI and SUD compared to usual care. Larger studies in diverse care settings are needed to demonstrate generalizability and explore which modality of CRC screening is most acceptable and which specific navigator activities are most effective for this disadvantaged population.

COMMUNICATING DIAGNOSTIC UNCERTAINTY IN PRIMARY CARE: DEVELOPMENT OF 7-ELEMENT TOOL OPERATIONALIZED BY VOICE ENABLED INTEGRATION INTO CLINICAL WORKFLOW

Maram khazen[1]; Maria Mirica[2]; Helen W. Haskell[3]; alissa groisser[1]; narath carlile[4]; Gordon D. Schiff[2]. [1]DIGM, Harvard, Belmont, MA; [2]Center for Patient Safety Research and Practice, Brigham and Women's Hospital, Boston, MA; [3]Administration, MAME, Columbia, SC; [4]BWH, Gen Center, Boston, MA. (Control ID #3391433)

BACKGROUND: A key challenge in establishing good communication between physicians and patients and ultimately improving health outcomes is more transparently and effectively communicating uncertainty about diagnosis. While most studies focus acknowledging uncertainty, few explore practical strategies for dealing with uncertainty in the clinical encounter in a way that respects workloads, workflow, and limited visit time. This study aimed to develop and test a practical tool for documenting and communicating uncertainty about diagnostic decision-making during primary care face-to-face encounters.

METHODS: The study was conducted in two stages and included personal interviews with 20 clinicians (10 master clinicians to review 4 common primary care scenarios (headache, URI, backpain, suspicious lymph node) to develop content; 10 MD's to react to workflow issues) and 5 informatics and communication experts, as well as 20 patients (via 3 focus groups). Initial stage was designed to develop themes and content for the tool. In the second stage, we obtained feedback which we iteratively refined tool to a one-page form incorporated into the patient assessment note via voice recognition.

RESULTS: Interviews distilled a 7-element tool for communicating diagnosis and associated uncertainties: explaining the most likely and differential diagnoses, follow-up observation, testing/treatment plan, acknowledging tests' limitations, expected improvement/time frames, facilitating access with clinician contact info, and space for patients to convey input/questions. The interviews pointed to challenges faced by physicians mainly integrating communicating uncertainty into the workflow, time required for electronic documentation, and tailoring uncertainty to different clinical problems and levels of patient health literacy. Patients universally expressed desire to be more engaged in these conversations; operationalizing this aim raised a myriad of conceptual and logistical issues. Physicians believed they the tool accurately identified key communication elements, though suggested it was also patients' responsibility to raise questions when needed. Patients mostly did not share this belief and expressed desires for more information verbally and in writing.

CONCLUSIONS: We identified 7 key elements for communicating uncertainty about diagnosis, which in turn were the basis for design and operationalizing a tool that incorporated the elements into the voice-text generated assessment portion of the note as well as a customized educational leaflet for patients. Implementing this tool enables verbal communication with the patient, simultaneous recording of patient assessment (via voice recognition), and provision of a patient-friendly customized visual diagnosis handout. This represents a novel and potentially time-saving approach for more effectively communicating diagnostic assessments and uncertainty and warrants larger scale testing and deployment.

COMMUNICATION STRATEGIES TO ENGAGE HIGH-NEED VETERAN PATIENTS IN VA'S PRIMARY CARE INTENSIVE MANAGEMENT (PIM) TEAMS: PATIENT PERCEPTIONS

Alicia Bergman[1]; Tana Luger[1]; Susan E. Stockdale[2]; Marian L. Katz[3]; Donna M. Zulman[4]; Evelyn T. Chang[5]. [1]Center for the Study of Healthcare Innovation, Implementation & Policy, VA Greater Los Angeles, North Hills, CA; [2]HSR&D Center of Excellence, Greater Los Angeles VA Healthcare System, Sepulveda, CA; [3]Research, Veterans Health Administration, North Hills, CA; [4]Internal Medicine, Stanford University and VA Palo Alto, Stanford, CA; [5]General Internal Medicine, VA- Greater Los Angeles, Los Angeles, CA. (Control ID #3392296)

BACKGROUND: Patient engagement among complex high-need patients in intensive primary care programs can be challenging, as many patients experience medical, social, and behavioral barriers to active participation in their care. The Veterans Health Administration (VA) has implemented and tested intensive primary care programs called PACT Intensive Management (PIM). Using a qualitative approach, our goal was to describe how patients experienced communication strategies employed by PIM providers to get them more fully engaged in their healthcare.

METHODS: Semi-structured interviews were conducted with 51 patients who had at least four encounters with the PIM team regarding their experiences with and reflections on PIM. Interviews were recorded, professionally transcribed, coded in ATLAS.ti, and analyzed to identify what engagement communication strategies employed by providers were discussed and/or perceived by patients to have made a difference.

RESULTS: Communication strategies enacted by PIM providers/staff that were most frequently highlighted by patients were 1) good provider bedside manners; 2) holding patients accountable; 3) simplifying language and taking extra time to explain; 4) active listening; and 5) eliciting questions or additional concerns. Good beside manners included non-judgmental body language, showing respect and minimizing power differentials, smiling, being polite and courteous, being nurturing and showing genuine concern, speaking kindly to patient's family members, remembering patients' names, conveying interest in knowing the patient as a person, and not taking patient moods personally. Patients detailed how PIM providers held them responsible in areas such as diet habits, medication adherence, and following through on recommended exams, in a way that was frank and persistent, but conveyed caring. A patient explained, "….It's not so much nagging; it's just kind of coming from a person that cares.". Patients said PIM providers took extra time to explain and simplified medical language regarding the chronic conditions, the purpose of medications and potential side effects, as well as difficult-to-understand paperwork. Patients also underscored how active listening by PIM providers often consisted of undivided attention. A patient explained, ""They make you feel like they really care, somebody is really listening. ….[With other providers] it's almost like they half-listen because they're on a schedule and they've got to keep that schedule." Finally, some patients described being pleasantly surprised by how PIM providers encouraged patients to ask questions during appointments, even if their concerns differed from their official stated reason for the visit.

CONCLUSIONS: Patients enrolled in PIM identified numerous provider communication strategies that influenced engagement with their healthcare and with PIM. Increased awareness of such strategies may inform intervention design for intensive primary care programs and other services for high-need patients.

COMMUNITY HEALTH WORKERS AS AN EXTENSION OF CARE CO-ORDINATION IN PRIMARY CARE: IDENTIFYING PATIENTS' UNMET SOCIAL DETERMINANTS OF HEALTH NEEDS

Jane W. Njeru[1]; Onelis Quirindongo-Cedeno[2]; Mark L. Wieland[2]. [1]Primary Care Internal Medicine, Mayo Clinic, Rochester, Rochester, MN; [2]Primary Care Internal Medicine, Mayo Clinic, Rochester, MN. (Control ID #3392390)

BACKGROUND: Social determinants of health (SDOH) affect the functional status and the onset, progression, and effective treatment of

disease in patients and populations, and are important mediators of health outcomes, influencing healthcare delivery across the age spectrum and multiple disease conditions. Interventions targeting these factors may lead to improvement in health outcomes and utilization. However, assessment of SDOH and impact on unmet needs remains a significant challenge for clinical teams, a gap which may be filled by working in partnership with outreach professionals, such as Community Health Workers (CHWs). In this study we sought to determine if there were significant differences between patients SDOH needs as identified by clinical team versus those identified by CHWs, who serve as an extension of care-coordination for patients with medical and social complexity.

METHODS: *Setting:* Academic primary care practice in the Midwest

Study Design and Population: This was a retrospective chart review of patients referred to a CHW by clinical teams during a 6 month period to identify the following: 1) reason for the referral as identified by the clinical team and, 2) needs identified by the patient during a CHW visit. These were grouped into 5 categories: Health insurance navigation; Health system navigation; Non-Health system navigation/Basic Needs; Health education and promotion and Psychosocial support. The two were then compared for agreement. A determination of whether the patient needs were met following the CHW intervention was also made.

Data Analysis:

Summary statistics were used to describe the demographic characteristics of the patients, and the differences between patients SDOH needs as identified by clinical team versus those identified by CHWs, were determined.

RESULTS: 204 patients were referred to a CHW during the 6 month period. Demographic characteristics: female- 128 (63%); White -140 (69%); Not Hispanic or Latino-176 (86%); Government issued insurance- 187 (92%); > high school education- 81 (40%) and unemployed or retired- 134 (66%).

Majority of patients had more than one need identified by the clinical team and CHW. There were significantly more non-Health system/Basic needs and Psychosocial support needs (63% of patients compared to 51%), and less health insurance navigation needs (15% of patients versus 29%) identified by the CHW compared to the clinical team. For the 137 cases where a determination could be made, following the CHW intervention, patients' needs were fully or partially met in 88 (45%) and not met 39 (19%).

CONCLUSIONS: Identifying needs of patients with unmet SDOH needs is the critical first step towards addressing these needs. Clinical teams should consider working in partnership with CHWs, not only for a more comprehensive assessment of SDOH needs, but also for intervention. The impact of these intervetnions on health outcomes and health care utilization needs further inquiry.

COMMUNITY HEALTH WORKERS EMBEDDED IN FOOD BANKS AND FOOD PANTRIES IN FRONTIER IDAHO

Isaiah J. Sommers[1]; Kathryn E. Gunter[2]; Shari Kuther[3]; Kelly McGrath[3]; Cody Wilkinson[3]; Marshall Chin[2]. [1]Medical School, University of Chicago Pritzker School of Medicine, Chicago, IL; [2]Medicine, University of Chicago, Chicago, IL; [3]St. Mary's/Clearwater Valley Health Clinics, Orofino, ID. (Control ID #3387081)

BACKGROUND: Community health worker (CHW) programs can improve health outcomes and health- related social needs. In rural communities, which often have high medical and social needs and unique barriers to healthcare access, CHWs may play an important role. In frontier North-Central Idaho, CHWs at St. Mary's/Clearwater Valley Hospitals & Clinics (SMH-CVHC) conduct health screenings at food distribution sites (FDSs) (e.g., food banks and pantries), to reach high-risk populations. This mixed-method study examines the factors influencing early implementation of FDS health screenings.

METHODS: CHWs (n=6) and FDS coordinators (n=10) participated in semi-structured interviews describing food distribution users (FDUs) and early successes and challenges with embedding CHWs at FDSs. Two reviewers independently coded interview transcripts and discussed codes to reach consensus. Quantitative data were obtained from health screening tests and survey responses. Data from FDUs (n=73), defined as participants in health screenings at FDSs, were compared with non-FDS screening data.

RESULTS: FDUs had significantly ($p \leq 0.05$) higher hemoglobin A1c levels (5.9 vs. 5.6%), systolic blood pressure (139 vs. 133 mm Hg), and BMI (29.6 vs. 27.2 kg/m^2), and were less likely to have insurance (10 vs. 33%) or regular healthcare provider (13 vs. 24%), than those screened at non-FDS sites.

Trust and relationships between community members were prominent themes in all interviews. FDUs were described as isolated, distrustful of institutions and outsiders, and unlikely to engage with community services other than food distribution. Therefore, CHWs described FDSs as ideal settings to reach high-risk and isolated populations. Interviewees were divided as to whether formal social needs screenings would be beneficial or engender distrust, and instead relied on a trusting environment where FDUs volunteered information about social needs.

FDS screenings were described as successful at reaching, building trust with, and providing referrals for high-risk populations. Personal relationships and often volunteer-dependent structure of FDSs simplified the process for establishing the FDS-CHW partnership. However, the informal structure also made FDSs vulnerable to changes in leadership, funding, or space. Other challenges included logistical issues, inability to reach some community members, and time required for CHWs to build and maintain relationships. Suggested changes included adding a nutritionist, mental health provider, or benefits counselor into screenings.

CONCLUSIONS: CHWs are integrated within their communities and are therefore well-suited to overcome the geographic isolation and distrust preventing some frontier residents from accessing healthcare.

Embedding CHWs in frontier FDSs appears to be a promising strategy to reach vulnerable and isolated residents. Further research should examine the unique nature of distrust in frontier communities and how deploying CHWs to frontier FDSs can improve access to care and health outcomes.

COMMUNITY RESOURCE REFERRAL TECHNOLOGY: LESSONS FROM EARLY ADOPTERS

Yuri N. Cartier[1]; Caroline Fichtenberg[2]; Laura M. Gottlieb[3]. [1]Social Interventions Research and Evaluation Network, University of California, San Francisco, San Francisco, CA; [2]Center for Health and Community, UCSF, San Francisco, CA; [3]Family and Community Medicine, UCSF, San Francisco, CA. (Control ID #3369400)

BACKGROUND: Several new technology products have emerged over the past five years that facilitate health care-based social risk screening, risk documentation, and community agency referrals. Little is known about the adoption and use of these platforms. The objective of this study was to explore health care organizations' experiences implementing community resource referral platforms and to distill lessons learned from early adopters' implementation experiences.

METHODS: Semi-structured interviews with leaders or managers at 35 U.S. health care organizations that were implementing community resource referral platforms. Participating organizations were identified through web-based research and by field experts familiar with platform adoption initiatives. Recorded interviews were professionally transcribed and subsequently analyzed by two researchers.

RESULTS: Regardless of the platform used, informants uniformly reported that implementation was slowed by challenges related to staff and CBO partner buy-in, privacy protections, IT integration, and workflow issues. Although most health systems were able to implement the directory search and make referrals, few had achieved closed-loop referral tracking with CBOs. Involving CBO partners early in the process facilitated adoption of referral tracking. None of the organizations had yet evaluated their platform's impacts on efficiency and effectiveness of social need referrals or patient health impacts. Overarching adoption and implementation recommendations included: engaging both internal staff and external partners to clearly define a collective vision for the platform's purpose; comparing costs and other users' experiences before purchasing a platform; leveraging existing community resource data and the expertise of staff familiar with CBOs; and building learning time into implementation rollout.

CONCLUSIONS: Lessons learned by organizations implementing community resource referral platforms include the importance of early communication and alignment with CBO partners and internal staff.

Technology-based products can support but do not replace the time-intensive process of building support internally and nurturing partnerships with CBOs to strengthen health care systems' social care programs. Future research should focus on the effectiveness of platforms and potential impacts of these systems on CBOs.

COMORBID MENTAL HEALTH ILLNESS AMONG ADULTS WITH CHRONIC PAIN TREATED WITH PRESCRIPTION OPIOID THERAPY WHO ARE NEWLY CERTIFIED FOR MEDICAL CANNABIS

Deepika Slawek[1,3]; Frances Levin[2]; Chenshu Zhang[1,3]; Nancy Sohler[4]; Joanna L. Starrels[5]; Haruka Minami[6]; Julia H. Arnsten[1]; Chinazo Cunningham[7]. [1]Medicine, Albert Einstein College of Medicine, Bronx, NY; [2]Columbia University, New York, NY; [3]Montefiore Medical Center, Bronx, NY; [4]City University of New York, New York, NY; [5]General Internal Medicine, Albert Einstein College of Medicine & Montefiore Medical Center, Bronx, NY; [6]Fordham University, Bronx, NY; [7]Medicine, Albert Einstein College of Medicine & Montefiore Medical Center, Bronx, NY. (Control ID #3391558)

BACKGROUND: Medical cannabis use is common and is increasing, particularly among adults with chronic pain. Until recently, chronic pain has been managed with prescription opioids, now resulting in adults taking both prescription opioids and medical cannabis. In addition, many adults report using cannabis to address mental health symptoms. Despite opioid use, medical cannabis use, and cannabis use to address mental health symptoms being common, little is known about their relationship with each other. Therefore, we sought to explore how opioid use and mental health symptoms are related among adults who are newly certified for medical cannabis.

METHODS: We conducted a cross-sectional analysis of participants enrolled from 11/2018-12/2019 in an observational cohort study of adults with chronic pain, opioid use, and new medical cannabis certification in New York. Questionnaires included: sociodemographic characteristics; opioid use (past 14 days), pain (Pain, Enjoyment, General activity scale), depression (Patient Health Questionnaire-9), anxiety (General Anxiety Disorder-7), post-traumatic stress disorder (PTSD, Abbreviated PTSD Checklist), and attention deficit hyperactivity disorder (ADHD, Adult ADHD Self-Report Screening Scale for DSM-5). We used chi-square and t-tests to explore how differing doses of prescription opioids affected mental health symptoms. Opioid use was categorized as high-dose opioid prescription (>90 morphine milliequivalents [MME]/day), less than high-dose opioid prescription (<90 morphine MME/day), and no opioid prescription based on the distribution of data and Center for Disease Control definition of high-dose opioids.

RESULTS: Of 54 participants, mean age was 53 years, 67% were female, and 42% were white. Eighteen percent used recreational cannabis. Of 63% taking opioids at baseline, median number of days of opioid use was 14 (in a 14-day period), and median daily dose was 45 MME. Nearly one-quarter (24%) took high-dose opioids. Mean PEG score was 7.6 (range=0-10). At least moderate symptoms of depression or anxiety were present in 44% and 33%, respectively. For PTSD and ADHD, 56% and 46% screened positive, respectively. Participants with (vs. without) high-dose opioid use were more likely to have higher pain levels (PEG score: 8.5 vs. 7.3, $p<0.05$) and at least moderate symptoms of depression (69.2% vs. 36.6%, $p<0.05$).

CONCLUSIONS: Adults with chronic pain, opioid use and new certification for medical cannabis in NY had high levels of mental health symptoms. Those with high-dose opioid use had particularly high symptoms of depression. Although medical cannabis use continues to increase, the effect of medical cannabis on mental health symptoms over time is unknown. Our findings suggest the importance of monitoring mental health symptoms in patients with chronic pain who are initiating medical cannabis. Understanding relationships between pain, opioids, mental health symptoms, and cannabis is critical, and can inform policies and patient care.

COMPARATIVE EFFECTIVENESS OF DIGITAL BREAST TOMOSYNTHESIS FOR BREAST CANCER SCREENING AMONG OLDER WOMEN

Akhil Upneja[7]; Jessica Long[1]; Jenerius Aminawung[5]; Kelly A. Kyanko[2]; Natalia Kunst[6,1]; Xiao Xu[4]; Susan Busch[3]; Cary Gross[1]; Ilana B. Richman[1]. [1]Division of General Internal Medicine, Yale School of Medicine, New Haven, CT; [2]Population Health, NYU School of Medicine, New York, NY; [3]Health Policy and Management, Yale University, New Haven, CT; [4]Department of Obstetrics, Gynecology and Reproductive Sciences, Yale University School of Medicine, New Haven, CT; [5]General Internal Medicine, Yale University School of Medicine, New Haven, CT; [6]Department of Health Management and Health Economics, University of Oslo, Oslo, Norway; [7]Yale School of Medicine, New Haven, CT. (Control ID #3390617)

BACKGROUND: Digital breast tomosynthesis (DBT) is a breast cancer screening modality that may provide incremental improvements over standard 2-dimensional mammography, including lower recall rates and higher cancer detection rates. However, DBT has not been well studied among older women, particularly women 75 and older. The benefits of breast cancer screening in this age group are uncertain and whether to adopt a new, more expensive screening technology is particularly unclear. The goal of this study was to evaluate screening outcomes for DBT compared to 2-D mammography alone among older women.

METHODS: We used data from the Surveillance, Epidemiology, and End Results (SEER)-Medicare database to evaluate the comparative effectiveness of DBT and 2D mammography in women 67-74 and among women 75 and older. We included women who had no history of breast or other cancer prior to January 2015 and who received a screening mammogram during 2015. We assessed recall (defined as diagnostic mammography or ultrasound) and biopsy in the 4 months following initial screening. We also assessed breast cancer diagnoses by stage within 4 months of screening using SEER registry data. We used logistic regression to adjust for age, race, screening history, use of screening ultrasound, comorbidity, and measures of poverty and education.

RESULTS: The study included 43,417 women who were screened for breast cancer, of whom 21% received DBT. In adjusted analyses, among women 75 and older, DBT was not associated with a statistically significant difference in recall (91 vs 97 per 1000 women screened with DBT versus 2-D respectively, p=0.30) or biopsy (19 vs 17 per 1000, p=0.30). Among women 67-74, recall rate (117.0 vs. 99.5 per 1000, p <0.001) and biopsy rate (22 vs 16 per 1000, p=0.001) were higher among women screened with DBT.

Among women 75 and older, DBT was associated a higher rate of stage 1 invasive cancer diagnosis (6.0 vs 4.9 per 1000, p=0.005) and carcinoma in-situ diagnosis (2.6 vs 1.5 p<0.001), with no differences in the rates of more advanced cancers. Among women 67-74, DBT was also associated with a higher rate of Stage 1 invasive carcinomas (4.7 versus 3.5 per 1000, p=0.003), but not other stages.

CONCLUSIONS: Previous studies have suggested that DBT is associated with lower rates of recall and higher cancer detection rates in women. We found that DBT is not associated with lower recall among older women, and further, that in situ diagnoses represent a large proportion of additional cancers detected among women over 75. Important questions remain about whether this increased cancer detection improves morbidity and mortality or whether increased sensitivity simply increases overdiagnosis.

COMPARING CORE VALUES BY PATIENT RACE IN TWO TRIALS USING VALUES AFFIRMATION TO REDUCE HEALTH DISPARITIES

Amir Ali Jaberizadeh[1]; Edward P. Havranek[9,2]; Laura Helmkamp[9]; Irene V. Blair[3]; L Miriam Dickinson[4,9]; Rebecca Hanratty[5]; Julie Maertens[9]; John F. Steiner[6]; Suma Vupputuri[7]; Stacie L. Daugherty[8,9]. [1]School of Medicine, University of Colorado, Aurora, CO; [2]Department of Medicine, Division of Cardiology, Denver Health Medical Center, Denver, CO; [3]Department of Psychology and Neuroscience, University of Colorado Boulder, Boulder, CO; [4]Family Medicine, University of Colorado, Aurora, CO; [5]General Internal Medicine, Denver Health, Denver, CO; [6]Institute for Health Research, Kaiser Permanente Colorado, Denver, CO; [7]Mid-Atlantic Permanente Research Institute, Washington, DC; [8]Department of Medicine, Division of Cardiology, University of Colorado School of Medicine, Aurora, CO; [9]Adult and Child Consortium for Health Outcomes Research and Delivery Science, University of Colorado School of Medicine, Aurora, CO. (Control ID #3392263)

BACKGROUND: We have shown values affirmation (VA), or affirming core values, before a medical visit increases patient engagement and communication during the visit. We compared the importance of values selected among African American, American Indian/Alaskan Native (AI/AN) and White participants enrolled in two trials using VA to reduce racial disparities.

METHODS: The trials are ongoing patient-level, randomized controlled trials enrolling non-Hispanic African American, White, and AI/AN participants with uncontrolled hypertension. At enrollment, participants complete a double-blinded VA writing exercise prior to a medical visit. Instructions for the exercise vary by treatment arm; from a list of 11 values, intervention patients pick their 3 most important and control patients pick their 3 least important. We compared the values chosen by participant race controlling for age and gender.

RESULTS: Of 365 participants, 38.4% were African American, 14.8% were AI/AN and 46.8% were White. White participants were older; more AI/AN participants were men. Age and gender did not vary by treatment arm. "Relationships with friends/family" and "independence" were the most important values selected in all groups. White participants selected "sense of humor" as important more often than Black participants. Black participants selected "religious values" as important more often than whites. Politics, artistic and athletic ability were least important in all groups; differences in the lack of importance of "religious values" were noted. (Table)

CONCLUSIONS: In trials using a VA intervention, the most and least important values chosen were similar across race with the exception of the importance of religion and humor. Affirmation of these core values prior to clinical visits may play a role in improving patient engagement, activating patients and reducing racial disparities in outcomes.

Values most often selected as "Most Important"

	White N = 85	African American N = 74	American Indian N = 28
Relationships w/ friends/family	82.4%	75.7%	92.9%
Independence	41.2%	47.3%	50.0%
Sense of humor	52.9%	33.8%*	39.3%
Religious values	30.6%	64.9%*	35.7%

Values most often selected as "Least Important"

	White N = 95	African American N = 79	American Indian N = 26
Politics	31.6%	39.2%	57.7%
Artistic ability	34.7%	31.6%	38.5%
Athletic ability	53.7%	41.8%	38.5%
Religious values	32.6%	16.5%*	38.5%

* Significant difference compared to White participants when adjusted for age and gender.
** Dark gray > 50% of participants selected, light gray > 30% of participants selected
***Values to choose from include: sense of humor, religious values, relationships with friends/family, music, politics, community, living in moment, independence, creativity, artistic ability and athletic ability

COMPARING RESPONDERS VERSUS NON-RESPONDERS OF A SURVEY COLLECTING SOCIAL DETERMINANTS OF HEALTH AMONG PATIENTS IN A LARGE URBAN HEALTHCARE SYSTEM

Jennifer V. Chavez[1]; Victoria Behar-Zusman[1]; Sunil Kripalani[3]; Leonardo Tamariz[2]; Ana M. Palacio[2]. [1]School of Nursing and Health Studies, University of Miami, Miami, FL; [2]Medicine, University of Miami, Miami, FL; [3]Medicine, Vanderbilt University Medical Center, Nashville, TN. (Control ID #3385812)

BACKGROUND: There is growing interest from healthcare systems to address health disparities through collection of Social Determinants of Health (SDoH). However, many health systems are struggling to find ways to collect determinants that will not affect clinical encounters, be overly intrusive, or place additional burden on their staff. As a result, many systems have opted to collect SDoH via surveys through patient portals. Surveys are often ridden with nonresponse bias, and surveys that ask for sensitive information (education level, financial strain, health literacy) are especially vulnerable to higher rates of non-response. The objective of this study was to understand demographic differences in responders versus non-responders to a SDoH survey deployed within

the University of Miami's Health System (UHealth) from September 2016 to July 2019.

METHODS: A survey collecting SDoH was developed and disseminated throughout the UHealth system. Initially, adult patients with a primary care appointment received a message via their electronic patient portal. In the message, patients were invited to complete the survey by navigating to the questionnaire tab of their patient portal. The survey was later expanded to include patients from all UHealth Clinics. Patient characteristics were compared using a chi squared test (Table 1).

RESULTS: The total number of patients included in the analysis was 14,616 where 12,414 were responders and 2,202 were non-responders, resulting in an overall response rate of 84.93%. The response rate was very similar for males and females, 85.25% and 84.55%, respectively. The lowest response rates by age were observed in adults aged 75 and older (60.59%). The response rate by race ranged from 82.68% (Black or African Americans) to 93.75% (Native Hawaiian or Other Pacific Islanders). Response rates by ethnicity were lowest among Hispanics (82.92%). Lastly, our lowest response rates were by patients that indicated that their preferred language was Creole (50%).

CONCLUSIONS: There are not major differences in response rate by gender, age, race, ethnicity and preferred language when collecting SDoH information through electronic patient portals. Although response rates were high, offering surveys using a different interface (paper versus patient portal) and in a patient's preferred language (ex. Creole) may expand reach of the survey and, as a result, the implications this survey may have on patient health. There may also be value in understanding whether patients seeking care in primary vs specialty clinics are more likely to report SDoH information.

COMPARING SPENDING DIFFERENCES BETWEEN BENEFICIARIES IN MEDICARE ADVANTAGE AND THE MEDICARE SHARED SAVINGS PROGRAM

Ravi Parikh[1,2]; Ezekiel J. Emanuel[2]; Nathan J. Marward[3]; Colleen Brensinger[4]; Kristen Caldarella[5]; Connor Boyle[2]; Bartholomew Kelly[3]; Raghu Santhanam[3]; Amol S. Navathe[1,2]. [1]Leonard David Institute of Health Economics, Philadelphia, PA; [2]Department of Medical Ethics and Health Policy, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [3]Oschner Health Systems, New Orleans, LA; [4]Department of Medicine, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [5]Department of Medical Ethics and Health Policy, University of Pennsylvania, Philadelphia, PA. (Control ID #3390633)

BACKGROUND: Medicare program rules tie spending benchmarks in its Medicare Advantage (MA) program to spending among fee-for-service (FFS) beneficiaries, including FFS beneficiaries at risk for total cost of care through the Medicare Shared Savings Program (MSSP). Comparisons between MSSP and MA populations are difficult because of differences in clinical risk, selection effects, and differences in coding patterns. In this study, our goal was to improve upon prior literature comparing MSSP and MA beneficiary spending by comparing patients of similar clinical risk, assessed using electronic health record data.

METHODS: We conducted a retrospective cohort study among beneficiaries at one large non-profit academic health system in which care patterns were similar across beneficiaries. Our cohort consisted of 15,772 patients who were alive at December 31st, 2014; were continuously enrolled from 2014 to 2018; and had a diagnosis in 2014 of either diabetes mellitus (DM), congestive heart failure (CHF), chronic kidney disease (CKD), or hypertension (HTN). We merged claims and electronic health record data containing demographic, comorbidity, pharmacy, vital sign, laboratory, and utilization-related information. Descriptive statistics were used to compare baseline characteristics. We constructed condition-based cohorts and used validated clinical risk models to compare spending among MSSP and MA beneficiaries with similar clinical risk. We created propensity-score matched cohorts within each disease group; all propensity matching and adjustment was based on 2014 data, prior to the system's participation in MA. Spending was assessed between 2015 and 2018. We also adjusted for changes in coding patterns between MA and MSSP.

RESULTS: Compared with MA enrollees, MSSP enrollees were more likely to be younger, female, non- White, from a low-income zip code, obese, and have high baseline emergency room and hospital utilization. In 2015, unadjusted per-member per-year MSSP vs. MA spending, by cohort, was $12,174.80 vs $9,515.30 for DM, $19,716.30 vs $15,832.00 for CHF, $14,047.50 vs $11,124.90 for CKD, $11,095.40 vs $8,555.70 for HTN. In propensity-matched analyses, adjusted spending in 2018 was higher for MSSP than MA beneficiaries (26% in DM, 57% in CHF, 34% in CKD, and 26% in HTN). Detailed matching and adjustment for clinical risk-stratification criteria and coding trends reduced spending differences by 20.6% in the HTN cohort, but widened spending differences by 9.1% in the DM cohort, 6.3% in the CKD cohort, and 38% in the CHF cohort.

CONCLUSIONS: Even after controlling for granular clinical data, clinical risk, and trends in coding patterns, residual spending differences were sizeable between MSSP and MA patients. Unmeasured selection effects into MA likely account for the majority of spending differences between MSSP and MA and should be taken into consideration in any spending comparisons between FFS and MA, such as setting benchmarks.

COMPARISON OF AN OPT-IN VERSUS PROGRAM-DIRECTED PHARMACIST POST- DISCHARGE TELEPHONE MEDICATION RECONCILIATION ON 30-DAY HOSPITAL READMISSIONS

Christa T. Brooker[1]; Anna Dunlap[1]; Frances M. Perucci-Bailey[1]; Paul Helgerson[2]; Donna m. White[1]. [1]Pharmacy, University of Virginia Health, Charlottesville, VA; [2]Internal Medicine, University Of Virginia Health, Charlottesville, VA. (Control ID #3376723)

BACKGROUND: Prior studies have demonstrated the impact of pharmacist intervention on reducing medication errors during transitions of care (TOC). The Interactive Home Monitoring (IHM) program is a post-discharge care program implemented at the University of Virginia (UVA) Health in October 2017 to facilitate TOC and reduce 30-day hospital readmissions for internal medicine and family medicine patients. During the initial phase (opt-in), patients elected to receive a medication reconciliation (MR) call from a pharmacist. A 2018 UVA study concluded that patients in this initial phase who received a post-discharge pharmacist-led MR call had a significantly lower rate of 30-day hospital readmission and ED visits (19.7% vs. 25.1%, p=0.008). Since November 2018 (program-directed), the MR call has been included as a standard component of the program to reach more patients and more quickly resolve medication-related issues. This change along with other factors that may influence readmissions such as timing of MR completion, receipt of bedside medication delivery and existence of language barriers have not been explored.

METHODS: This was an observational, retrospective cohort study of patients enrolled in the IHM program from October 2017 to November 2019. Data was collected from the electronic medical record and a UVA data repository. The primary objective was to compare the prevalence of 30-day hospital readmissions and emergency department (ED) visits between the opt-in and program-directed phases. The secondary objective was to identify factors that may influence readmission risk. Statistical analysis was performed using chi- square tests.

RESULTS: The IHM program enrolled 4,084 patients during the study period, with 2,307 in the opt-in phase and 1,777 in the program-directed phase. A change in program structure did not further reduce 30-day hospital readmissions (9.2% vs. 8.9%, p=0.802) or ED visits (10.2% vs. 13%, p=0.065). In the program- directed phase, significantly more patients received a MR than in the opt-in phase (59% vs. 30%, p<0.001) and those who received a MR continued to have significantly lower rates of readmission (9.2% vs. 14.9%, p<0.001). A reduction in ED visits (10.2% vs. 15.3%, p=0.001) was an improvement compared to the opt-in phase. On average, the MR was completed on post-discharge day three – one day sooner than in the opt-in period. There was no significant difference in readmission rate when the MR was completed within 48 hours post-discharge. Receipt of bedside medication delivery and native language did not significantly impact readmission rates.

CONCLUSIONS: A program-directed approach for post-discharge MR did not result in incremental readmission reduction when compared to an opt-in approach. However, readmission and ED reduction continued to be significant in the pharmacist-led MR group. Further study may focus on alternate prioritization strategies for these efforts.

COMPARISON OF LENGTH OF STAY AND HOSPITAL COST AMONG TEACHING INTERNAL MEDICINE AND HOSPITALISTS SERVICES IN A TERTIARY CENTER: A PROSPECTIVE COHORT STUDY

Marwa Sabha[1]; Sarah Mustafa[2]; Momen Banifadel[2]; Sami Ghazaleh[2]; Kanana Aburayyan[2]; Marcel Ghanim[2]; Mohammed Awad[2]; Damynus Gekonde[2]; Amala Ambati[2]; Ahmad Ramahi[2]; Ahmed Elzanaty[2]; Zeid Nesheiwat[2]; Pinang Shastri[2]; Mohammed Alsarie[3]; Moaath Mustafa Ali[1]. [1]Internal Medicine, University of Maryland, Ellicott City, MD; [2]Internal Medicine, University of Toledo, Toledo, OH; [3]Einstein Medical Center, Philadelphia, PA. (Control ID #3373524)

BACKGROUND: Hospitalists are considered as the largest internal medicine sub-specialty in the U.S with three quarters of hospitals utilizing their services for inpatient care. There are several retrospective studies comparing teaching internal medicine services to hospitalists but there are no prospective studies. We ought to compare length of stay and cost of hospitalization in patients treated by teaching internal medicine versus non-teaching hospitalist services at a single institution.

METHODS: We conducted a classical prospective cohort study. Consecutive patients were recruited dynamically between 2/25/2019 -4/30/2019. Patients included were ≥18 years admitted to internal medicine services for any reason. Excluded patients who did not consent and patients admitted to academic services. We collected following data: age, sex, ethnicity, assistance at home, food security most the year, residence prior to admission, type of insurance, admission diagnosis (16 categories) and comorbidities (17 categories).

Length of stay and hospital cost were outcomes of interest. Propensity score by inverse probability of treatment weighting followed by multiple linear regression was used to compare teaching and nonteaching services to determine average treatment effect. Baseline characteristics were compared using parametric and non-parametric analysis. Diagnostics were used to assess propensity score model and multiple regression models.

RESULTS: A total of 1273 patients were admitted in study period. The mean age of 61 ± 19 years and females were 52%. Teaching IM admitted 526 patients and Non-teaching admitted 747 patients. Baseline characteristics were well balanced with standardized biases less <0.1 post propensity matching (figure 1.). Using average treatment effect as an estimand, teaching IM provided a shorter adjusted hospital stay by 0.7 days (CI: -0.2- -1, p-value=0.0028) compared to non-teaching medicine. Hospital cost in patients treated by teaching services was 168 dollars more than nonteaching, however this was not statistically significant (CI: -560-896, p-value= 0.64).

CONCLUSIONS: Teaching internal medicine services care was associated with shorter stay and no increased cost, readmission or mortality compared to non-teaching hospitalist services.

COMPARISON OF SHORT-TERM IN-HOSPITAL OUTCOMES OF REVASCULARIZATION VIA CABG VERSUS PCI IN PATIENTS CHRONIC KIDNEY DISEASE

Kenneth S. Johnson, Joanna Rowe, Victoria Gordon, Clayton Marolt, Adam Lewis, Kanwalgeet Hans. Anatomy, Kansas City University of Medicine and Biosciences, Kansas City, MO. (Control ID #3391767)

BACKGROUND: Previous studies have compared the long-term outcomes of patients who have undergone either coronary artery bypass graft (CABG) or percutaneous coronary intervention (PCI). Primary outcome consisting of death, stroke, or myocardial infarction has been shown to be higher at five years for PCI, with death of all causes higher in PCI as well. However, cerebrovascular events were decreased in PCI patients. This study aims to investigate the effects of chronic kidney disease on patients on short-term outcomes on patients who underwent PCI and CABG.

METHODS: We performed this retrospective cohort study utilizing the 2012-2015 Nationwide Inpatient Sample (NIS) database. Utilizing ICD-9 procedure codes, we identified patients who underwent either PCI (ICD-9 procedure codes 36.03-36.09) or CABG (36.10-36.19) while omitting those who had codes for both procedures. We then identified those patients who had a diagnosis of chronic kidney disease (CKD) and grouped them by stage; No CKD (n=415,516), Stage 1 (585.1, n=472), Stage 2 (585.2, n=4,084), Stage 3 (585.3, n=26,657), Stage 4 (585.4, n=5,767), Stage 5 (585.5, n=600) and end-stage renal disease (585.6, n=13,648). We omitted individuals with conflicting staging diagnoses. We utilized chi-square to analyze the effects of CKD on mortality while utilizing independent-samples t-test to investigate influences on length of stay and total charges.

RESULTS: 324,804 PCIs (248 stage 1, 2,443 stage 2, 16,887 stage 3, 3,961 stage 4, 438 stage 5, and 9,615 ESRD) and 141,940 CABGs (224 stage 1, 1,641 stage 2, 9,770 stage 3, 1,806 stage 4, 162 stage 5, and 4,033 EDRD) were performed. Mortality was significantly higher in CABG patients with Stage 3 (3.26% vs. 2.45%, p<.0005) and ESRD (6.48% vs. 4.17%, p<.0005) compared to PCI. Length of stay and total charges were both was significantly higher in CABG patients with all stages of CKD (p<.0005); stage 1 (9.15 vs. 3.17 days and $150,145.49 vs. $77,362.80), stage 2 (9.33 vs. 4.42 days and $155,149.91 vs. $82,037.68), stage 3 (10.75 vs. 5.36 days and $170,981.18 vs. $90,014.21), stage 4(13.28 vs. 6.67 days and $199,847.96 vs. $100,300.39), stage 5 (13.57 vs. 6.97 days and $215,150.99 vs. $103,477.65), and ESRD (14.52 vs. 6.42 days and $248,513.58 vs. $113,669.59).

CONCLUSIONS: While previous studies have indicated long-term outcomes, including death and stroke favoring CABG, the results of this study indicate that PCI has immediate advantages in those with chronic kidney disease. Both length of stay and total charges were significantly lower for PCI compared to CABG, and mortality was decreased in both stage 3 and ESRD. These results suggest that a patient's chronic kidney disease status should be taken into consideration in determining the most appropriate procedure for revascularization.

COMPARISON OF THE 7TH AND 8TH EDITIONS OF THE AMERICAN JOINT COMMITTEE ON CANCER (AJCC) STAGING FOR OROPHARYNGEAL SQUAMOUS CELL CARCINOMAS (OPSCC): A SURVEILLANCE, EPIDEMIOLOGY AND END RESULTS PROGRAM (SEER) DATABASE ANALYSIS

Pooja Vijayvargiya[1]; Sumita Trivedi[1]; Haocan Song[2]; Yuan Liu[2]; Conor Steuer[3]; William Stokes[4]; Azeem Kaka[5]; Mihir Patel[5]; Georgia Chen[3]; Dong Shin[3]; Jonathan Beitler[4]; Ashley Aiken[6]; Nabil Saba[3]. [1]Medicine, Emory University, Atlanta, GA; [2]Department of Biostatistics & Bioinformatics, Emory University, Atlanta, GA; [3]Department of Hematology and Medical Oncology, Emory University, Atlanta, GA; [4]Department of Radiation Oncology, Emory University, Atlanta, GA; [5]Department of Otolaryngology, Emory University, Atlanta, GA; [6]Department of Radiology and Imaging Sciences, Emory University, Atlanta, GA. (Control ID #3392035)

BACKGROUND: The recently released eighth edition of the American Joint Committee on Cancer (AJCC) Staging Manual, Head and Neck Section, incorporates significant changes to the prior seventh edition. These changes reflect the improved understanding of tumor biology, prognostic factors and molecular markers that effect outcomes in Head and Neck cancers. Key updates restage oropharyngeal squamous cell carcinoma (OPSCC) by human papilloma virus (HPV) positivity as data demonstrates that these tumors have markedly improved prognostic outcomes compared to HPV negative tumors, which is better reflected by the eighth edition staging.

METHODS: Using the Surveillance, Epidemiology, and End Results (SEER) database from 2004 – 2014, we identified male patients with squamous cell carcinomas of the tonsil, base of tongue and soft palate aged between 21 and 64 years old, using these clinical characteristics as surrogate markers for HPV positive status. We re-classified them by the AJCC 7th edition staging for HPV positive OPSCC as well as by AJCC 8th edition staging. The prediction performance by two staging editions were compared for overall survival (OS) and Disease free survival (DFS). Kaplan-Meier method and Cox proportional hazard model were applied, and the discrimination performance was measured by the concordance statistics (C-statistics).

RESULTS: A total of 8202 eligible patients were included in the analysis with a median follow up period of 51 months. After comparing the change of 7th edition and 8th edition staging groups, the clinical staging changed for 93.9% of patients. 10-year overall survival (OS) for AJCC 8th stages I (74%), II (78%), III (55%) and IV (32%). Using Stage I as reference, the hazard ratio for stage II, III, and IV is 0.98 (95% CI: 0.87-1.09), 2.29 (95% CI: 2.04-2.57), and 5.88 (95% CI: 4.96-6.98). Similar results were noted for ten year disease free survival. The C-statistics measured overall discrimination for 7th and 8th edition was 0.63 and 0.68 (P<0.001), respectively.

CONCLUSIONS: Based on this SEER analysis, the overall performance of discrimination improved from AJCC 7th to 8th edition incorporating HPV status more effectively with >93% change in clinical staging. Despite not having statistically significant differentiation of Stage I and II, it does so more effectively for Stages III and IV. Potential study limitations include the use of surrogate markers for HPV status and continued need for staging guideline improvement.

COMPREHENSIVE CARE CLINIC. A MULTIDISCIPLINARY APPROACH TO THE CARE OF HIGH-RISK PATIENTS IN AN URBAN AMBULATORY RESIDENCY CLINIC; ITS IMPACT ON UTILIZATION

Dino A. Messina[1]; Angie Seo[2]; Mark Schleinitz[2]; Alison Chambers[1]; Gregory Yungtum[2]; David Harriman[3]. [1]Medicine, Brown University, Providence, RI; [2]General Internal Medicine, Alpert Brown School of Medicine, Providence, RI; [3]Operations Excellence, Rhode Island Hospital, Providence, RI. (Control ID #3387511)

BACKGROUND: Our clinic provides medical care for many of the most medically and socially complex patients in our health care system. Our ACO has a vested interest in reducing cost and unnecessary hospitalizations. In September 2017, we started our Comprehensive Care Clinic (C3), a multi-disciplinary visit type designed to identify barriers to care for our high-risk patients. These visits are 60 minutes in length, allowing us to screen for non-medical determinants, and address care gaps with the patient's resident, social worker, and pharmacist. We develop personalized care plans for each patient with the goal of reducing unnecessary utilization.

METHODS: Each quarter we determined which of our patients were eligible for C3, defined as having poorly controlled diabetes or HTN or greater than 3 ED visits or 2 hospitalizations in a single year. Eligible patients were offered appointments. A generalized linear model with Poisson distribution comparing number of visits pre and post C3 visit for 3 groups of patients: those seen in C3, those eligible, but not yet seen, and those not eligible. All statistical models were run using Proc Glimmix (SAS: version 9.2; SAS Institute Inc, Cary, NC).

RESULTS: The C3 group saw a significant decrease in number of ED visits (2.24 [1.88, 2.65] to 1.26 [1.01, 1.58], p<0.0001, mean [95% CI]). Non-C3 clinic patients saw a decrease which approached significance (0.93 [0.86, 1] to 0.85 [0.81, 0.9], p=0.0848). Conversely the C3 waitlist patients saw a significant *increase* in ED usage (1.37 [1.13, 1.65] to 1.83 [1.54, 2.17], p=0.0004).

Inpatient use; The C3 group saw a significant decrease in number of inpatient visits per patient (1.69 [1.4, 2.05] to 1.25 [0.98, 1.6], p=0.0096). The non-C3 patients also saw a significant decrease in inpatient visits (0.88 [0.84, 0.92] to 0.58 [0.52, 0.64], p<0.0001). The C3 waitlist patients saw no detectable change in inpatient visits (0.97 [0.89, 1.05] to 0.95 [0.83, 1.07], p=0.763)

CONCLUSIONS: C3 is an opportunity to identify individual barriers to care and offer targeted solutions for our high-risk patients. As a result of this effort we were able to significantly reduce both ED and inpatient utilization identified by our reporting system as high-risk. High risk patients identified but not seen experienced increased utilization of the ED and no change in their inpatient usage. We offer personalized care coordination, screen for the non-medical determinants of care and address medication issues. This patient- centered model of care allows us time to offer immediate assistance with medications, transportation and care gaps and allows our residents time to make longer term health goals. Patients are educated to use same day visits (in lieu of the ED) for primary care problems. Patients and residents have expressed high satisfaction for this approach to complex care. Going forward, we will be conducting interviews to determine which aspects of C3 seemed most useful to our patients.

CONCOMITANT PROBLEMS AND OUTCOMES IN PATIENTS HOSPITALIZED FOR ACUTE HEART FAILURE

Kimberline Chew[2]; Andreas P. Kalogeropoulos[1]; Hal Skopicki[1]. [1]Cardiology, Stony Brook University, Stony Brook, NY; [2]School of Medicine, Stony Brook University, Brooklyn, NY. (Control ID #3378843)

BACKGROUND: Patients hospitalized with acute heart failure (AHF) often have multiple co-morbid conditions, which may contribute or exacerbate the current presentation and lead to worse outcomes. In this study, we used in-hospital consults as a proxy for acute concurrent problems to evaluate the impact of these problems on AHF outcomes.

METHODS: We evaluated 440 patients admitted to Stony Brook University Hospital with a diagnosis of AHF during the 2017 calendar year. Requests for consults were identified and verified through individual chart reviews. Reasons for consults were grouped into clinically relevant clusters. Follow-up data was collected for a minimum of 1 year or till death. The primary endpoint was 1-year mortality or readmission. The secondary endpoint was 30-day mortality or readmission. The impact of each consult-prompting condition on outcomes was quantified trough logistic regression models adjusting for baseline characteristics.

RESULTS: Mean age was 75 (14) years; 43.9% were women. Among the 440 patients, 24 (5.5%) had NYHA Class IV HF, 213 (48.4%) had a previous hospitalization for HF within 1 year, 126 (28.6%) were on medications for chronic pulmonary disease, 45 (10.2%) were on dialysis, 228 (51.8%) had diabetes, and 50 (11.4%) had active cancer. In terms of medications, 293 (66.6%) were on angiotensin-modulating agents, 348 (79.1%) were on beta-blockers, and 300 (68.2%) were on diuretics.

Overall, 222 (50.4%) of 440 patients had ≥ 1 consult. The frequencies of different consult types include 137 (31.1%) renal consults, 70 (15.9%) pulmonary consults, 25 (5.7%) psychiatry consults, 31 (7.1%) endocrine consults, 25 (5.7%) oncology consults, and 24 (5.5%) palliative consults.

Mean length of stay was 5 (3-8) days. Out of 440 patients, 222 (50.5%) had a readmission; 72 (16.4%) within 30 days, 136 (30.9%) within 90 days, and 218 (49.6%) within 1 year. 54 (12.3%) of patients had experienced death within 1 year.

Table 1 presents a summary of the impact of each type of consult, reflecting a related problem, on patient outcomes. Renal consults were associated with elevated risk for death or readmission in 1 year and in 30 days. Oncology consults were associated with elevated risk for death or readmission in 30 days but not in 1 year. None of the other consult types showed a significant associated risk.

CONCLUSIONS: Acute concurrent problems are common in patients hospitalized with AHF. Renal problems have the most prominent impact on outcomes. Further research is needed to identify the optimal time for preventive interventions to reduce the impact of these concomitant conditions on patient outcomes.

CONTEMPORARY ESTIMATES OF PREDIABETES AND DIABETES PREVALENCE IN THE UNITED STATES BY SEX, RACE/ETHNICITY, AND SOCIOECONOMIC STATUS, 2015-2016

Natalie A. Cameron[1]; Megan E. McCabe[2]; Lucia C. Petito[2]; Nilay S. Shah[3]; Sadiya S. Khan[4]. [1]Internal Medicine, Northwestern Memorial Hospital, Chicago, IL; [2]Preventive Medicine, Northwestern University, Chicago, IL; [3]Cardiology and Preventive Medicine, Northwestern University, Chicago, IL; [4]Cardiology and Preventive Medicine, Northwestern University, Chicago, IL. (Control ID #3371973)

BACKGROUND: Significant disparities in cardiometabolic health exist by race/ethnicity and socioeconomic status (SES). Contemporary prevalence estimates of prediabetes and diabetes (DM) in key age, sex, race/ethnicity and SES subgroups are needed to inform prevention strategies.

METHODS: We used cross-sectional data from the National Health and Nutrition Examination Survey (NHANES) (2015-2016). We included adults ≥ 20 years who completed measurement of fasting glucose. Prediabetes was defined as a fasting glucose 100-125mg/dL or Hemoglobin A1c (HbA1c) 5.7 – 6.4%. DM was defined as a fasting glucose ≥ 126 mg/dL, HbA1c ≥ 6.5%, or a self-reported diagnosis of DM. We calculated unadjusted prevalence estimates overall and by age (20-39, 40-59, 60+ years), and age- standardized prevalence estimates by sex-race (non-Hispanic white [NHW], non-Hispanic black [NHB], and Mexican American [MA] men and women), education (<high school, high school graduate and >high school) and poverty income ratio tertiles using the projected 2000 US Census population for standardization (SAS v9.4, Cary, NC).

RESULTS: Overall prevalence of prediabetes was 48.0% (95% CI: 44.2, 51.8) and consistently high among each subgroup even among younger adults aged 20-39 years (Table). The prevalence of DM was 16.4% (95% CI: 13.9, 18.9). Within each race/ethnicity, there was a higher prevalence of DM among males than females, except among NHBs in which the prevalence was similar. The prevalence of DM was higher in MAs and NHBs, and in lower education and income strata.

CONCLUSIONS: Almost 2 in 3 US adults have prediabetes or DM. Increasing prevalence estimates in key race/ethnicity and SES demographics highlight the need to focus on social determinants of health to elucidate and address disparities in the burden of poor cardiometabolic health. Furthermore, the substantial burden of prediabetes in young adults reinforces the need for prevention and screening efforts earlier in life.

CONTEMPORARY USE AND DRIVERS OF PREOPERATIVE CARDIAC STRESS TESTING

Matthew A. Pappas[1]; Michael B. Rothberg[2]. [1]Medicine Institute, Cleveland Clinic Foundation, Cleveland, OH; [2]Internal Medicine, Cleveland Clinic, Cleveland, OH. (Control ID #3391339)

BACKGROUND: Current guidelines recommend preoperative stress testing for patients whose predicted risk of a major adverse cardiac event exceeds 1% and whose functional status is poor or unknown, when stress testing would change management. However, each of those three decision points likely vary by provider, and real-world use is unclear. In order to understand contemporary use and drivers of preoperative cardiac stress testing, we set out to explain variation in preoperative stress testing using rich clinical data from a large integrated health system.

METHODS: The Internal Medicine Preoperative Assessment, Consultation and Treatment (IMPACT) Center assesses patients prior to noncardiac surgery at the Cleveland Clinic. Between 1/1/2008 and 12/31/2018, we identified 118,552 patients seen in that clinic by 104 providers across 159,795 visits. Using a multivariable multilevel logistic regression model, we tested variables linked to stress test ordering and completion rates from six constructs: measures of perioperative risk (RCRI, MICA, and surgical categorizations), measures of functional status (METs, functional class), measures of social and financial support (race, marital status, neighborhood deprivation index), medical comorbidities (age, BMI, numerous diagnoses), measures of physician tendencies and experience (years of previous experience, number of patients seen previously in this clinic), and date (continuous and dichotomized at the most recent guideline's publication date). We used multiple imputation to address missing data and tested models clustering visits by either physician or by patient.

RESULTS: Of 159,795 visits to the IMPACT clinic, 8,300 (5.2%) resulted in a referral for cardiac stress testing, 8,085 (5.1%) of whom completed the test before surgery or within 30 days. Key patient factors associated with preoperative stress testing included predicted surgical risk, patient functional status, type of surgery, a previous diagnosis of ischemic heart disease, and BMI. Type of surgery under consideration had the largest effect: a patient scheduled for aortic surgery had an estimated marginal stress testing rate of approximately 21%, and a patient undergoing peripheral vascular surgery has an estimated marginal rate of approximately 7.1%. Patients living in either the most deprived census tracts or the least-deprived census tracts were more likely to be referred for stress testing. Even after fully adjusting for patient factors, provider effects had a substantial impact on rates of preoperative stress testing (3.3% in the lowest decile, compared to 6.5% in the highest decile). Rates of stress testing appear to be decreasing over time.

CONCLUSIONS: In this large cohort of patients seen for preoperative risk assessment at a single health system, key drivers of preoperative stress testing included estimated perioperative risk and functional class, but also socioeconomic, physician, and procedure factors.

CONTINUITY OF CARE IN AN OUTPATIENT SETTING AMONG CHILDREN AND YOUNG ADULTS WITH COMPLEX CHRONIC CONDITIONS

Mariecel Pilapil[1]; Jincy Chacko[5]; Caren Steinway[2]; Joseph Conigliaro[3]; Sophia Jan[4]. [1]Internal Medicine, Pediatrics, Zucker School of Medicine at Hofstra/Northwell, New Hyde Park, NY; [2]Pediatrics, Cohen Children's Medical Center of Northwell Health, New Hyde Park, NY; [3]Internal Medicine, Zucker School of Medicine, New Hyde Park, NY; [4]Pediatrics, Northwell Health, New Hyde Park, NY; [5]Population Health, Northwell Health, New Hyde Park, NY. (Control ID #3392281)

BACKGROUND: The Institute of Medicine (IOM) has identified continuity of care as a core attribute of primary care. Better continuity has been shown to reduce ED utilization and costs in specific patient populations including asthmatics, children with medical complexity, and older adults.

METHODS: The aims of this study are to: (1) describe continuity of care in both primary care and subspecialty care settings for children and young adults with complex chronic conditions, and (2) identify factors associated with improved continuity. This project is an observational retrospective cohort study that collected data from the electronic medical record (EMR) across multiple outpatient sites in a large, urban academic health system. Patients were identified as having a complex chronic condition (CCC) based on ICD-10 codes previously published by Feudtner et al. Patients were included if they were 2 to 26 years old, seen in at least one of the institution's outpatient sites from 2016 to 2019 and had >4 outpatient visits within the same practice. For each of the patients, the continuity of care index (COCI)(a.k.a. Bice-Boxerman Index) was calculated for each patient at each practice he/she sought care based on the billing providers seen. The COCI provides a score from 0 to 1 where 1 indicates perfect continuity with only one provider is seen consistently and 0 indicates a different provider is seen at each visit. Primary care visits were considered those that occurred in general internal medicine, family medicine, general pediatrics, and adolescent medicine practices.

RESULTS: There were 5551 unique patients in the cohort with a mean age of 19.5 years (range 2 to 26 years old). 53.7% (n=2982) were female and 12.2% (n=4870) had a preferred language other than English. The majority of patients were white (48.9%), and the remainder were Black (15.2%), Asian (5.6%), and other (17.4%) with 9% having an unknown ethnicity according to the EMR. 13% identified as Hispanic or Latino. The majority of patients had 1 CCC (range 1-5). The mean COCI score of the entire cohort was 0.69. When comparing continuity in primary care vs. subspecialty care, continuity was significantly higher in subspecialty care (0.59 vs. 0.73, $p<0.01$).

CONCLUSIONS: Patients with complex chronic conditions are at high risk for adverse health outcomes.

Although primary care may serve as their major source of both routine preventative and acute care, continuity between providers is lower compared to subspecialty care. Future studies are needed to examine how improvements in primary care continuity could affect health outcomes in this patient population.

CONTRASTING MENTAL AND BEHAVIORAL HEALTH WORKFLOWS TO IMPROVE PROCESSES ACROSS PRIMARY CARE CLINICS IN A LARGE ACADEMIC HEALTH SYSTEM

Samvel Gyurdzhyan[2]; Robert Rudin[1]; Sara Singer[2]. [1]RAND, Boston, MA; [2]Stanford University School of Medicine, Stanford, CA. (Control ID #3390794)

BACKGROUND: Health systems struggle to design reliable processes for providing high-quality care. Workflows for common care activities, such as referring a patient to a mental health specialist, often vary widely within health systems, and best-practice workflows are not widely established. We examined variation in clinical workflows and barriers for patients requiring mental health services at primary care clinics within one academic health system to identify improvement opportunities.

METHODS: From a sample of 15 primary care clinics, we selected 5 representing the distribution of performance on a national staff survey, which measured how often (1=least, 5=most) staff completed clinical process tasks related to facilitating mental health referrals ("mental health integration").

We interviewed 6 primary care physicians (PCPs; at least 1 from each clinic), 4 administrators, and 2 PCP/admins to understand workflow processes, challenges in obtaining mental services for patients, and improvement opportunities. For each clinic, we coded emergent themes and created and confirmed workflow process maps.

RESULTS: Average mental health integration for sample clinics (3.9) was similar to the average for the health system overall (4.1) and the 59 clinics from the 20 health systems in the national study (3.9). Process maps revealed different processes at all 5 clinics. Differences included thresholds for positive screens for depression, breadth of resource lists to help patients find mental services, and extent to which PCPs provided counseling and first-line drugs and leveraged their informal networks to access specialists.

Promising practices included using in-house social workers to counsel and link patients with services and using EHR tools to assign patients health tasks and to set reminders for PCP follow-up. Some clinics had a culture of going-the-extra-mile, e.g., searching online for counselors for patients and calling insurers to get patients referred to specialists.

Barriers for patients included costs and lengthy provider waitlists. Process barriers also emerged: Clinics had no passive mechanisms for receiving information from specialists outside the health system. PCPs relied on patients to inform them of medication changes and treatment efficacy. PCPs bemoaned a lack of consultation that would allow them to manage medications with more certainty and timeliness.

Interviewees identified opportunities for system-level improvement. Resource lists could be consolidated across the system rather than created by individual PCPs. A standard assessment for depression could more reliably identify patients requiring mental services. Dissemination of standard treatment guidelines and workflow tools could reduce PCP stress and improve the standard of care for patients.

CONCLUSIONS: Our study of 5 clinics in one health system revealed contrasting and inadequate processes for mental health referrals and opportunities to improve referrals through standardization of organizational best practices and EHR tools.

COORDINATING HEALTH SERVICES FOR HOMELESS VETERANS IN VETERANS AFFAIRS AND COMMUNITY SETTINGS

Audrey Jones[1,2]; Sonya Gabrielian[3,4]; Young-il Kim[5]; Aerin DeRussy[6]; Ann E. Montgomery[6]; Kevin R. Riggs[5,6]; Sally K. Holmes[6]; Erika Austin[7]; David Pollio[8]; Lillian Gelberg[4,3]; John Blosnich[9,10]; April E. Hoge[6]; Allyson Varley[5]; Adam Gordon[1,2]; Stefan Kertesz[5,6]. [1]IDEAS Center,

VA Salt Lake City Health Care System, Salt Lake City, UT; [2]Internal Medicine, University of Utah School of Medicine, Salt Lake City, UT; [3]VA Greater Los Angeles Health Care System, Los Angeles, CA; [4]David Geffen School of Medicine at UCLA, Los Angeles, CA; [5]University of Alabama at Birmingham School of Medicine, Birmingham, AL; [6]Research, Birmingham VA Medical Center, Birmingham, AL; [7]Biostatistics, UAB, Birmingham, AL; [8]University of Alabama at Birmingham School of Public Health, Birmingham, AL; [9]Center for Health Equity Research and Promotion, VA Pittsburgh Healthcare System, Pittsburgh, PA; [10]Suzanne Dworak-Peck School of Social Work, University of Southern California, Los Angeles, CA. (Control ID #3389717)

BACKGROUND: With passage of the 2014 Veterans Access, Choice and Accountability Act, the U.S. Congress committed to ensuring Veterans' access to care in Veterans Affairs (VA) and non-VA community settings. However, vulnerable Veteran subpopulations could feel poorly received in non-VA healthcare environments. In particular, homeless-experienced Veterans (HEV), who have high rates of co-occurring medical, mental health, and social service needs, may experience challenges with coordination of care between VA and non-VA settings. We leverage data from a national survey of HEV to examine use of non- VA community care under the Veterans Choice Program, satisfaction with non-VA community care, and perceptions of access and coordination of services from a VA primary care environment.

METHODS: The Primary Care Quality and Homeless Service Tailoring study recruited HEV for a survey of VA primary care experience in 2018. Use of community care was assessed with 1 item; satisfaction with 2 items, and accessibility & coordination of needed services from a VA primary care environment with a validated scale (11 Likert-type items) categorized as unfavorable or not. We used cross-tabulations to characterize community care use and satisfaction with community care. We used survey-weighted multivariable logistic regressions to examine whether use of community care (compared to no community care) related to patients' likelihood of reporting unfavorable experiences with accessibility/coordination from the VA primary care envrionment, and on 2 specific coordination items. Models controlled for demographics, medical conditions, alcohol/drug problems, and history of being unsheltered and chronic homelessness.

RESULTS: Respondents included 3,394 HEV receiving VA primary care services, of whom 3,142 (91%) had data on study variables and 809 (26%) used community care. Most HEV who used community care reported being somewhat or very satisfied with the care they received (84%) and with their time to receiving care (79%). A greater percentage of HEV who used community care reported unfavorable experiences with access/coordination from a VA primary care environment, compared to HEV not using community care (31% vs 25%, adjusted odds ratio [AOR]=1.31, p=0.001). HEVs who used community care were also more likely than HEV with no community care to disagree that their VA provider reduced hassles following referral (21% vs 16%; AOR=1.41, p=0.005) and to agree that they wait too long for needed services (37% vs 28%; AOR=1.43, p<0.001).

CONCLUSIONS: One-quarter of VA primary care patients with recent homeless experiences received community care under the Veterans Choice Program. High ratings of satisfaction with the quality and timeliness of community care suggest these services are valued by HEV and could mitigate access barriers experienced in some VA settings. Improvements in referral processes may be needed to facilitate care coordination and ensure high quality care for homeless Veterans in VA and non-VA healthcare settings.

CORRELATES OF PATIENT PORTAL ACTIVATION AND USE IN A FEDERALLY QUALIFIED HEALTH CENTER NETWORK

Iman Sharif[1]; Judd H. Anderman[6]; Paulo Pina[5]; Rhett Pilao[4]; Doreen Colella[3]; Isaac Dapkins[2]. [1]Family Health Centers at NYU Langone, Brooklyn, NY; [2]Family Health Centers at NYU Langone, NYU, Brooklyn, NY; [3]Quality Department, Family Health Centers at NYU Langone, Brooklyn, NY; [4]Quality, Family Health Center at NYU Langone, Brooklyn, NY; [5]Pediatrics, NYU Langone Health, Brooklyn, NY; [6]Quality Improvement, Family Health Centers at NYU Langone, Brooklyn, NY. (Control ID #3385896)

BACKGROUND: Patient Portals(PP) allow access to medical records and interaction with providers; however activation(PPA) and use (PPU) are limited by language barriers, low health/computer literacy, and poor internet access which are prevalent issues in Federally Qualified Health Centers(FQHC). Little is known of the drivers and patterns of PPA in such settings. We aimed to describe the prevalence of PPA and PPU in adult patients of an FQHC; describe PPU activity, and test demographic, condition, and utilization-related correlates of PPA and PPU.

METHODS: We conducted a retrospective chart review in an FQHC that launched a PP in September 2016. We extracted demographics, PPA status(active/not) at data pull, PPU activities, presence of a chronic condition on the problem list, # emergency department, inpatient, subspecialty visits over past year (utilization summed, dichotomized >1 vs. 0-1 visit). Missing values for homelessness were coded to majority category(0). Analyses included descriptive statistics, bivariate analyses, then logistic regression to test odds of PPA and PPU by. demographics, chronic conditions, and utilization. We report [adjusted odds ratios(confidence interval)].

RESULTS: Data were analyzed for 62,610 adults [mean age 45(SD 17), 21% Black, 47% Hispanic, 46% Medicaid, 25% Selfpay, speaking English(60%), Spanish (31%), Chinese(6%), Other(3%), with: hypertension(19%), diabetes(11%), depression(8%), asthma(6%), CVD(5%); 21% had utilization>1. Overall 23,104(37%) activated the PP. PPU included viewing test results(69%), medications(62%), immunizations(51%), billing (38%), asking advice (29%), and scheduling appointments(16%). PPA and PPU varied by demographics, chronic condition, and utilization, but were consistently higher for females, those who were not Medicaid recipients or Self-pay, English speakers and those with asthma, hypertension, and depression.

CONCLUSIONS: PPA was lower for non-whites and poorer patients, but higher for patients speaking the predominant languages of this FQHC, suggesting that language concordance helps engage patients. Patients with chronic conditions and more healthcare utilization had greater odds of PPA and PPU. On the other hand, Spanish-speakers were less likely to actively use the portal for functions such as scheduling appointments, suggesting that improvements in language capabilities of the platform are needed.

COVERAGE, FORMULARY RESTRICTIONS AND AVERAGE RETAIL PRICES OF SGLT2 INHIBITORS AND GLP-1 RECEPTOR AGONISTS ACROSS MEDICARE PART D PLANS IN 2019

Jing Luo[1]; Robert Feldman[1]; Scott D. Rothenberger[2]; Walid F. Gellad[3]. [1]University of Pittsburgh, Pittsburgh, PA; [2]Medicine, University of Pittsburgh, Pittsburgh, PA; [3]Medicine, VA Pittsburgh/University of Pittsburgh, Pittsburgh, PA. (Control ID #3386703)

BACKGROUND: Access to SGLT2 inhibitors (SGLT2i) and GLP-1 receptor agonists (GLP-1RA) may be limited by high drug prices and insurance related barriers including prior authorization or step therapy

requirements. These barriers are particularly challenging for seniors covered under Medicare's prescription drug benefit (Part D).

METHODS: We used Q1 2019 national Part D Formulary files to examine: 1) the proportion of plans (weighted by enrollment) that cover a SGLT2i or GLP-1RA without prior authorization or step therapy and 2) the average retail price [IQR] for a 30-day supply of each medication.

RESULTS: Among 3,992 plans (enrolling at least 37,980,936 beneficiaries), weighted coverage without prior authorization or step therapy for canagliflozin, dapagliflozin and empagliflozin was 53.2% (95% CI: 49.1 to 57.4), 63.7% (95% CI: 60.1 to 67.3) and 95.4% (95% CI: 94.3 to 96.4), respectively. Coverage without prior authorization or step therapy for GLP-1RA of ranged from 3.2% (95% CI: 1.8 to 4.6) for lixisenatide to a high of 87.4% (95% CI: 85.5 to 89.3) for dulaglutide. The mean retail price [IQR] for a 30- day supply of a SGLT2i or a GLP-1RA ranged from $295 [$285-$303] (ertugliflozin) to $512 [$501-$527] (canagliflozin) and $641.38 [$629-$657] (lixisenatide) to $946.17 [$930-$968] (liraglutide), respectively.

CONCLUSIONS: In 2019, coverage without prior authorization and step therapy for SGLT2i and GLP-1RA were mixed across Part D plans. Most beneficiaries enrolled in plans that covered at least one SGLT2i and one GLP-1RA without restrictions. Cost sharing (i.e. high out-of-pocket payments) may be more problematic for patients than either prior authorization or step therapy.

CROWDING OUT: TRENDS IN INTENDED UTILIZATION OF THE NATIONAL HEALTH SERVICE CORPS AND THE PUBLIC SERVICE LOAN FORGIVENESS PROGRAMS BY MEDICAL SCHOOL GRADUATES PURSUING PRIMARY CARE, 2010-2018

Justin Grischkan[1]; Benjamin P. George[2]; David A. Asch[3]. [1]Medicine, Massachusetts General Hospital, Boston, MA; [2]Neurology, University of Rochester, Rochester, NY; [3]Medicine, University of Pennsylvania, Philadelphila, PA. (Control ID #3386787)

BACKGROUND: Recent studies have estimated a deficit of 20,000 – 46,000 primary care physicians by 2025, particularly in underserved areas. The federally funded National Health Service Corps (NHSC) aims to encourage physicians to pursue primary care in underserved areas by forgiving educational debt. However, a federally funded program, the Public Service Loan Forgiveness (PSLF) program offers more generous loan forgiveness terms, less restrictive employment requirements and may compete with the NHSC program. We sought to compare trends in intended loan forgiveness participation among indebted medical school graduates pursuing a career in primary care.

METHODS: We used deidentified data from the 2010-2018 Association of American Medical Colleges Graduation Questionnaire sent to all medical students graduating from schools accredited by the Liaison Committee on Medical Education (LCME). To reflect medical school graduates likely to pursue primary care, we restricted our analysis to: (1) graduates reporting no plans to complete subspecialty training and (2) graduates intending to pursue the following specialties: family medicine, internal medicine, pediatrics, preventive medicine, and combined internal medicine and pediatrics. Within this group, we examined intentions to pursue loan forgiveness programs.

RESULTS: PSLF requires only that physicians be employed for ten years in government or nonprofit settings, making nearly 75% of U.S. hospitals eligible. NHSC participants receive tax exempt loan repayments of $50,000 after 2 years of full time service in underserved areas and participants who continue working with the NHSC may apply for additional loan repayment awards subject to available funds. Ten years of NHSC loan repayment awards would total $150,000. The same physician might receive $226,000 after ten years of PSLF participation (tax-exempt). From 2010 to 2018, 9,332 to 11,529 (approximately 63%-80%) of medical school graduates responded to both specialty and loan forgiveness plans. Among those graduates, 846 to 1871 were classified as aiming toward primary care; of those, 358 to 825 (43%-56%) intended to pursue loan forgiveness. The PSLF and NHSC were the two most popular loan forgiveness responses. From 2010 to 2018 interest in the NHSC program decreased from 25% of graduates pursuing primary care to 15% and interest in the PSLF program increased from 22% to 56%.

CONCLUSIONS: Our analysis shows a decline in NHSC interest alongside an increase in PSLF interest among medical school graduates intending to pursue primary care. This analysis suggests that interest in PSLF may be crowding out interest in NHSC. If the federal government aims to increase the number of primary care physicians working in underserved areas, it should reexamine the incentives it is providing to physicians participating in this program. The NHSC program may attract more interest if it provides the same or greater financial benefit than other federally funded programs such as the PSLF program.

CURRENT PRACTICE AND KNOWLEDGE REGARDING USE OF HUMAN PAPILLOMAVIRUS VACCINATION FOR ADULTS AGED 27-45 YEARS: SURVEY OF U.S. PRIMARY CARE PHYSICIANS, 2019

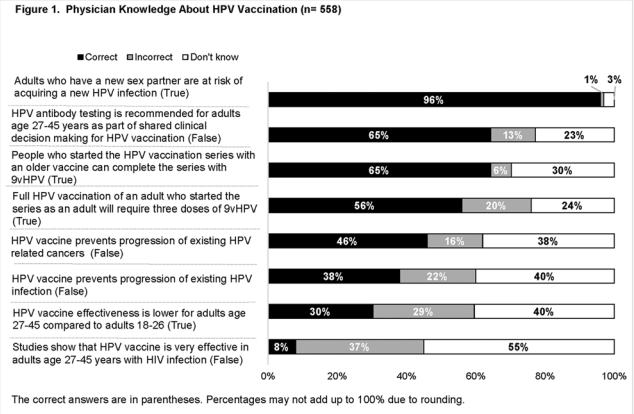
Laura P. Hurley[1,5]; Lauri Markowitz[2]; Elissa Meites[2]; Megan C. Lindley[2]; Sean T. O'Leary[5,3]; Lori A. Crane[4,5]; Carol Gorman[5]; Jessica R. Cataldi[5,3]; Michaela Brtnikova[5,3]; Brenda Beaty[5]; Allison Kempe[5,3]. [1]Division of General Internal Medicine Denver Health, Denver, CO; [2]Division of Viral Diseases, National Center for Immunization and Respiratory Diseases, Centers for Disease Control and Prevention, Atlanta, GA, Atlanta, GA; [3]Pediatrics, University of Colorado Anschutz Medical Campus, Aurora, CO; [4]Community and Behavioral Health University of Colorado Anschutz Medical Campus, Aurora, CO; [5]Adult and Child Consortium for Health Outcomes Research and Delivery Science, University of Colorado Anschutz Medical Campus and Children's Hospital Colorado, Aurora, CO, Aurora, CO. (Control ID #3389765)

BACKGROUND: In October 2018, the licensed age range for HPV-9-valent vaccine (9vHPV) was expanded from 9-26 years to 9-45 years. In June 2019, the Advisory Committee on Immunization Practices (ACIP) recommended shared clinical decision-making regarding potential HPV vaccination for adults age 27-45 years. Our objectives were to assess among primary care physicians: 1) current practice regarding 9vHPV use in adults 27-45 years and whether the 2019 ACIP recommendation will change their practice, and 2) knowledge about HPV vaccination and shared clinical-decision making recommendations for this vaccination.

METHODS: In October to December 2019, we administered an Internet and mail survey to national networks of 494 general internist (GIM) and 474 family physician (FP) members of the American College of Physicians and American Academy of Family Physicians, respectively.

RESULTS: Response rate was 58% (558/968). 57% were aware of the new ACIP recommendation. 76% stocked 9vHPV. Before the 2019 recommendation, physicians reported recommending 9vHPV to adults 27-45 years for those without known risk factors (21%), and for those with risk factors, including multiple sex partners (35%), a new sex partner (29%), an immunocompromising condition (26%), or men who have sex with men (33%). The majority would be more likely to recommend 9vHPV in all these patient populations because of the new recommendation. In the 3 months before the survey, 73% reported not giving 9vHPV to any adults 27-45 years; 22% to 1-3 patients. Figure 1 shows knowledge about HPV vaccination. 55% agreed that they were unsure what to emphasize in a shared clinical decision-making conversation about 9vHPV with an adult 27-45 years.

CONCLUSIONS: Although ACIP does not recommend routine catch-up vaccination of adults >26 years, physicians report the new ACIP recommendations will increase their likelihood of recommending 9vHPV to adults 27-45 years. Our data demonstrate substantial knowledge gaps about HPV disease and vaccination among primary care physicians, and that many were unsure about how implement shared decision-making recommendations for this vaccination.



DEARTH OF HOSPITAL MEDICINE CLINICIAN INVESTIGATORS ACROSS UNITED STATES ACADEMIC MEDICAL CENTERS

Lindenauer[7]; Melissa Mattison[8]; Kevin O'leary[9]; Sumant Ranji[10]; Edmondo Robinson[11]; Gregory Ruhnke[12]; Neil Seghal[4]; Eduard E. Vasilevskis[13]; Mark V. Williams[14]; Andrew D. Auerbach[15]; Jeffrey L. Schnipper[16]. [1]Division of General Internal Medicine, Brigham and Women's Hospital, Boston, MA; [2]Internal Medicine, University of Michigan, Ann Arbor, MI; [3]DOM, University of Pennsylvania, Philadelphia, PA; [4]Division of Hospital Medicine, University of California San Francisco, San Francisco, CA; [5]Medicine, Beth Israel Deaconess Medical Center, Brookline, MA; [6]Medicine, Vanderbilt University Medical Center, Nashville, TN; [7]Institute for Healthcare Delivery and Populatin Science, University of Massachusetts medical School - Baystate, Springfield, MA; [8]Medicine, Massachusetts General Hospital, Boston, MA; [9]Medicine, Northwestern Medicine, Chicago, IL; [10]Medicine, University of California San Francisco, San Francisco, CA; [11]Medicine, Christiana Care Health System, Wilmington, DE; [12]Department of Medicine, University of Chicago, Chicago, IL; [13]Medicine, Vanderbilt University, Nashville, TN; [14]University of Kentucky, Lexington, KY; [15]Medicine, UCSF Division of Hospital Medicine, San Francisco, CA; [16]Division of General Medicine, Brigham and Women's Hospital, Boston, MA. (Control ID #3390492)

BACKGROUND: Hospital medicine is the fastest growing subspecialty within internal medicine, growing from 10,000 hospitalists in 2002 to over 50,000 in 2016. Despite this growth, there remain relatively few hospitalists who are clinician investigators. We sought to quantify the number of clinician investigators, their dedicated time for research, and identify potential gaps in resources for researchers at major United States academic medical centers.

METHODS: We performed a survey of hospital medicine programs at academic medical centers in the United States affiliated with the Hospital Medicine Reengineering Network (HOMERuN), a hospital medicine research collaborative. Questions regarding the number of hospitalists and full-time equivalents (FTE) were free response. Questions regarding research services available, mentorship and services needing improvement were multiple choice. Surveys were distributed via email to division/section chiefs and/or senior leaders of unique hospitalist groups between January and August 2019. Responses are reported as numbers and proportions or median and interquartile range (IQR) as appropriate.

RESULTS: We received responses from representatives of 43 hospital medicine groups from 86 invitees (50%). The number of hospitalists per program ranged from 4 to 150 with a median of 50. The median number of total clinician investigators per hospital medicine group was 0 (IQR 0-2). Similarly, the median protected FTE (including grant support and dedicated salary support) for all clinician investigators within each program was 0 (IQR 0-1.6). Most groups reported having research services available, but these were most often shared with another department/division; some programs reported having no access to statisticians (22%), statistical programmers (31.7%), or research assistants (56.1%). Most clinician investigators primarily reported mentorship from faculty within their hospitalist group (53.5%), but large proportions obtained mentorship from generalists outside the group (27.9%) or from subspecialists (34.9%). The following were identified as needing improved support for junior researchers: mentoring "at a distance" (53.5%), networking with other researchers (60.5%), access to administrative and clinical data from multiple sites (62.8%), consultation around developing researchers in hospital medicine (60.5%), and fellowships (53.7%).

CONCLUSIONS: Across many major U.S. academic medical centers, there are very low numbers of hospitalist clinician investigators. The limited availability of research resources, training, and mentorship within hospital medicine may contribute to this phenomenon. Further research is needed to understand why there are relatively low numbers of hospitalist clinician investigators compared to ambulatory general internal medicine investigators.

DECLINE IN COUNTY-LEVEL EVICTION RATES AMONG VULNERABLE POPULATIONS AFTER MEDICAID EXPANSION: A DIFFERENCE-IN-DIFFERENCES STUDY

Jackie V. Rodriguez[1,2]; Julia Raifman[2]. [1]General Internal Medicine, Boston University Medical Center, Boston, MA; [2]School of Public Health, Boston University, Boston, MA. (Control ID #3392611)

BACKGROUND: As critical as housing is to health, the health care system can be a source of serious financial strain related to housing instability and eviction. Medical bills commonly push families to spend less on food, deplete their savings, or take on more loans. Medical debt may even lead to housing eviction. We hypothesize that statewide Medicaid Expansion may reduce eviction rates.

METHODS: This study employed a quasi-experimental difference-in-difference design to estimate the change in eviction rate before versus after exposure to the Affordable Care Act (ACA) 2014 Medicaid Expansion among renters across the US, stratified by vulnerable populations. We used publicly available county-level Eviction Lab, Census, and County Health Rankings data from 2012 to 2016, to estimate the eviction rate. We excluded early Expansion states: Arizona, Delaware, Hawaii, New York, Vermont, District of Columbia, Massachusetts, and Maryland; and counties that had undergone renaming or restructuring that rendered it infeasible to merge our data sources. The final sample consisted of 15,000 observations: 3,000 counties followed over the study period. Our Poisson models included county fixed effects, robust standard errors clustered at the state-level, and population weights. Covariates included median property value, median household income. Additionally, our sensitivity analyses included a 1-year lag, least squares fitting, and adjusting for county and state-level variables commonly seen in the literature.

RESULTS: Our primary analysis showed that overall counties that experienced Medicaid Expansion showed a 14% reduction in the rate of eviction compared to counties that did not expand (IRR=0.86, 95% CI: 0.76-0.98), when controlling for median property values and median

household income at the county level. In Expansion counties with large representation of Hispanic/Latino residents, the effect estimate showed a 24% reduction in rate of eviction (IRR=0.76, 95% CI: 0.70-0.83). Among Expansion counties with a high proportion of renters, rate of eviction was reduced by 14% (IRR=0.86, 95% CI: 0.75-0.99). In Expansion counties with high rent burden, there was an 18% reduction in rate of eviction compared to non-Expansion states (IRR=0.82, 95% CI: 0.68-0.99), when controlling for median property value and median household income. Conversely, Expansion was not protective for counties with a large representation of African- American residents as eviction rate increased by 32% (IRR=1.3, 95% CI: 1.0-1.7).

CONCLUSIONS: This study showed that county-level eviction rates decreased significantly among vulnerable populations after Medicaid Expansion was in effect, deeming such policies as an important part in addressing the current affordable-housing crisis occurring in many US cities.

DEFINING ACCESS MANAGEMENT

Susanne Hempel[1,2]; Lara Hilton[9]; Susan E. Stockdale[4]; Peter J. Kaboli[5]; Isomi Miake-Lye[10]; Marjorie Danz[2]; Susan Kirsh[8]; Danielle Rose[6]; Idamay Curtis[7]; Lisa V. Rubenstein[3]. [1]Preventive Medicine, University of Southern California, Los Angeles, CA; [2]RAND Corporation, Santa Monica, CA; [3]Medicine, RAND and UCLA, Medford, OR; [4]HSR&D Center of Excellence, Greater Los Angeles VA Healthcare System, Sepulveda, CA; [5]Internal Medicine, Iowa City VAMC, Iowa City, IA; [6]VA HSR&D Center for the Study of Healthcare Provider Behavior, VA GLA Healthcare System, Sepulveda, CA; [7]PACT Demonstration Laboratory Initiative, Veterans Health Administration, Seattle, WA; [8]central office, veterans health administration, Pepper pike, OH; [9]Deloitte, Los Angeles, CA; [10]Department of Veterans Affairs, Los Angeles, CA. (Control ID #3391691)

BACKGROUND: Managing patient access to care in healthcare delivery organizations is critical for shaping patient healthcare experiences. Conceptual work to understand the components of access and access management is critical for improvement initiatives. The work aims to advance primary care access management practice and research to support healthcare delivery organizations.

METHODS: We convened a stakeholder panel, informed by evidence review, to establish access and access management definitions. Stakeholders were selected based on a patient-centered framework and included patients, healthcare providers, policy makers, product makers, payers, and purchasers of healthcare. Methods included evidence review; written surveys; in-person stakeholder panel discussions; and concurrent subpanels to establish recurring, cross-panel themes.

RESULTS: Literature review results showed variation in the definition of the concept "access" but consistent operationalization of the temporal measure “time to third next available appointment” as an indicator of access. Panel deliberations highlighted the importance of patient-centeredness and resulted in three comprehensive definitions: 1) “*Access management* encompasses the set of goals, evaluations, actions and resources needed to achieve patient-centered healthcare services that maximize access for defined eligible populations of patients; ” 2) “*Optimal access management* engages patients, providers, and teams in continuously improving care design and delivery to achieve optimal access;” and 3) “*Optimal access* balances considerations of equity, patient preferences, patient needs, provider and staff needs, and value.”

CONCLUSIONS: Access to healthcare is substantially determined by how healthcare delivery organizations manage it. The developed concepts of access management suggest that access management, improvement initiatives, and research studies require ongoing attention to organizational processes and multiple–often mutually exclusive–relevant outcomes. Healthcare organizations and researchers can use the definitions as starting points for initiatives to improve access management and evaluations of access initiative success.

DELAYS IN CLINIC VISITS FOR CONTRACEPTION DUE TO NOT WANTING A PELVIC EXAMINATION AMONG YOUNG WOMEN WITH A HISTORY OF PHYSICAL, SEXUAL, OR VERBAL ABUSE

Hunter K. Holt[1]; George F. Sawaya[2]; Alison El Ayadi[2]; Jillian T. Henderson[3]; Corinne Rocca[2]; Carolyn Westhoff[4]; Cynthia Harper[2]. [1]Family and Community Medicine, University of California, San Francisco, San Francisco, CA; [2]Department of Obstetrics, Gynecology, and Reproductive Sciences, University of California, San Francisco, San Francisco, CA; [3]Center for Health Research, Kaiser Permanente, Northwest, Portland, OR; [4]Epidemiology and Population and Family Health, Columbia University, New York, NY. (Control ID #3391687)

BACKGROUND: Avoidance of pelvic examinations may be heightened among women experiencing intimate partner violence, representing an important barrier to preventive healthcare, including contraception or other reproductive health services. Our current analysis aims to understand women’s attitudes towards pelvic examination by history of physical, sexual, or verbal abuse.

METHODS: We conducted a secondary analysis of data from a cluster-randomized trial on contraceptive access. 1500 women aged 18-25 receiving contraceptive counseling and not desiring pregnancy in the next 12 months were recruited at 40 health centers across the United States. Data were collected between 2011 and 2013. We examined variation in positive responses to this question: “In the past, I have put off going to the clinic for birth control because I did not want to have a pelvic examination” by history of physical, sexual, or verbal abuse, coded by frequency (never, rarely, sometimes, often). We used multivariable logistic regression with generalized estimating equations for clustered data. Covariates included age, race, parity, health insurance, site type, and trial arm.

RESULTS: Of 1500 participants, mean age was 21.5 (SD 2.2). 49.6% identified as White, 27.2% as Latina, 14.8% as Black and 8.4% as other. Physical abuse was reported in 10.2% of participants. Pressured sex was reported by 32.4%, with 16.5% reporting it “rarely”12.1% reporting it “sometimes”, and 3.8% reporting it “often”. Forced sex was reported in

10.8% participants. Verbal abuse was reported in 19.4% of participants. Overall, 13.1% of participants reported delaying going to the clinic for birth control because they did not a pelvic exam. In multivariate analysis, the odds of delaying going to clinic was 76% higher in women reporting pressured sex "rarely" (aOR 1.76 95%CI 1.31-2.37 p<.005) and 210% higher among women reporting pressured sex "often" (aOR 3.10 95%CI 1.39-6.93 p=.006). No significant associations were found for verbal abuse or physical abuse.

CONCLUSIONS: Women with a history of sexual abuse are more likely to delay clinic visits for contraception due to not wanting a pelvic examination. Communicating that routine pelvic examinations are no longer recommended by professional societies could potentially remove barriers and increase preventive health care visits for these women.

DEMOGRAPHICS OF FOOD INSECURITY IN AN URBAN COUNTY HOSPITAL

Senxi Du[3]; Kira Watson[1]; Andrew Young[2]. [1]Health Administration, LAC+USC Medical Center, Los Angeles, CA; [2]Division of Geriatric, Hospital, Palliative and General Internal Medicine, Keck School of Medicine, Los Angeles, CA; [3]Keck School of Medicine, Los Angeles, CA. (Control ID #3392201)

BACKGROUND: Food insecurity is a modifiable social determinant of health (SDH), which is associated with chronic disease management, cost-related medication underuse, and annual healthcare expenditures. As little is known about food insecurity in the inpatient setting, we seek to characterize its prevalence and the relevant circumstances of food insecure patients to better understand how to intervene on future patients who screen positive.

METHODS: We conducted two sets of surveys with patients hospitalized on the general medicine service in an urban, county hospital in Los Angeles, CA. In the first survey, patients were screened for food insecurity using the Hunger Vital Signs tool. In the second survey, we aimed to illustrate the nuances of food insecurity by collecting targeted questions on access in this same population. Data was analyzed using Microsoft Excel. Incomplete responses were excluded from analysis. To compare ZIP codes of food secure versus food insecure patients, we used the Community Needs Index (CNI), which analyzes data at the ZIP code level and assigns a score to each area, ranging from 1.0 (lowest need) to 5.0 (greatest need).

RESULTS: The combined survey data (n=225) demonstrates that 39% of our patient population experiences food insecurity, and 44% of our food-insecure patients are homeless. In the second survey (n=75), we found that 68% of patients enrolled in CalFresh, known federally as the Supplemental Nutrition Assistance Program, still experience food insecurity. Yet, only 53% of all food insecure patients in the sample reported enrollment in CalFresh. Of patients who were food secure, 81% reported access to a grocery store that stocks healthy and varied fruits and vegetables, while only 34% of food insecure patients reported such access. For both groups, CNI scores ranged from 3.6 to 5.0. Among food secure patient ZIP codes, the average score was 4.54. Among food insecure patients, the average score was 4.70.

CONCLUSIONS: Food insecurity is extremely prevalent, over four-times the national rate, among patients hospitalized the general medicine service in an urban county hospital. Providers may assume food insecurity affects only the significantly disenfranchised, but our data shows that nearly half of food insecure patients are not homeless. Despite enrollment in CalFresh, the majority of food insecure patients continue to report food insecurity and poor access to healthy foods. ZIP code data shows that food insecure patients live in areas with greater need than food secure patients, and these environmental factors may further contribute to food insecurity and poor health. Further research is needed to better characterize how food insecurity may manifest differently amongst different populations, such as homeless versus housed, what other interventions beyond supplemental resources may better address food insecurity, and its impact on health outcomes.

DEPLOYMENT OF AN INPATIENT EARLY WARNING SYSTEM WITH CENTRALIZED MONITORING: A QUALITATIVE ASSESSMENT ON NURSING COMMUNICATION AND WORKFLOW

Emilie J. Braun[6]; Erin A. Strong[2,6]; Michael E. Stadler[3,6]; Siddhartha Singh[4,6]; Kathlyn Fletcher[1,6]; Quinn C. Bongers[5]; Annie C. Penlesky[5,6]; Ann Nattinger[1,6]; Bradley H. Crotty[1,6]. [1]Medicine, Medical College of Wisconsin, Milwaukee, WI; [2]Surgery, Medical College of Wisconsin, Milwaukee, WI; [3]Otolaryngology, Medical College of Wisconsin, Milwaukee, WI; [4]Department of Clinical Affairs, The Medical College of Wisconsin, Milwaukee, WI; [5]Center for Advancing Population Science, Medical College of Wisconsin, Milwaukee, WI; [6]Collaborative for Healthcare Delivery Science, Medical College of Wisconsin, Milwaukee, WI. (Control ID #3391587)

BACKGROUND: Early warning systems (EWS) use patient data, such as vital signs, nursing assessments, laboratory values, and cardiac tracings, to continuously compute a composite score of a hospitalized patient's condition. In June 2018, we deployed a commercially available EWS (Rothman Index) using the above data points across a 600-bed academic hospital with the goal of reducing mortality. EWS alerts triggered based on absolute or relative score decline. Unique to this deployment, a centralized virtual team of experienced nurses monitored EWS alerts and investigated the alert's cause in the patient's record before contacting the patient's bedside nurse to communicate risk and offer suggestions. The objective of this quality improvement study was to understand the effect of the EWS implementation on nursing workflow.

METHODS: We conducted and audio-recorded semi-structured focus groups during nurse staff meetings on six inpatient units sampled across alert frequency. Discussion guide topics included EWS experiences, scenarios where the EWS was helpful/unhelpful, EWS implementation, and ideas for improvement. Investigators analyzed the focus group transcripts using grounded theory and agreed on a coding scheme. Transcripts were coded accordingly, and themes emerged.

RESULTS: Each of six units completed at least two focus groups. We conducted 28 focus groups with 227 bedside nurses across all shifts. Nurses reported that the impact of the implemented EWS was muted by 6 themes: (1) *alert timeliness,* as nurses reported being aware of the patient's deterioration before the EWS alert, (2) *lack of accuracy,* with most alerts being perceived as false positives, (3) *workflow interruptions* caused by EWS alerts, (4) questions of *actionability of alerts,* as nurses were often uncertain about next steps, (5) concerns around an *underappreciation of core nursing skills* via reliance on the tool, and (6) the *opportunity cost* of deploying the tool. Nurses reported value in the implementation of the EWS as a *safety net* and to prioritize sicker patients at the beginning of their shifts.

CONCLUSIONS: EWS benefits were tempered by nurse concerns related to both the system itself as well as the implementation. The lack of clear actionability related to alerts led to confusion about next steps and was possibly intertwined with concerns around accuracy. While a centralized team reviewed alerts, calls to notify the bedside nurse about the EWS warning often caused workflow interruptions. Nurses wondered if the cost of the tool may have been better invested elsewhere, citing the need for hands-on support rather than virtual support. Our study provides information to organizational leaders making decisions about further deployment of the tool. The next steps are to review implementation design with

nurse engagement and provide more discretion to virtual nurses for when to engage the bedside nurse when a patient triggers an alert.

DEPRESSION SCREENING IN A SAFETY NET CLINIC

Natalie C. Curtis[1]; Neha Gupta[1]; David Tian[2]. [1]Internal Medicine, Alameda Health System, Oakland, CA; [2]Internal Medicine, Highland Hospital, Alameda Health System, Oakland, CA. (Control ID #3392228)

BACKGROUND: Depression is a common and often undertreated problem. In the US, 6.7% of adults have reported at least one major depressive episode, but less than half receive treatment[1][2]. Untreated depression is a leading cause of disability among adults and carries significant mortality due to suicide[3]. Therefore, in 2009 the USPSTF recommended annual screening for depression in the adult population[4]. Increased barriers exist to screening and treatment of depression in racial and ethnic minorities due to stigma, lack of culturally competent care, inadequate mental health services, etc[5]. For this reason, effective depression screening in primary care settings is necessary to facilitate treatment strategies. The Highland Adult Medicine Clinic is a hospital-based safety net clinic in Oakland, CA. Depression screening rates in this clinic lagged behind state and national benchmarks. This project identifies strategies to improve screening rates in an urban, multi-lingual, safety net clinic. [1] National Institute of Mental Health. Major depression. 2017. [2] Olfson M, et al. Treatment of adult depression in the United States. JAMA Intern Med. 2016;176:1482-1491. [3] Friedrich MJ. Depression Is the Leading Cause of Disability Around the World. JAMA.2017;317(15):1517. [4] USPSTF Final Recommendation Statement: Depression in Adults – Screening. [5] Cooper LA, et al. The acceptability of treatment for depression among African-American, Hispanic, and white primary care patients. Med Care. 2003;41:479-489.

METHODS: Depression screening rates, defined as the completion of the Patient Health Questionnaire-2 (PHQ2), were audited pre and post- intervention. Interventions included: (1) adoption of system-wide standard work to increase screening frequency from annual to every visit, (2) modification of the screening form to improve usability, and (3) same-day auditing of outpatient visits and outreach to patients to complete depression screening telephonically. When screening all patients, we used the PHQ2 and followed up with the PHQ9 if the PHQ2 was positive.

RESULTS: Depression screening rates in the Highland Adult Medicine clinic increased from 53.1% (April, 2019) to 54.5% (May, 2019) after implementation of the system wide standard work. Rates further increased to 66.5% (July, 2019) with implementation of interventions 2 and 3. Other primary care clinics within the system showed increased rates with the system-wide standard work with increases of 6.8% compared to Highland's rate increase of 12.0% during the same time period.

CONCLUSIONS: The three documented interventions had a positive effect on depression screening rates in a safety net clinic. The two interventions outside of the standard work had an even stronger effect on screening rates. Next steps may include using population health outreach workers to conduct similar outreach as our volunteer. With rates of screening still below HEDIS targets, there is still much more that needs to be done to address underscreening in a safety net clinic.

DESCRIBING FACULTY EXEMPLARS OF MEDICAL PROFESSIONALISM

Penelope Lusk[1]; Lisa Altshuler[2]; Verna Monson[3]; Lynn Buckvar-Keltz[4]; Ruth Crowe[5]; Linda Tewksbury[6]; Molly Poag[7]; Victoria Harnik[7]; Rafael Rivera[8]; Adina Kalet[9]. [1]Medicine, New York University-Langone Health, New York, NY; [2]General Internal Medicine, NYU School of Medicine, New York, NY; [3]Consultant, Minneapolis, MN; [4]medicine, NYU School of Medicine, New York, NY; [5]Medicine/Office of Medical Education, NYU School of Mediicne, New York, NY; [6]Pediatrics, NYU School of Medicine, New York, NY; [7]NYU Grossman School of Medicine, New York, NY; [8]Radiology, NYU School of Medicine, Rumson, NJ; [9]Medical College of Wisconsin, Milwaukee, WI. (Control ID #3391591)

BACKGROUND: Internalizing a strong medical professional identity (PI) is a critical part of medical education. Recent studies of medical students have documented that students' PI, measured by the Professional Identity Essay (PIE), a reflective writing assessment of PI based on Kegan's theory of adult development and Bebeau's developmental model of PI, vary and are impacted by education. Little is known about the PI of exemplary professional physicians. We sought to: 1) describe the PI of physicians who exemplify the highest principles of the medical profession, and 2) evaluate NYU faculty identified as professional exemplars by peers to provide data and demonstrate clear role models for learners

METHODS: We elicited nominations for professional exemplar physicians from NYU faculty, chief residents, and 4th-year students, using the definition of professionalism developed by Colby and Damon (1992). Participants were recruited after receiving at least 3 nominations; select participants who received 1 or 2 nominations were also recruited to diversify the participants in terms of specialty, years of practice, gender and race. We also used snowball techniques to get nominations from study participants. After consenting, faculty received the 11-question PIE. We analyzed demographic data of nominated faculty and completed a content analysis of the PIE.

RESULTS: 206 individual faculty were nominated at least one time by 70 community members. 32 individuals were recruited to the study; to date 22 have completed the PIE. The 206 nominees/22 participants represent: 34/12 specialties, average years in practice 17.6/23.8, range of years in practice 62 for nominees/44 for participants. We identified 3 primary themes through the content analysis: (1) Response to Expectations, "Everything. The profession demands everything… As much as this profession takes from me, it is dwarfed by what I have received in return." (2) Response to Failure: "I fail to live up to expectations every day. Some days this motivates me, other days I disappoint myself." (3) Learning from Others: "I view teaching as integral to medical professionalism." There was a range of developmental levels in the responses with some focusing more on external rather than internal motivations: "I can say that the [malpractice] process for me was very threatening, emotionally consuming and had the potential to alter professional behavior in the wrong way."

CONCLUSIONS: Nominated faculty represented a diverse group with respect to PI. Many participants demonstrated great professionalism and a sense of internal PI in responses to the PIE questions, while others focused on more external motivations to drive their professional behaviors. Further analysis is needed to define the qualities of a true exemplary professional. The range of responses of the exemplars can both serve as role models for learners and provide multiple pathways for learners and faculty to strengthen their own professional identities.

DESIGNING A CANCER PREVENTION COLLABORATIVE GOAL SETTING APPLICATION FOR PRIMARY CARE PATIENTS: AN ITERATIVE, PATIENT-LED PROCESS

Daniel Resnick[1]; Allison Bautista[2]; Jazmine Smith[5]; Matthew Kearney[4]; Liz Jones[3]; Marilyn M. Schapira[5]; Jaya Aysola[6]. [1]Internal Medicine, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; [2]Department of Medicine, University of Pennsylvania, Philadelphia, PA; [3]Design, Transmogrify, Conshohocken, PA; [4]Community Health, Drexel University, Philadelphia, PA; [5]Internal Medicine, University of Pennsylvania, Philadelphia, PA; [6]Medicine, Division of General Internal Medicine, University of Pennsylvania, Philadelphia, PA. (Control ID #3391208)

BACKGROUND: Evidence suggests up to 80% of the cancer burden is related to modifiable lifestyle behaviors, such as diet, exercise, smoking cessation, and maintaining a healthy weight. Despite this, we lack primary care interventions that promote lifestyle changes for the purpose of cancer prevention. This study iteratively designed and evaluated a collaborative goal setting application (CCPG) that utilizes evidence- based behavior change techniques to facilitate cancer prevention goal setting, tracking, and sharing with known and unknown social ties.

METHODS: We conducted semi-structured interviews with primary care patients (n=33) in batches of 5 to 7 per week. The study focused on non-Hispanic black patients, as the application was specifically conceived to help reduce the disproportionate cancer burden in racial and ethnic minority communities. Initial interviews elicited feedback on intervention modality and content by asking participants (n=16) about their technology usage, experiences setting health goals, and attitudes about sharing health information. We also showed these participants paper mock-ups of the app and elicited their preferences on specific features, functions, and content. These findings informed the digital prototype, which was shown to different participants (n=17) for feedback on content, features, function, and overall usability. The study team analyzed all participant feedback weekly to iteratively refine and optimize the application. Two study team members further coded and analyzed the data in NVivo to identify overarching themes.

RESULTS: Of total participants (n=33), 79% self-identified as female and the mean age was 49 (SD 13). Initial testing revealed that 14 of the 16 (88%) participants owned a smartphone, 13 (81%) tracked their health in some way and 15 (94%) expressed comfort in sharing health information with close ties. Qualitative data showed that participants valued both setting goals to promote health behaviors and sharing health information with others to facilitate achieving these health goals. Iterative analysis of user feedback informed the optimization of the digital prototype, leading to: 1) modification of the user "leaderboard" to a progress board to emphasize cooperation over competition; 2) addition of an intra-app messaging tool; 3) enhancements in functionality to allow for ease in selecting and modifying pre-determined goals. Among participants providing feedback on our digital prototype (n=17), 17 (100%) rated the app as easy to use and 13 (76%) stated they would like to use the app frequently.

CONCLUSIONS: This study used an iterative process to design and evaluate a novel, participant endorsed mobile application that facilitates setting, tracking, and sharing health goals with known and unknown social ties in a collaborative rather than competitive way. These findings suggest the acceptability and utility of a future mobile CCPG application to promote healthy behaviors among primary care patients.

DESIGNING AND DEPLOYING A PHARMACIST-MEDIATED ADVERSE DRUG REACTION SURVEILLANCE SYSTEM USING A PATIENT PORTAL.

Samuel Bennett[2,1]; Maria Mirica[2,1]; Adam Wright[3,4]; Lynn A. Volk[5,1]; Alejandra Salazar[1,2]; Sonam N. Shah[6,7]; Maram Khazen[1,2]; Tewodros Eguale[8,1]; Gordon D. Schiff[1,9]. [1]General Medicine, Brigham and Women's Hospital, Somerville, MA; [2]Center for Patient Safety Research and Practice, Brigham and Women's Hospital, Boston, MA; [3]Medicine, Brigham and Women's Hospital, Newton, MA; [4]Vanderbilt University School of Medicine, Nashville, TN; [5]Clinical and Quality Analysis, Partners HealthCare, Wellesley, MA; [6]Department of General Internal Medicine, Brigham and Women's Hospital, Jamaica Plains, MA; [7]Pharmacy Practice, MCPHS University, Boston, MA; [8]Pharmacoeconomics and Policy, MCPHS University, Boston, MA; [9]Harvard Medical School, Boston, MA. (Control ID #3391069)

BACKGROUND: More than half of the US population reports using a prescription medication in the past year, and approximately one in four patients prescribed a new medication experiences an adverse drug reaction (ADR)[1-6]. Presently, however, there is no ubiquitous system by which ADRs are tracked and reported in the clinical setting, nor is there a way for providers to monitor and act on feedback from patients regarding any medication-related issues. To fill this gap, our team is conducting a study to screen for ADRs through a patient portal. The primary aim of this study is to design and deploy a comprehensive surveillance system to monitor potential ADRs in patients newly started on medications.

METHODS: We generated daily Epic data pulls of medications newly prescribed at two Brigham and Women's Hospital Primary Care clinics. Certain categories of medications (e.g., vitamins) were excluded. Only patients with an active portal account were included. We sent messages approximately one week after a new medication was prescribed asking if: a) they had started the medication and b) were experiencing any new symptoms. Two study pharmacists communicated with the participants on the portal and, when needed, by phone. The main activities of the pharmacists were to provide guidance for potential ADRs, assist in adherence, address other medication concerns, and route the correspondence to the patient's PCP when appropriate. A second follow-up message was sent to all participants 2-4 weeks after the initial message.

RESULTS: Between 8/1/19 and 12/9/19 8,129 new prescriptions were written for study patients. A total of 1,349 patients met eligibility criteria and were contacted via the patient portal. Of these, 302 (22.4%) patients replied. Respondents were on average 48 years old (range 24-69). 22.7% of males, 22.3% of females and 14.5% of Hispanic patients replied. Of the 279 patients who responded to the symptoms question, 77 (27.6%) reported an ADR, a rate similar to previous studies[1,4]. The patients' PCP was contacted in 46 cases. 120 (48.4%) patients replied to the follow-up messages, of whom 20 reported new symptoms.

CONCLUSIONS: Results of this study show that monitoring of ADRs via a patient portal can be an effective way to identify symptoms that may be otherwise undetected, as well as a way to assist patients in addressing other medication-related issues, including those that impacted adherence. Demographic data showed similar participation rates between sexes and lower participation from Hispanic patients. These participation rates may reflect the general pattern of patient portal use and could be used to inform policies to improve patient engagement with health information technology. Further research is needed into ways to scale up such a pharmacovigilance system to be rolled out across multiple primary care clinics and to increase patient engagement across the demographic categories.

DESPITE HIGH MORBIDITY AND MORTALITY, AFRICAN AMERICANS WITH ESRD MISS EOL CARE DISCUSSIONS

Daniel Ahn[2]; Akilah King[3]; Milda R. Saunders[1]. [1]General Internal Medicine, University of Chicago Medicine, Chicago, IL; [2]Pritzker School of Medicine, University of Chicago Medicine, Chicago, IL; [3]BSD- Nephrology, University of Chicago, Chicago, IL. (Control ID #3391564)

BACKGROUND: End-stage renal disease (ESRD) is associated with high mortality and morbidity and disproportionately impacts minorities. The adjusted 5-year survival rate of ESRD patients is 42% which is lower than that for all adult cancer patients. Prior work has shown that African Americans with ESRD are less likely than their White counterparts to have discussed end-of-life (EOL) care preferences. We sought to examine the causes of the low rates EOL care planning among African American dialysis patients.

METHODS: From June to September 2019, we surveyed African American adults receiving hemodialysis at three urban Midwest dialysis clinics about experience with and views on EOL care planning. Surveys included questions about their prior EOL care planning and preferences in various EOL situations. We analyzed summary measures of patients' EOL care

views with bivariable and multivariable logistic regression models using several covariates including age, gender, education level, income, insurance, and previous experience with EOL care discussions.

RESULTS: Of the 101 African American ESRD patients interviewed, the mean age was 58.7 years, 52% were female, 42% had >5 years on dialysis, 91% had hypertension and 46% had diabetes. Almost 70% (69/101) of patients denied prior EOL care discussion with any healthcare team member. Of this group, 95% (64/69) stated their healthcare team never initiated EOL care conversations, even though 37% (25/69) desired them. Of 32 patients who reported having an EOL care discussion with a healthcare team member; they most commonly had these discussions with the dialysis unit social worker (62.5%, 20/32) and their primary care physician (50%, 16/32). The majority of patients (53%, 17/32) reported these EOL discussions occurred within the first year of dialysis, while only a few (15.6%, 5/32) reported having regular EOL care discussions. Prior EOL care discussions with the healthcare team was significantly associated with an increased likelihood of having spoken to family members about EOL care wishes (OR 3.1, p>0.05). In a multivariable model, there was no association between any patient clinical or demographic patient co- variates, and likelihood of prior EOL care discussion. In addition, the relationship between prior EOL care discussions with a medical team member was significantly associated with a decreased preference for life- extending care in one EOL care scenario.

CONCLUSIONS: Most African American patients with ESRD reported no prior EOL care discussions, even among those with important clinical risk factors including older age, recent hospitalization or longer time on dialysis. EOL care discussions are associated with better EOL care communication with family members and, to some extent, an increased preference for less aggressive measures at the EOL. Many patients are open to speaking about EOL care with healthcare team members, but may be unwilling to initiate these discussions.

DETECTING COGNITIVE IMPAIRMENT AND DEMENTIA AND PRIMARY CARE: CURRENT PRACTICES AND FEASIBILITY OF THE MYCOG DETECTION PARADIGM

Rachel O'Conor[1]; Julia Yoshino Benavente[2]; Laura M. Curtis[2]; Marina Arvanitis[2]; Richard Gershon[3]; Michael S. Wolf[4]. [1]Division of General Internal Medicine, Northwestern University, Chicago, IL; [2]General Internal Medicine, Northwestern University, Chicago, IL; [3]Medical Social Sciences, Northwestern University, Chicago, ID; [4]Medicine, Northwestern University, Chicago, IL. (Control ID #3390529)

BACKGROUND: As the age of the US population increases, so does cognitive impairment (CI); therefore early detection of CI is critical for ensuring its appropriate management. While primary care is an ideal setting for identifying CI, it frequently goes undetected. Available screening tools may be unsuitable for implementation in this setting due to their administration time, cost, or need for specialized equipment or highly trained administrators. As part of a NINDS Consortium to detect CI and dementia in primary care (DetectCID), we are implementing and evaluating a brief 2-step CI detection paradigm (MyCog) that can be delivered in clinics with diverse populations. The first step is case finding via a brief questionnaire administered through the electronic health record (EHR), and the second step is an iPad-based cognitive assessment. We sought feedback from primary care practices to inform the implementation of our CI detection paradigm.

METHODS: We conducted focus groups with 25 clinicians and administrative leaders from academic and community primary care practices to 1) understand how CI is currently being assessed, and 2) evaluate the feasibility of implementing the MyCog paradigm into existing primary care workflows. The research team took detailed notes during the discussion groups and reviewed them for common themes across participants.

RESULTS: No proactive detection strategy for CI was regularly used outside of the Medicare Annual Wellness Visits (AWV); variable assessments including the Minicog, MoCA, or MMSE were used to fulfill the AWV requirement. Regarding the feasibility of our MyCog Paradigm, our 2-step process was positively received, with the brief case-finding step 1 satisfying AWV requirements and replacing the longer assessments currently being used. Clinicians preferred that step 2 be self-administered due to limited clinician time for wellness visits, and highlighted logistical challenges such as room availability and storage and maintenance of the iPad. Clinicians emphasized the importance of the direct transfer of results into the EHR. There was also some concern that addressing cognitive issues could detract from the management of patients' other chronic conditions. Overall, clinicians felt that the identification of CI was valuable and supported standardization, but indicated regular case finding was unlikely without clear guidance on clinical decision- making.

CONCLUSIONS: CI is not routinely detected in primary care outside of the Medicare AWV. Overall, clinicians felt that the identification of CI was valuable and supported standardization, but indicated regular case finding was unlikely without clear guidance on clinical decision-making.

DETECTION AND EFFECT OF POSITIVE SCREENS FOR GERIATRIC SYNDROMES AT THE MEDICARE ANNUAL WELLNESS VISIT

Stephanie Nothelle[1]; Maura J. McGuire[2,3]; Cynthia M. Boyd[1]; Jessica Colburn[1]. [1]Geriatric Medicine and Gerontology, Johns Hopkins University School of Medicine, Baltimore, MD; [2]Medicine, Johns Hopkins University School of Medicine, Baltimore, MD; [3]Johns Hopkins Community Physicians, Baltimore, MD. (Control ID #3391857)

BACKGROUND: The Medicare Annual Wellness Visit (AWV) is an annual office visit to update preventive health needs and screen for health risk in older adults. Little is known about how often geriatric syndromes are detected or how positive AWV screens impact care. We examined the prevalence of positive screens for three geriatric syndromes: falls, cognitive impairment, and impairment in activities of daily living (ADL), and we assessed referrals, orders and diagnoses generated from positive screen(s).

METHODS: We used electronic health record (EHR) data from Medicare beneficiaries age ≥65 who received primary care in a large group practice between 2014-2017. This group completed AWVs using a standardized EHR template. Patients were identified using AWV billing codes. Fall risk, memory concern, and ADL impairment were determined by positive responses to a standard questionnaire. For each geriatric syndrome, we identified referrals and orders from the AWV for those who screened positive vs. negative. In patients who screened positive for falls or cognitive concerns, we assessed for high-risk medications based on 2019 Revised Beers Criteria. We compared the incident number of dementia diagnoses in the year following the cognitive screen. Statistical significance was determined using a two-sample test of proportions.

RESULTS: We identified 21,080 adults ≥65 years who were eligible for the AWV. Seventy-one percent received at least 1 AWV and of those 78% had questionnaire data to assess geriatric syndromes. Prevalence of positive screens was 37% for falls, 23% for cognitive screen, and 31% for ADL impairment. Older adults with a positive fall screen were more likely to be referred to physical therapy (PT), occupational therapy (OT) or home care than those with a negative screen (36% v 20%, p<0.0001), however those with a positive fall screen were also more likely to be given a medication known to increase fall risk in the year after the screen. Those with a positive cognitive screen were more likely to have vitamin B12 or TSH ordered (43% v 36%, p<0.0001), more likely to have a referral to memory clinic, geriatrics or neurology (15% v 6%, p<0.0001), and more likely to receive a medication that should be avoided in cognitive

impairment in the year after the screen. There also was an increase in dementia diagnosis by screening status (2% v 0.2%, p<0.0001). Older adults with a positive ADL screen were not more likely to have a referral to PT, OT or home care than those with a negative screen (21% v 12%, p<0.0001).

CONCLUSIONS: A significant minority of older adults who received the AWV in our sample had a positive screen for a geriatric syndrome (falls, cognitive impairment, ADL impairment). Positive screens generated a higher rate of referrals and testing; however, a positive screen did not change prescribing patterns related to the condition of concern. These results may indicate a need for enhanced geriatrics education in primary care.

DEVELOPING AND TESTING THE HOMELESS-FOCUSED PRIMARY CARE ORGANIZATIONAL EVALUATION (HOGE)

April E. Hoge[1]; Allyson Varley[2,1]; Adam Gordon[3]; Aerin DeRussy[4]; Ann E. Montgomery[5]; Erika Austin[6]; Sally K. Holmes[1]; Audrey Jones[7]; Lillian Gelberg[8]; Sonya Gabrielian[9]; Kevin R. Riggs[2]; Stefan Kertesz[10]. [1]Research, Birmingham VA Medical Center, Birmingham, AL; [2]Division of Preventive Medicine, University of Alabama at Birmingham, Birmingham, AL; [3]University of Pittsburgh and VA Pittsburgh Healthcare System, Pittsburgh, PA; [4]Research, Birmingham VA Medical Center, Birmingham, AL; [5]Birmingham VAMC, U.S. Department of Veterans Affairs, Birmingham, AL; [6]Biostatistics, UAB, Birmingham, AL; [7]IDEAS Center, VA Salt Lake City Health Care System, Salt Lake City, UT; [8]Department of Family Medicine, UCLA, Los Angeles, CA; [9]VA Greater Los Angeles Health Care System and David Geffen School of Medicine at UCLA, Los Angeles, CA; [10]Medicine, Birmingham VA Medical Center & U. Alabama Birmingham, Homewood, AL. (Control ID #3389764)

BACKGROUND: Homeless persons experience barriers to primary care (PC) access, and describe problems even when care is obtained. The US Department of Veterans Affairs (VA) tailors service design to serve this population by varying hours of service, staffing arrangements, support for clothing or food, training, and other program features. However, the optimal service package is not known. Research to guide the delivery of PC for homeless populations requires a credible method to describe variations in how care is organized so that service variations can be evaluated. We developed and tested an organizational survey capable of detecting plausibly important distinctions.

METHODS: A multidisciplinary team conducted 57 semi-structured interviews across five VA and non-VA homeless PC clinics. Interviews queried access arrangements, care coordination/continuity, and PC team culture. Interview notes were thematically coded, then used to develop structured survey items member-checked with 4 homeless healthcare providers. The survey was administered to the lead nurse and prescribing provider of the 29 largest VA homeless PC clinics. We revised proposed scales based on dimensionality as supported by principle component analyses and internal reliability statistics. We also developed inventories of yes/no descriptive items to buttress the scales. Additionally, we described participants' response patterns.

RESULTS: The resultant Homeless-focused primary care OrGanizational Evaluation (HOGE) has 6 scales with 4-10 items each, along with 6 inventories. Cronbach α's for the scales range from .58 to .81 (Table). In 29 homeless PC clinics; 45% of clinicians reported it was not likely for the prescribing provider to see a non-emergent walk-in at the end of the day. Among the yes/no descriptive items, variation among was seen in how clinics handled tangible needs; 28% offered laundry, 52% clothes, and 62% food assistance. Also, opportunities to coordinate/integrate services were often problematic: 31% had no pharmacy in or near the clinic, and 35% had no specialty medical services in or near the clinic.

CONCLUSIONS: Understanding the optimal design of tailored PC for persons experiencing homelessness requires a method to measure the tailoring itself. Here we report the first effort to offer a survey of that nature. Future work will need to assess whether scale scores correlate meaningfully with patient-level outcomes, and whether the HOGE scales and inventories produce valid insights for clinics seeking to improve care and the agencies that fund them.

Scale (alpha)	Example Likert-type item
Staff and Team Dynamics (.81)	All team members feel free to express their feelings with the team.
Access (.58)	How would you characterize your patients' access to specialty medical services (Endocrine, ID, cardiology)?
Coordination (.72)	How often is there a personal warm handoff (phone or in person) between staff of the Emergency Department and the H-PACT team?
Accommodation (.68)	H-PACT staff include patients in treatment planning and decision making.
Leadership Support (.74)	Senior leaders help resolve problems and barriers we experience.
Intraorganizational Networks and Communication (.59)	Please indicate how much Formal Meetings help your team work together.

DEVELOPMENT OF A NEW PREDICTIVE MODEL FOR FALLS AMONG INPATIENTS USING BEDRIDDENNESS RANK IN DAILY LIVING; A RETROSPECTIVE OBSERVATIONAL STUDY OF 7,858 PATIENTS IN ACUTE CARE SETTING

Masaki Tago[1]; Naoko E. Katsuki[1]; Yoshimasa Oda[1,2]; Hidetoshi Aihara[1]; Yoshinori Tokushima[1]; Motoshi Fujiwara[1]; Shu-ichi Yamashita[1]. [1]General Medicine, Saga University Hospital, Saga, Saga, Japan; [2]General Medicine, Yuai-Kai Foundation & Oda Hospital, Kashima, Japan. (Control ID #3368400)

BACKGROUND: Falls can be devastating events leading to severe injuries and reduced activities of daily living. Previous studies have identified a variety of risk factors and several predictive formulas for falls have been developed; however, they require examinations and techniques seldom used in routine clinical settings as well as time-consuming assessment items, which pose a serious impediment to its use. Therefore, we have developed and subsequently validated a more straightforward predictive model that uses information routinely obtained at admission in Japan. We use the classifications for abilities of daily living advocated by the Japan Ministry of Health, Labour and Welfare, which are commonly used evaluation tools in the National Nursing Care Insurance System in Japan.

METHODS: We retrospectively analyzed data from Japanese adult inpatients in an acute care hospital from April 2012 to January 2015. Data including age, sex, activity of daily living, the MHLW classifications for abilities of daily living (Bedriddenness rank: normal; J, independence/autonomy; A, house-bound; B, chair- bound; C, bed-bound), referral letter, medications, previous fall, and the route of admission were derived from hospital records. Available data were randomly divided into the test set and validation set at a ratio of 2:1. The candidate predictive factors that fulfilled the following conditions—(i) be assessable at admission, (ii) had low collinearity with each other (coefficient of correlation [r] <0.7), and (iii) can be assessed by an ordinary person—were included in the multivariate model (model 1). A parsimonious model was also made by using predictive factors that showed a significant difference by multivariate logistic regression of model 1 (model 2). A predictive model was created from the multivariate model. The predictive performance was assessed by area under the receiver-operating curve (AUC) for the validation set.

RESULTS: During the study period, total 7,858 adult participants were enrolled. In the test set of 5,257 patients, the median age was 77 years, 34% were men. Model 1 was consisted of 12 factors: age, sex (male), emergency admission, use of ambulance, referral letter, admitted department (Neurosurgery, Internal Medicine), use of a hypnotic, permanent damage by stroke, history of falls, visual impairment, eating, and bedriddenness rank. Model 2 was consisted of 8 factors: age, male, emergency admission, department of Neurosurgery, use of hypnotic, previous falls, requiring assistance with eating, and bedriddenness rank.

Regarding the validation set, the ROC-AUC as the predictive performance of model 1 was 0.789 (95% CI: 0.757–0.821) and that of model 2 was 0.787 (95% CI: 0.755–0.819).

CONCLUSIONS: We developed a new and accurate predictive model for falls in adult inpatients using bedriddenness rank, which is more easily gathered than variables used in previously reported models.

DEVELOPMENT OF A UTILIZATION-BASED ALGORITHM TO IDENTIFY A POTENTIALLY COST-SENSITIVE HOUSING FIRST TARGET POPULATION IN MEDICAID CLAIMS DATA FOR THE CHICAGO FLEXIBLE HOUSING POOL

Keiki Hinami, Kruti Doshi, Laura Sadowski, William Trick. Medicine, Cook County Health, Chicago, IL. (Control ID #3373144)

BACKGROUND: The Chicago Flexible Housing Pool (FHP) combines public/private investments to create new supportive housing units for homeless individuals with chronic health conditions, and its sustainability depends on early evidence of associated societal cost savings. However, rigorously conducted trials to date indicate that societal cost savings are obtained only among select subpopulations. In particular, top-tier high utilizers, despite their largest potential effect size, were less likely than lower-tier but persistent/emergent utilizers to be associated with relative cost savings upon provision of supportive housing. Our objective was to develop a portable data algorithm for the FHP that can reliably identify homeless individuals who (1) exhibit characteristics of the Housing First target population, and (2) are most likely to experience reductions in utilization-related costs with supportive housing.

METHODS: In October 2018, we linked CountyCare (an Illinois Medicaid managed care program) claims, the electronic health record of Cook County Health inclusive of jail-based healthcare, and Chicago's Homelessness Management Information System (HMIS). We empirically developed a utilization-based algorithm to identify persistent utilizers, and confirmed they experienced serious mental illness or substance use disorder, without introducing new measurable disparities. We assessed their utilization phenotype with respect to their potential for cost savings using sequence analysis and successfully replicated 6 clusters of 2-year utilization patterns previously observed among homeless beneficiaries of New York City Medicaid. We assessed the proportion of persistent utilizers that mapped to phenotypes validated in NYC to be associated with housing-attributable relative cost reductions.

RESULTS: N=1045 individuals in HMIS were beneficiaries of CountyCare. Our algorithm flagged n=232 (22%) persistent utilizers. Persistent utilizers compared to others were similar in age (mean (95% CI): 48 (47, 50) vs. 47 (45, 47)), %women (34% vs. 29%), and jail registrations (median (IQR): 2 (1, 2) vs. 2 (1, 2)), but used EDs more frequently (median (IQR): 8 (8, 16) vs. 2 (1,4), Mann-Whitney p<0.001), used more hospital days (median (IQR): 10 (6, 30) vs. 7 (4, 16), Mann-Whitney p=0.002), and were more likely to be assigned diagnosis codes for serious mental illness (73% vs. 40%, p<0.001), or substance use disorders (72% vs. 33%, p<0.001). Ninety-six percent exhibited 2-year utilization patterns of sequence clusters associated with a greater likelihood of yielding cost reductions.

CONCLUSIONS: Based on an evidence-based assumption that service utilization patterns better inform phenotype than potential effect size for predicting societal cost-effectiveness of a supportive housing intervention, we developed an algorithm capable of identifying a target population that may exhibit housing- related cost reductions in an Illinois Medicaid program.

DIABETES DISTRESS IS ASSOCIATED WITH AMBULATORY CARE-SENSITIVE HOSPITALIZATIONS AMONG ADULTS WITH DIABETES COVERED BY ALABAMA MEDICAID

Caroline Presley[1]; Favel Mondesir[2]; April Agne[1]; Lei Huang[3]; Kevin R. Riggs[1]; Maria Pisu[1]; Emily B. Levitan[3]; Janet Bronstein[4]; Andrea L. Cherrington[1]. [1]Medicine, University of Alabama at Birmingham, Birmingham, AL; [2]Medicine, University of Utah, Salt Lake City, UT; [3]Epidemiology, University of Alabama at Birmingham, Birmingham, AL; [4]Health Care Organization and Policy, University of Alabama at Birmingham, Birmingham, AL. (Control ID #3387426)

BACKGROUND: Diabetes distress, the emotional burden of living with diabetes, is common in adults with diabetes and associated with reduced adherence to diabetes self-management behaviors and worse glycemic control. The relationship of diabetes distress with healthcare utilization has been minimally studied.

METHODS: We conducted a cohort analysis as part of a larger observational study of the quality of care of adults with diabetes covered by Alabama Medicaid. Participants completed a one-time survey, which was linked to their Medicaid claims data. We included adults (ages 18-64 years old) with a diagnosis of diabetes and continuous enrollment in Alabama Medicaid for the 6 months prior to and following the survey date. We assessed diabetes distress using the 17-item Diabetes Distress Scale. We classified utilization as the number of months with a diabetes-related ambulatory care-sensitive (ACS) hospitalization for uncontrolled diabetes, short-term or long-term complications in the 6 months after the survey date. We performed stepwise, Poisson regression models to evaluate the association diabetes distress and the number of months with an ACS hospitalization. Model 1 was unadjusted; in model 2, we adjusted for demographics (age, sex, race, ethnicity, education, marital status, income, eligibility, and rurality), and in model 3, we adjusted for demographics plus clinical variables (comorbidities, diabetes duration, insulin use, and diabetes education).

RESULTS: In total, 363 participants were included in this analysis. Participants' average age was 53.7 years (SD 9.2); 258 (71.1%) were women, 134 (36.9%) were white and 224 (61.7%) were black. The average duration of diabetes was 14.5 years (SD 12.0); 49.3% used insulin; 39.4% had previously received diabetes education. One third (N=121) had elevated diabetes distress (DDS ≥2). For healthcare utilization, 70 (19.3%) had a month with an ACS hospitalization; 23.1% of participants with elevated diabetes distress had a month with an ACS hospitalization versus 17.4% of participants with low distress, p= 0.21. In regression analyses, diabetes distress was associated with an increased incidence rate ratio (IRR) of number of months with an ACS hospitalization; in model 1, the IRR was 1.25 (95% CI 1.12, 1.38), 1.34 (1.21, 1.47) in model 2, and 1.29 (1.14, 1.44) in model 3.

CONCLUSIONS: We found elevated diabetes distress was associated with increased diabetes-related ACS hospitalizations among adults with diabetes covered by Alabama Medicaid while accounting for key demographic and clinical factors. Diabetes distress may be an important indicator of increased healthcare utilization, including diabetes-related preventable hospitalizations.

DIABETES SCREENING AMONG OVERWEIGHT AND OBESE PATIENTS IN NORTHERN NEW ENGLAND ACCORDING TO RURALITY

Timothy B. Plante[1]; Insu Koh[2]; Katherine Wilkinson[2]; Neil A. Zakai[1,2]; Mark E. Pasanen[1]; Jennifer Gilwee[4]; Kathleen Fairfield[3]. [1]Deparment of Medicine, Larner College of Medicine at the University of Vermont, Burlington, VT; [2]Department of Pathology & Laboratory Science, Larner

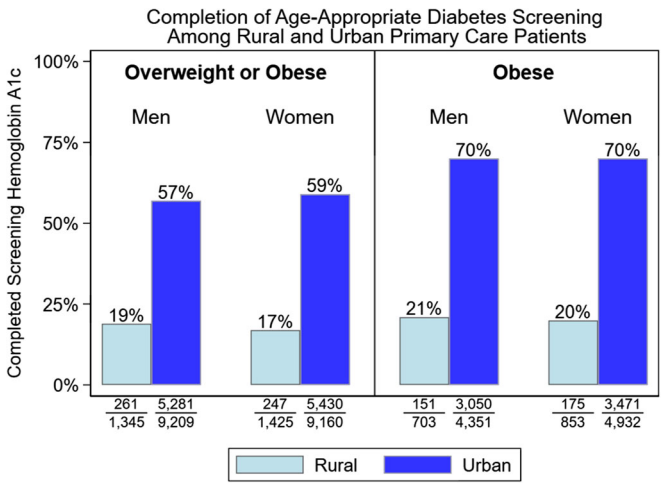
College of Medicine at the University of Vermont, Burlington, VT; [3]Medicine, Maine Medical Center, Portland, ME; [4]Medicine, University of Vermont, Shelburne, VT. (Control ID #3392535)

BACKGROUND: National guidelines recommend diabetes screening among adults aged 40-70y with body mass index (BMI) ≥25 kg/m^2, since overweight and obesity are risk factors for diabetes. Relative to urban, rural adults experience a greater prevalence of overweight and obesity. We sought to quantify the proportion of age-appropriate diabetes screening among rural vs. urban primary care patients with overweight and obesity.

METHODS: We included adults aged 40-67 at the first visit receiving primary care between 2010-2018 at University of Vermont affiliates. We excluded those with <2 visits and prevalent type 1 or 2 diabetes. We defined rural and urban status applying home ZIP to Rural-Urban Commuting Area codes. We tabulated proportion of overweight or obese (≥25 kg/m^2) and obese (≥30 kg/m^2) by rural/urban status. Among these BMI groups, we tabulated proportions ever receiving diabetes screening with a hemoglobin A1c by rural/urban status, stratified by sex. Comparisons used χ^2.

RESULTS: Among 86,864 in the cohort, we excluded 52,966 not aged 40-67, 3,620 with <2 visits, and 598 with prevalent diabetes. Of the 29,670 participants (mean [SD] age 54 (8) years, BMI 29 (7) kg/m^2), 56% were women, 93% were white, and 12% lived in rural areas. In comparison to urban dwellers, overweight or obesity was more common among rural adults (men 85% vs. 81%; women 72% vs. 63%, P<0.001 for each sex), as was obesity (men 44% vs. 38%; women 43% vs. 34%; P<0.001). As shown in the *Figure*, a majority of urban overweight or obese patients (men 57% and women 59%) underwent diabetes screening, whereas only a minority of such rural patients underwent this screening (men 19% and women 17%; P<0.001 for sex- stratified comparisons). Similar patterns were seen among those with obesity.

CONCLUSIONS: In a cohort of overweight or obese primary care patients, age-appropriate diabetes screening with hemoglobin A1c occurred in 1-in-5 rural patients, which was 1/3rd of the frequency of urban adults. Targeted interventions to increase guideline-concordant diabetes screening is a critical step to addressing rural health disparities.



DIFFERENCES IN BONE MINERAL DENSITY BY PRIMARY SPOKEN LANGUAGE STATUS IN WOMEN OF HISPANIC ETHNICITY

Jessica Himmelstein[1]; Jeanne Darbinian[2]; Malini Chandra[2]; Nailah Thompson[1]; Bruce Ettinger[2]; Joan Lo[1,2]. [1]Internal Medicine, Kaiser Permanente Oakland Medical Center, Oakland, CA; [2]Division of Research, Kaiser Permanente Northern California, Oakland, CA. (Control ID #3372160)

BACKGROUND: The public health burden of osteoporosis in older women is substantial for both Hispanic and non-Hispanic women. Those of Hispanic ethnicity comprise the largest ethnic minority in California, with varying levels of acculturation. Primary language is a field typically captured in the electronic health record (EHR) and can be been used to identify patients self-reporting potentially limited English proficiency. This study reports bone mineral density (BMD) and BMD T-scores in Hispanic women and examines whether having Spanish versus English as a primary spoken language is associated with differences in skeletal health.

METHODS: We utilized data from Hispanic women age 50-79y who underwent BMD testing on Hologic DXA densitometers in a large Northern California healthcare system during 1998-2017, excluding those who received osteoporosis therapy in the 2 years prior to BMD testing and those with recent fracture, secondary metastatic cancer, metabolic bone disease, kidney dialysis or transplantation. Hispanic ethnicity was captured from the EHR and BMD data input. Primary (or preferred) spoken language was derived from EHR. Femoral neck BMD was classified as normal (T ≥ -1.0), osteopenia (-2.5 < T-score < -1.0) or osteoporosis (T-score ≤-2.5). Using each woman's first available BMD test acquired during the study period, we compared mean BMD, median T-scores, and proportions with osteoporosis by primary spoken language (English vs Spanish), using Student's t-test, Wilcoxon test, or Chi-squared test.

RESULTS: Among 18,245 Hispanic women with BMD data (age 64.0 ± 7.1y), 6,618 (36.3%) had Spanish and 11,627 (63.7%) had English as their primary spoken language. When BMD was examined by 5y age groups, older women age 65-79y with Spanish as a primary spoken language had significantly lower mean BMD compared to those with English as their primary spoken language; these differences were 0.704 vs 0.713 (65-69y); 0.673 vs 0.685 (70-74y); and 0.644 vs 0.656 (75-79y), g/cm2, respectively. As a result, significantly lower median T- scores were found among those with preferred Spanish as their spoken language (65-69y: -1.4 vs -1.3; 70-74y: -1.7 vs -1.6; 75-79y: -1.9 vs -1.8), respectively. As expected from our findings, a slightly greater proportion of older women age 70-79y with Spanish vs English as a primary spoken language had osteoporosis (70-74y: 14.4% vs 17.5%; 75-79y: 23.2% vs. 28.3%).

CONCLUSIONS: Among older Hispanic women with Spanish (compared to English) as a primary or preferred language, there was a slightly higher prevalence of osteoporosis. While differences in BMD were small, future studies should examine whether osteoporotic fracture outcomes differ by language status in Hispanic women and whether there are modifiable fracture risk factors that can be addressed in the primary care setting. Assessing primary or preferred language may be useful for examining the effect of acculturation and skeletal health in other ethnic minorities.

DIFFERENCES IN CARDIOVASCULAR AND MENTAL HEALTH OUTCOMES BETWEEN US VETERANS BORN IN THE US MAINLAND AND TERRITORIES

Karen Wang[2]; Carol Oladele[1]; Cynthia Brandt[2]. [1]Internal Medicine, Yale University, New Haven, CT; [2]Informatics/Department of Internal Medicine, Yale School of Medicine, New Haven, CT. (Control ID #3392213)

BACKGROUND: The US Veteran population comprises veterans who were born in US territories. Evidence from civilian populations shows that place of birth has a significant impact on health outcomes. However, this has not been well studied among veterans. Given the paucity of evidence in the veteran population, we sought to examine differences in health outcomes between veterans born in the US mainland and US territories.

METHODS: Data (n=881,506) from the Women Veterans Cohort Study (WVCS) was used for analyses. Our sample included military personnel 21 and older who: 1) were discharged from the U.S. military after October

1, 2001, and 2) enrolled for Veterans Health Administration (VHA) services or received VHA care before November 19, 2014. Place of birth was based on veterans' self-report during enrollment into the VHA and measured as Territory-born and US mainland-born. We examined cardiovascular and mental health outcomes obtained from electronic health records. They included diabetes, hypertension, stroke, coronary artery disease (CAD), and major depressive disorder (MDD). Chi-square tests and logistic regression were used for analysis to test differences between groups. Models were adjusted for sociodemographic characteristics.

RESULTS: Veterans born in the US mainland were younger on average than those born in territories. A higher proportion of veterans born in territories were men, Hispanic, married, and had a high school education or greater compared to those born in the US mainland. Veterans born in territories were less likely to smoke (44% vs. 29%) but more likely to be obese (35% vs. 33%). Those born in territories had higher prevalence of diabetes (7.4% vs. 2.9%), hypertension (22.9 vs. 13.2), stroke (.45% vs. .29%), CAD (2.0% vs. 0.83%), and MDD (17.5% vs. 9.7%). Results from multivariate analyses showed that after adjustment for covariates, veterans born in territories had greater odds of CAD (OR: 1.4, 1.3-1.6) and MDD (OR: 2.1, CI: 2.0-2.2) compared to those born in the US mainland.

CONCLUSIONS: Findings show important differences in cardiovascular and mental health outcomes between veterans born in the US mainland and territories. Understanding variation according to place of birth could help to identify target areas for intervention to improve health among veteran subgroups.

DIFFERENCES IN PATIENT REPORTED RATES HORMONE THERAPY USE FOR MENOPAUSAL SYMPTOMS BY PROVIDER SPECIALTY

Megan McCarty, Holly N. Thomas. Internal Medicine, UPMC, Pittsburgh, PA. (Control ID #3387846)

BACKGROUND: Hormone therapy (HT) is a safe, effective treatment for menopause symptoms. As women age, they may see a generalist more frequently than a gynecologist. Research is lacking on prescribing practices between specialties. This study aimed to determine rates of HT use among women who see a gynecologist versus a generalist most frequently.

METHODS: This was a cross-sectional analysis using a US-population-based sample of individuals aged 39-90. Data were collected via telephone interview and self-administered questionnaire. Current HT use and most frequently seen healthcare provider type were each assessed by a single question. Univariate logistic regression was used to assess factors that may be related to HT use. Variables with $p<0.10$ were used in a multivariable model.

RESULTS: Of the 2,362 postmenopausal female respondents, 1,602 (78%) saw a generalist most frequently and 57 (2%) saw a gynecologist most frequently; 270 (14%) currently used HT for menopause symptoms. Type of most seen healthcare provider was not associated with HT use when controlling for other factors. More chronic conditions, higher self-rated health, past hysterectomy, more frequent hot flashes and seeing a gynecologist at all were associated with greater odds of HT use. Higher BMI and current smoking were associated with lower odds of HT use.

CONCLUSIONS: The overall rate of HT use for menopause symptoms was low. The rate did not significantly vary by which specialty was seen most frequently. However, seeing a gynecologist for care had three times higher odds of HT use. Given that this data is cross-sectional, causality of cannot be determined. Ensuring that generalists feel comfortable prescribing HT in appropriate scenarios may help eliminate disparities in care among menopausal women as they are the most seen provider type by nearly ¾ of women.

DIFFERENCES IN PREFERRED LANGUAGE FOR LIMITED ENGLISH PROFICIENCY PATIENTS BETWEEN THE ELECTRONIC MEDICAL RECORD AND USE OF PROFESSIONAL INTERPRETERS

Lev Malevanchik[1]; Archna Eniasivam[2]; Priya A. Prasad[3]; Yumiko Abe-Jones[4]; Kirsten Kangelaris[4]. [1]Internal Medicine, UCSF, San Francisco, CA; [2]Internal Medicine, Pediatrics, UCSF, San Francisco, CA; [3]Division of General Internal Medicine, Department of Epidemiology and Biostatistics, UCSF, San Francisco, CA; [4]Medicine, Division of Hospital Medicine, University of California at San Francisco, San Francisco, CA. (Control ID #3392256)

BACKGROUND: Patients with limited English proficiency (LEP) face communication barriers and worse clinical outcomes than English proficient (EP) patients. Therefore, accurate identification of LEP status is critical for patient communication and quality improvement efforts. The need for a professional interpreter is likely a very close surrogate for LEP status. However, there is no standardized way to document LEP status. We measured the concordance of a combined, EMR-based metric – patient-described preferred language plus need for language interpretation – with the language used during video-mediated interpreter (VMI) calls.

METHODS: We performed a retrospective cohort study at a linguistically-diverse urban academic medical center. We included all patients who used VMI to speak with their inpatient medical providers from July 2018 to April 2019. VMI data were obtained from billing records from Language Line Solutions, an interpreter services company. The EMR provided the patients' preferred language for healthcare and preferred need for an interpreter ("Yes" / "No"). We classified the patients into four categories: Non-English / Interpreter needed ("True LEP"), Non-English / No interpreter needed ("Bilingual"), English / No interpreter needed ("True EP"), and English / Interpreter needed ("Misclassified English"). We then calculated the sensitivity of True LEP compared to the gold standard of actual VMI use. For True EP and Misclassified English patients, we examined the VMI languages they used and quantified their VMI use.

RESULTS: The 2,410 patients in our dataset used 21,144 VMI calls across the ten-month period, accounting for 281,717 minutes and 29 languages. The most common languages by VMI and EMR, were Spanish (39% / 31%), Cantonese (31% / 26%), Russian (10% / 7%), and Mandarin (7% / 8%); EMR-reported English speakers used 13% of VMI calls. 81% of patients that used VMI were True LEP, 6% were Bilingual, 10% were True EP, and 3% were Misclassified English. For the True EP patients, 46% of VMI calls were in Spanish. Most of the VMI calls made by the Misclassified English patients were in Russian (26%), Spanish (24%), or Cantonese (23%). The average number of VMI calls made per hospitalization were 7.6 for True LEP patients, 5.5 for Bilingual patients, 2.3 for True EP patients, and 5.1 for Misclassified English patients.

CONCLUSIONS: Classifying patients as LEP by the True LEP definition is only 81% sensitive compared to the gold standard of interpreter use. In fact, a large number of VMI users are currently classified as True EP in the EMR. Underreporting LEP status could lead to underutilization of interpreter services and patient difficulties communicating with medical providers. LEP patients could also be missed by quality improvement initiatives. When using EMR-based definitions of LEP, hospital systems should have a flexible approach to classification that involves frequent audits by front-line providers and administrators to ensure better care for LEP patients.

DIFFERENCES IN SOCIAL DETERMINANTS OF HEALTH AMONG PATIENTS ON CHRONIC OPIOID THERAPY FOR NON-CANCER PAIN WITH MENTAL HEALTH CONDITIONS AND HIGH-DOSE PRESCRIPTIONS

Eboni Price-Haywood[1,4]; Jeffrey Burton[1]; Jewel Harden-Barrios[1]; Robert Jamison[2]; Lizheng Shi[3]; Alessandra Bazzano[3]; John Lefante[3]. [1]Center for Outcomes and Health Services Research, Ochsner Health System, New Orleans, LA; [2]Harvard Medical School, Boston, MA; [3]Tulane University School of Public Health and Tropical Medicine, New Orleans, LA; [4]Ochsner Clinical School, University of Queensland, New Orleans, LA. (Control ID #3373773)

BACKGROUND: Epidemiologic surveillance of the opioid crisis has demonstrated several correlates of substance use, misuse and mortality including socioeconomic status, family stress, social isolation, psychiatric conditions as well as increased availability of and access to prescriptions. In addition to safe opioid prescribing practices, providers must incorporate social determinants of health (SDoH) assessments and tailored case management as a risk mitigation strategy.

METHODS: This retrospective observational study examined race and sex differences in SDoH among chronic opioid users within an integrated delivery health system in Louisiana. The cohort included patients on opioid therapy for non-cancer pain seen within the health system between January 2017 and November 2019. Chronic opioid use was defined as have been prescribed an opioid for three of the last four months. Patients are included in the chronic opioid health maintenance registry if they are age 18 and older and do not have cancer or enrolled in hospice or palliative care. Registry patients with the SDoH questionnaire completed within Epic electronic health records and opioid prescriptions documented within 12 months of joining the registry were included in the data analysis. Chi-squared tests for association between questionnaire items by race and sex were conducted.

RESULTS: Among 27,747 registry patients, 1,644 were included in the analysis. Among the 1644, most patients were white, non-Hispanic (76%), female (69%) with an average age of 56.6 years; had depression (41%), anxiety (44%), or substance abuse disorder (19%). Also 82% were prescribed opioids with MEDD <50mg; 13% MEDD 50-89mg; and 5% MEDD>90mg. A higher proportion of patients with mental health conditions compared to patients without reported major financial resource strain (8% vs. 3%); worry about food insecurity often (10% vs 3%); have medical transportation needs (12% vs 5%) and other transportation needs (11% vs 5%); report daily stress (23% vs 10%); and never engage in socialization with relatives or friends (13% vs 8%, all P<0.001). A lower percentage of patients with depression compared to those without reported phone communication with family/friends more than 3x/week (61% vs. 66%, P<0.03) as did patients with substance abuse compared to those without (60% vs. 65%, P<0.02). A larger proportion of patients prescribed high-dose opioids compared to lower dosages worry about food insecurity (MEDD 90 vs. 50-89 vs. <50: 17% vs 7% vs 7%) and reported having medical transportation needs (22% vs 9% vs. 9%) as well as other transportation needs (18% vs 8% vs. 8%, all P<0.02).

CONCLUSIONS: This study confirmed differences in SDoH by mental health condition and prescription dosage among patients on chronic opioids for non-cancer pain within a single healthcare institution. To combat the opioid crisis, it is imperative that health systems collect measures of SDoH to inform risk mitigation and population health management strategies.

DISCONTINUATION OF CHRONIC OPIOID THERAPY AMONG MEDICARE BENEFICIARIES, 2012-2016

Michael L. Barnett[1]; Hannah Neprash[2]; Adrienne Sabety[3]. [1]Health Policy and Management, Harvard T.H. Chan School of Public Health, Boston, MA; [2]Health Policy & Management, University of Minnesota School of Public Health, Minneapolis, MN; [3]Harvard University, Cambridge, MA. (Control ID #3391141)

BACKGROUND: Even though opioid prescribing has been falling since 2011, millions of Americans still use chronic opioid therapy (COT). Many have raised concerns that increasingly restrictive state policy on opioid prescribing is leading to increased rates of abrupt withdrawal of treatment for COT patients, resulting in untreated pain, mental distress and even suicide. Guidelines strongly discourage discontinuing COT with a dosage taper faster than 10% per week. However, little is known about national patterns of COT discontinuation or adherence to these recommendations nationally.

METHODS: In a 20% sample of Medicare beneficiaries, we defined patients on COT as those with at least 4 consecutive quarters with >60 days of opioids supplied quarterly with an average morphine-milligram equivalent (MME) daily dose of >25. Our primary outcome was discontinuation of COT, defined as >60 consecutive days of no opioids supplied. We additionally examined whether discontinuation was "tapered" or "abrupt" by comparing COT users' daily MME dose in the last month of therapy to their average dose in the 6 months prior (i.e. 2 to 7 months before discontinuation). Patients with "abrupt" discontinuation had a decrease of 10% or less in daily MME, representing the absence of a meaningful taper against guideline recommendations. Any reductions in dose >10% we considered potentially "tapered" to at least some extent. We used linear regression to estimate trends over time in discontinuation patterns, controlling for beneficiary demographics.

RESULTS: From 2012-2016, we identified 197,484 COT users, 12,792 of whom discontinued therapy. Adjusted rates of discontinuation increased from 5.0% of COT users in 2012 to 7.3% in 2016, a 46% relative increase (p<0.001). There was a similar increase in annual discontinuation rate for users on lower (26-90 MME, 5.3% to 7.4%, p<0.001) vs. higher doses (>90 MME, 4.3% to 6.8%, p<0.001). Discontinued users were more likely to be Medicaid eligible than continuing users (54% vs. 47%, p<0.001) but were otherwise similar demographically. The majority of COT discontinuations, 84%, were stopped abruptly, including 63% of those on >90 MME daily dose. The proportion of abrupt discontinuations changed little over time (83% to 82.5%, 2012-2017). COT users with abrupt discontinuation were demographically similar compared to potentially tapered users, though they were much less likely to be on high >90 daily MME doses (20% vs. 33%, p<0.001).

CONCLUSIONS: Medicare beneficiaries on COT for a year or more are increasingly likely to have their therapy discontinued. The vast majority of discontinuing users, even those on extremely high doses, had no meaningful reduction in dose prior to discontinuation. This abrupt withdrawal of COT is extremely likely to have caused severe opioid withdrawal and implies that physicians are largely ignoring guidelines for cessation of COT. These results raise questions about potentially unintended consequences of policies designed to curb chronic opioid use.

DISCONTINUING DOCUSATE

Bradford S. Bennett[1]; Megan Buckley[1]; Isabella Bergagnini[1]; Rebecca Mazurkiewicz[2]. [1]Internal Medicine, Lenox Hill Hospital, New York, NY; [2]Medicine, Lenox Hill Hospital, New York, NY. (Control ID #3378264)

BACKGROUND: Docusate is one of the most commonly prescribed medications in many hospital systems. However, the evidence in support

of docusate is poor, and there is an increasing body of high-quality evidence showing docusate to be no more effective than placebo for the purposes of treating constipation and increasing stool water content. Both the American Journal of Gastroenterology and the American Society of Colon and Rectal Surgeons recommend against docusate and endorse other more effective agents for first- line therapy. Despite this, it remains a preferred option for many clinicians, leading to increased healthcare costs, increased pill burden, and delay of effective treatment. We hypothesized that the removal of docusate as an inpatient treatment option would significantly decrease the number of patients for whom docusate is prescribed on dischargre.

METHODS: Our method was a chart review of the number of patients for whom docusate was prescribed on discharge. We reviewed a 90-day period prior to the discontinuation of docusate from formulary and a 56-day period afterwards. Included were all inpatients discharged from our city hospital on any service with docusate in their home medication reconciliation, either as a new medication or a continued home medication. Excluded were patients discharged within the ten days after the formulary change, to allow time for full implementation and avoid carried-over orders. We compared the frequency of these cases on a per-month basis.

RESULTS: In the 180 days prior to the formulary change, there were 1,191 patients for whom docusate was either continued as a home medication or prescribed as a new medication at the time of discharge. This equated to 198.5 discharges on docusate per 30-day period. In the 58 days after the formulary change, there were 102 discharges on docusate, equating to 52.8 discharges per 30-day period. This was a reduction of 74.4%.

CONCLUSIONS: Our findings support the idea that clinical inertia and convenience are major factors when choosing discharge medications. In this case, the amount of patients being sent home on docusate was cut to nearly a quarter simply by limiting its inpatient use. The availabilty of different drugs on the hospital formulary has an impact that reaches beyond the inpatient stay. Therefore, the importance of keeping a formulary updated based on the latest evidence-based guidelines cannot be understated.

DISCUSSING CERVICAL CANCER SCREENING OPTIONS: OUTCOMES TO GUIDE CONVERSATIONS BETWEEN PATIENTS AND PROVIDERS

Hunter K. Holt[1]; Shalini Kulasingam[2]; Erinn C. Sanstead[2]; Fernando Alarid-Escudero[3]; Karen Smith- McCune[4]; Steven Gregorich[7]; Michael Silverberg[5]; Wendy Leyden[5]; Megan Huchko[6]; Miriam Kuppermann[4]; George F. Sawaya[4]. [1]Family and Community Medicine, University of California, San Francisco, San Francisco, CA; [2]Epidemiology and Community Health, University of Minnesota, Minneapolis, MN; [3]Drug Policy Program, Center for Research and Teaching in Economics (CIDE), Mexico City, Mexico; [4]Department of Obstetrics, Gynecology, and Reproductive Sciences, University of California, San Francisco, San Francisco, CA; [5]Division of Research, Kaiser Permanente, Oakland, CA; [6]Obstetrics & Gynecology and Global Health, Duke University, Durham, NC; [7]Medicine, University of California, San Francisco, San Francisco, CA. (Control ID #3381849)

BACKGROUND: In 2018, the US Preventive Services Task Force endorsed 3 strategies for cervical cancer screening in women ages 30-65: cytology q3 years, testing for high-risk types of human papillomavirus (hrHPV) q5 years or cytology plus hrHPV testing q5 years. It further recommended that women discuss with their health care provider "which testing strategy is best for them". To help inform such discussions, we used decision analysis to forecast screening outcomes for each strategy over a short-time (15-year) horizon, similar to what is used for breast cancer screening.

METHODS: We constructed a Markov decision model using estimates of the natural history of HPV and cervical neoplasia. Transition probabilities between health states were age- and HPV type-specific. The cohort started at age 10 with no existing HPV infection and was followed until age 45. Every year, women were at risk of HPV infections that could clear, persist or progress to cervical intraepithelial neoplasia (CIN); CIN lesions could regress, persist or progress to higher grades or to cancer. Validation was by comparison with SEER data and with outcomes from a randomized trial of hrHPV testing compared with cytology. Management of abnormal test results and CIN were based on current guidelines. Outcomes were colposcopies with biopsy, false-positive testing, treatments, cancers and cancer mortality. We evaluated current recommended strategies and no screening (Table). A 15-year horizon allowed comparisons of 5 rounds of q3 year screening with 3 rounds of q5 year screening.

RESULTS: All strategies resulted in substantially lower cancer and cancer death rates compared with no screening. Strategies with the lowest likelihood of cancer and cancer death generally had higher likelihood of colposcopy and false-positive testing (Table).

CONCLUSIONS: Informing women of the potential benefits and harms of these screening strategies will help ensure their preferences are consistent with their goals.

DISCUSSING THEIR CREATIONS: ANALYSIS OF REFLECTION IN CLINICAL MEDICINE WORKSHOPS FOR THIRD-YEAR MEDICAL STUDENTS

Danielle Wallace[1]; Kaitlin Kyi[1]; Christopher J. Mooney[2]; Jennifer Pascoe[1]. [1]Medicine, University of Rochester, Rochester, NY; [2]University of Rochester, Rochester, NY. (Control ID #3359117)

BACKGROUND: Reflective writing and expression has been increasingly incorporated into medical education as a means to increase empathy, foster professional development, and encourage well-being. To this end, we introduced a mandatory exercise and workshop for third-year medical students in the inpatient medicine clerkship in the 2019-2020 academic year. In addition to allowing for written and non-written forms of expression, we integrated an additional opportunity for reflection with peer-driven discussion of student pieces. This study examines the value of both reflective expression and subsequent workshops for students during their clinical training.

METHODS: As part of the third-year inpatient medicine clerkship, students were asked to create a reflective piece, which could be written (including prose or poetry), photographic, or any other expressive form, including multimedia and performance. Pieces were disseminated within the clerkship cohort for each block (approximately 8-10 students). Subsequently, the clerkship cohort met for an hour-long, student-led discussion of their pieces and their clinical experiences with the help of a faculty moderator. Students were then asked to complete an anonymous survey, using Likert scales and short response format, regarding their enjoyment and perceived benefit from the experience.

RESULTS: Interim analysis of students from July-November 2019 was performed. 41 students completed the exercise and survey with a 100% survey response rate. 19.5% of students anticipated that they would find the overall experience "very" or "extremely" enjoyable. Following completion of the workshop, 68.3% found the overall experience "very" or "extremely" enjoyable indicating that over half of the students found the experience more positive than they anticipated. Student feedback indicated that the subsequent discussion portion was more enjoyable than the creation process: 75.7% enjoyed the creation process compared to 95.1% who enjoyed the small-group discussion of the pieces. In short answer responses, many students counted the "open and honest," "cathartic" discussion as the greatest strength of the process, with one student

commenting, "It is healthy to reflect on these experiences and refreshing to hear from other students."

CONCLUSIONS: These results have promising implications on how creative reflection can be used to promote well-being in medical students. While the creation process was perceived as valuable, nearly all the students found the subsequent small-group discussion enjoyable and valuable. This implies that reflective, medical humanities exercises are more constructive in conjunction with group sessions that provide an opportunity for students to receive feedback and support from their peers. Future studies could characterize the components of what guides a positive group discussion and how to incorporate formal debriefing through the clerkship.

DISPARITIES AFTER DISCHARGE: HOW LIMITED ENGLISH PROFICIENCY PATIENTS FARE AFTER HOSPITALIZATION

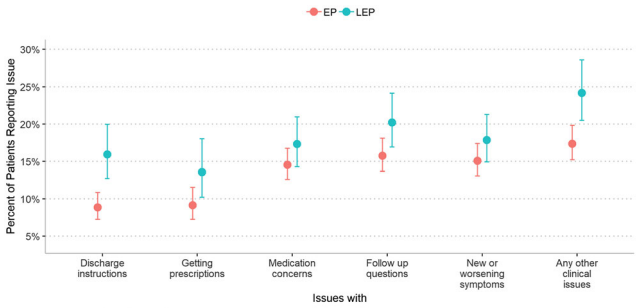
Lev Malevanchik[1]; Margaret Wheeler[3]; Kristin Gagliardi[3]; Leah S. Karliner[4]; Sachin J. Shah[2]. [1]Internal Medicine, UCSF, San Francisco, CA; [2]Division of Hospital Medicine, Department of Medicine, University of California, San Francisco, San Francisco, CA; [3]UCSF, San Francisco, CA; [4]Medicine, UCSF, San Francisco, CA. (Control ID #3387816)

BACKGROUND: Patients with limited English proficiency (LEP) face barriers communicating with clinicians and understanding their treatment plans. Prior works shows limitations in LEP patients' understanding of discharge instructions. However, little is known about disparities in care transitions outcomes between LEP and English proficient (EP) patients. To address this gap, we measured the prevalence of patient-reported, post-discharge outcomes among 18,000 patients.

METHODS: We performed a retrospective cohort study at an urban academic health system. We included patients ≥18 years discharged home from a medical or surgical services between May 2018 and April 2019. We obtained demographic and clinical data from the EMR. Within 72 hours of discharge, patients received an automated phone call asking about six post-discharge outcomes: discharge instruction questions, follow up care questions, new or worsening symptoms, medication concerns, help obtaining prescriptions, and other issues. Patients could answer in English, Cantonese, or Spanish. Program nurses called patients who did not respond to the automated system or reported an issue. We classified patients as LEP if, in the EMR, their preferred language was not English and they required an interpreter. We determined the association of LEP and post-discharge outcome using log-binomial generalized linear models adjusting for baseline differences.

RESULTS: Of the 18,463 eligible discharges, 79% responded to an automated or manual call, and 12% were LEP. Compared with EP patients, LEP patients were more likely to be older (median 65yrs vs. 57yrs, p<0.001), Medicaid-insured (37% vs. 22%, p<0.001), Hispanic (41% vs. 14%, p<0.001), and Asian (44% vs. 12%, p<0.001). After adjusting, LEP patients were more likely to report discharge instruction questions (16% vs. 9%, p<0.001), needing help to get prescriptions (14% vs. 9%, p=0.003), medication concerns (17% vs. 15%, p=0.047), follow up care questions (20% vs. 16%, p=0.001), new or worsening symptoms (18% vs. 15%, p=0.036), and having other clinical questions (24% vs. 17%, p<0.001) (Figure).

CONCLUSIONS: Compared to EP patients, LEP patients reported higher rates of all post-discharge issues assessed. These disparities may stem from inadequate communication during the discharge and logistical difficulties after discharge. Discharge processes tailored to LEP patients need to be implemented to mitigate observed disparities.



DISPARITIES IN HIV TESTING RATES: DOES PREDOMINANT CLINIC RACIAL/ETHNIC POPULATION PLAY A ROLE?

Victoria Twito[2]; Finn D. Schubert[1]; Sandeep Bhat[1]; Isaac Dapkins[1]. [1]Family Health Centers at NYU Langone, NYU, Brooklyn, NY; [2]CUNY School of Medicine, New York, NY. (Control ID #3391729)

BACKGROUND: Race, ethnicity, and language have been identified as factors impacting uptake of HIV testing. This project sought to compare testing rates between predominant and non-predominant ethnic, racial, or language populations within neighborhood FQHCs.

METHODS: We identified Family Health Center network locations at which more than 50% of patients served identified as the same race, and/or had the same preferred language, and focused our analysis on these sites. We used Excel and SPSS to compare HIV testing rates between predominant and non-predominant population groups at each clinic.

RESULTS: At 2 of 5 sites with a predominant non-English preferred language, speakers of the predominant language were more likely to receive an HIV test than speakers of other languages (p<0.001 for both sites). The other sites showed no difference by language. Of 2 clinics with a predominant racial population, there was no difference between predominant and non-predominant populations in terms of HIV testing. At all included sites, with one exception, Hispanic ethnicity was associated with a significantly higher rate of HIV testing.

CONCLUSIONS: Predominant/non-predominant race did not affect HIV testing rates, but language and ethnicity did. One mechanism for this may be increased trust associated with patient-provider language concordance, resulting in greater uptake of tests. There is a need for future research to further explore the factors associated with these findings.

DISPARITIES IN MORTALITY AMONG DUALLY ENROLLED MEDICARE BENEFICIARIES LIVING IN RURAL VS. URBAN AREAS, 2004-2017

Eméfah C. Loccoh[1,3]; Karen E. Joynt Maddox[2]; Jiaman Xu[3]; Changyu Shen[3]; Jose Figueroa[4]; Dhruv S. Kazi[3]; Robert Yeh[3]; Rishi Wadhera[3]. [1]Cardiology, Beth Israel Deaconess Medical Center, Boston, MA; [2]Medicine/Cardiology, Washington University School of Medicine, Saint Louis, MO; [3]Smith Center for Outcomes Research, Beth Israel Deaconess Medical Center, Boston, MA; [4]Department of Health Policy and Management, Harvard T.H. Chan School of Public Health, Boston, MA. (Control ID #3389687)

BACKGROUND: Little is known about rural Medicare beneficiaries who are dually enrolled in Medicaid due to poverty. Therefore, we evaluated whether all-cause mortality rates changed for rural and urban dually enrolled beneficiaries from 2004 to 2017 and if differences between these two groups narrowed or widened over time.

METHODS: We used Medicare denominator files to identify individuals aged ≥65 years that were enrolled in the Medicare Program (Fee-for-Service [FFS] or Medicare Advantage [MA]) from 2004 to 2017. Medicare beneficiaries were considered dually enrolled if they were also enrolled in Medicaid for at least one month within a given year. Dually-enrolled beneficiaries were classified as residing in a rural or urban area based on the rural-urban commuting area codes (RUCA). All-cause mortality rates per 100,000 dually enrolled beneficiaries in rural and urban areas were calculated and standardized by age, sex, and race. To assess whether the difference in outcomes between these two groups narrowed or widened over time, we evaluated the interaction between rural residence and time.

RESULTS: Overall, there were 11.7 million unique dually-enrolled (FFS and MA) beneficiaries. Between 2004 and 2017, mean age decreased among rural (78.0±8.23 to 76.4±8.18) and urban (77.5±7.99 to 76.5±8.14) dually-enrolled beneficiaries, and the proportion of females in both groups also declined (rural: 71.1% to 66.7%; urban: 70.9% to 65.9%). Annual rates of enrollment in MA increased among both rural and urban beneficiaries (rural: 3.1% to 26%; urban: 14% to 46.6%).

Little: In the Medicare (FFS and MA) dually-enrolled population, standardized all-cause mortality rates were consistently higher among rural beneficiaries compared with their urban counterparts. Among rural dually- enrolled beneficiaries, mortality declined from 9,083 to 8,691 per 100,000 from 2004 to 2017. In comparison, among urban dually-enrolled beneficiaries, declines in mortality were more pronounced (8,893 to 7,707 per 100,000). The difference in all-cause mortality between rural and urban dually-enrolled beneficiaries widened from 2004 to 2017 ($p<0.001$ for interaction between rural status and time). In 2017, mortality rates were highest for rural beneficiaries in the Central Northeast (9,722/100,000) and lowest in the Northeastern United States (6,397/100,000).

CONCLUSIONS: Among dually-enrolled Medicare beneficiaries (FFS and MA) age 65 or older, those living in rural areas had higher all-cause mortality rates than their urban counterparts. All-cause mortality rates declined for both rural and urban dually enrolled beneficiaries from 2004 to 2017, but disparities in mortality between these groups widened. These findings suggest that gains in health outcomes have not been equally realized among dually-enrolled individuals living in rural areas compared to those living in urban areas. There is an urgent need for policy efforts to focus on improving care and outcomes for this vulnerable population.

DISPARITIES IN PATIENT CARE OUTCOMES BASED ON MARKERS OF SOCIAL VULNERABILITY IN A RESIDENT CONTINUITY PRIMARY CARE CLINIC

Maelys Amat, Elizabeth Norian, Kelly L. Graham. Medicine, Beth Israel Deaconess Medical Center, Boston, MA. (Control ID #3384638)

BACKGROUND: Little is known about social inequities and disparities in care outcomes for patients that self-select into a resident continuity clinic. At our institution, we found that resident continuity patients experience higher rates of loss to follow-up and poorer clinical outcomes compared to faculty patients. We hypothesize that there are clinician, systems and patient-related factors that contribute to these outcomes. Specifically, we hypothesize that there are higher degrees of social vulnerability in the resident practice compared to the faculty practice. The aim of the current study is to describe the social determinants of health among a resident continuity panel compared to a faculty cohort as potential predictors of inequities in care outcomes.

METHODS: We collected a random sample of 300 unique patients, half from the resident and faculty practices at an academic hospital-based teaching practice. We developed an a priori list of variables that we hypothesized would represent markers of social vulnerability under the following domains: low health literacy, economic vulnerability, psychiatric illness burden, high risk behaviors and markers of disengagement with the healthcare system. Using a standardized data extraction tool, we reviewed each chart in our sample to measure these variables. To test for significance, we used chi-squared tests for binary outcomes, and t-tests and wilcoxon ranked sum testing for parametric and non-parametric continuous outcomes respectively.

RESULTS: Across all domains of social vulnerability, resident continuity patients had higher percentages of unfavorable social determinants of health. Compared to faculty patients, resident patients had higher rates of markers of low health literacy (9.4% with limited English proficiency compared to 3.4%; 11.4% with less than a high school education compared to 3.4%). Resident patients had higher levels of economic vulnerability (18.9% required public insurance compared to 7.1%; 24.5% lived in neighborhoods historically marked for disinvestment compared to 14.3%, and 34% required consultation for community resources compared to 14%). Resident patients had higher levels of psychiatric illness burden (17% with a major psychiatric illness compared to 3.6%). Resident patients had higher rates of risky behaviors, including tobacco use (13.2 vs. 5.4%); alcohol use disorder (15.1 vs.10.7%), and substance use disorders (28.3 vs. 3.6%). Lastly, resident patients tended to be more transient participants in healthcare (9.4% were students vs. 3.4%) and tended to be less engaged (18% unkept visit rate vs. 5%).

CONCLUSIONS: In conclusion, patients who select into a resident primary care practice have higher burdens of social vulnerability across many domains. They also tend to have poorer clinical outcomes, in particular for those that rely on practice engagement with the patient. These findings will help inform necessary systems-based interventions to build equity into the care of this vulnerable patient population.

DISPARITIES IN TELEHEALTH USE AMONG PATIENTS WITH LIMITED ENGLISH PROFICIENCY: CALIFORNIA HEALTH INTERVIEW SURVEY, 2015-2018

Jorge A. Rodriguez[1]; Altaf Saadi[2]; Lee Schwamm[2]; David W. Bates[1]; Lipika Samal[1]. [1]General Internal Medicine, Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School/Massachusetts General Hospital, Boston, MA. (Control ID #3391511)

BACKGROUND: Telehealth may ameliorate disparities for limited English proficient (LEP) patients. Previous studies revealed gaps in telehealth use by underserved patients, but there is little data on LEP patients. We had two research objectives: 1) assess the association between limited English proficiency and telehealth use and 2) evaluate the impact of telehealth on care for LEP patients.

METHODS: We used data from the 2015-2018 California Health Interview Survey (CHIS), a telephone survey conducted in 6 languages. We defined LEP patients as those who spoke English not well/not at all. The first part of our study examined telehealth use (care through a video or telephone) among LEP patients compared to English proficient patients. For our second objective, we limited our sample to LEP patients and evaluated the association of telehealth use with 1) delays in care and 2) Emergency Department (ED) utilization in the past year. We used survey-supplied weights to produce population estimates. Analyses were performed using SAS software version 9.4.

RESULTS: Our study included 84,419 people, representing 29,406,792 people, and 8,063 were LEP, representing 4,410,605 people. LEP patients were older, female, less educated, poorer, less insured, and less likely to have a usual source of care. In bivariate analysis, LEP patient were less likely to use telehealth (4.8% vs. 12.3%, $p<0.001$). In adjusted analyses, LEP patients still had a lower likelihood of using telehealth (Table). For LEP patients, telehealth use was associated increased ED utilization (OR:

2.47, p= 0.004), but did not impact delays in care (OR: 1.75, p = 0.133) in adjusted analyses.

CONCLUSIONS: Our study reveals disparities in telehealth use among LEP patients. Telehealth use was associated with increased ED utilization. Though the association may be related to selection bias or unmeasured confounders, these results suggests that telehealth may not reduce utilization. Implementation must focus on promoting technology equity and decreasing divides.

Table. Association of English Proficiency and Telehealth Use

DISTRESS EXPERIENCED BY YOUNGER ADULTS NEWLY DIAGNOSED WITH TYPE 2 DIABETES: A QUALITATIVE STUDY

Anjali Gopalan, Maruta A. Blatchins, Andrea Altschuler, Richard W. Grant. Division of Research, Kaiser Permanente Northern California, Oakland, CA. (Control ID #3391750)

BACKGROUND: Prognoses may be particularly poor for the growing number of adults diagnosed with type 2 diabetes (T2D) before age 45. These younger individuals present with more severe hyperglycemia and are at significantly increased risk for developing diabetes-related complications that may arise earlier in the life course. Despite the gravity of this diagnosis, little is known about how a new T2D diagnosis is first communicated to and received by younger adults.

METHODS: We conducted six focus groups to learn about the diagnosis experiences of individuals with younger-onset T2D. Participants were members of an integrated healthcare delivery system, had been diagnosed with T2D during the prior two years, and were 21-44 years old at diagnosis. The groups were led by an experienced facilitator, audio-recorded, and transcribed verbatim. Two reviewers coded each transcript using thematic analysis, with discrepancies resolved by team discussion.

RESULTS: The average age of the 41 participants was 38.4 years (SD 5.8 years); 20 were women, 10 were Latino, 12 were Black, 12 were White, and 7 were of multiple or other races. Four main themes regarding T2D diagnosis experiences were noted. First, participants differed in their expectation for the diagnosis, with some anticipating it ("My mouth was super-dry and my mother has diabetes, so I kind of knew") and others surprised by it ("Doctor had me do like bloodwork…for nothing related to that"). Second, there was no standard disclosure process. Some participants were told in-person, others via phone, some received a secure message ("I got an email. 'You got diabetes'"), and several saw their results on the patient portal ("I actually seen my results online…I didn't know what any of it meant"). Third, the perceived tone of the initial conversation ranged from casual ("He called me and was just real nonchalant. He was like, 'Hey, I just want let you know that, you know, you're diabetic'"), to fear-centered ("My doctor scared the crap out of me"), to supportive ("This is hard, but it's going to be easy, because we're going to do it together"). Fourth, common initial emotions included self-blame ("I had done it to myself"), denial ("I was like I don't care no more"), resignation ("I'm going to probably end up with [T2D]. And sure enough, here I am"), and fear, which was often rooted in personal experience ("my dad died from diabetes and I kinda got scared").

CONCLUSIONS: The identified themes highlight opportunities to improve the disclosure of T2D diagnoses to younger patients by: 1) providing information and counseling prior to diagnostic testing, 2) identifying patient-centered diagnosis communication strategies and the preferred mode of delivery, and 3) developing care approaches that address and help mitigate the emotional distress triggered by this life-altering diagnosis. Honing T2D communication processes from the outset may support high-risk, younger patients establish a trajectory towards improved health.

DOCTORS HATE DEDUCTIBLES: PHYSICIANS AND OTHER HEALTH SYSTEM EMPLOYEES PAY THOUSANDS PER YEAR TO AVOID HIGH DEDUCTIBLE PLANS

Sara Abrahams[1,2]; Lauren Block[2,1]; Joseph Conigliaro[2,1]; Adam Block[3]. [1]Medical School, Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY; [2]Medicine, Northwell Health, Lake Success, NY; [3]Internal Medicine, Northwell Health, New Hyde Park, NY. (Control ID #3375457)

BACKGROUND: Employees often have a choice of health insurance plans. High deductible plans offer lower monthly premiums in exchange for higher deductibles before insurance coverage begins. High deductible plans are thought to reduce unnecessary healthcare utilization through cost sharing, making them attractive to employers. Nobel Prize winning economist, Richard Thaler, has stated that many people select plans that are "wrong," meaning a person could have saved money selecting a different health plan, regardless of the health services used in a year. Using data from over 18,000 employees of a large health system, including 1,429 physicians, we examined health insurance plan selection between a high deductible ($3,000 deductible) and a high premium plan (no deductible) to investigate potential employee savings associated with high deductible plans.

METHODS: We completed a cross-sectional, retrospective analysis of plan selection among employees of a large health system from fiscal year 2018. Using this data and the health system's benefits information, we created a tool that uses plan selection, annual premium costs, deductible costs, and coinsurance costs to estimate individual employee spending for a given health plan and coverage type (i.e. family or single) over a range of healthcare spending estimates. We then applied this tool to the employee data to compare potential employee costs in the high deductible plan versus the high premium plan. This allowed us to predict spending

differences and identify opportunities for cost saving across plan types with similar coverage.

RESULTS: Among all physicians, nearly 90% (1,277/1,429) chose the high premium plan. After accounting for the $3,000 deductible, switching to the high deductible plan would save $3,800-$4,182 in annual premium costs for physicians with family coverage (n=632). Cumulative potential savings among all 1,492 physicians ranges from $1-$3.8 million depending on the amount of spending if they were to switch to the high deductible plan. In addition to physicians, we examined potential savings for 4,434 full-time, non-union, non-physician employees with family coverage enrolled in the high premium plan. Switching to the high deductible plan would save up to $4,000, more than the cost of the $3,000 deductible for family coverage.

CONCLUSIONS: Using employee health insurance data from a large health system, we identified potential savings associated with switching to high deductible coverage. Nearly 90% of physicians chose the high premium plan, foregoing $3,800-$4,182 annually in savings for family coverage if they had chosen the high deductible plan. These findings persisted for all employees with family coverage. High deductible health plans are becoming more common, but our study contributes to the growing body of evidence that even highly educated professionals who understand health insurance will pay thousands in extra premiums to avoid deductibles.

DOES INPATIENT NALOXONE ADMINISTRATION ACCURATELY IDENTIFY OPIOID ADVERSE EVENTS?: VALIDATION OF A PROPOSED QUALITY MEASURE

Kristy Deep, Will Ford, Tim Saidi. Internal Medicine, Univ of Kentucky, Lexington, KY. (Control ID #3390568)

BACKGROUND: Centers for Medicare and Medicaid Services (CMS) has proposed a new measure of Opioid-Related Adverse Respiratory Events (ORARE) defined as inpatient naloxone administration within 24 hours of opioid administration, excluding reversal immediately following a procedure. This measure may become part of the inpatient quality reporting program that impacts hospital payment. The purpose of this study was to determine if inpatient naloxone administration is an accurate marker of opioid-related adverse drug events.

METHODS: All adult medical admissions at a large academic medical center in a 12-month period were electronically abstracted to identify events of naloxone administration within 24 hours of inpatient opioid administration. We excluded intra-operative naloxone reversal and non-urgent use for opioid side effect management (i.e. itching). Data abstraction included demographic data, diagnoses, opioid and naloxone dose and timing, presence of other sedating medications, and whether the encounter was coded by the hospital as an opioid overdose. Clinical documentation was qualitatively reviewed by study physicians to determine the indication for naloxone and assess whether the patient had a clinical response consistent with an ORARE. Analysis included descriptive statistics.

RESULTS: There were 43 naloxone events in 42 patients from 6126 discharges for an event rate of 0.7%. Acute or chronic kidney disease was present in 47%, liver disease present in 16%, and 42% were >65 years old. In the 24 hours prior to naloxone, the mean+SD Morphine Milligram Equivalents (MME) administered to patients was 28.8+20.1mg in an average of 2.5+1.4 doses. In 63% of events, other sedating medications were given in the same time span including gabapentin (29%), benzodiazepines (22%), anticholinergic medications (25%), and skeletal muscle relaxants (16%).

The most common indication for naloxone was encephalopathy which occurred as a primary or contributing factor in 37 events. Other reasons included hypotension (9), respiratory depression (9) and cardiac arrest (1). After receiving naloxone, 20 patients (46%) showed clinical improvement consistent with an ORARE. Alternative diagnoses in patients not responding to naloxone included sepsis, hepatic encephalopathy, sedation from other medications, and other etiologies of hypercarbic respiratory failure. Hospital coding captured 20.9% of events as an opioid overdose.

CONCLUSIONS: This single-institution study demonstrates that inpatient naloxone was most often given for non-specific alterations in mental status and less commonly for respiratory depression or hypotension. It reversed targeted symptoms less than 50% of the time. The majority of patients also received other non- opioid sedating medications and had decreased clearance due to liver and kidney disease. These results suggest inpatient naloxone may be an inaccurate marker of opioid-related adverse events.

DOES MENTAL HEALTH CARE INTEGRATION AFFECT PRIMARY CARE CLINICIAN BURNOUT? RESULTS FROM A LONGITUDINAL VETERANS AFFAIRS SURVEY

Lucinda B. Leung[3,1]; Danielle Rose[2]; Lisa V. Rubenstein[3]; Rong Guo[1]; Timothy Dresselhaus[4]; Susan E. Stockdale[5]. [1]Division of General Internal Medicine, UCLA David Geffen School of Medicine, Los Angeles, CA; [2]VA HSR&D Center for the Study of Healthcare Provider Behavior, VA GLA Healthcare System, Sepulveda, CA; [3]HRS&D, GLA VA, North Hills, CA; [4]Primary Care, VA San Diego Healthcare System, San Diego, CA; [5]HSR&D Center of Excellence, Greater Los Angeles VA Healthcare System, Sepulveda, CA. (Control ID #3390396)

BACKGROUND: Burnout among primary care clinicians (PCPs) is associated with negative health and productivity consequences. Team-based health care are thought to improve clinician well-being, but it remains unclear if effects are observed in models as implemented broadly in multiple primary care practices. Over the past decade, the Veterans Health Administration (VA) implemented Primary Care Mental Health Integration nationally. This initiative embedded mental health specialists, care managers, and PCPs jointly manage common psychiatric diseases in primary care. This study examined the relationships between PCP- reported burnout and two key mental health integration variables in the VA.

METHODS: 210 PCPs in one VA region (17 clinics in 4 healthcare systems) reported burnout symptoms on the Maslach Burnout Inventory Emotional Exhaustion subscale via 286 cross-sectional surveys in fiscal years 2012 (November 2011 to March 2012; *n*=171; response rate = 54%) and 2013 (August 2013 to January 2014; *n*=115; response rate =48%). Using multilevel regression models, we examined PCP-reported burnout, mental health communication ratings, and clinic engagement in mental health integration (i.e., proportion of clinic patients who saw integrated clinicians) for associations. Models controlled for PCP characteristics (e.g., gender, years in practice), PCP ratings of team functioning (communication, knowledge/skills, satisfaction), and organizational factors.

RESULTS: On average, PCPs in our VA study region reported high levels of burnout (29, range=9-54), unchanged over time. There was no significant variation in aggregated burnout levels across healthcare systems (27 to 32 in 2012, p=.64; 29 to 36 in 2013, p=.23). 46% of PCPs reported that communication with mental health specialists was "very easy." On average, study clinics where PCPs practiced had 9% of their primary clinic patients seeing integrated mental health clinicians. PCP-reported burnout was *not* significantly associated with mental health communication ratings (β=-.96, standard error [SE]=1.29, p=.46), nor with clinic engagement in mental health integration (β=.02, SE=.11, p=.88). The two key mental health integration variables did not appear to have a relationship, and, thus, no mediation analysis was necessary. Among study participants, PCPs with poor team functioning, as exhibited by low team communication ratings, reported highest levels of burnout (β=-1.28, SE=.22, p<.001).

CONCLUSIONS: As locally implemented, primary care and mental health integration did not appear to impact VA PCP-reported burnout. While the VA strives to lead in quality measurement and to achieve high-quality population-based care, it should also consider measurement and interventions to tackle reductions in burnout within the primary care workforce serving veterans. More research is needed to explore team-based care model variation among clinics in order to optimally implement care models that additionally enhance PCP well-being.

DOES NEIGHBORHOOD FOOD ACCESS ALTER LIFE EXPECTANCY IN OLDER ADULTS?

Roma Bhatia[1]; Steven Melly[2]; Alice Arnold[3]; Anne B. Newman[4]; Samaneh Farsijani[4]; Calvin Hirsch[5]; Stephen P. Juraschek[6]; Gina Lovasi[2]; David Siscovick[7]; Kenneth J. Mukamal[8]. [1]General Medicine and Primary Care, Beth Israel Deaconess Medical Center, Boston, MA; [2]Drexel University, Philadelphia, PA; [3]Cardiovascular Health Study, Seattle, WA; [4]University of Pittsburgh School of Public Health, Pittsburgh, PA; [5]University of California, San Diego, San Diego, CA; [6]Medicine, BETH ISRAEL DEACONESS MEDICAL CENTER, Boston, MA; [7]New York Academy of Medicine, New York City, NY; [8]Medicine, BIDMC, Brookline, MA. (Control ID #3384653)

BACKGROUND: Although a healthier diet has been associated with a lower burden of chronic disease and a compressed period of disability on an individual basis, the impact of dietary built environment (DBE) on life expectancy and disability-free life expectancy are not known. We sought to determine if DBE is associated with life expectancy, disability-free life expectancy, and compression of disability among older adults.

METHODS: In the Cardiovascular Health Study, a cohort of 5888 adults from 4 US communities, we measured counts of supermarkets, non-supermarket food outlets, and fast food restaurants within a 5-km radius of each participant using retail data. Participants were followed for up to 29 years. Disability-free life expectancy was defined as participant study years without reported difficulties in activities of daily living. Compression was defined as the proportion of a participant's life without disability and calculated as disability-free life expectancy/life expectancy. We examined the associations of DBE with these outcomes using linear regression with adjustment for participant and neighborhood characteristics.

RESULTS: We included 4,379 eligible participants. The mean numbers of establishments within a 5-km radius of each participant were 10.8 (SD 8.5; IQR 4-17) for supermarkets, 27.9 (22.4; 8-43) for fast food restaurants and 84.6 (77.6; 24-115) for non-supermarket food outlets. For every additional 100 non- supermarket food outlets, life expectancy was 1 year longer, and disability-free life expectancy was 1.2 years longer (Table), with a borderline increase in disability compression. Sensitivity analyses revealed no effect modification by race or gender. We observed no significant associations of supermarkets or fast food restaurants with any outcomes.

CONCLUSIONS: Non-supermarket food outlets such as convenience stores vastly outnumbered supermarkets and fast food restaurants and were associated with increased life expectancy and disability-free life expectancy in older adults. Food access may be more important than quality in extending life in elders.

DOES NEIGHBORHOOD WALKABILITY PREDICT LONG-TERM SURVIVAL FOLLOWING CABG SURGERY?

Sarah O. Crowe, Scott D. Rothenberger, Kaleab Abebe, Amy M. Anderson, Bruce L. Rollman. Department of Medicine, University of Pittsburgh, Pittsburgh, PA. (Control ID #3379615)

BACKGROUND: Proximity to resources and amenities is an aspect of the built environment that links place to social determinants for better health. Yet while living in more walkable neighborhoods has been associated with lower rates of hypertension and diabetes, less is known about the relationship between neighborhood walkability and mortality. We addressed this question among a cohort of patients with coronary artery disease (CAD) who enrolled in a NIH-funded trial to treat depression following coronary artery bypass graft (CABG) surgery using WalkScores™, a validated measure to determine pedestrian friendliness and distance to amenities.

METHODS: Between 3/04 and 9/07, we enrolled 453 post-CABG patients from eight Pittsburgh-area hospitals. They included 302 depressed (inpatient PHQ-2(+)/2-week outpatient follow-up PHQ-9 ≥10) and 151 randomly sampled non-depressed control subjects (PHQ-2 (-)/PHQ-9 <5). We obtained the WalkScore™ (www.walkscore.com) for each patient's home address on the date of CABG surgery, and then classified each neighborhood into one of four categories: Very Car Dependent (WalkScore™: 0-24); Car Dependent (25-49); Somewhat Walkable (50-74); and Walkable (75-100). We confirmed patient vital status as of 12/31/2018, and then used Kaplan-Meier analyses to calculate patients' 10-year mortality and cox proportional hazards models to assess for statistical significance.

RESULTS: We obtained WalkScores™ for 445 (98%) patients, including 297 (67%) who met criteria for post-CABG depression. Their mean age was 65 (SD:11), 60% were male, 88% were White, 83% had hypertension, and 41% had diabetes. Patient distribution by WalkScore™ category was as follows: 52% Very Car Dependent, 27% Car Dependent, 17% Somewhat Walkable, and 4% Walkable. This distribution did not differ by baseline depression status. The 10-year incidence of all-cause mortality was similar by WalkScore™ category for the overall cohort (36%; P=0.23) and among those depressed at baseline (40%; P=0.62). However, among non-depressed patients, compared to Very Car Dependent (reference group) the mortality hazard ratio was 1.48 (95% CI: 0.67-3.26) for Car Dependent, 2.40 (1.06-5.40) for Somewhat Walkable, and 4.06 (1.46-11.29) for Walkable neighborhoods (P=0.03).

CONCLUSIONS: Neighborhood walkability predicts 10-year survival among non-depressed, but not depressed post-CABG patients. Our findings need to be confirmed for other cardiac conditions and among patients who live in more walkable and less car dependent areas.

DO FUNCTIONAL AND SOCIAL RISK FACTORS EXPLAIN THE HIGHER RISK OF ALL- CAUSE READMISSIONS AMONG DUALLY-ENROLLED MEDICARE BENEFICIARIES?

Lok Wong Samson[1]; Rachael Zuckerman[1]; Sarah E. Lewis[3]; Karen E. Joynt Maddox[2]. [1]Office of the Assistant Secretary for Planning and Evaluation, Department of Health and Human Services, Washington, DC; [2]Medicine/Cardiology, Washington University School of Medicine, Saint Louis, MO; [3]Center for Medicare & Medicaid Innovation, Baltimore, MD. (Control ID #3389460)

BACKGROUND: Prior studies have shown a higher risk of readmission for poorer patients than for their wealthier counterparts. However, the reasons for these findings are incompletely understood. One possibility is that readmissions are partially driven by functional risk factors – frailty, functional dependence, mental health disorders, and potentially disabling conditions – that are more common in poor beneficiaries but not captured in current risk-adjustment. This study's objective was to determine whether functional risk factors explain the worse performance on Medicare's all-cause readmission measure among poor beneficiaries, defined as those dually enrolled in Medicare and Medicaid.

METHODS: Retrospective cohort study of Medicare beneficiaries with a hospitalization from 2012-2015, eligible for one of 5 cohorts in Medicare's all-cause 30-day readmission measure. We compare duals to non-duals using previously published claims-based algorithms to identify frailty, functional dependence, mental health disorders, and potentially disabling conditions. We use random-effects models to determine the odds of readmission for duals compared to non-duals attributed to the same physician group with and without adjustment for functional risk factors. We evaluate the impact of including functional risk and dual status in measure risk adjustment on provider performance.

RESULTS: Of 5.7 million qualifying hospital episodes, 21.8% were for duals. The prevalence of frailty, functional dependence, mental health disorders, and potentially disabling conditions was higher among duals than non-duals. Duals had higher raw readmission rates (19.5% vs. 14.5%) and risk-adjusted readmission rates (18.4% vs. 14.8%) than non-duals. Raw odds of readmission ranged from 1.19 (medical cohort) to 1.52 (surgical cohort); risk-adjusted odds of readmission ranged from 1.08 (medical cohort) to 1.20 (cardiovascular cohort). Of the functional risk factors evaluated, adjusting for potentially disabling conditions reduced the odds ratios for dual status the most (OR 1.01 to 1.08 across cohorts); in particular, dual status was no longer significant for the medical cohort. When all functional risk factors were added to the model, there was little further explanatory power of dual status beyond the functional risk factors alone (OR 1.02 to 1.08). Under the current readmission measure, high-dual practices have a slightly higher readmission rate than other practices (15.7% vs. 15.5%). Adjusting for functional risk reduces the readmission rates to 15.6% and 15.5%, respectively; additional adjustment for dual status does not further reduce the rates.

CONCLUSIONS: Risk-adjustment of Medicare's readmissions measure could be improved, particularly for dually-enrolled individuals and the providers that serve them, without additional data collection, by including claims-based functional risk factors.

DO I HAVE TO WEAR IT FOR TWO FULL WEEKS? CARDIAC PATCH MONITOR ADHERENCE BY LENGTH OF PRESCRIPTION

Travis J. Cohoon[1]; Christoffel J. van Niekerk[2]; Poulina Uddin[2]; Jorge Gonzalez[2]; John Rogers[2]. [1]Department of Medicine, Scripps Clinic, La Jolla, CA; [2]Division of Cardiovascular Disease, Scripps Clinic, La Jolla, CA. (Control ID #3392189)

BACKGROUND: Ambulatory adhesive cardiac patch monitors are often used immediately after hospital discharge for arrhythmia identification. Almost 90% of arrhythmias detected during a standard 14-day prescription are identified within the first 7 days, but patients often do not wear the device for the full prescription. We aimed to evaluate if patient were more adherent to 7-day prescriptions as compared to 14- day prescriptions, potentially allowing for shorter prescriptions for patients who may refuse longer monitoring.

METHODS: We requested de-identified data from iRhythm for all Zio XT patch monitors prescribed for 7 or 14 days over a 6-month period from 10/1/2018 to 3/31/19 at a single center. Statistical analyses were performed using the Mann-Whitney U test and the Pearson's chi-squared test.

RESULTS: From 10/1/2018 to 3/31/2019, 711 Zio XT devices were analyzed. 638 were prescribed for 14 days and 73 were prescribed for 7 days. The mean and median wear durations were 10.9 days and 13.6 days for 14-day prescriptions, and 6.3 days and 7.0 days for 7-day prescriptions. The adherence (median percent of prescription worn) was higher for 7-day prescriptions, as compared to 14-day prescriptions (p-value < 0.01). The proportion of patients with who wore the patch monitor for fewer than 6 days did not significantly differ by length of prescription (p = 0.18).

CONCLUSIONS: Adherence was significantly higher for 7-day as compared to 14-day prescriptions. There was not a significant association between length of prescription and wearing the patch monitor for fewer than 6 days, suggesting that a shorter duration of monitoring may be able to maintain fair sensitivity for arrhythmia detection for those patients reluctant to undergo two full weeks of patch monitoring.

DO NEIGHBORHOOD FACTORS AFFECT PARTICIPATION IN CARDIAC REHABILITATION IN PATIENTS WITH HEART FAILURE WITH REDUCED EJECTION FRACTION?

Andrew Lutz[5]; Emily Guhl[8,5]; Julia P. Holber[4,6]; Kwonho Jeong[1]; Kaleab Abebe[1,2]; Amy M. Anderson[3]; Jared W. Magnani[4]; Daniel E. Forman[8,7]; Bruce L. Rollman[4]. [1]Internal Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA; [2]Biostatistics, and Clinical and Translational Science, University of Pittsburgh School of Medicine, Pittsburgh, PA; [3]Internal Medicine, University of Pittsburgh, Pittsburgh, PA; [4]Medicine, University of Pittsburgh, Pittsburgh, PA; [5]Internal Medicine, University of Pittsburgh Medical Center, Pittsburgh, PA; [6]Albert Einstein College of Medicine, Bronx, NY; [7]Geriatrics, University of Pittsburgh Medical Center, Pittsburgh, PA; [8]Cardiology, University of Pittsburgh Medical Center, Pittsburgh, PA. (Control ID #3372411)

BACKGROUND: Cardiac rehabilitation (CR) has well-established benefits for patients with heart failure with reduced ejection fraction (HFrEF), but is highly underutilized. Little is known about transportation, access to care, and other neighborhood barriers that may contribute to this underutilization. We examined the impact of Area Deprivation Index (ADI), Walk Score™ (WS), and Transit Score™ (TS) on participation in CR among a cohort of depressed HFrEF patients we enrolled into the National Heart, Blood, and Lung Institute-funded Hopeful Heart Trial to treat depression in this population.

METHODS: At 12-month follow up calls, we asked patients if they had ever participated in one or more session of CR. We compared WS, TS, and ADI percentile, by baseline demographics.

RESULTS: Of the 496 depressed patients with EF <=35%, 176 responded. 110 (63%) participated in CR. There were no significant differences in WS (p=0.23), TS (p=0.85) or ADI percentile (p=0.79) between patients who had participated in CR and those who had not. WS and ADI percentile were associated with white race (p<0.001), and better ADI percentile was associated with age>65 (p=0.008) in our cohort.

CONCLUSIONS: Among patients with HFrEF and depression, neighborhood factors including ADI, WS, and TS were not associated with participation in CR. These data suggest that these neighborhood-specific factors are unlikely to explain the underutilization of CR. Further studies are needed to identify other barriers to participation in CR in order to increase utilization.

Table 1. Mean neighborhood scores by participation in cardiac rehab

	No Participation (n=66 (37%))	Participated (n=110 (63%))	p-value
Walk Score	(n= 66) 27.9±25.8	(n=110) 32.7±25.1	0.23
Transit Score	(n= 20) 38.9±22.0	(n= 44) 39.8±16.4	0.85
ADI National Percentile	(n= 20) 59.8±24.8	(n= 39) 61.6±23.4	0.79

Values represented as mean ± standard deviation.

DO PROVIDERS DOCUMENT SOCIAL DETERMINANTS? OUR EMRS SAY…!

Jeffrey Wilhite, Sondra R. Zabar, Kathleen Hanley, Lisa Altshuler, Harriet Fisher, Adina Kalet, Khemraj Hardowar, Amanda Mari, Barbara Porter, Andrew Wallach, Colleen Gillespie. Division of General Internal Medicine, New York University School of Medicine, New York, NY. (Control ID #3391704)

BACKGROUND: There's been a recent shift toward addressing social determinants of health (SDoH) during the clinical encounter through discussion and documentation. SDoH documentation in the problem list and through billing-related z-code use is necessary for accurate, individual patient and population level tracking and may improve quality of care. We sought to better understand if/how providers document their patient's SDoH when elicited during a clinical visit.

METHODS: Unannounced Standardized Patients (USPs) were sent to two safety-net clinics to assess how medicine residents care for a new patient presenting with one of six unique chief complaints, and accompanying underlying financial, housing, and social concerns. USPs assessed resident practices after the encounter through a behaviorally anchored checklist and systematic chart review. USPs volunteered financial concerns while housing insecurity and social isolation needed to be elicited by the provider. Checklist items assessed if the USP was able to fully disclose their SDoH to the provider. Provider documentation in the electronic medical record (EMR) in one of three spaces: the history of present illness (HPI), the problem list, or through use of a social determinant-specific Z-code was examined when a USP was able to share their concerns.

RESULTS: 384 USP visits were sent to medical residents from 2017 to 2019. USPs were able to share their financial concerns during 84% of the encounters, but were less likely to be able to share their housing or social concerns with providers (35% and 28%, respectively). Documentation in the HPI and treatment list remained low across cases (<15%) and only one Z-code was used across all visits. On an individual case level, providers addressed housing insecurity most frequently in the asthma case (discussion 65%; documentation: HPI 39%, Plan 16%) and social isolation in the fatigue case (discussion 57%; documentation: HPI 49%, Plan 2%). Providers were least likely to discuss and document SDoH for patients presenting with acute pain.

CONCLUSIONS: In clinical scenarios where SDoH concerns were elicited, residents documented SDoH in less than half of visits. Omission of SDoH not only effects clinical care but also panel management and SDoH population-level estimations. New education strategies are needed to address resident's ability to elicit and accurately document SDoH.

DOSE EFFECT OF ACA MEDICAID EXPANSION: AN EXAMINATION OF TOTAL JOINT ARTHROPLASTY UTILIZATION

Michael K. Paasche-Orlow[1]; Karen E. Lasser[2]; Meng-Yun Lin[3,2]; Shuting Wang[2]; Leo Hsia[2]; Amresh D. Hanchate[3,2]. [1]Medicine, Boston University, Boston, MA; [2]Medicine, Boston Medical Center, Boston, MA; [3]Social Sciences and Health Policy, Wake Forest School of Medicine, Winston-Salem, NC. (Control ID #3382295)

BACKGROUND: The Affordable Care Act (ACA) resulted in a common eligibility income threshold across expansion states; however, expansion magnitude i.e., dose, varied due to pre-ACA differences in state eligibility thresholds. Total joint arthroplasty (TJA) is a common inpatient elective procedure and has evidence of significant racial/ethnic disparities. We examined changes in TJA rates to test for a dose effect of Medicaid expansion.

METHODS: Using all-payer inpatient data (2011-2015) we identified all discharges with a total knee or total hip arthroplasty for patients aged 45 to 64 from 15 Medicaid expansion states (AR AZ CA CO IA IL KY MA MD NJ NM NV NY OR PA) and 7 non-expansion states (FL GA NC SC TX VA WI). Using census population, we stratified each state by age (45-55; 54-64), sex, and race/ethnicity [Hispanics; non-Hispanic blacks; non-Hispanic whites and others]. Our main outcome was the number of TJA discharges each year for each state cohort (N=1,308). Using each state's Medicaid eligibility criteria in 2011 and 2014 we calculated Medicaid Generosity, i.e., the proportion of state population (aged 18-64) who would be eligible for Medicaid. We then categorized expansion states as high dose (≥ 10 %) vs low dose (< 10 %) stated based on change in Medicaid Generosity between 2011 and 2014. Using a quasi-experimental difference-in-differences study design and Poisson regression models, we estimated changes in TJA rate by dose of Medicaid Generosity change (high vs low), treating non-expansion states as controls. We also estimated rate changes by race/ethnicity. All regression models used state-level fixed effects with standard errors clustered at the state level.

RESULTS: There were 4 low dose expansion states (IL, MA, NJ and MD) with Medicaid eligible population increasing by 3.1% (IL) to 9.2% (MD) between 2011 and 2014. There were 11 high dose expansion states (CA, CO, AZ, NV, NM, IA, NY, KY, PA, OR, AR) with Medicaid eligible population increasing by 10.1% (CA) to 15.1% (AR). Non-expansion states had < 2% increase in Medicaid eligible population. Annual volume of TJA in these 22 states was 234,839 in 2011 and 280,713 in 2015. In 2011, TJA rate by race/ethnicity (# TJA/1000 pop): whites = 4.8; black=3.7; Hispanics=1.70. Between 2011 and 2015, observed TJA rate increased in all groups:13.7% (whites); 21.8% (blacks); 22.3% (Hispanics). Among blacks, TJA rate increased more in both higher dose (9.1%; 95% CI = 3.9% to 14.7%) and lower dose (7.6%; 95% CI = 1.01% to 14.6%) states, compared to non-expansion states. Medicaid expansion was not associated with change in TJA rate among whites or Hispanics. While Medicaid expansion was not associated with a change in TJA rate for Hispanics, white-black and white-Hispanic differences narrowed.

CONCLUSIONS: We observed clear dose effects of Medicaid expansion in changes of population rates for TJA. Narrowed racial and ethnic disparities may reflect improved access to outpatient providers and elective inpatient care.

DO WE ASK NEW MOMS IF THEY ARE DEPRESSED?

Sneha Shrivastava[1]; Stephanie McNally[2]. [1]General Internal Medicine, Northwell Health, Westbury, NY; [2]Obstetrics and Gynecology, Northwell Health, Garden City, NY. (Control ID #3387505)

BACKGROUND: Postpartum depression (PPD) is common. While the exact incidence of PPD varies in the literature, 1 in 5-9 mothers experience PPD in the United States. One study reported an increase of PPD for women screened in the hospital during their postpartum course while another set in the ambulatory setting suggested a decrease in PPD. This discrepancy may be due to inconsistent postpartum screening and therefore, less documented PPD. Moreover, in the last decade, the definition of PPD has also expanded to include a 12 month period as opposed to the traditional six-week time frame and to include other Perinatal Mood and Anxiety Disorders (PMAD) as well depression. To understand the gaps and trends in PPD/PMAD screening, we surveyed obstetrics-gynecologists (OB/GYN) at a large urban healthcare center.

METHODS: We conducted a PPD/PMAD screening survey of OB/GYN providers in 2016 and repeated in 2019 at multiple OB/GYN sites within our healthcare system. The survey consisted of key demographic questions, frequency of PPD screening, type of screening tool used, and personal perceptions of PPD screening on a 5-point Likert scale (strongly disagree=1 to strongly agree=5).

RESULTS: The response rates for the surveys were 17% (93/546) in 2016 and 27.4% (87/318) in 2019. Participant cohorts were similar in both the surveys. The average number of patients diagnosed with PPD increased by 8.7% from 2016 to 2019 per participant. While a majority of the OBGYN providers screen for PPD (86.7% in 2016 and 87.2% in 2019), the number of providers who screen at every postpartum visits increased from 36.0% in 2016 to 51.3% in 2019. Edinburgh postnatal depression scale was the most common screening tool used, and its usage increased from 57.1% to 89.2% between 2016 and 2019. All providers strongly agreed that they should screen for PPD (Mean=4.8(2016) and 4.9(2019) on a 5-point Likert scale, p=0.38), and believed that PPD is common enough to warrant screening (M= 4.7(2016) and 4.9(2019), p=0.14). They reported a significantly increased confidence in screening for PPD (M=3.8(2016) and 4.2(2019), p=0.02) and awareness about the difference between postpartum blues and PPD (M=4.1(2016) and 4.5(2019), p=0.03). More OB/GYNs knew the criteria to maintain a diagnosis of PPD (M=3.5(2016) and 3.9(2019), p=0.02), and fewer OB/GYNs felt PPD screening would take too much effort (M=2.2(2016) and 1.8(2019), p=0.02).

CONCLUSIONS: Although there has been an increase in awareness and agreement with PPD/PMAD screening, it is concerning that not all OB/GYNs screen at all postpartum follow up visits. In addition to improving screening during the postpartum course to identify patients with PPD/PMAD, it is important to expand PPD/PMAD screening at primary care since new mothers are more likely to present to their PCP with mood and depression symptoms after their initial OB/GYN postpartum visit. Primary care awareness along with provider education and standardizing screening protocols would further improve PPD/PMAD screening.

DRIVERS BEHIND OPIOID PRESCRIPTION REFILLS WITHIN PRIMARY CARE FOLLOWING A SURGICAL EPISODE

Nicholas Sanchez. Feinberg School of Medicine, Northwestern University, Chicago, IL. (Control ID #3390735)

BACKGROUND: Opioid prescriptions for acute pain play a significant role in the opioid epidemic as they can lead to chronic opioid use, misuse, and addiction. Between 3-7% of opioid naïve patients use opioids long-term following surgery. Within the first three months after surgery, most opioid refills are provided by surgeons, but after three to six months the majority (36%) is prescribed by primary care physicians (PCPs). The reasons for this continuation are unclear and may be driven by physicians' lack of understanding of the distinction between chronic opioid use and chronic pain. By identifying the drivers of PCPs' continuation of post-operative opioid prescriptions, we aim to add to the evidence that could allow health care providers to improve their practices.

METHODS: Between August 2018 and August 2019, we conducted semi-structured interviews (N=13) with Northwestern Medicine affiliated Internal Medicine physicians (n=10) and Family Physicians (n=3). Interviews were audio recorded and transcribed verbatim. Two researchers analyzed the transcripts separately to identify emerging drivers of refills and discussed results with a third researcher to resolve discrepancies. The analysis was both deductive, by applying a framework distinguishing domains of primary care structure and processes, and inductive, based on the interview content. Each driver was further described as a "positive driver" to refill opioids and "negative driver" to delay or avoid refills.

RESULTS: Generally, PCPs reported a lack of comfort with the treatment of post-surgical pain and prescribing opioid refills. The lack of comfort is further driven by structural characteristics (lack of education on pain management), as well as current processes (lack of coordination with the surgeon), the comprehensiveness of care (PCPs' perception that this is the surgeon's duty) and the subjectivity of the patients' pain. Important positive drivers to opioid refills relate to the core dimensions of primary care: accessibility (the PCP is sometimes more accessible than the surgeon) and continuity of care (the PCP knows the patient best). Generally, PCPs reported that the treatment of post-operative pain is the surgeon's duty, whereas treatment of chronic pain is the PCPs' own responsibility. Finally, PCPs reported that refills have become less common these days both due to the context (patients' awareness of the opioid epidemic and low demand) and the structure (combined EMR makes it easy to refer the patient back to the surgeon).

CONCLUSIONS: An improved understanding of reasons for opioid refills following surgery can contribute to physicians' decision-making processes in determining patients' post-surgical needs. We identified a need for improvement of education, as well as increased PCP-surgeon coordination to support PCPs' in making a distinction between chronic use and chronic pain following surgery.

DRIVERS OF INSTITUTIONAL PLACEMENT AMONG A NATIONAL COHORT OF ADULTS WITH INTELLECTUAL / DEVELOPMENTAL DISABILITIES

Sophia Jan[1,3]; Caren Steinway[2]; Colleen Brensinger[4]; Jack Chen[1]. [1]Pediatrics, Northwell Health, New Hyde Park, NY; [2]Pediatrics, Cohen Children's Medical Center of Northwell Health, New Hyde Park, NY; [3]Internal Medicine, Northwell Health, Manhasset, NY; [4]University of Pennsylvania, Philadelphia, PA. (Control ID #3392451)

BACKGROUND: Long term care is the fastest growing segment of health care spending, particularly Medicaid spending given the growth of aging and disabled populations. The goal of this study is to identify the effect of state of residence and home and community based services spending on long-term care placement for adults with intellectual/developmental disabilities (IDD) who are Medicare and Medicaid dual enrollees.

METHODS: We conducted a retrospective study using 2008-2012 claims data from CMS Medicaid Analytic eXtract (MAX) data files from CA, FL, NY, OH and PA linked with Medicare data. Study cohort included individuals who were 18 to 64 years old, community-dwelling, dually enrolled in Medicare and Medicaid, were continuously enrolled in Medicaid (defined as 10 of 12 months) in each year of enrollment, and had an ICD9 diagnostic code for intellectual disability in any inpatient, outpatient, or long-term encounter. The outcome was the first long-term institutional placement after the baseline year, defined as the presence of at least one claim for services received in a nursing facility or intermediate care facility for the intellectually disabled (ICF-ID) for ≥3 months, obtained from the Long Term Care files of MAX data files. The primary predictors were spend on home and community based services and state of residence. Other independent measures included acute and ambulatory utilization measures; Medicaid or Medicare eligibility status; demographic characteristics; comorbid conditions or medical complexity, including Charlson Comorbidity Index, number of Complex Chronic Conditions, presence of mental health diagnosis; and polypharmacy. Risk of long-term placement were determined by cox regression models.

RESULTS: There were a total of 159,275 individuals with IDD who met inclusion and exclusion criteria. Of those, 14% had a long-term care placement claim. Compared to those without long-term placement, those with long-term placement were more likely to be older, white Caucasian, living in OH, have at least one short-term nursing home or ICF-ID stay, higher levels of acute care or ambulatory utilization, higher Charlson comorbidity scores, higher numbers of complex chronic conditions, mental health diagnosis, and polypharmacy. After adjustment, these factors remained associated with institutional placement. Compared to Florida, residents of Ohio had a HR 2.12 [1.9-2.3, P<0.0001] while every additional $10,000 HCBS spend was protective with a HR 0.97 [0.97-0.98, P<0.001].

CONCLUSIONS: Each $10,000 incremental increase in HCBS services, even for dual-eligible adults with IDD, is protective against long-term care placement. However, significant variation in institutional placement risk exists across states, warranting closer examination of long-term care policy features protective against long-term care placement among severely disabled adults.

DRUG CHARACTERISTICS ASSOCIATED WITH GENERIC UPTAKE AFTER LOSS OF MARKET EXCLUSIVITY

Benjamin N. Rome[1,2]; ChangWon C. Lee[1]; Aaron S. Kesselheim[1,2]. [1]Program On Regulation, Therapeutics, And Law, Division of Pharmacoepidemiology and Pharmacoeconomics, Department of Medicine, Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA. (Control ID #3371643)

BACKGROUND: In the US, brand-name drugs are invariably expensive until their market exclusivity ends and lower-cost, equally safe and effective generics become available. Delayed uptake of generic drugs after loss of exclusivity could lead to excess health care spending and reduced patient adherence to essential medications. Factors that influence generic uptake are unknown.

METHODS: We identified all drugs facing new generic or biosimilar competition from 2012 – 2017. Using claims data from a national insurer of commercial and Medicare Advantage patients (Optum Clinformatics DataMart), we identified generic uptake in the first and second years after generic entry, defined as the percent of generic (or authorized generic [AG]) prescriptions. We used linear regression to evaluate associations between generic uptake and 9 drug characteristics identified from FDA and other publicly available sources, adjusted for other characteristics. The characteristics were: route of administration (oral vs. non-oral), novelty (first-in-class vs. new but non-first-in-class vs. modified formulation), priority review, Orphan Drug Act designation, number of FDA-approved generic manufacturers in the first year, whether the first generic manufacturer received 180-day generic exclusivity (a special legislative incentive to encourage generic entry), whether an AG was released in the first 6 months, number of brand-name prescriptions in the year before generic entry (in tertiles), and generic entry date.

RESULTS: Among 226 drugs in the cohort, mean generic uptake was 65.3% (SD 22.6%) in the first year and 82.2% (SD 21.9%) in the second year after generic entry. In the adjusted model, generic uptake decreased 4.6%/year from 2012 to 2017 (95% CI 2.9%–6.2%, p<0.001). Generic uptake was significantly lower among non-oral drugs (mean 54.5% vs 69.7%, p<0.001), drugs with Orphan Drug Act designation (55.6% vs 66.5%, p=0.006), and drugs without an AG (62.6% vs 68.6%, p=0.004). Except for Orphan Drug Act designation, the same characteristics were significantly associated with generic uptake in the second year after generic entry. The R^2 for the model with all characteristics was 0.25 for generic uptake for the first year and 0.20 for the second year.

CONCLUSIONS: We found substantial variability in the extent of early generic uptake after a brand-name drug loses market exclusivity. Early generic uptake has significantly decreased over the past several years, which may be contributing to increased US health care spending and leading to lower patient medication adherence. Drugs with alternate routes of administration (e.g. injected, topical, inhaled) had slower generic uptake than oral drugs, so new policies may be needed to encourage generic competition among these drugs. While AGs were associated with higher early generic uptake, because AGs do not reflect true market competition, they may have less impact on lowering price and spending.

EARLY EXPERIENCES AND PERSPECTIVES OF PEDIATRIC AND ADULT PROVIDERS WHO DELIVER CARE USING TELEMEDICINE

Natalie Laub[2]; Anish Agarwal[3]; Catherine Shi[4]; T. Arianna Sjamsu[5]; Krisda H. Chaiyachati[1]. [1]General Internal Medicine, The University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]Pediatrics, Childrens Hospital of Philadelphia, Philadelphia, PA; [3]Emergency Medicine, The University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [4]Medicine, The University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [5]New York Institute of Technology College of Osteopathic Medicine, Old Westbury, NY. (Control ID #3391990)

BACKGROUND: Direct-to-consumer telemedicine is being developed by existing health systems and providers are quickly adapting to the delivery of virtual medicine. How to transition today's workforce and trainees to provide high-quality, safe, and effective telemedicine is uncharted and, therefore, likely unsystematic. Providers may be providing virtual care with minimal training on the best "webside" manner or lack skills for achieving high-quality care virtually. The objectives of this study were to describe the clinical practice experiences of early adopters – providers who have transitioned their career to providing direct-to- consumer telemedicine and capture their perspectives on high-quality telemedicine care.

METHODS: We conducted semi-structured interviews with physician and non-physician providers who care for pediatric or adult patients from six academic medical centers throughout the United States. Providers participated in direct-to-consumer telemedicine services for low-acuity illnesses. Interviews were conducted using an interview guide piloted for this study, audio-recorded, transcribed, coded, and analyzed using the constant comparative technique. Recruitment ended when thematic saturation was reached after 20 providers were interviewed. Six interviews were double coded with an average inter-rater reliability of 0.74. Interviews lasted approximately 30 minutes.

RESULTS: Among the providers interviewed, 90% were female, 65% were nurse practitioners, 30% physicians, 5% physician assistants, and 61% identified as white, non-Hispanic. Overall, providers aspired to deliver high- quality care, equal to in-person care but recognized the constraints of telemedicine such as the inability to conduct full physical examinations and testing limitations. In order to achieve high quality, three key attributes were believed necessary. First, the technology platform must be easy for patients and providers. Second, virtual competency – facial expressions and verbalizing on-screen actions – were important for effective provider-to-patient communications because patients can, oftentimes, only visualize the provider's face. Third, providers needed strategies for addressing the unique clinical pressures of caring for telemedicine patients, such as requests for antibiotics when they were not clinically necessary because these patients were more likely to expect immediate gratification in a virtual medium that is highly convenient and could provide care instantaneously.

CONCLUSIONS: Clinicians who provided telemedicine identified key aspects of delivering high-quality health care: a provider and patient-centric technology platform, the need for providers to develop virtual competency, and clinical pressures unique to patients using telemedicine. As the future of health care will involve more telemedicine, capturing the real-world experiences of providers who have, early on, adopted telemedicine will be informative for future telemedicine providers who will similarly aspire to provide high- quality care.

EARLY LIFE SEXUAL TRAUMA AND LATE LIFE FUNCTIONAL OUTCOMES IN A NATIONALLY REPRESENTATIVE COHORT OF U.S. WOMEN

Alison J. Huang[2]; Nadra Lisha[2]; Carolyn J. Gibson[1]; Pooja Lalchandani[2]. [1]Medical Service Line, San Francisco VA Health Care System, San Francisco, CA; [2]Division of General Internal Medicine, University of California, San Francisco, San Francisco, CA. (Control ID #3378983)

BACKGROUND: One in four U.S. women may experience a form of early life sexual trauma, with potentially long-lasting consequences on their health and functioning. Past research on sexual trauma has focused almost exclusively on outcomes in reproductive age women, with little research addressing potential long-term effects in older age.

METHODS: We analyzed cross-sectional data from women aged ≥50 in the National Social Life, Health, and Aging Project, a national cohort of older community-dwelling U.S. adults. During home-based visits from 2010-2011, women answered standardized questions about exposure to two forms of early sexual trauma, 1) childhood sexual abuse (being touched sexually before age 12) and 2) unwanted first sexual experience (forced or coerced first sexual intercourse). Women also completed questionnaires about several types of late life functional outcomes: 1) symptomatic genitourinary dysfunction (including urinary incontinence, other urinary symptoms, pain during sex, or lack of pleasure during sex), and 2) general functional disability (difficulty performing any of 7 activities of daily living [ADLs] or 8 instrumental activities of daily living [IADLs]). We developed multivariable logistic regression models to examine associations between early sexual trauma and late life functional outcomes adjusting for age, race/ethnicity, and education.

RESULTS: Of 1,745 women (age range 50 to 91), 11% reported a history of childhood sexual abuse and 39% an unwanted first sexual experience. In multivariable models, childhood sexual abuse was associated with late life genitourinary dysfunction (pain during sex [OR 1.9, 95% CI 1.1-3.3], other urinary problems [OR 1.9, 95% CI 1.2-3.1]) and difficulty with ADLs/IADLs (walking across the room [OR 1.9, 95% CI 1.2-3.1], getting in or out of bed [OR 2.0, 95% CI 1.2-3.3], bathing [OR 2.0, 95% CI 1.2-3.5], prepping meals [OR 2.4, 95% CI 1.5-3.8], shopping for food [OR 1.6, 95% CI 1.0-2.4], completing light work [OR 1.6, 95% CI 1.0-2.4]). Unwanted first sexual experience was also associated with lack of pleasure with sex [OR 1.7, 95% CI 1.1- 2.5]) and difficulty with ADLs/IADLs (walking one block [OR 1.5, 95% CI 1.1-2.1], completing light work [OR 1.6, 95% CI 1.1-2.1]) in adjusted analyses.

CONCLUSIONS: Early sexual trauma may be an under-recognized marker of risk for aging-related genitourinary and functional decline in women. Findings from this national sample underline the importance of examining the impact of trauma across the lifespan and adopting a trauma-informed approach to care of women even in older age.

EARLY MORTALITY AMONG AFRICAN AMERICANS IN THE JACKSON HEART STUDY

Katherine C. Brooks[1]; Mark J. Ommerborn[2]; Cheryl R. Clark[2]. [1]Hospital Medicine, University of California San Francisco, San Francisco, CA; [2]General Medicine & Primary Care, Brigham and Women's Hospital, Boston, MA. (Control ID #3347510)

BACKGROUND: Young black Americans are more likely to die than their white age-matched counterparts, including from chronic conditions that occur later in life among whites. Few studies have explored how social context impacts early mortality among African Americans (AA), including conditions related to 'deaths of despair'. Our research objective was to explore predictors of early mortality among African Americans.

METHODS: We conducted a survival analysis to examine contributors of early mortality among AA in the Jackson Heart Study (JHS). The JHS cohort is comprised of non-institutionalized AA living in Jackson Mississippi. We included JHS adult participants from 18 to 64 years at baseline (n=3,999). Primary outcome was death before 65. Descriptive statistics were calculated by mortality status and differences were detected using chi-squared and Krukal-Wallis tests. We then calculated multivariable adjusted hazard ratios and used multiple imputation techniques for missing data. Our hazard models included clinical, lifestyle, demographic and socioeconomic status covariates, as well as exposure to discrimination and neighborhood safety.

RESULTS: In descriptive analysis, those who died young before 65 years old were more likely to be men (46.6% vs. 36.7%, p<0.01), have poor functional status (30.6% vs. 17.9%, p<0.001), report drug use (40.0% vs. 24.1%, p<0.001), report heavy episodic alcohol drinking (31.2% vs. 13.6%, p<0.001), be current smokers (35.1% vs. 13.9%, p<0.001), and have comorbidities such as cancer (6.9% vs. 3.4%, p<0.05), asthma (14.7% vs. 9.7%, p<0.05), depression (19.4% vs. 12.4%, p<0.01), obesity (64.1% vs. 55.2%, p<0.01), poor blood pressure control (32.4% vs. 16.5%, p<0.001) and poor glucose control (15.0% vs. 8.3%, p<0.001). They were also more likely to be in the lowest income bracket (32.5% vs 19.7%, p<0.001). In multivariate hazard models, those with income < $25,000 were more likely to suffer early mortality than those with an income over $75,000 (HR 1.64, CI 1.004-2.69). Adjusting for cardiovascular health, discrimination, neighborhood safety, education, income, and healthcare access, drug use (HR 1.66, CI 1.20-2.28), heavy episodic alcohol drinking (HR 1.80, CI 1.27, 2.55) and cancer (HR 2.20, CI 1.26-3.85) were predictive of early mortality. Of the cardiovascular risk behaviors measured, predictors included current smoking (HR 2.28, CI 1.65-3.15), poor glucose control (HR 1.85, CI 1.17-2.91), and poor blood pressure control (HR 3.31, CI 2.00-5.49).

CONCLUSIONS: Among AA in the JHS cohort, drug and heavy episodic alcohol drinking, as well as low income were predictive of early mortality. Recent data shows that early mortality is increasing across all racial groups in the US, despite decades of improvement in life expectancy, thus increased attention towards early mortality is needed at this time. Among AA in Mississippi, efforts to invest in smoking and alcohol cessation programs, as well as poverty reduction strategies, may be most effective.

E-CIGARETTE USE BEHAVIORS AMONG CURRENT CIGARETTE SMOKERS AFTER THE OUTBREAK OF E-CIGARETTE LUNG ILLNESS AND A STATEWIDE E-CIGARETTE SALES BAN

Sara Kalkhoran[1]; Kelly Kalagher[1]; Nancy A. Rigotti[2]. [1]Medicine, MGH, Boston, MA; [2]General Medicine Division, Massachusetts General Hospital, Boston, MA. (Control ID #3391672)

BACKGROUND: The 2019 U.S. outbreak of lung injury cases associated with electronic cigarettes (e-cigs) raised concern about the products' safety and led Massachusetts (MA) to ban the sale of all vaping products for 3 months (9/25/19-12/11/19), after which a new state law banned flavored e-cig sales only. We aimed to assess e-cig use behaviors after these events, focusing on current cigarette smokers because most e-cig users also smoke.

METHODS: We identified adults aged 40-80 years receiving primary care at Mass General Hospital and identified in the electronic health record as a cigarette smoker. A phone survey done 11/07/19 to 1/10/20 asked about current and past e-cig use/vaping, types of e-cigs used, reasons for use, and quit intentions.

RESULTS: Among 189 participants (mean age, 59 yo; 53% female; 81% non-Hispanic white; 35% college educated), 112 (59%) had ever used e-

cigs and 17 (9%) were current (past 30-day) users. Of 112 ever-users, 94 (84%) had vaped nicotine, 35 (31%) vaped marijuana, and 24 (21%) vaped both; a minority vaped flavors only. Of current e-cig users, 15 (88%) were current dual users of cigarettes and nicotine e-cigs, 172 (91%) only smoked cigarettes, and 2 (1%) reported e-cig use only. Current vaping of THC, CBD, or marijuana was rare (1%). Among current e-cig users, JUUL was the most common brand (61%) and menthol/mint was the most common flavor (50%). Over half of ever e-cig users reported quitting smoking as the primary reason for using e-cigs (60%, 56/94). Most current e-cig users reported having tried to quit e-cigs in the past (59%, 10/17) and 91% of current cigarette smokers reported having tried to quit cigarettes in the past (170/187). 9% (10/116) of ever e-cig users reported quitting e-cigs as a result of the EVALI outbreak, 6% (7/116) cut down as a result of the outbreak, and 66% (77/116) quit before the outbreak; 9% had not heard of the outbreak. 2 (2%) ever e-cig users reported having previously quit cigarettes but returning to tobacco cigarette smoking after the EVALI outbreak, and 4 (5%) reported increasing the number of tobacco cigarettes they smoked after the EVALI outbreak. 47% of current e-cig users reported planning to quit e-cigs in the next 6 months (8/17), and 46% of current cigarette smokers reported planning to quit cigarettes in the next 6 months (86/187). While 90% of participants reported being screened for cigarette use by a doctor in the past 12 months (171/189), only 25% (47/189) reported being screened for e-cig use.

CONCLUSIONS: After a statewide ban on e-cig sales triggered by lung injury cases, 10% of adult cigarette smokers in a primary care network still used e-cigs. Interest in quitting e-cigs was high, but few users reported that clinicians screened them for e-cig use. Clinicians should routinely screen for e-cigs as well as cigarettes and offer treatment to those interested in quitting either product.

EDUCATIONAL LAPSES AND SIGNALS IN DISCHARGE CARE: A MULTI-INSTITUTIONAL SURVEY

Shreya P. Trivedi[1]; Zoe Kopp[2]; Alice Tang[3]; Dharmini Pandya[6]; Leora I. Horwitz[4]; Mark D. Schwartz[5]. [1]Internal Medicine, NYU, New York, NY; [2]Internal Medicine, UCSF, San Francisco, CA; [3]Internal Medicine, New York University, New York, NY; [4]Population Health, NYU School of Medicine, New York, NY; [5]Population Health, NYU School of Medicine, New York, NY; [6]Internal Medicine, Temple University, Philadelphia, PA. (Control ID #3392439)

BACKGROUND: Hospital discharge is a vulnerable time for patients, which can lead to adverse outcomes and hospital readmissions. Suboptimal communication with patients and their caregivers, as well as inadequate understanding of post-discharge plans contribute to readmissions. Prior health services research and national society guidelines have identified key components to be addressed with patients on the day of discharge. Yet, we don't know whether residents are using these best practices, or if existing transitions of care curricula are effective in fostering these practices. Critically assessing types of educational instruction and communication practices residents report using at discharge is critical to informing how we train physicians to be transitions of care champions within our fragmented healthcare system.

METHODS: Internal Medicine residents at seven large academic medical centers completed a cross- sectional survey characterizing the types of education on transitions of care they received and the self- reported frequency of using six communication practices at discharge. We calculated the proportion of each communication domain done frequently (>60% of the time) for each respondent. Using multiple linear regression, we explored which types of educational exposures were associated with residents using best communication practices frequently. A content analysis was done to examine a free-response question on which factors residents reported as motivation for changing their discharge practices.

RESULTS: The response rate was 63% (613/966). The majority of residents (82.3%) received some form of instruction around transitions of care, although only about one in five (18.9%) reported being observed and getting feedback on their discharge education with patients. Resident discharge communication practices were variable, with less than half of residents reporting frequently addressing symptom expectations or self-management of disease. Notably, less than a fifth of residents (17.0%) reported routinely asking patients to teach back their understanding of the discharge plans. Workplace-based learning, such as explicit teaching on rounds and direct observation and feedback on discharge education, was associated with increased proportion of discharge communication practices reported being done frequently. In open-ended comments, residents pointed to adverse events after the post-discharge continuum as their impetus for practice change.

CONCLUSIONS: This study exposes the gaps in resident discharge communication practices with patients, the impact of adverse events as a source of hidden curriculum, and the benefits of workplace-based training on discharge communication skills. Our results suggest that developing faculty to incorporate transitions of care in their rounds teaching and integrating experiences across the post-discharge continuum will foster systems-minded physicians-in-training.

EDUCATIONAL SCHOLARSHIP NEEDS OF CLINICIAN-EDUCATOR AND EARLY FULL-TIME PHYSICIAN FACULTY AT A LARGE DEPARTMENT OF INTERNAL MEDICINE

Donna Windish. Internal Medicine, Yale University, Cheshire, CT. (Control ID #3356746)

BACKGROUND: Clinician-educator faculty must participate in scholarship to be promoted. This study aimed to determine the educational scholarship training needs for clinician-educator and early full-time physician faculty in a large Department of Medicine.

METHODS: From January to February 2019, an online anonymous survey assessed the educational scholarship needs for full-time physician clinician-educators and instructors and assistant professors not on a designated track in Yale's Department of Internal Medicine. The survey assessed past training, self-perceived proficiency, and desire for more instruction in 20 educational scholarship skills in 4 areas: a) curriculum/program development and evaluation; b) statistical methods; c) library research and IRB navigation; and d) writing for presentation and publication. Training questions were rated from "none" to "a lot" and self-perceived proficiency was rated from "poor" to "excellent".

RESULTS: 119 of 346 (34%) faculty responded. Many faculty (57.4% - 85.6%) indicated little or no training in the 20 educational scholarship skills. In self-assessment, 20.6% - 70.3% rated their proficiency as poor or fair and many (33.3% - 53.5%) wanted a moderate or a lot more training in the 20 skills assessed.

Curriculum/Program Development and Evaluation Skills

Most faculty indicated they had little or no training (69.8% - 82.4%) in the 5 curricular skills assessed. More than half (57.4%) rated themselves as having poor or fair proficiency with 48.3% desiring a moderate or a lot more training in these areas.

Statistical Methods Skills

Faculty indicated the least amount of training in the 4 areas of statistical methods assessed with 72.8% - 82.4% indicating little or no training in these skills. On average, 60.8% rated their proficiency in statistical methods as poor or fair, and 47.5% wanted a moderate or a lot more training.

Library Research and IRB Navigation Skills

Library research and IRB navigation skills were classified into 5 categories with 63.1% - 85.6% of respondents indicating little or no training in these skills. On average, 54.1% rated these skills as poor or fair, and 42.5% wanted a moderate or a lot more training.

Writing for Presentation and Publication Skills

In the 6 skill categories of writing for presentation and publication, many respondents indicated they had little or no training (57.4% - 71.3%). Faculty rated their writing skills as poor or fair in the 6 skills assessed (35.8%) and 40.6% wanted a moderate or a lot more writing skills training.

CONCLUSIONS: Many clinician-educator and early full-time physician faculty in this large Department of Internal Medicine lack training in educational scholarship skills and rate their skills in these areas as poor or fair. Lack of scholarly expertise continues across institutions and can have a detrimental effect on faculty promotion and career satisfaction. Continued work on developing educational scholarship skills for clinician- educators must persist.

EFFECTIVENESS OF ACUTE CARE REMOTE TRIAGE SYSTEMS: A SYSTEMATIC REVIEW

Joel C. Boggan[2,1]; John P. Shoup[3]; John Whited[4]; Elizabeth van Voorhees[4]; Adelaide Gordon[4]; Sharron Rushton[7]; Allison Lewinski[4]; Amir Alishahi-Tabriz[8]; Soheir Adam[4]; Jessica Fulton[4]; Andrzej Kosinski[4]; Megan van Noord[4]; John Williams[1]; Karen M. Goldstein[5]; Jennifer M. Gierisch[6]. [1]General Internal Medicine, Duke University Health System, Durham, NC; [2]Medicine, Durham VA Medical Center, DURHAM, NC; [3]Internal Medicine and Pediatrics, Duke University, Durham, NC; [4]Research (151), Durham VA Health Care System, Durham, NC; [5]General Internal Medicine, Duke University School of Medicine, Durham, NC; [6]Center for Health Services Research in Primary Care, Durham VA Medical Center, Durham, NC; [7]Nursing, Duke University, DURHAM, NC; [8]UNC Chapel Hill, Chapel Hill, NC. (Control ID #3374758)

BACKGROUND: Technology-based systems can facilitate remote decision-making to triage patients to the appropriate level of care. Despite technologic advances, the effects of implementation of these systems on patient and utilization outcomes are unclear. We evaluated the effects of remote triage systems on healthcare utilization, case resolution, and patient safety outcomes.

METHODS: English-language searches of MEDLINE (via PubMed), EMBASE, and CINAHL were performed from inception until July 2018. Randomized and nonrandomized comparative studies of remote triage services that reported healthcare utilization, case resolution, and patient safety outcomes were included. Two reviewers assessed study and intervention characteristics independently for study quality, strength of evidence, and risk of bias.

RESULTS: The literature search identified 5,026 articles, of which eight met eligibility criteria. Five randomized, two controlled before-and-after, and one interrupted time-series study assessed 3 categories of remote triage services: mode of delivery, triage professional type, and system organizational level. No study evaluated any other delivery mode other than telephone and in-person. Meta-analyses were unable to be performed because of study design and outcome heterogeneity; therefore, we narratively synthesized data. Overall, most studies did not demonstrate a decrease in primary care (PC) or emergency department (ED) utilization, with some studies showing a significant increase. Evidence suggested local, practice-based triage systems have greater case resolution and refer fewer patients to PC or ED services than regional/national systems. No study identified statistically significant differences in safety outcomes.

CONCLUSIONS: Our review found limited evidence that remote triage reduces the burden of PC or ED utilization. However, remote triage by telephone can produce a high rate of call resolution and appears to be safe. Further study of other remote triage modalities is needed to realize the promise of remote triage services in optimizing healthcare outcomes.

EFFECTIVENESS OF A LABORATORY-BASED INTERVENTION FOR IMPROVING URINE TOXICOLOGY INTERPRETATION, DOCUMENTATION, AND RESULTS COMMUNICATION FOR PATIENTS RECEIVING CHRONIC OPIOID THERAPY

Isaac S. Chua[1,2]; Jaime Ransohoff[1]; Zain Virk[2]; Ethan Katznelson[2]; Athena Petrides[6,2]; E. John Orav[1,3]; Christiana Demetriou[4,5]; Stacy Melanson[6,2]; Gordon D. Schiff[7,2]. [1]General Internal Medicine, Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Biostatistics, Harvard T.H. Chan School of Public Health, Boston, MA; [4]Primary Care and Population Health, University of Nicosia Medical School, Nicosia, Cyprus; [5]The Cyprus Institute of Neurology and Genetics, The Cyprus School of Molecular Medicine, Nicosia, Cyprus; [6]Pathology, Brigham and Women's Hospital, Boston, MA; [7]Center for Patient Safety Research, Brigham and Women's Hospital, Boston, MA. (Control ID #3391730)

BACKGROUND: Despite widespread recommendations and utilization of urine drug testing (UDT) to assess adherence in patients receiving chronic opioid therapy (COT), clinicians often fail to correctly interpret UDT results, particularly those UDTs performed by mass spectrometry. A prior study by our group revealed serious quality gaps with clinicians failing to recognize and document aberrant findings, both potentially harmful/consequential errors. We designed an intervention that featured a lab toxicology expert interpretation of the results based on patients' prescribed medication(s).

METHODS: Prospective cohort study with a matched concurrent control evaluated the effectiveness of a laboratory-generated interpretation of UDT results for clinicians prescribing opioids for COT patients at 4 ambulatory clinics (primary care [2], palliative care, and pain management) in a U.S. academic medical center. The intervention group received a written laboratory interpretation in their electronic medical record in-basket for UDTs ordered from November 2018 to May 2019. A concurrent control group was matched to the intervention group by clinic location, level of training, age and sex. After the study period, two blinded reviewers (Z.V., E.K.) reviewed clinician documentation in the pre-intervention and post-intervention periods for both arms. Our primary outcome was concordance between clinician and laboratory interpretation.

Secondary outcomes included provider documentation of UDT results and documented communication of results to the patient. A logistic regression model using generalized estimating equations was used to assess differences in change between intervention and control groups.

RESULTS: A total of 8 intervention clinicians (7 physicians and 1 nurse practitioner; 2 [25%] women) participated: 4 primary care, 2 palliative care, and 2 chronic pain management. Their mean age (SD) was 57.1 (9.8). There was an 87% match between intervention and control group clinician covariates. In both arms, 201 unique patient charts were reviewed: pretest intervention (n=51), posttest intervention (n=50), pretest control (n=50), and posttest control (n=50). When an interpretation was documented, clinician-laboratory interpretation concordance improved from 69% to 88% in the intervention arm compared to a decline from 84% to 77% in the control arm (p=0.07). There were no differences in clinician interpretation documentation (p=0.71) or documented communication of results to patient (p=0.77).

CONCLUSIONS: Implementation of an innovative laboratory-generated UDT interpretation led to improvement in the accuracy of clinician UDT interpretation but was not statistically significant. While this intervention was unable to demonstrate significant changes in clinician documentation of UDT results or results communication to patients, our findings suggest this is a needed and useful service, warranting consideration for routine use for all UDT results.

EFFECTIVENESS OF AN ONLINE WEIGHT MANAGEMENT PROGRAM INTEGRATED WITH POPULATION HEALTH MANAGEMENT SUPPORT IN PRIMARY CARE: RESULTS FROM THE PROPS STUDY (PARTNERSHIPS FOR REDUCING OVERWEIGHT AND OBESITY WITH PATIENT-CENTERED STRATEGIES)

Heather J. Baer[1]; Barbara A. De La Cruz[1]; Ronen Rozenblum[1]; Nyryan V. Nolido[1]; Endel J. Orav[1]; Kristina Secinaro[2]; Jason P. Block[3]; Florencia Halperin[4]; Katherine D. McManus[5]; Louis Aronne[6]; Guadalupe Minero[7]; David W. Bates[1]. [1]DGIM, Brigham and Women's Hospital, Boston, MA; [2]Department of Nutrition, Brigham and Women's Hospital, Boston, MA; [3]Department of Population Medicine, Harvard Pilgrim Health Care Institute/Harvard Medical School, Boston, MA; [4]Endocrinology, BWH, Boston, MA; [5]Nutrition, Brigham and Women's Hospital, Boston, MA; [6]Medicine, Weill Cornell Medical college, New York City, NY; [7]BMIQ Professionals Program, San Diego, CA. (Control ID #3392354)

BACKGROUND: Online programs offer an important opportunity for improving management of overweight and obesity, but they have not been widely implemented in primary care. The purpose of this study was to examine whether an online weight management program integrated with population health management support is an effective strategy for weight loss among primary care patients.

METHODS: We adapted an existing online weight management program (BMIQ) and integrated it with population health management support at primary care practices. We then conducted a pragmatic, cluster-randomized trial in 15 primary care practices (24 clinics) to compare the effectiveness of the combined intervention (CI) with the online weight management program alone (OP) and with usual care (UC). Participants were ages 20 to 70, had body mass index (BMI) ≥ 27 and < 40 kg/m^2, and had hypertension or type 2 diabetes. They attended routine visits at their primary care practices and completed surveys at baseline and 6, 12, and 18 months after enrollment. The primary outcome was change in body weight at 12 months after enrollment, calculated from weights measured at primary care visits and recorded in the electronic health record. Secondary outcomes included percent weight change, $\geq 5\%$ weight loss, and changes in cardiovascular risk factors, self-reported health status, weight-related quality of life, confidence in ability to lose weight, diet, and physical activity. We used repeated measures mixed effects regression models to compare weight change and other outcomes across the three arms.

RESULTS: A total of 840 participants were enrolled in the trial (326 UC, 216 OP, and 298 CI). There was a significant difference in weight change at 12 months across the arms ($p = 0.0002$), with a mean weight loss of 3.0 pounds in the UC arm, 4.1 pounds in the OP arm, and 7.1 pounds in the CI arm. There also was a significant difference in percent weight change at 12 months ($p = 0.002$), with a mean weight loss of 1.6% in the UC group, 1.9% in the OP group, and 3.1% in the CI group. In addition, there was a significant difference in the percentage of patients who had $\geq 5\%$ weight loss across the arms ($p < 0.0001$), with 16.0% in the UC arm, 21.1% in the OP arm, and 32.9% in the CI arm. Finally, there was a significant difference in change in confidence in ability to lose weight ($p = 0.0001$), with a mean decrease of 0.7 points (on a scale from 1-10) in the UC arm and a mean decrease of 0.4 points in the OP arm, but a mean increase of 0.5 points in the CI arm. There were no significant differences in the intervention effects by age, race, or education.

CONCLUSIONS: We found significant differences in weight change and other related outcomes at 12 months across the three arms. These data provide strong evidence for the effectiveness of the online weight management program integrated with population health management support in primary care.

EFFECTIVENESS OF THE PARTYWISE INTERVENTION IN IMPROVING YOUNG WOMEN'S KNOWLEDGE AND SAFE CONSUMPTION OF ALCOHOL; A RANDOMIZED TRIAL

E. Bimla Schwarz[1]; Margaret Fix[1]; Carrie Lewis[1]; Maneesha Muriki[1]; Jason Satterfield[2]. [1]Division of General Medicine, University of California, Davis, Sacramento, CA; [2]Medicine, UCSF, San Francisco, CA. (Control ID #3391938)

BACKGROUND: Alcohol and binge drinking pose significant health risks; nonetheless, binge drinking is relatively common in the United States.

METHODS: We conducted a randomized trial to evaluate the PartyWise intervention which was designed to increase awareness of the risks of binge drinking and sex differences within those risks. Intervention participants received a digital pamphlet by text or email, a link to an educational website http://www.partywise.org/, and up to 8 weekly text messages. A research assistant contacted participants by phone and conducted screening and a brief intervention with referral to treatment if needed. We used social media to recruit 517 women, aged 15-19, who were interested in discussing health issues with their peers and using highly-effective contraception; 260 participants were allocated to the PartyWise intervention; 257 participants were allocated to an attention-control intervention about contraceptive communication. Participants received $25 for each survey they completed. Follow-up data were collected after 3-months from 77% of participants; retention was similar between groups.

RESULTS: Participants' median age was 18 years; 89% were students. Most (70%) were white; 12.5% were Hispanic. At baseline, 60% reported having had more than four alcoholic drinks on at least one occasion in the past month, without differences between groups. Of those who drank alcohol in the past month, more than four alcoholic drinks were reported on a median of 2 (range 1-16) days. Although 91% had participated in a class about alcohol, few could define binge drinking, and only 79% were aware of sex differences in alcohol's effects. Intervention phone calls averaged 6 (median 5, range 4-14) minutes. Risky drinking was identified for 37% of participants who had either consumed alcohol on 6 or more days in the past year and/or had 3 or more alcoholic drinks in a single day in the past year (34%). Of those, who reported risky drinking, 93% accepted referral information and 60% opted to receive weekly text messages for 8 weeks.

At 3-month follow-up, intervention recipients were more likely to know there are sex differences in alcohol's effects (98% vs 82%, $p<0.001$). At 3-month follow up there was a small difference between groups in the median number of days on which alcohol was consumed (3 vs. 4) in the past month; on the days alcohol was consumed, intervention recipients were more likely to report fewer than 3 alcoholic drinks (55% vs 44%, $p=0.05$). In addition, intervention recipients were more likely to report that in the past month they had not consumed 4+ alcoholic drinks on more than one occasion (67% vs 55%, $p=0.054$), although rates of any binge drinking in the past month were similar between groups (40% vs 37%).

CONCLUSIONS: The Partywise intervention is an innovative and promising approach to reducing risks of binge-drinking among young women.

EFFECT OF CAREGIVER BURDEN ON CAREGIVERS' HEALTH BEHAVIORS AND OUTCOMES: A SCOPING REVIEW

Alexandra King[1]; Judy Stribling[2]; Madeline R. Sterling[3]. [1]Internal Medicine, NewYork Presbyterian Cornell, Long Island City, NY; [2]Weill Cornell Medical College, New York, NY; [3]General Internal Medicine, Weill Cornell Medicine, New York, NY. (Control ID #3391635)

BACKGROUND: At least 17.7 million adults in the US provide unpaid support to older adults, with data suggesting that family caregivers provide as much as 90% of this in-home long-term care. Caregiver burden (a.k.a. caregiver strain), defined as the extent to which caregivers perceive that caregiving has had an adverse effect on their emotional, social, financial, physical and spiritual functioning, has the potential to affect caregivers' own health behaviors and outcomes. Herein, we conducted a scoping review of the literature to examine the effect of caregiver burden on the health behaviors and outcomes of caregivers themselves.

METHODS: Guided by a research librarian, we searched three databases (PubMed, Embase, CINAHL) using pre-specified search terms. We included articles published in English from 1999-2019. Non-English, opinion/perspective articles, and qualitative studies were excluded. We used Covidence software to organize and analyze data.

RESULTS: 457 abstracts were screened, 36 underwent full-text review, and 11 met inclusion criteria. The majority of included studies were published from 2011-18 and focused on adult children and spouse caregivers. Six observational studies discussed caregivers' overall health; among them five found highly burdened caregivers to have lower self-reported physical health. Indeed, the converse was also seen; one study found that caregivers with low burden had better overall health than their non-caregiving counterparts. One five-year prospective cohort study found that caregivers with elevated depressive symptoms were more likely to develop self-reported physically co-morbid conditions. Two studies investigated caregiver health behaviors. One found that highly burdened caregivers exercise less, sleep poorly, and are less likely to seek medical care when ill, compared to their less burdened counterparts. The second study found that caregivers of care-recipients with high care needs were more likely to engage in risky health behaviors, such as smoking and difficulty taking medications. Two large prospective cohort studies examined the effect of caregiver burden on all-cause mortality, both finding that highly burdened caregivers had higher mortality risk, compared to less burdened caregivers. Only one study evaluated underlying pathophysiologic mechanisms of these associations, finding that caregiver burden was associated with higher levels of pro-inflammatory cytokines (IL-6, IL-1).

CONCLUSIONS: The majority of existing studies demonstrate that highly burdened caregivers have worse physical health and engage in less healthy behaviors than their less burdened counterparts. Limited data is available regarding caregivers for adults with specific conditions. Although two studies found caregiver burden to be associated with an increase in all-cause mortality, few studies include adjudicated health outcomes for caregivers. Further research is needed to examine these associations longitudinally, in disease- specific contexts, and in more diverse populations.

EFFECT OF COMBINED DEPRESSIVE SYMPTOMS AND GLOBAL COGNITIVE IMPAIRMENT ON ALL-CAUSE MORTALITY AMONG REGARDS STUDY PARTICIPANTS WITH HEART FAILURE

Yulia Khodneva[1]; Parag Goyal[2]; Emily B. Levitan[1]; Raegan Durant[1]; Madeline R. Sterling[3]; Elizabeth Jackson[1]; Andrea L. Cherrington[1]; Monika M. Safford[4]. [1]Medicine, University of Alabama Birmingham, Birmingham, AL; [2]Weil Cornell Medicine, New York, NY; [3]Internal Medicine - Primary Care, New York Presbyterian - Weill Cornell, New York, NY; [4]Department of Medicine, Weill Cornell Medical College, New York, NY. (Control ID #3390412)

BACKGROUND: Depression and cognitive impairment have each been shown to be independently related to premature mortality in heart failure (HF). However, it is unclear if combined depressive symptoms and cognitive impairment present a greater risk for death in HF patients than either condition alone among adult with HF.

METHODS: We utilized Medicare linkage data from the Reasons for Geographical and Racial Difference in Stroke (REGARDS), a biracial prospective cohort of 30,000 US community dwelling adults, aged > 45, recruited in 2003-7, with ongoing follow up. Participants were considered to have HF diagnosis if they had 1 inpatient or 2 outpatient Medicare claims. Depressive symptoms were defined as a score ≥4 on the 4-item Center for Epidemiological Studies-Depression scale (CED-D-4). Global cognitive impairment was a score ≤4 on the Six-Item Screener (SIS) that assessed 3-item recall and orientation to year, month, and day of the week. Deaths were expert-adjudicated. The association between depressive symptoms, cognitive impairment and death were examined in the sequentially adjusted Cox proportional hazard models.

RESULTS: At baseline, 886 REGARDS participants had HF, of them 115 (13%) reported depressive symptoms only, 105 (12%) had global cognitive impairment only and 19 (2%) had both. Over the median of 6.9 years (IQR 3.5-10) of follow-up 599 (68%) persons died. In the unadjusted model, presence of global cognitive impairment only was significantly associated with increased mortality, HR 1.33(95% CI 1.05-1.68), compared to persons with neither depressive symptoms nor cognitive impairment. This was not observed for depressive symptoms only or for a combination of both (table). However, after adjustment for covariates, this association has disappeared. Among covariates, age, gender, income, marital status, history of coronary artery disease, diabetes, smoking, physical inactivity, albumin to creatinine ratio, and lack of statin use were associated with mortality.

CONCLUSIONS: In this nationally representative sample of HF patients neither depressive symptoms nor impaired global cognition nor their combination were associated with all-cause mortality. Rather, increased mortality in HF was explained by health behavior and comorbidities in this study.

EFFECT OF ENTERING MEDICARE FROM PRIVATE INSURANCE ON HEALTH CARE SPENDING, USE, AND PRICE: EVIDENCE FROM THE AGE-65 DISCONTINUITY

Zirui Song[1,2]. [1]Department of Health Care Policy, Harvard Medical School, Boston, MA; [2]Department of Medicine, Massachusetts General Hospital, Boston, MA. (Control ID #3390141)

BACKGROUND: As the nation considers expanding Medicare, the effects of transitioning from private insurance to Medicare on spending, use, and price remain poorly understood. Causal effects of Medicare are hard to measure due to the dearth of individual-linked data before and after age 65. To overcome this challenge, this work uses a regression

discontinuity design to study people who transitioned from private insurance into traditional Medicare (TM) or Medicare Advantage (MA) at age 65. Specifically, it studies 4 distinct transitions: from unmanaged or managed private plans (fee-for-service/PPO or HMO) into unmanaged or managed versions of Medicare (TM or MA).

METHODS: This study used 2007-2017 Marketscan claims data from 278,338 individuals who were enrolled in private insurance and entered Medicare at age 65: 123,426 who transitioned from unmanaged plans (fee-for-service, PPO) into TM (cohort 1), 24,707 from managed care plans (HMO) into TM (cohort 2), 98,714 from unmanaged plans into MA (cohort 3), and 31,491 from managed care plans into MA (cohort 4). There was no entry or exit at the age 65 discontinuity. Regression discontinuity statistical models allowed different age trends before and after 65, with time and individual fixed effects. Standard errors were clustered by individual.

RESULTS: The 278,338 individuals averaged 65.0 years with 55.0% male. Descriptive characteristics and risk scores were similar across cohorts.

On average, entering Medicare led to a 28.3% decrease in outpatient spending ($p<0.001$) and 33.1% decrease in inpatient spending ($p<0.001$) across all cohorts. The effect on outpatient spending was explained by lower prices, and the effect on inpatient spending mostly by lower prices (with one-third of the effect explained by fewer hospitalizations).

Cohorts that transitioned into TM saw larger discontinuities in outpatient and inpatient spending: -47.8% and -51.4%, respectively, for cohort 1, and -57.7% and -58.7%, respectively, for cohort 2 (all $p<0.001$). Lower prices in TM largely explained these effects. These cohorts had base (pre-65) averages of $44-46 in outpatient spending and $187-203 in inpatient spending per member per month (PMPM). In contrast, cohorts that transitioned into MA saw smaller effects: +3.3% ($p=0.04$) in outpatient spending and -9.2% ($p=0.03$) in inpatient spending for cohort 3, and -4.5% ($p=0.20$) and -13.3% ($p=0.06$), respectively, for cohort 4. These cohorts had lower base spending of $37 outpatient and $176-189 inpatient PMPM. Differences in use generally explained these effects. There were no effects at age 65 among SSDI beneficiaries (a falsification test).

CONCLUSIONS: Entering Medicare reduced outpatient and inpatient spending, largely explained by lower prices in Medicare and among individuals who transitioned into TM. These causal estimates inform proposals to expand Medicare or change the Medicare eligibility age. Heterogeneous effects across cohorts may be due to selection into cohorts, payer vs. provider market power, or practice patterns.

EFFECT OF MEDICARE ON PRESCRIPTION DRUG SPENDING, VOLUME, AND PRICE: EVIDENCE FROM THE AGE-65 DISCONTINUITY

Zirui Song[1,2]. [1]Department of Health Care Policy, Harvard Medical School, Boston, MA; [2]Department of Medicine, Massachusetts General Hospital, Boston, MA. (Control ID #3391388)

BACKGROUND: Prescription drug spending has grown rapidly. Unlike physician and hospital services, for which Medicare sets prices, Medicare is legislatively prohibited from negotiating prices for prescription drugs. To date, little is known about the effect of Medicare on prescription drugs relative to private insurers, particularly whether traditional Medicare (TM) and Medicare Advantage (MA) affect prescription drug spending, volume, or pricing differently. Causal estimates of this effect have been difficult to obtain given the shortage of continuous pharmaceutical claims data at the individual level before and after people enter Medicare.

METHODS: Using 2007-2017 Marketscan pharmaceutical claims data, this study follows 278,338 people as they transitioned from private health insurance into Medicare at age 65. This transition occurred in 4 distinct ways: from unmanaged private plans (fee-for-service, PPO) into TM (cohort 1, N=123,426), from managed care plans (HMO) into TM (cohort 2, N=24,707), from unmanaged plans into MA (cohort 3, N=98,714), and from managed care plans into MA (cohort 4, N=31,491). Regression discontinuity models produced the effect of entering Medicare on spending, volume, and price. The statistical model used second-order polynomials that allowed for different age trends before and after 65, with time and individual fixed effects. Standard errors were clustered by individual.

RESULTS: The 278,338 subjects averaged 65.0 years, 55.0% male, and had descriptive characteristics and risk scores that were similar across cohorts.

Entering Medicare led to a $6 per member per month (PMPM) average decrease in prescription drug spending across all cohorts ($p<0.001$), a -2.9% change from a base of $200 PMPM in pre-65 drug spending. Overall, this effect was explained by a lower quantity of prescribed drugs, averaging 1.9 fewer days PMPM supplied in Medicare ($p<0.001$), a -2.2% change from a base of 86.3 days of supply PMPM. On average, prices were higher in Medicare than in private insurance in most classes of drugs.

Effects on spending were larger among cohorts that entered Medicare from managed care plans: -6.1% in cohort 2 and -11.0% in cohort 4 ($p<0.001$), explained by lower quantities supplied with no effects on price. In contrast, effects on spending were smaller among cohorts that entered Medicare from unmanaged plans: +0.2% in cohort 1 ($p=0.76$) and -3.8% in cohort 3 ($p<0.001$) driven by lower quantities supplied.

CONCLUSIONS: The effect of Medicare on spending for prescription drugs was substantially smaller than its effect on spending for physician services and hospitalizations (which are about -30%). This is likely attributable to Medicare's inability to negotiate prices with manufacturers. In prescription drugs, any savings that Medicare achieves relative to private insurance are derived from lower utilization. That MA achieves slightly larger savings than does TM may be attributable to selection into the cohorts, prescribing differences, or heterogeneous PBMs and formularies.

EFFECT OF PRIMARY TEAM ON HEART FAILURE READMISSIONS

Daniel H. Kelly, Haroon M. Mujahid, Emily F. Ware, Robert C. Long, James J. Pitcock, Jamie L. Wagner. Internal Medicine, University of Mississippi Medical Center, Jackson, MS. (Control ID #3388637)

BACKGROUND: An estimated $30.7 billion is spent on heart failure each year, with a significant portion due to readmissions. While follow-up within 7 days of discharge is associated with better outcomes, readmission rates remain high. Thus, a closer inspection of the patients that avoid readmissions is needed to devise a better discharge plan. This study looks to accomplish this by comparing readmission rates and discharge practices of cardiology and internal medicine services.

METHODS: Patients admitted for a heart failure exacerbation between January 1st, 2018 and December 31st, 2018 were included in this single-center retrospective cohort study. Patients were excluded if they had a ventricular assist device, heart transplant, or the advanced heart failure service functioning as the primary team. Included patients were divided into those on the cardiology service vs internal medicine services. The primary objective was to determine the impact of primary team on discharge medication optimization. Secondary outcomes included length of stay, 30-day readmission, and inpatient and 30-day all-cause mortality.

RESULTS: A total of 168 patients were included, with 100 (59.5%) managed by internal medicine, and 68 (40.5%) by cardiology. There was no statistically significant difference in the primary or secondary outcomes. However, it was found that 97% of patients discharged from the cardiology service had documented follow-up appointments, compared to

85.9% of patients discharged from internal medicine (p = 0.018). Of those with a documented follow-up, those discharged from cardiology were more likely to have their appointments scheduled before discharge (75% vs 56%; p=0.019).

CONCLUSIONS: While there was no statistically significant difference in the primary or secondary outcomes, it was found that patients admitted to the internal medicine service had a lower rate of scheduled outpatient follow-up upon discharge. This finding could imply that interdepartmental communication is needed to ensure that patients obtain consistent follow-ups upon discharge. Further data is needed to evaluate if obtaining a cardiology consult translated to more consistently scheduled follow-up appointments.

EFFECT OF SOCIAL DETERMINANTS OF HEALTH ON HOSPITAL RISK SCORE

Shirlene Obuobi[1]; Rhys Chua[3]; Stephanie Besser[3]; Corey Tabit[2]. [1]Internal Medicine, University of Chicago, Chicago, IL; [2]Cardiology, University of Chicago, Chicago, IL; [3]Biological Sciences Division, University of Chicago, Chicago, IL. (Control ID #3391234)

BACKGROUND: The HOSPITAL Risk Score (HRS) is an internationally validated tool used to predict 30- day hospital readmissions. Studies using nationwide datasets have suggested that Social Determinants of Health (SDOH) may have a variable effect on readmission rates. We hypothesized that adding SDOH to the HRS could improve its predictive accuracy.

METHODS: Records of 37,105 inpatient admissions at the University of Chicago Medical Center were reviewed. HRS was calculated for each patient. Census tract-level SDOH were then combined with the HRS and the resultant "social HRS" was compared against the HRS using ROC analysis. Patients were then assigned to 1 of 7 typologies defined by their SDOH (Figure 1) and a balanced dataset of 14,235 admissions was sampled from the larger dataset to avoid over-representation by any 1 sociodemographic group. Principal component analysis was then performed to determine the effect of SDOH on the HRS.

RESULTS: The c-statistic for the HRS predicting 30-day readmission was 0.71, consistent with published values. However, the addition of SDOH to the HRS did not improve the c-statistic (0.68). Patients with unfavorable SDOH (no high-school, limited English, crowded housing, disabilities, and age >65yrs) had higher HRS (p<0.05 for all), although the effect was small. SDOH explained 0.2% of the HRS.

CONCLUSIONS: At an urban tertiary care center, the addition of census tract-level SDOH to the HRS did not improve its predictive power. Rather, the effects of SDOH are already reflected in the HRS, though their overall effects appear very small.

EFFECTS OF A PHYSICIAN COMMUNICATION TRAINING INTERVENTION ON PROCESSES AND OUTCOMES RELATED TO CHRONIC PAIN IN PRIMARY CARE: A RANDOMIZED TRIAL

Stephen G. Henry[1]; Joshua Fenton[2]; Mark D. Sullivan[3]; Cynthia Campbell[4]; Richard L. Kravitz[5]. [1]Internal Medicine, University of California Davis, Sacramento, CA; [2]Family & Community Medicine, University of California, Davis, Sacramento, CA; [3]Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA; [4]Department of Research, Kaiser Permanente, Oakland, CA; [5]General Medicine, UC Davis, Sacramento, CA. (Control ID #3390590)

BACKGROUND: Primary care physicians and patients report that discussions about chronic pain and prescription opioids are often frustrating and unproductive. Interventions that bolster physician communication skills and self-efficacy may improve processes and outcomes of care related to chronic pain.

METHODS: We conducted a pilot randomized controlled trial of a physician communication training intervention to estimate effects on physician communication behavior (primary outcome), physician self-efficacy for pain and opioid-related communication, physician-reported visit difficulty, and patient-reported pain-related interference and visit experience. The intervention consisted of 2 announced standardized patient visits; trained actors portrayed patients on opioids for chronic pain and then provided immediate feedback on physicians' use of targeted communication skills (history taking and report building, goal setting, and treatment planning); the intervention also included a brief didactic video, a pocket card, and a detailed pamphlet. The control was a CDC handout on opioid prescribing. Resident physicians were recruited from 2 academic primary care clinics. Following the intervention, each physician was audio recorded during 1-2 regularly scheduled clinic visits with established patients taking opioids for chronic pain who agreed to enroll in the study. Trained coders assessed physician communication skills from audio recordings and transcripts. Analyses used generalized linear models, accounting for clustering within physician via generalized estimating equations. Models for pain-related interference and self-efficacy controlled for baseline values.

RESULTS: 45 physicians were randomized and received either intervention or control; 37 had a visit recorded with ≥1 study patient and were retained in the primary analysis. 46 patients were recruited (mean age 60, mean pain-related interference 7 out of 10). There was no between-arm difference in the primary outcomes of the number of targeted communication behaviors coded per visit (Incidence Rate Ratio (IRR) 1.28, 95%CI 0.76, 2.13); however, the intervention was associated with significantly more communication behaviors per visit related to history taking and rapport building (IRR 2.20, 95%CI 1.34, 3.61, $P = 0.003$). The intervention was also associated with significantly greater physician self-efficacy for pain and opioid- related communication (β 0.42 on a 5-point scale, 95%CI 0.12, 0.72, $P = 0.006$). There was no significant between-arm difference in pain-related interference, patient experience, or physician-reported visit difficulty.

CONCLUSIONS: An intervention using standardized patient instructors to improve physicians' pain-related communication skills did not improve pain-related interference or use of targeted communication behaviors but did improve physician self-efficacy and improved communication around history taking and rapport building. The efficacy of a modified intervention should be evaluated in fully-powered trial.

EFFECTS OF A STANDARDIZED COMMUNITY HEALTH WORKER INTERVENTION ON HOSPITALIZATION: RESULTS OF A POOLED ANALYSIS OF THREE RANDOMIZED CLINICAL TRIALS

John W. Morgan[1,5]; Aditi Vasan[4]; Nandita Mitra[3]; Chang Xu[2]; Judith A. Long[2,5]; David A. Asch[1]; Shreya Kangovi[2]. [1]Medicine, University of Pennsylvania, Philadelphia, PA; [2]General Internal Medicine, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA; [3]Biostatistics, University of Pennsylvania, Philadelphia, PA; [4]Pediatrics, Childrens Hospital of Philadelphia, Philadelphia, PA; [5]Medicine, Philadelphia VA Medical Center, Philadelphia, PA. (Control ID #3374490)

BACKGROUND: Low income individuals are at high risk of frequent hospitalizations to multiple hospitals, which is associated with increased mortality and higher costs of care. Social determinants of health are increasingly recognized as targets for reducing healthcare costs,

improving quality, and increasing equity of care. Community health workers (CHWs)—trusted laypeople with similar backgrounds to patients—are well- positioned to address social determinants but evidence of their ability to reduce hospital utilization is limited. *Individualized Management for Patient-Centered Targets* (IMPaCT) is a standardized model utilizing specially trained CHWs to provide social support, health behavior coaching, and health services navigation.

METHODS: We pooled data from our three two-armed, single-blinded randomized clinical trials comparing IMPACT with usual care (n = 1340) at a single academic center between 2011 and 2016. All three trials utilized a common study design, intervention and outcomes, but were not powered to assess hospital utilization. Inclusion criteria included English-speaking adults from high-poverty regions of Philadelphia who were uninsured or Medicaid-insured. Trial one (n=446) tested 2 weeks of IMPaCT among hospitalized medicine patients. Trials two and three (n=302 and 592, respectively) tested 6 months of IMPaCT among outpatients at academic, Veterans Affairs (VA), and Federally Qualified Health Center primary care practices. Our primary pooled outcome is hospital days per patient. Our secondary outcome is fragmentation of hospital care, defined as the proportion of hospitalizations outside patients' primary health system. Hospitalization data were collected from statewide and VA databases. Binary and continuous outcomes were analyzed using mixed effects logistic and linear regression, respectively, with negative binomial regression used for skewed outcomes. We included indicators for trial and recruitment site, with incorporation of random effects to account for within site clustering.

RESULTS: Baseline demographic characteristics were similar between pooled intervention and control groups. Over 9398 observed patient months, the number of hospital days per patient in the intervention versus control group was 1.26 vs. 1.90 (incidence rate ratio 0.66; 95% CI 0.56 - 0.77; p<0.0001). Results were driven by fewer hospitalizations per patient (0.27 vs. 0.34; p<0.0001) and shorter mean length of stay (4.72 vs. 5.57; p = 0.03) in the intervention versus control groups. The intervention decreased rates of hospitalization outside patients' primary health system (18.8% vs. 34.8%; p = 0.0016).

CONCLUSIONS: Pooled data from three randomized clinical trials across multiple settings show a standardized CHW intervention reduced hospital utilization and fragmentation of care among a population of socioeconomically disadvantaged participants. This is the largest analysis of randomized trials to demonstrate reductions in hospitalization with a health-system based social intervention.

EFFECTS OF SOCIAL DETERMINANTS OF HEALTH AS RISK FACTORS FOR GLYCEMIC CONTROL: AN ANALYSIS OF PATIENTS IN THE MIAMI VA HEALTHCARE SYSTEM.

Elizabeth Bast[1]; Jason Dahn[1]; Fei Tang[2]; Leonardo Tamariz[3]; Ana Palacio[3,1]. [1]Internal Medicine, Miami VA Medical Center, Miami, FL; [2]Miami VA, Miami, FL; [3]Medicine, University of Miami, Miami, FL. (Control ID #3392179)

BACKGROUND: The risk of diabetes continues to rise and will affect half a billion people by 2030. Disadvantaged groups may be at even higher risk of diabetes. Veterans are more likely to experience physical, social or psychological adversities. We aim to evaluate the role that social determinants of health play on incident diabetes among Veterans in South Florida.

METHODS: We conducted a retrospective cohort study of all Veterans who had at least two Hemoglobin A1C values measured between 2015 and 2019 and who receive primary care at the Miami VA Healthcare System. We used a previously validated algorithm to categorize Veterans into 4 mutually exclusive glycemic (A1C) categories at baseline and at follow up: normal<5.7, low risk prediabetes (5.7-6.0), high risk prediabetes (6.1-6.4) and diabetes. We collected from the Computerized Patient Record System (CPRS) demographic data and social determinants of health such as age, sex, marital status, homelessness, census based zip code data (mean household income, median household income, Gini index), mental health diagnoses and attendance to lifestyle modification clinics. We report glycemic control at baseline and its correlates, diabetes conversion rate at follow up and used multivariable ordinal logistic regression models to test predictors of worsening glycemic status.

RESULTS:

In a multivariate ordinal regression model BMI, age, Black race, male gender, marital status, percent of population below the poverty line and GINI index by zip code were significantly associated with worsened glycemic control (p<0.01).

In the cohort of patients with high-risk prediabetes, the 3 year conversion rate was 12% and increased BMI, age, and male gender were highly associated with progression disease (p <0.01). Being separated had worse status compared to being married and compared to non-Hispanic white, being black was associated with worse glycemic outcome (p<0.01), while Hispanic showed a non-significant trend towards worsening glycemic status. Attending at least four visits to either a nutritionist or the MOVE program was significantly associated with better glycemic status.

CONCLUSIONS: Among Veterans, in adjusted models black race, income and GINI index were associated with worse glycemic status at baseline and among high risk prediabetics, black race, not being married were associated with high risk of developing diabetes within 3 years. This risk is mitigated by participation in lifestyle modification clinics.

EFFECTS OF THE AFFORDABLE CARE ACT ON SAFETY-NET HOSPITAL FINANCIAL MARGINS AND QUALITY

Paula Chatterjee[1]; Mingyu Qi[2]; Rachel M. Werner[3]. [1]General Internal Medicine, University of Pennsylvania, Philadelphia, PA; [2]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; [3]Medicine, University of Pennsylvania and Philadelphia VA, Philadelphia, PA. (Control ID #3391987)

BACKGROUND: Safety-net hospitals (SNHs), which care for uninsured and low-income patients, provide the bulk of uncompensated care in the US. The expansion of Medicaid under the Affordable Care Act (ACA) may have been of particular benefit to SNHs in that its passage has been associated with reductions in uncompensated hospital care. Furthermore, if SNHs can improve their financial circumstances, this could translate to improvements in quality of care. However, whether financial margins or quality at SNHs improved as a result of the ACA remains unknown.

METHODS: Difference-in-differences (DID) linear regression comparing changes over time in financial parameters, patient experience, and clinical outcomes between SNHs in states that expanded Medicaid in 2014 compared to those that did not.

RESULTS: From 2011-2016, we identified 376 SNHs, defined as hospitals in the highest quartile of uncompensated care costs out of total operating expenditures, averaged over a baseline period (2011-2013). Among SNHs, 167 were in states that did not expand Medicaid and 209 were in states that did. SNHs in expansion states were more often in the Northeast (21.0% in expansion states vs. 9.9% in non-expansion states, p<0.001) and were more likely to be non-profit (58.1% vs. 45.2%, p<0.001). Baseline levels of uncompensated care were similar between both groups (1.11 vs. 1.19, p=0.05). Following the ACA, SNHs in expansion states had greater reductions in uncompensated care (DID=-0.21, p=0.003), though other markers of financial health, such as net hospital operating revenues (DID=-$529,769, p=0.80) or operating margins (DID=1.09, p=0.61) did not significantly change. SNHs in states that expanded Medicaid had a small improvement in all-cause readmission

rates following the ACA as compared to SNHs in non-expansion states (DID=-0.37%, p<0.001); however, there were no differences in quality of patient experience (-0.39% change in overall hospital rating, p=0.58), condition-specific readmission rates (-0.09% change in 30-day heart failure readmissions, p=0.69; -0.10% change in acute myocardial infarction 30-day readmissions, p=0.70; -0.38% change in 30-day pneumonia readmissions), or condition-specific mortality rates (0.03% change in 30-day heart failure mortality, p=0.89; 0.13% change in 30-day acute myocardial infarction mortality, p=0.43; -0.04% change in 30-day pneumonia mortality, p=0.86).

CONCLUSIONS: Medicaid expansion under the ACA was associated with reductions in uncompensated care at SNHs; however, other markers of hospital financial status did not improve. Despite reductions in uncompensated care, SNHs only showed modest improvements in quality in the single dimension of all-cause readmissions, with no improvements in other quality measures. Future work should examine why reductions in uncompensated care have not translated into broader improvements in the financial circumstances of these hospitals, and how these barriers might limit their ability to invest in quality improvement efforts.

EFFECTS OF THE ELIMINATION OF THE FREE TEXT FIELD IN ACR SELECT ON ORDERING TRENDS FOR LOW BACK PAIN IMAGING IN THE EMERGENCY DEPARTMENT

Vineel Mallavarapu[1]; Kyle Christiason[2]. [1]Molecular and Cellular Biology, Johns Hopkins University, Cedar Falls, IA; [2]Family Medicine, UnityPoint Clinic, Cedar Falls, IA. (Control ID #3391930)

BACKGROUND: Low back pain (LBP) is a common condition that affects around 80% of all adults at some point during their lives, and is the second most common reason for provider visits in the United States. Several studies suggest that routine imaging for acute LBP has no observable benefit and in fact, leads to excess costs and increased risk of patient harm, especially if it leads to unnecessary clinical interventions. The utilization of computerized alerts within electronic medical records attempt to support appropriate clinical decision making. ACR Select is a clinical decision support database which is based on the American College of Radiology (ACR) Appropriateness Criteria, intended to improve advanced imaging decisions for patient care.

Allen Hospital, a 204-bed community hospital located in Waterloo, Iowa, underwent a modification to its clinical decision support system in April, 2017. The "free text" field, which allowed providers to bypass the ACR Select tool within Epic electronic health records, was removed. The intended purpose of this modification was to increase provider adherence to the ACR Select tool, encouraging the ordering provider to match the appropriate advanced image order to the most appropriate documented indication. The objective of our study was to examine the patterns of ordering advanced imaging for the evaluation of lower back pain in the emergency department, after the "free text" field was removed from the ACR Select clinical decision support tool.

METHODS: Quantitative data was retrospectively collected utilizing UnityPoint Health electronic medical records and health informatics after approval by the Allen College IRB. UnityPoint Health is a healthcare organization serving areas in Iowa, Illinois, and Wisconsin. Data was collected from the emergency department of Allen Hospital in Waterloo, Iowa using the primary diagnosis code of "Acute Low Back Pain," and ICD-10 codes of 351, 352, 610, 611, and 612. The number of CT scans and MRIs were tracked 12 months prior to and 10 months after the modification. Monthly trends in ordering patterns were compared using a two-sample t-test. A total of 19,233 records were reviewed for this time period, and 287 scans satisfied the inclusion criteria.

RESULTS: After aggregating the data by month, there was an average of 13 scans per month prior to the modification, and 11.6 scans per month after the modification. However, results from the two-sample t-test indicate that this difference was not statistically significant (p=.54).

CONCLUSIONS: Elimination of the "free text" field within ACR select was not enough to modify provider behavior. This suggests that providers predetermine their decisions when ordering advanced imaging procedures, which could lead to ignoring ACR select prompts when certain orders are flagged. Other strategies to modify provider ordering behavior and increase provider adherence to clinical decision support tools may need to be considered.

EFFICACY OF OPICAPONE COMPARED TO ENTACAPONE IN PARKINSON'S PATIENTS WITH MOTOR FLUCTUATIONS AND ON HOEHN & YAHR ≤2.5: A POST HOC ANALYSIS OF BIPARK-1

Mark Lew[2]; Robert Hauser[3]; Stuart Isaacson[4]; Joaquim J. Ferreira[5]; Michael Serbin[1]; Khodayar Farahmand[6]; Olga Klepitskaya[6]; Francisco Rocha[7]; Patrício Soares-da-Silva[7,8]; Grace Liang[6]. [1]Medical Affairs - HEOR, Neurocrine Biosciences, Inc., San Diego, CA; [2]University of Southern California, Los Angeles, CA; [3]University of South Florida, Tampa, FL; [4]Florida International University Herbert Wertheim College of Medicine, Miami, FL; [5]Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal; [6]Neurocrine Biosciences, Inc., San Diego, CA; [7]BIAL-Portela & Ca SA, Sao Mamede do Coronado, Portugal; [8]University Porto, Porto, Portugal. (Control ID #3391354)

BACKGROUND: Opicapone is a catechol-O-methyltransferase (COMT) inhibitor approved in Europe and under US FDA review as an adjunct to carbidopa/levodopa for Parkinson's disease (PD) patients experiencing OFF episodes. In the Phase 3 BIPARK-1 (NCT01568073) study, opicapone met the predefined non-inferiority criteria versus entacapone and statistical significance versus placebo for change in absolute OFF-time (primary endpoint). The objective of this post hoc analysis was to compare the efficacy of opicapone versus entacapone in a subgroup of PD patients with motor fluctuations and a lower baseline Hoehn and Yahr (H&Y) stage (1-2.5) in the ON-state.

METHODS: This analysis included BIPARK-1 participants with a baseline H&Y of 1-2.5 in the ON-state who received opicapone 50mg or entacapone 200mg for 14-15 weeks. The population was categorized by OFF-time at baseline in 30-minute increments starting with >90 minutes. Outcomes included mean changes from baseline (±standard error) in absolute OFF-time and UPDRS III during ON based on a mixed model for repeated measures.

RESULTS: The analysis included 157 BIPARK-1 participants with H&Y of 1-2.5 (opicapone 50 mg [n=74], entacapone 200 mg [n=83]). At Week 14/15 in the subgroup with >90 minutes of baseline OFF-time, opicapone treatment resulted in a numerically greater reduction in OFF-time (opicapone, -121.9±17.0; entacapone, -105.7±16.3 minutes; P=0.46) and a significant reduction in UPDRS III score (opicapone, -4.6±0.8; entacapone, -2.4 ±0.8; P=0.04 versus entacapone). Improvements in OFF-time and UPDRS III score were more pronounced in participants with >450 minutes of OFF-time at baseline: OFF-time (opicapone, -168.3 ±37.9; entacapone, -118.7±32.1; P=0.27); UPDRS III score (opicapone, -7.0±2.0; entacapone, -1.6±1.7; P=0.03).

CONCLUSIONS: In BIPARK-1 participants with PD motor fluctuations and baseline H&Y stage 1-2.5, treatment with once-daily

opicapone 50mg resulted in numerically greater OFF-time reduction and significant UPDRS III score improvement compared to entacapone.

ELECTRONIC CONSULTS IN A LARGE SAFETY NET SYSTEM IMPROVE WAIT TIMES

Michael L. Barnett[1]; Hannah Byrnes-Enoch[2]; Xuan Xue[2]; Marema Gaye[1]; Ateev Mehrotra[3]. [1]Health Policy and Management, Harvard T.H. Chan School of Public Health, Boston, MA; [2]NYC H+H, New York City, NY; [3]Health Care Policy, Harvard Medical School, Boston, MA. (Control ID #3391114)

BACKGROUND: Lack of timely access to specialty care is a persistent challenge in safety-net systems. To address this challenge, New York City Health + Hospitals (H+H), the nation's largest public health system serving over 1 million New Yorkers, rolled out an electronic specialty referral system ("eConsult") to improve specialty access. In the eConsult model, primary care providers (PCPs) request all specialty input electronically. The eConsults are reviewed by a specialist within 72 hours, who can decide to address questions via electronic dialogue or a face-to-face visit with the patient. We examined the association between H+H eConsult adoption on specialty appointment wait times.

METHODS: Using data from July 2016 through July 2019, we performed an interrupted time series analysis of specialty referrals from 36 months prior to 6 months after eConsult implementation at 9 specialty departments in 3 hospitals. This was among the first wave of eConsult adoption. Our primary outcome was time until a scheduled appointment after specialty referral. Secondary outcomes were monthly volume of specialty referrals and what fraction of specialty referrals post eConsult implementation were resolved without a face-to-face visit. We used linear regression to estimate the average change in these outcomes after eConsult adjusting for specialty and facility fixed effects.

RESULTS: Across the 9 specialty departments, there were 20,981 referral requests (583 per month) in the 36 months prior to eConsult and 3,481 requests (580 per month) in the 6 months post-eConsult implementation (p=0.44 for change). After implementation, 24% of referral requests were resolved without a face-to-face appointment, ranging from 13% in urology to 40% in gastroenterology. The average wait time to appointment decreased from 53.6 days pre-implementation to 39.8 days post-eConsult implementation (p<0.001), a 26% relative decrease. All 9 specialty departments individually had statistically significant decreases in wait time. The proportion of appointments scheduled within 30 days increased from 37% of visits pre-implementation to 53% post-eConsult (p<0.001). The largest increases were observed in endocrinology (16% to 31%) and gastroenterology (51% to 82%).

CONCLUSIONS: Adoption of the eConsult system in the largest safety net system in the US was associated with a substantial decrease in average wait time after 6 months. Roughly 1 in 4 referral requests were addressed without a face-to-visit, though this varied by specialty. This likely opened up scheduling space for patients whose care required face-to-face specialist interaction without increasing specialty referral volume. To our knowledge, this is the first multi-specialty evaluation of changes access with eConsult following outcomes pre- and post-implementation. Additional research is needed to assess the effects of these changes on provider workflow, patient outcomes and satisfaction.

ELECTRONIC SCREENING AND CLINICAL DECISION SUPPORT FOR DRUG USE BRIEF INTERVENTION IN PRIMARY CARE: RESULTS FROM A PILOT STUDY OF THE SUBSTANCE USE SCREENING AND INTERVENTION TOOL (SUSIT)

Jennifer McNeely[1,2]; Medha Mazumdar[1]; Antonia Polyn[1]; Noa Appleton[1]; Steven Floyd[1]; Akarsh Sharma[1]; Charles Cleland[1]. [1]Population Health, NYU Grossman School of Medicine, New York, NY; [2]Medicine, Division of General Internal Medicine and Clinical Innovation, NYU Grossman School of Medicine, New York, NY. (Control ID #3390676)

BACKGROUND: Primary care providers (PCPs) face multiple barriers to offering substance use interventions, including lack of time, knowledge, and information about their patients' drug use. We developed a tablet-based Substance Use Screening and Intervention Tool (SUSIT) to assist PCPs by delivering screening results and clinical decision support for conducting a brief intervention (BI) to address unhealthy drug use. The SUSIT screener is an electronic self-administered tool consisting of the Substance Use Brief Screen (SUBS), followed by a modified World Health Organization Alcohol, Smoking and Substance Involvement Screening Test (WHO-ASSIST) for those who screen positive. The objectives of this pilot study were to: 1) assess whether the SUSIT could increase delivery of BI during primary care visits (primary aim); and 2) evaluate the impact of the SUSIT on patients' drug use

METHODS: A pre-post design compared a control period to an intervention period during which PCPs received the SUSIT. Adult patients completed screening in the waiting room and identified their drug of most concern (DOMC); those with moderate-risk use of any drug (without high-risk alcohol or drug use) were eligible. Patients completed an after-visit survey documenting BI delivery by the PCP, and a 90-day timeline follow-back measuring drug and alcohol use at baseline and 3 months. Multilevel models with random intercepts and patients nested within PCPs examined the effect of the SUSIT intervention on PCP delivery of BI and on patient drug use.

RESULTS: 27 PCPs and 78 unique patients (42 control, 36 intervention) participated. Patients were 76% male, with mean age of 46 (SD=13). Marijuana was the most prevalent DOMC (n=53; 68%); cocaine was the second (n=7; 9.0%). Mean days of DOMC use at baseline was 38.8 (SD=37.7) days of use in the past 90 days. During the intervention period, PCPs used the SUSIT with 86% of patient participants. Patients in the intervention condition were more likely to report receiving any BI [91.7% vs. 40.5%, P<0.001], and receiving more elements of BI [mean 8.7 (SD=4.8) vs. mean 3.1 (SD=4.7); P<0.001]. Patients in the intervention had 6.4 fewer days of use of the DOMC at 3 months (95% CI: -36.1-23.3) in the adjusted model, in comparison to the control condition.

CONCLUSIONS: Using the SUSIT to provide drug use screening results and clinical decision support increased PCP delivery of BI during routine primary care visits. The SUSIT showed promise for facilitating the delivery of effective BI to reduce moderate-risk drug use among primary care patients, and warrants further study in a larger sample.

EMBEDDING COMMUNITY HEALTH WORKERS (CHWS) IN A SAFETY-NET PRIMARY CARE SETTING FOR COMPLEX CARE IN LOS ANGELES THROUGH THE CARE CONNECTIONS PROGRAM: PERSPECTIVES FROM CHWS AND PATIENTS

Arleen F. Brown[1]; Heidi Behforouz[2]; Savanna Carson[1]; Lydia Zacher Dixon[3]; Sheba George[4]; Jenebah Lewis[2]; Maria Morales[1]; Courtney Porter[2]; Ami Shah[2]; Stefanie D. Vassar[6]; Clemens S. Hong[5]. [1]Division of General Internal Medicine and Health Service Research, UCLA, Los Angeles, CA; [2]Department of Health Services, Los Angeles County, Los

Angeles, CA; [3]Health Science, California State University, Channel Islands, Camarillo, CA; [4]Charles Drew University, Los Angeles, CA; [5]Department of Health Services, Los Angeles County, Los Angeles, CA; [6]Division of Internal Medicine & Health Service Research, UCLA, Los Angeles, CA. (Control ID #3391871)

BACKGROUND: Although primary care has been shown to improve outcomes for high risk, vulnerable patients, these patients disproportionately use acute services for routine medical care, contributing to disparities and higher healthcare costs. The Care Connections Program aimed to promote primary care utilization by embedding community health workers (CHWs) in eight clinics in the Los Angeles County Department of Health Services. Through clinic, home, and phone visits, CHWs helped clinically and socially complex patients navigate the healthcare system and linked them to community resources. We conducted patient and CHW focus groups to obtain perspectives on the impact of the newly implemented program.

METHODS: Five patient focus groups, two conducted in English (n=12) and three conducted in Spanish (n=12), solicited perspectives regarding barriers and facilitators to accessing care and the impact of CHWs on their engagement in care. Four focus groups with CHWs (n=16) solicited perspectives regarding program implementation and the effect on patient barriers in primary care. Thematic analysis was performed in ATLAS.ti.

RESULTS: Patients and CHWs described several communication barriers: patient literacy and language barriers, mistrust, and poor connection with providers. Unique themes identified by patients included obstacles in navigating the healthcare system (i.e., tracking and attending appointments, medication management, transportation). A patient explains, "*I used to leave the same way I entered the place because I didn't understand a word they said*." CHWs also identified social determinants, mental health, and system barriers (i.e., lack of physician time, dysfunctional physician-patient interactions, power imbalances, and perceived mistreatment by clinic staff). A CHW states, "*the greatest advantage that we have is the opportunity to go into their homes and see how they live, how they eat or what they're not eating, or don't have access to*."

In discussing how the CHWs influenced patient barriers to receipt of primary care, patients and CHWs described linkage to resources, health coaching, and empowerment of patients to advocate in care. Patients also identified CHW influences on care coordination and comprehension of care, while CHWs emphasized increasing provider understanding of patient priorities and social needs to improve treatment. Both patients and CHWs highlighted the importance of establishing trust in the patient-CHW relationship, as a patient explains, "*the doctor gives you medications, but she heals you inside by listening to you*."

CONCLUSIONS: Clinically and socially complex patients in the safety net face unique barriers in primary care. CHWs help to promote primary care engagement for high-risk patients by serving as a bridge between patients, providers, the healthcare system and the community. Further work is needed on strategies to optimize the CHW role and understand the long term impact on patients and health systems.

EMERGENCY CARE TRENDS AMONG UNDOCUMENTED IMMIGRANTS, 2014-2018

Joseph Nwadiuko[1]; Kavita Chapla[2]; Jashalynn German[3]; Frances Wang[3]; Sarah Polk[4]. [1]Internal Medicine, University of Pennsylvania School of Medicine, Philadelphia, PA; [2]Internal Medicine, Johns Hopkins School of Medicine, Baltimore, MD; [3]Internal Medicine, Johns Hopkins Bayview Medical Center, Baltimore, MD; [4]Johns Hopkins School of Medicine, Pediatrics, Baltimore, MD. (Control ID #3392150)

BACKGROUND: Anti-immigrant rhetoric has increased since the 2016 presidential election. Increased immigration enforcement may discourage undocumented patients from receiving healthcare. Prior studies have demonstrated a decrease in primary care and inpatient hospitalizations since the June 2015 announcement of President Trump's campaign, but there is no data available regarding emergency care utilization trends during this period.

METHODS: The following study analyzes trends in emergency care utilization in a pool of low income, Medicaid-ineligible patients (composed of a predominantly (92%) undocumented population) and Medicaid controls receiving care at two hospitals in a mid-Atlantic health system between 2014-2018. Medicaid-ineligible patients were identified by membership in charity and sliding scale programs sponsored by the health system that provide primary, subspecialty and emergency/inpatient care. To be included in analysis, patients must have had a single primary care visit between January 1, 2014-October 31, 2015 covered by Medicaid or the charity/sliding scale program and not have died before the 2016 election. Visit records were extracted from the health system's electronic medical record system. Estimates were calculated using a mixed effect model, controlling for age and gender and baseline comorbidity.

RESULTS: There are 17,504 patients in the sample, 1,429 (8%) in the Medicaid-ineligible group and 16,075 (92%) in the Medicaid-insured group. Emergency care utilization data were just made available by the health system and analysis is underway.

CONCLUSIONS: Foregoing healthcare for whatever reason can result in poorer health outcomes. For the sake of positive population health outcomes, health systems and municipalities need to understand the healthcare utilization trends of vulnerable communities in order to respond in their best interests.

EMERGENCY CONTRACEPTION ACCESS IN A HISTORIC SOUTHERN CITY: MYSTERY CALLER STUDY IN BIRMINGHAM, ALABAMA

HeaMi Yi[1]; Carol A. Stamm[2]; Laura Borgelt[3]; Wei-San Mondie[4]; Leanne Rupp[5]. [1]College of Liberal Arts and Sciences, University of Colorado Denver, Denver, CO; [2]General Internal Medicine, University of Colorado Health Sciences Center, Denver, CO; [3]Clinical Pharmacy and Family Medicine, University of Colorado Anschutz Medical Campus, Aurora, CO; [4]Family Medicine, University of Colorado, Englewood, CO; [5]Uptown Primary Care, The Colorado Health Foundation, Denver, CO. (Control ID #3390773)

BACKGROUND: Emergency contraception pills (ECPs) may be taken after unprotected intercourse or contraceptive failure. There are two widely available types in the USA: levonorgestrel and ulipristal acetate pills. Mystery shopper studies have shown that access has improved, but barriers remain. We explored ECP access in Birmingham, Alabama, which has been previously understudied. This is important because Alabama recently passed legislation that may severely restrict abortion access, so it is essential to understand if emergency contraception access is adequate in this geographic region.

METHODS: A list of independent, chain, and 24-hour retail pharmacies for the city of Birmingham proper was generated using referenceUSA, a pubic database, and then cross-referenced with Anthem and VIVA pharmacy directories. Exclusion criteria included specialty pharmacies, compounding pharmacies, permanently closed pharmacies, and pharmacies that are not open to the general public. A standardized telephone script was developed to call up to 85 pharmacies that met the initial inclusion criteria. Data from the calls will be uploaded into the REDCAP electronic data capture system for further statistical analysis regarding ECP availability and accessibility.

RESULTS: We have submitted the project to the institutional review board (IRB). In our preparation, we called five pharmacies in the surrounding areas to test our telephone script. We found that only two of the five had ECPs immediately in-stock. We anticipate IRB approval soon and can make all calls within a two- day period once IRB approval is gained. We do not anticipate difficulty getting this study approved, completed, and analyzed by the conference date based on our past experience with this type of research.

CONCLUSIONS: ECPs are important for women who face contraceptive failure or non-use. Recognizing how accessible ECPs are in Birmingham, Alabama can help policy makers understand the impact of legislation involving contraception and abortion. We hope this study will bring useful policy information to the city of Birmingham, Alabama where there is currently a need for an ECP access study.

EMPATHY CHANGE AND PARTICIPATION IN A PRIMARY CARE STUDENT-FACULTY COLLABORATIVE CLINIC

Mie Hashimoto, Sydney Howard, Gina R. Kruse, Marya J. Cohen. Division of General Internal Medicine, Massachusetts General Hospital, Boston, MA. (Control ID #3391396)

BACKGROUND: Physician empathy is an important correlate of quality of care and patient satisfaction. It is important to understand how medical education influences empathy. Previous studies show that medical students' empathy scores decrease throughout their academic career. At the Crimson Care Collaborative (CCC), a student-faculty collaborative of seven clinics where students are engaged in all parts of clinic operations, patient care, and research, students gain experience in a primary care setting with longitudinal relationships and underserved populations around Boston. Our objective was to explore the relationship between CCC participation, career interest, and empathy.

METHODS: Harvard Medical School students accepted into CCC are asked to complete a pre-survey measuring career interests and empathy using the Jefferson Scale of Empathy (JSE) student version at CCC orientation prior to their first clinic. On Match day, CCC students are invited to complete a post-survey regarding CCC experience and the JSE. Composite empathy scores are calculated with the JSE from the pre- and post-surveys. Scores range from 20 to 140, with higher scores indicating greater empathy. We used linear regression models to measure association between semesters of CCC participation and change in empathy score adjusting for baseline score, time between surveys, demographics, and career interests.

RESULTS: From 2011-2019, we collected 149 Match day post-surveys. Of these, 52 students completed the JSE and provided identifiable information to allow matching with a pre-survey. Matched surveys did not differ from the unmatched surveys by demographics, participation, or career interests. In the matched sample, mean age was 26.3 years, 38.5% were male, 94.2% were single, 44.2% identified as white, 40.4% Asian/Pacific Islander, 7.7% black, and 9.6% Hispanic. Pre-CCC mean empathy score was 117.1 and post- CCC score was 119.3 ($p=0.24$). Mean time between surveys was 3.1 years. In models adjusting for pre-CCC score, years between surveys was positively associated with empathy ($\beta=2.82$, $p=0.03$), but semesters of CCC participation was not ($\beta=-1.35$, $p=0.17$). When demographics and career interests were added to the model, independent variables did not reach statistical significance, including female gender ($\beta=5.48$, $p=0.10$), Hispanic ethnicity ($\beta=-12.55$, $p=0.09$), interest in primary care ($\beta=-3.17$, $p=0.22$), importance of patient relationships ($\beta=7.70$, $p=0.05$), and semesters of CCC ($\beta=-1.35$, 0.22).

CONCLUSIONS: Among students participating in a student-faculty collaborative clinic, more time spent participating in the collaborative clinic was not associated with increased empathy, but in contrast to prior studies, empathy increased over time in this group. Further work is needed to understand what influenced the observed increase in empathy among CCC students. These results could have implications in implementing student-faculty collaboratives as part of the medical education curriculum.

EMPOWERING MEDICAL ASSISTANTS TO INCREASE INFLUENZA VACCINATION RATES IN AN URBAN ACADEMIC PRIMARY CARE CLINIC: AN INTERPROFESSIONAL QI PROJECT

Stanley Cheng[1]; Jonathan De Shields[1]; Richard Cui[1]; John H. O'Neill[2]; Gretchen Rickards[2]. [1]Internal Medicine, Christiana Care, Bear, DE; [2]Medicine, Christiana Care Health System, Middletown, DE. (Control ID #3391817)

BACKGROUND: Influenza vaccination is recommended in all persons $\geq$ 6 months without contraindications but significant health disparities in immunization rates exist.1 In 2016-2017, the influenza vaccination rate in our resident clinic was 38% compared to the national average of roughly 50%.2 However, preliminary work revealed a significant data gap, as the influenza immunization status was not recorded for 42% of patients. Process analysis also revealed marked workflow variability among the medical assistants (MAs) administering the vaccines.3 The goal of this project was to increase influenza vaccination rates in a racially diverse, academic primary care practice in the latter half of the 2018-2019 influenza season through a medical assistant-led initiative, with a focus on standardization of processes and documentation.

METHODS: A MA-led influenza vaccination intervention was developed which included enhanced education and standardization of processes and documentation. Two Plan-Do-Study-Act (PDSA) cycles were performed in December 2018 and January 2019 which included peer-driven engagement among MAs, objective feedback on vaccination and documentation performance, and a competition among MA care teams. Influenza vaccination status was obtained through sequential chart review of adult patients seen in clinic, performed monthly from November 2018 to February 2019 with 459 unique patient visits reviewed. MAs were surveyed for feedback at the end of the intervention period in March 2019.

RESULTS: Influenza vaccination rates of patients seen in clinic increased nearly 20% over the intervention period (48% to 65% from November to January). The data capture rate of influenza vaccination status increased from 58% to 82% over the same period. The influenza vaccination rate was sustained in February at 67%. The post-intervention survey of MAs (n=7) found all were aware of the flu vaccination initiative, all changed their intake and documentation practices due to the intervention, and nearly all (6/7) strongly agreed that a midseason data update "motivated me to support the flu vaccination cause."

CONCLUSIONS: Medical assistants are on the front lines of vaccination processes in primary care. Targeted interventions to enhance MA training, standardize processes and documentation, and incentivize MA vaccination activities can significantly enhance vaccination rates and practices in at-risk communities.

Vaccination rates can be sustained throughout the season when MAs are motivated to the cause.

EMULATING A CAROTID TRIAL USING OBSERVATIONAL DATA: COMPARATIVE EFFECTIVENESS OF REVASCULARIZATION COMPARED TO MEDICAL THERAPY FOR PATIENTS WITH ASYMPTOMATIC CAROTID STENOSIS

Salomeh Keyhani[1]; Eric M. Cheng[2]; Katherine J. Hoggatt[1]; Peter C. Austin[3]; Erin Madden[4]; Paul Hebert[9]; Ethan Halm[5]; Ayman Naseri[6];

Jason Johanning[7]; Danielle Mowery[8]; Wendy Chapman[8]; Dawn Bravata[10]. [1]Medicine, University of California at San Francisco, San Francisco, CA; [2]Neurology, UCLA, Los Angeles, CA; [3]ICES, Toronto, ON, Canada; [4]Research, NCIRE, SAn Francisco, CA; [5]Internal Medicine, Univ of TX Southwestern Med Ctr, Dallas, TX; [6]Ophthalmology, UCSF, San Francisco, CA; [7]Vascular Surgery, University of Nebraska, Nebraska, NE; [8]Biomedical Informatics, University of Utah, Salt Lake City, UT; [9]Puget Sound VA, Seattle, WA; [10]Indianapolis VA, Indianapolis, IN. (Control ID #3372474)

BACKGROUND: Carotid endarterectomy (CEA) is a primary prevention surgery that prevents stroke among patients with asymptomatic carotid stenosis. CEA involves a tradeoff between higher perioperative short-term risks in exchange for a lower long-term risk of stroke. However, the secular declines in stroke rates raise concerns that CEA may no longer be superior to medical therapy. Furthermore, outcomes in real world practice may differ from those observed in randomized controlled trials (RCT). We examined the effectiveness of CEA compared to medical therapy (MT) among asymptomatic patients in preventing fatal and non-fatal stroke within 5 years of follow-up in two populations: a sample that reflects real-world practice (pragmatic sample) and a sample that adheres to RCT inclusion criteria (RCT-like sample).

METHODS: We identified Veterans ≥65 years old with carotid stenosis between 2005 to 2009 without a history of stroke or transient ischemic attack and who were followed for 5 years. We used recently described "target trial" methods to mimic analyses from the Asymptomatic Carotid Stenosis Trial, the last published trial to compare CEA to MT. We accounted for "immortal time" bias by randomizing patients to CEA and MT groups and censoring patients if their actual treatment became inconsistent with the arm in which they were randomized (e.g., patient received CEA, but was randomized to MT). We accounted for the informative censoring by estimating time-dependent inverse probability of censoring weights using measured covariates (demographics and 52 time-varying comorbidities). We computed weighted Kaplan-Meier curves and estimated the risk of fatal and non-fatal stroke in each group over 5 years of follow-up.

RESULTS: 2712 patients received CEA and 2509 patients received MT. The observed rate of stroke or death (perioperative complications) within 30 days in the CEA arm was 2.5%. The 5-year risk of fatal and non-fatal stroke was lower among patients assigned to CEA (5.6%) compared to patients assigned to MT (7.8%) (risk difference, -2.3%, 95% CI -4.0% to -0.3%). In an analysis that incorporated the competing risk of death, the risk difference between the two arms was lower and non-significant ([risk difference -0.8% (95% CI, -2.1% to 0.5%)]. Among patients who met RCT inclusion criteria (N=2012, CEA and N=1890 MT), the 5-year risk of fatal and non-fatal stroke among patients assigned to CEA was 5.5% versus 7.6% in the MT arm (risk difference -2.1%, 95% CI -4.4% to -0.2%) and accounting for competing risks resulted in a non-significant risk difference of -0.9% (95% CI, -2.9% to 0.7%).

CONCLUSIONS: The absolute reduction in the risk of stroke due to early CEA was less than half that observed in trials initiated over two decades ago and was reduced even further when the competing risk of non-stroke deaths were accounted for in the analysis. Given the non-negligible peri-operative 30-day risks and the improvements in stroke prevention, medical therapy may be an acceptable therapeutic strategy.

ENGAGING FAMILY SUPPORTERS TO IMPROVE DIABETES OUTCOMES: A RANDOMIZED CONTROLLED TRIAL

Ann-Marie Rosland[2,3]; John D. Piette[4,5]; Ranak Trivedi[1,6]; Aaron A. Lee[7]; Margaret Zupa[3]; Shelley Stoll[4,9]; Maria K. Mor[2,8]; D. Scott Obrosky[2]; Elijah Lovelace[2]; Eve A. Kerr[4,9]; Michele Heisler[4,9]. [1]Center for Innovation to Implementation/Psychiatry and Behavioral Sciences, VA Palo Alto Health Care System, Menlo Park, CA; [2]Center for Health Equity Research and Promotion, VA Pittsburgh Healthcare System, Pittsburgh, PA; [3]School of Medicine, University of Pittsburgh, Pittsburgh, PA; [4]VA Ann Arbor Healthcare System, Ann Arbor, MI; [5]Center for Management of Chronic Disease, School of Public Health, University of Michigan, Ann Arbor, MI; [6]Stanford University, Stanford, CA; [7]Department of Psychology, University of Mississippi, Oxford, MS; [8]Department of Biostatistics, Graduate School of Public Health, University of Pittsburgh, Pittsburgh, PA; [9]Division of General Medicine, Department of Internal Medicine, University of Michigan, Ann Arbor, MI. (Control ID #3371468)

BACKGROUND: Evaluate the effectiveness of an intervention targeting patient-family dyads and aimed at improving diabetes self-management, patient activation, support satisfaction, and physiologic outcomes for adults with diabetes at risk for complications.

METHODS: 239 adults with diabetes (AWD) receiving primary care at two Veterans Health Administration (VHA) sites were randomized with an adult family supporter to an intervention group vs. usual primary care for 12 months. The intervention provided dyads with one health coaching session, biweekly automated phone calls to prompt action plans related to new diabetes health concerns, coaching calls to prepare for primary care visits, and summaries of primary care visit discussions. AWD eligibility criteria were baseline HbA1c>8% or systolic blood pressure (SBP)>150mmHg. Pre-specified primary outcomes were baseline to 12 month changes in 1) Patient Activation Measure (PAM, range 0-100); and 2) 5-year UKPDS Diabetes- Specific Cardiac Event Risk. Pre-specified secondary outcomes were 12 month changes in HbA1c, SBP, self- management behaviors, and patient satisfaction with diabetes social support. Intention-to-treat analyses of changes in outcomes were adjusted for baseline outcome levels, whether patients lived with supporters, and patients' baseline insulin use.

RESULTS: 21% of those initially contacted via letter were recruited. Enrolled patients were on average 60(SD±9) years old, and had HbA1c levels of 8.5(SD±1.6)% and SBP 140(IQR 128,150)mmHg. 70% lived with their supporter. 96% of dyads had complete 12-month outcome data. Over 12 months, 2.4 mean visit prep calls were completed per dyad, and 76% of automated calls were completed. PAM scores increased significantly more in the intervention group (intervention effect +2.6 points (95%CI 0.005, 5.149). There were no statistically significant differences by arm in cardiac risk score, HbA1c, or SBP change. Patient self- reported adherence to healthy eating increased significantly more in the intervention group (intervention effect +0.7 days/week (95% CI 0.2, 1.2) but not for other self-management behaviors. Family supporter involvement in helping patients remember to take medications, do home testing, and attend appointments increased significantly more in the intervention group (p's<0.05). 97% of patients and 94% of supporters in the intervention group agreed they would recommend the program to others.

CONCLUSIONS: Family supporter-patient dyads were successfully recruited, engaged, and retained in a hybrid coaching + automated call intervention, and participants were highly satisfied with the intervention.

While physiologic outcomes did not improve during this 12-month follow-up period, the intervention produced significant increases in patient activation, healthy eating, and family involvement in care, all of which have been associated with improved longer term clinical outcomes in diabetes studies.

ENHANCING CAREGIVER-PATIENT CONNECTIONS SO EMPATHY & TRUST CAN THRIVE: A CLUSTER-RANDOMIZED CONTROLLED TRIAL TO TEST A NOVEL INTERVENTION

Susannah L. Rose[1,2]; Caroline Franke[10,3]; Mary Beth Mercer[3]; Sabahat Hizlan[1]; Leonard Calabrese[9,10]; Kathryn A. Martinez[4,10]; Christopher M. Whinney[5]; Josalyn Meyer[7]; Craig Nielsen[6]; Vicente J. Velez[8]; Adrienne

Boissy[3,10]. [1]Office of Patient Experience, Cleveland Clinic, Cleveland, OH; [2]Department of Bioethics, Cleveland Clinic, Cleveland, OH; [3]Office of Patient Experience, Cleveland Clinic, Cleveland, OH; [4]Center for Value-Based Care Research, Cleveland Clinic, Cleveland, OH; [5]Hospital Medicine, Cleveland Clinic, Solon, OH; [6]Internal Medicine, Cleveland Clinic, Cleveland, OH; [7]Nursing Institute, Cleveland Clinic, Cleveland, OH; [8]Department of Hospital Medicine, Cleveland Clinic, Cleveland, OH; [9]Medicine - Rheumatic and Immunologic Disease, Cleveland Clinic, Cleveland, OH; [10]Cleveland Clinic Lerner College of Medicine, Cleveland Clinic, Cleveland, OH. (Control ID #3391494)

BACKGROUND: Finding ways to integrate empathy into healthcare without additional burden to clinicians is essential. The aim of the study was to determine if an intervention designed to empower inpatients to share who they are leads to greater physician empathy, shared decision-making and trust.

METHODS: A cluster randomized controlled trial was conducted with patients admitted to four medicine units (2 intervention/2 control) at the Cleveland Clinic. The intervention was called a "Care to Share" poster that patients created upon admission and was hung on the wall facing professional caregivers when they walked into the room. The control group did not create the poster. Patients completed a survey 48 hours later asking them about their experiences with the poster. Surveys also included the Jefferson Scale of Patient's Perceptions of Physician Empathy (JSPPPE), CollaboRATE to measure shared decision making, and the Interpersonal Physician Trust Scale (IPTS). Nurses and hospitalists were surveyed before and after the intervention; measures included the Jefferson Scale of Empathy (JSE) and the Maslach Burnout Inventory (MBI). We compared empathy, shared decision making and trust among patients and caregivers between the study groups using t-tests or ANOVA, as appropriate. Surveys included a free text field where participants could share their experiences with the intervention. Content analysis was used to identify themes in these survey comments.

RESULTS: The sample included 160/185 control patients and 160/267 intervention patients (86% and 60% response rates); of whom 53% were female, 52% were White, and their mean age was 59 years. Intervention and control patients did not differ significantly in demographic characteristics. The majority (96%) of intervention patients reported that they talked with hospital caregivers about poster content and it helped them connect with their caregivers in a personal way (82%). One patient said *"People really stopped and looked at me. I wasn't just a patient in a bed anymore, I was a person."* Both nurses (84%) and hospitalists (63%) agreed that the posters prompted them to talk with their patients about what's important to them. In bivariate analyses, nurse and hospitalist baseline and post-intervention empathy and burnout scores did not differ by study group, and patient-perceived empathy and shared decision-making did not differ. However, patient-reported trust scores were significantly higher in the intervention group (43.2.±6.9 vs 41.4±8.2, p=0.04).

CONCLUSIONS: Patients and caregivers felt that the "Care to Share" posters fostered more personal connections between them. While empathy and shared decision-making were not significantly different between the control and intervention groups, patient trust was significantly higher in the intervention arm. Future studies should evaluate patient trust.

ENROLLMENT STABILITY AND DRIVERS OF ACO MEMBER DEPARTURE IN A LARGE MEDICAID ACO IN MASSACHUSETTS

Anna Goldman[1]; Heather E. Hsu[2]; John Goldie[5]; Erin M. Ashe[3]; Karen E. Lasser[4]; Michael Silverstein[3]. [1]Medicine, Cambridge Health Alliance, Cambridge, MA; [2]Pediatrics, Boston University School of Medicine, Boston, MA; [3]Pediatrics, Boston Medical Center, Boston, MA; [4]Medicine, Boston Medical Center, Boston, MA; [5]Boston Medical Center, Boston, MA. (Control ID #3391479)

BACKGROUND: A growing number of state Medicaid programs have implemented Accountable care organization (ACO) programs. ACOs aim to improve healthcare quality and cost through capitated payments and value-based purchasing. ACOs have incentives to maintain a stable patient population, as this allows the organization to effectively invest in health related social needs and to manage financial risk more confidently. Conversely, ACO models may disincentivize the provision of care for vulnerable patients due to global payments, in which high-cost enrollees can become a financial liability. No studies to date have characterized enrollment dynamics in Medicaid ACOs. The objectives of this study were to evaluate the stability of enrollment in Massachusetts' largest Medicaid ACO at Boston Medical Center and to assess the most frequent drivers of ACO departure.

METHODS: We used monthly, member-level data on members of Boston Medical Center's Medicaid ACO from April 2018 to September 2019, and included all non-elderly adults and children who entered the ACO at its inception in April 2018. We calculated average monthly enrollment change for the entire ACO population as well as 5 subgroups: non-elderly adults ages 19-64 years old; non-newborn children ages 3 months-18 years old; disabled adults; disabled, non-newborn children; and homeless adults. We then analyzed data from the state of Massachusetts Electronic Verification system to determine the most common causes of ACO departure.

RESULTS: Across the full sample (n=110,385), the average monthly change in enrollment was -2.1% percentage points (pp) per month (95% CI [1.3, 3.0]). By the end of the 18 month study period, total ACO member enrollment decreased by 30.7%. Enrollment decreased by an average of -2.3 pp per month (95% CI [1.4, 3.2]) among adults and -1.7 pp per month (95% CI [0.8, 2.6]) among non-newborn children. Disabled adults and children had an average monthly decline of -1.3 (95% CI [1.0, 1.7]) and -1.1 pp per month (95% CI [0.6, 1.7]) respectively. Among homeless adults, the population decreased by -4.0 pp per month (95% CI [1.5, 9.5]). The three most common reasons for ACO member departure were: loss of Medicaid eligibility; transition to a different Massachusetts Medicaid ACO; and failure to re-enroll in Medicaid despite continuing eligibility.

CONCLUSIONS: Among the population of non-elderly adult and child Medicaid enrollees that joined BMC's ACO at the outset of the program, over 30% had disenrolled after 18 months. Non-disabled adults were more likely to disenroll compared to disabled adults and children. Homeless adults had the highest rates of disenrollment. Loss of Medicaid coverage, either due to changes in eligibility status or challenges with re- certification, was the most common cause of ACO attrition. The insights provided by our findings can help inform state- and institution-level policy changes to strengthen stability of ACO enrollment and improve continuity of care for this vulnerable patient population.

EPIDEMIOLOGY OF INFLUENZA: 5 SEASON REVIEW WITH FOCUS ON SEASON START, PEAK AND END.

Chelsey Hill[2]; Joseph Tholany[2]; Mohamed H. Yassin[3]; Yasser Eldaour[1]; Marie Tuft[4]. [1]Internal Medicine, UPMC, Pittsburgh, PA; [2]Internal Medicine, UPMC Mercy, Pittsburgh, PA; [3]ID, UPMC, Pittsburgh, PA; [4]UPMC Mercy Hospital., Pittsburgh, PA. (Control ID #3369862)

BACKGROUND: Influenza is a highly contagious seasonal infection that is responsible for a half a million deaths annually. Identification of the start and the peak of the season helps healthcare facilities to better prepare and deliver vaccination. This is exceptionally important to avoid spread of Influenza infection within healthcare facilities. The aim of the our study was to review the epidemiology of Influenza cases in our institution in the last 5 seasons.

METHODS: This is a descriptive retrospective study performed at a 440-bed academic medical center. There were 4670 inpatients tested for respiratory viral panels (RVP) extracted from the electronic medical records between September 2014 and Augest 2019. The start, peak and end of the season were identified in these 5 seasons. Basic demographic data were also collected on these patients.

RESULTS: The median age of patients was 61 years and females were 60%. Influenza type A was diagnosed in 86% of the cases and 60% of them were H3 subtype. Influenza type B seems to appear later in the season. Fifteen percent of patients with Influenza were admitted to the intensive care unit. 2015-2016 season peaked at end of March 2016 and 2018-2019 peaked at mid-February 2019. The other 3 seasons peaked between last week of December to mid-January.

CONCLUSIONS: Peak of Influenza season occured at end of December or after with considerable variation. The information about Influenza peak affects the intensity of testing and reduces missed undiagnosed cases and mitigate the potential of hospital acquired cases.

ESTABLISHING COMPETENCIES FOR LEADERSHIP DEVELOPMENT FOR INTERNAL MEDICINE RESIDENTS

Sarah B. Merriam[1,2]; Jennifer Corbelli[3]. [1]Internal Medicine, University of Pittsburgh Medical Center, Pittsburgh, PA; [2]Medicine, VA Pittsburgh Healthcare System, Pittsburgh, PA; [3]Medicine, University of Pittsburgh Medical Center, Pittsburgh, PA. (Control ID #3391820)

BACKGROUND: Physicians lead complex, multidisciplinary teams, yet often lack formal leadership training. Given current challenges facing healthcare, the development of effective physicians is paramount. The ACGME has emphasized that leadership skills related to competencies of communication, systems-based practice, and professionalism should be included in GME training. However, it remains unclear which skills are most important for early-career physicians. This study aims to create a prioritized list of leadership skills to guide curricular development for internal medicine (IM) residents.

METHODS: We developed and implemented a 2-round Delphi study to establish consensus in this educational content area. Participants were IM physicians in leadership roles with experience in medical education and/or leadership programming within professional societies. Authors developed a preliminary list of leadership skills through review of published literature regarding competencies for healthcare professionals. Local clinician-educators with interest in leadership vetted this list to establish face and content validity. A priori rules for consensus were established. Participants ranked 31 leadership skills on importance (1=not important, 5=essential) for categorical IM residents, with the goal of competency by the second half of residency and mastery during the first 3-5 years of career. Respondents also commented on number of content hours and curricular format recommended to teach each skill.

RESULTS: Sixteen respondents completed the first round of ranking and 14 completed the second round (response rate 88%). Most were female (71%), in clinical practice for > 15 years (64%), full (57%) or associate (36%) professors and held a variety of high-level university and hospital leadership roles. Thirteen skills were ranked as essential and 9 as very important. Essential topics were primarily in domains of self- awareness, emotional intelligence, team management, professional development, communication, and professionalism/advocacy. Experts generally recommended between 2-5 content hours per topic. Most frequently recommended modes for content delivery included mentorship/coaching, work-based reflection, and interactive discussion.

CONCLUSIONS: Expert consensus identified 13 essential leadership skills for IM residents. Most recommended delivery methods were not didactics, but rather direct observation and debrief through coaching/reflection. These results suggest that curricular time and space, a commonly cited barrier in GME, may not exist in this content area. Initial steps in curricular development might best start by training faculty to dovetail leadership coaching with daily teaching workflow and existing feedback structure. Case studies with discussion of leadership skills may be an effective adjunct. These findings highlight the importance of developing targeted leadership skills development programs for IM residents, and lend insight into optimal curricular methods to provide this education.

EVALUATING A HEALTH-RELATED SOCIAL NEEDS SCREENING AND REFERRAL PROGRAM AMONG VETERANS

Alicia Cohen[1]; Lauren E. Russell[2]; Steven Chrzas[2]; Dawn Mello[3]; Lisa Lehmann[2,4]. [1]Primary Care; Family Medicine and Health Service, Policy & Practice, Providence VA Medical Center; Brown University, Providence, RI; [2]Chief Medical Office, VA New England Healthcare System, Bedford, MA; [3]Center of Innovation in Long Term Services and Supports, Providence VA Medical Center, Providence, RI; [4]Medicine, Harvard Medical School, Boston, MA. (Control ID #3391273)

BACKGROUND: Given the adverse impact of unmet social needs on health equity, professional societies have called for improved identification and management of health-related social needs (HRSN). The Veterans Administration (VA) currently screens Veterans for food and housing insecurity but lacks a process to screen for HRSN more broadly. We developed and piloted an HRSN screening and referral program—Assessing Circumstances & Offering Resources for Needs (ACORN). We assessed: 1) prevalence and sociodemographic characteristics associated with screening positive for HRSN; 2) Veteran acceptability of ACORN; and 3) effectiveness of tailored resource guides in helping Veterans connect with services.

METHODS: Mixed methods multi-site pilot. In the context of routine care, Veterans at 3 VA clinics in the Boston area are completing an electronic assessment encompassing 8 HRSN domains. Based on identified needs, Veterans are provided with tailored resource guides composed of VA and non-VA resources. Follow- up interviews are being conducted with a purposive sample of Veterans to understand acceptability of ACORN, effectiveness of the resource guides in connecting Veterans with services, and remaining barriers to addressing needs. Multivariable logistic and multinomial regression models will be used to identify sociodemographic characteristics associated with screening positive for HRSN. Interviews are being analyzed using directed content analysis.

RESULTS: To date, 311 Veterans have been screened. Of these, 72.4% reported ≥1 HRSN; 23.5% reported ≥3 needs. Rates of HRSN included housing (13.8%), utility (13.4%), food (11.9%), and transportation (9.1%) insecurities, as well as legal needs (11.5%) and concerns for personal safety (15.6%). Over 1/3 (36.5%) of Veterans needed employment assistance; 45.7% reported social isolation. Preliminary qualitative results show Veterans overall find screening for HRSN both acceptable and appropriate and feel the VA should continue such screening. While some Veterans found the resource guides helpful, others did not use the guides for reasons ranging from having already received needed assistance to feeling uncomfortable contacting non-VA organizations. Final analyses including sociodemographic correlates of identified HRSN will be presented.

CONCLUSIONS: Early findings show Veterans feel ACORN is both acceptable and important. Nearly 3/4 of Veterans reported at least 1 HRSN. Almost half reported social isolation, and 1 in 7 reported at least one form of material hardship. Screening for HRSN is a critical step towards connecting Veterans with needed services, identifying gaps in the current service delivery system, and informing future VA resource allocation. This pilot will provide information to better ensure equitable

and ethical delivery of health care to Veterans at risk for health-related social needs.

EVALUATING A PRIMARY CARE DELIVERY MODEL TO IMPROVE COMORBIDITY MANAGEMENT FOR CANCER PATIENTS

Laura C. Pinheiro[3]; Evgeniya Reshetnyak[3]; Priscilla Bresler[2]; Clare Whipple[2]; Monika M. Safford[3]; Nina A. Bickell[1]. [1]Population Health Science & Policy, Icahn School of Medicine at Mount Sinai, New York, NY; [2]General Internal Medicine, Mount Sinai Hospital, New York, NY; [3]Department of Medicine, Weill Cornell Medical College, New York, NY. (Control ID #3391124)

BACKGROUND: There are 19 million cancer survivors in the United States, 70% of whom have co- occurring chronic conditions. Comorbidity management during active cancer treatment is often sidelined. However, comorbidities may negatively impact cancer outcomes through treatment delays and incomplete treatment completion. Care coordination between primary care physician (PCPs) and oncologists has been identified as a barrier to effective comorbidity management. To address this issue, a New York City medical center implemented a primary care model using "oncogeneralists", PCPs with cancer-specific training, embedded within oncology clinics, to manage comorbidities during active cancer treatment. The objective of our study is to describe cancer patients who utilize this primary care model and determine the model's ability to effectively manage comorbidities in cancer patients undergoing active cancer treatment.

METHODS: We used electronic medical records from a New York academic medical center that serves a diverse patient population. Cancer patients were diagnosed between 1/1/2015-12/31/2018 with follow-up through 12/31/2019. Using ICD-9 diagnosis codes, we identified adult patients with incident breast, prostate, colorectal, lung, and multiple myeloma cancers. All patients had pre-existing diabetes or hypertension at the time of cancer diagnosis. First, we characterized the model's patient population and used chi-square tests to compare characteristics between patients who received oncogeneralist care to those who did not. We then examined 1) diabetes and hypertension control and 2) emergency department (ED) visits and hospitalizations after cancer diagnosis.

RESULTS: We included 3,566 cancer patients with comorbid diabetes or hypertension. Of these, 472 (13%) received care from an oncogeneralist and 3,094 (87%) did not. Compared to patients who did not see an oncogeneralist, patients who saw an oncogeneralist were more likely to be younger (70 vs. 65 years, $p<00001$), female (51% vs. 74%, $p<0.0001$), Black (16% vs. 28%, $p<0.0001$), Spanish-speaking (5% vs. 16%, $p<0.0001$), have pre-existing diabetes (28% vs. 40%, $p<.0001$), and hypertension (74% vs. 80%, $p=0.0072$). On average, patients who saw an oncogeneralist had 12 hospital stays and 3.6 ED visits compared to 6.5 hospital stays and 2 ED visits in the non-oncogeneralist group.

CONCLUSIONS: Patients who received oncogeneralist care during active cancer treatment were more likely to be young, Black, Spanish speaking, and have diabetes. As minorities have greater comorbidity burden and are often face various barriers to managing both cancer and non-cancer conditions, improved comorbidity management may especially benefit these patients. Within the context of national efforts to reduce cancer disparities, the oncogeneralist model could be a promising care delivery innovation with potential to reduce disparities.

EVALUATING HYPERTENSION SCREENING, DIAGNOSIS, TREATMENT, AND CONTROL AT A LARGE PRIVATE HOSPITAL IN KAMPALA, UGANDA: A QUANTITATIVE ANALYSIS

Usnish Majumdar[2]; Rose C. Nanyonga[3]; Andrew Moran[5,6]; Gidio Agaba[4,3]; Dennis Sentamu[3]; David J. Heller[1]. [1]General Internal Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; [2]Arnhold Institute for Global Health, Icahn School of Medicine at Mount Sinai, New York, NY; [3]Administration, Clarke International University, Kampala, Kampala, Uganda; [4]Medicine, Mulago National Referral Hospital, Kampala, Uganda; [5]Medicine, Vagelos College of Physicians and Surgeons, New York, NY; [6]Resolve to Save Lives, Vital Strategies, New York, NY. (Control ID #3391976)

BACKGROUND: Essential hypertension (HTN) is common in Uganda, but rates of awareness, treatment, and control are poor. Prior studies report a nationwide prevalence rate of 27%, with only 8% aware of their diagnosis (Guwatudde et al, 2015). Although private sector clinics in Uganda often test and treat for hypertension, little is known about their efficacy in diagnosing and controlling this condition, even as they provide half of all chronic disease care nationwide. Recent qualitative data suggests that patients with hypertension struggle to reconcile conflicting advice on how to treat it (Lynch et al, 2019), while providers have limited time to counsel them (Green et al, 2020). But the efficacy of private clinics in achieving blood pressure control is largely unknown.

METHODS: We investigated rates of hypertension screening, diagnosis, treatment and control at Uganda's largest private hospital by analyzing electronic medical record and prescription data from July 2017 to August 2018. We calculated blood pressure screening rates among 17,777 adult patients in 39,235 outpatient primary care visits, and hypertension diagnosis, treatment, and control rates among a subset of 5,090 of these patients with at least two blood pressure checks who receive prescriptions at the hospital's pharmacy. We defined a patient as having hypertension based on either 1) two or more blood pressure readings averaging over 140 mm Hg systolic or 90 mm Hg diastolic; or 2) receiving any antihypertensive medications. We defined as controlled any patient with hypertension whose most recent blood pressure reading was under the systolic and diastolic values above.

RESULTS: 25,352 (64.7%) of visits involved a blood pressure check. Among the subset of 5,090 patients with at least two blood pressure checks and one hospital prescription as per above, 2,085 (41.0%) screened positive for hypertension: 1915 (37.6%) with elevated mean blood pressure, and 170 (3.3%) with normal blood pressure but on antihypertensive medication. 838 (40.2%) of patients with hypertension were treated with medication at least once. 223 of treated patients (26.6%) achieved blood pressure control at their most recent visit, as did 158 (12.7%) of untreated patients with hypertension. Overall, 381 of 2,085 persons with hypertension (18.3%) achieved blood pressure control at their last visit.

CONCLUSIONS: Hypertension is common and incompletely treated in this Ugandan primary care private- sector population. Although hypertension diagnosis, treatment, and control rates are greater than in the general population, this relatively high-resource cohort still lags behind blood pressure control rates in high- income countries. More research into providers' approach to patient counseling and pharmacotherapy - and patients' access to and engagement in hypertension care - may suggest initiatives to address this global disparity.

EVALUATING TELEHEALTH AS A MEDIATOR OF VETERANS HEALTH ADMINISTRATION EVIDENCE-BASED QUALITY IMPROVEMENT IMPACTS

Taona P. Haderlein[1]; Danielle Rose[2]; Susan E. Stockdale[3]. [1]Center for the Study of Health Innovation, Implementation, and Policy, Department of

Veterans Affairs, Los Angeles, CA; [2]VA HSR&D Center for the Study of Healthcare Provider Behavior, VA GLA Healthcare System, Sepulveda, CA; [3]HSR&D Center of Excellence, Greater Los Angeles VA Healthcare System, Sepulveda, CA. (Control ID #3389876)

BACKGROUND: Although Veterans Health Administration (VHA) facilities implemented open access principles as part of the patient centered medical home (PCMH) transformation in 2010, patient ratings of access vary widely. To maximize access, VHA expanded availability of non-traditional care modalities, including telehealth. We introduced Evidence-Based Quality Improvement for PCMH transformation (EBQI- PCMH) to address PCMH implementation challenges, including access to care. Evidence shows positive EBQI-PCMH impacts on patient experiences; however, less is known about mechanisms of EBQI-PCMH effects. Telehealth may enhance the EBQI-PCMH patient experience by offering a convenient alternative to face-to-face care. This study aimed to 1) identify clinic-level correlates of telehealth use; 2) evaluate telehealth as a predictor of patient-reported access to care; and 3) evaluate telehealth as a mediator of the association between EBQI-PCMH and patient-reported access to care.

METHODS: EBQI-PCMH was rolled out in 3 phases at ten sites; seven sites were categorized as early or late adopters based on implementation start date (October 2010-May 2011 and April 2012). Three PCMH- only control sites were identified based on comparable geographical location, patient survey data availability, and monthly patient load. Patient-reported access to care was assessed using six questionnaire items from the Survey of Healthcare Experiences of Patients (SHEP); items assessed access to urgent care, routine care, and weekend, holiday, or evening (WHEN) care. We analyzed SHEP data collected from December 2012 – March 2015.

Clinic-specific ratios of quarterly telephone visits and outbound electronic messages (OMs) were utilized to assess telehealth use, with total quarterly clinic visits as the denominator. We used correlation analyses to test associations between telehealth visit ratios and clinic characteristics (community vs. medical center, nurse visits, same day visits, patient load). We used multilevel regression analyses to test telehealth as a predictor of patient-reported access to care, and to test telehealth as a mediator of EBQI-PCMH effects.

RESULTS: The sample included 19,076 patients seen in EBQI-PCMH or control-site primary care clinics (*M* age= 65.88, 66% White).

Telephone visits were negatively correlated same-day visits ($p<.05$) and patient loads ($p<.05$). OMs were positively correlated with same day visits ($p<.01$). Rates of telephone visits and OMs were higher for community centers than medical centers ($p<.01$). Telephone visits were positively associated with access to urgent, routine, and WHEN care ($p<.05$). OMs were negatively associated with access to urgent care ($p=.02$). Telephone visits partially mediated the association between EBQI-PCMH and WHEN access ($p=.02$).

CONCLUSIONS: This study provides preliminary evidence supporting telehealth as a component of VHA quality improvement efforts.

EVALUATING THE FEASIBILITY OF CAPTURING A CORE SET OF HARMONIZED DEPRESSION OUTCOME MEASURES IN PRIMARY CARE AND MENTAL HEALTH PATIENT REGISTRIES

Michelle Leavy[1]; Elise Berliner[2]; Sarah Hajjar[3]; Diana Clarke[4]; Debbie Gibson[4]; Richard Gliklich[1]. [1]Health Policy, OM1, Inc., Boston, MA; [2]Agency for Healthcare Research and Quality, Rockville, MD; [3]American Board of Family Medicine, Lexington, KY; [4]American Psychiatric Association, Washington, DC. (Control ID #3392455)

BACKGROUND: Major depressive disorder is a significant public health problem in the United States that reduces quality of life for millions of individuals. Many critical questions exist about depression treatment and outcomes, and new, efficient approaches are needed to address these questions and improve patient outcomes. Patient registries already collect large amounts of data on depression treatment and outcomes from diverse patient populations and could be useful for answering some of these questions. Yet, differences in the data collected in each registry makes it challenging to aggregate or compare data. Collection of a core set of harmonized outcome measures across depression patient registries would yield a robust data infrastructure to answer questions about depression treatment and outcomes in the real-world setting.

METHODS: The Agency for Healthcare Research and Quality (AHRQ) recently supported an effort to harmonize depression outcome measures across patient registries and clinical practice. The harmonized measures use the PHQ-9, along with other clinical data, to measure and monitor depression outcomes over time at the patient level. Implementation of these measures in patient registries and in the clinical practice setting would support both measurement-based care using the PHQ-9 and development of data infrastructure to address new depression-related research questions. The purpose of this project was to assess the technical and operational feasibility of implementing the harmonized measures in two registries: the PRIME Registry, sponsored by the American Board of Family Medicine, and PsychPRO, sponsored by the American Psychiatric Association.

RESULTS: The feasibility assessment identified technical barriers related to the availability of data, particularly for measures such as suicide ideation and behavior where data may be entered in notes as opposed to in structured fields. Cause of death is also challenging to capture in the registry setting. Operational issues include developing workflows for collection of the PHQ-9 at consistent intervals, review of the outcome measures, particularly when patients report worsening symptoms, and developing appropriate language and processes for patients who indicate suicide ideation on the PHQ-9 outside of an office visit. These issues will be addressed in the second phase of this project, which will focus on implementation of the measures at twenty pilot sites.

CONCLUSIONS: While many efforts have developed harmonized or core sets of outcome measures, few efforts have worked with registries and health systems to understand the impact and potential challenges of implementing the harmonized measures. This project assessed feasibility and identified potential barriers that may be useful for informing other harmonization initiatives and implementation efforts.

EVALUATING THE IMPACT OF HOUSING INSECURITY ON HOSPITALIZED PATIENTS: A QUALITATIVE STUDY

Erin Bredenberg[1]; Julie Knoeckel[2]; Gregory J. Misky[1]; Sarah A. Stella[2]; Lauren McBeth[1]; Ellen Sarcone[2]; Kathryn L. Havranek[3]; Mackenzie L. Garcia[3]; Robert Cragg[4]; Lauryn Dombrouski[4]. [1]Hospital Medicine, University of Colorado, Aurora, CO; [2]Department of Medicine, Denver Health, Denver, CO; [3]University of Colorado School of Medicine, University of Colorado, Denver, CO; [4]University of Colorado School of Nursing, Denver, CO. (Control ID #3391833)

BACKGROUND: Housing insecurity, which includes both frank homelessness and vulnerable housing, affects a substantial proportion of hospitalized patients. There are well-described disparities in patient care for patients experiencing homelessness compared to those who are not homeless, including discrepancies in length of stay, readmission, and mortality rates. Outcomes for patients who are vulnerably housed are less clear, though some data suggests that patients across the spectrum of housing insecurity experience poorer outcomes. Few studies have assessed how housing insecurity impacts hospitalized patients. This qualitative study

explores hospitalized patients' perspectives regarding how housing insecurity affects their health and health care experiences.

METHODS: We identified a random sample of inpatients on General Medicine services at two acute-care hospitals in Denver, Colorado. Following informed consent, participants were screened for housing insecurity. If participants screened positive for housing insecurity, an in-depth, semi-structured interview was completed. Audio-recordings of interviews were transcribed, inductively coded, and qualitatively analyzed via phenomenological approach.

RESULTS: To date, a total of 18 of 28 eligible patients have completed interviews. Of these, nine were vulnerably housed while the remainder of participants were frankly homeless. All participants surveyed believed their current housing situation affected their health. One participant reported: "Sleeping in the car, I am too tall to be comfortable. I'm only 5'8", but still, laying sideways is a no-no" … "I am moving all night, shifting, trying to get comfortable. I just had a right hip replacement, so that's very difficult to do." Homeless participants spoke to the inherent hardships of homelessness, and the difficulties recovering after hospitalization. A subset of patients expressed that they do not expect their housing situation to be assessed during hospitalization, and had low expectations for the provision of resources. For example, one participant noted: "I don't really think them (doctors) knowing about my housing situation's really going to fix my health." … " I don't really care for them to know about my housing."

CONCLUSIONS: Emerging themes from this qualitative study suggest that patients experiencing housing insecurity believe that their housing status strongly impacts their health and may affect healthcare utilization. Despite this, some participants believed it is not the responsibility of inpatient providers to screen patients for housing insecurity, and have low expectations for resources provided during hospitalization. Consideration of these perspectives is crucial to inform the development of effective interventions to address the significant known disparities among patients who are housing insecure.

EVALUATING THE REAL-WORLD CLINICAL APPROACH TO THE DIAGNOSIS AND CODING OF PATIENTS WITH HYPOACTIVE SEXUAL DESIRE DISORDER

Sharon J. Parish[1]; Amod Athavale[2]; Rahul Ravindranath[2]; Nandini Hadker[2]; Amama Sadiq[3]; Michelle Lim-Watson[3]. [1]Internal Medicine, Psychiatry, Weill Cornell Medical College, White Plains, NY; [2]Trinity Partners, LLC, Waltham, MA; [3]AMAG Pharmaceuticals, Waltham, MA. (Control ID #3356446)

BACKGROUND: Hypoactive sexual desire disorder (HSDD) is defined as lack of sexual desire accompanied by distress. While HSDD affects 10% of US women, there is limited awareness of HSDD symptoms and appropriate application of relevant billing codes among physicians. The objective of this study is to understand how physicians diagnose and code patients with HSDD.

METHODS: An IRB-approved 30-minute web-based survey was administered to 154 physicians. Screening criteria required physicians to have practiced medicine >3 and <45 years, manage >150 female patients per month, manage ≥5 patients diagnosed with female sexual dysfunction (FSD) each month, and have a baseline HSDD awareness level >5 (on a 9-point awareness scale). Physicians were exposed to 6 blinded patient profiles: pre- and postmenopausal HSDD patients with and without comorbidities and 2 non-HSDD patient profiles (other FSDs). HSDD symptoms described in the profiles were consistent with the Decreased Sexual Desire Screener, a validated HSDD diagnostic instrument. Physicians were exposed to 1 patient profile at a time and were asked to diagnose and code it.

RESULTS: Of the 154 physicians included in the study, 32% were obstetricians/gynecologists (OB/GYNs), 32% were psychiatrists, and 35% were primary care physicians (PCPs, which included family medicine and internal physicians). They managed a mean number of 269 female patients per month, among which 36 had any type of FSD, of which 11 had HSDD. From the profiles with or without comorbidities, 54% and 40% were not diagnosed with HSDD as the primary condition; and 42% and 31% were miscoded, respectively. For profiles without comorbidities, the top reason for physicians diagnosing but not coding for HSDD was that they needed more information about HSDD symptoms (47%). The primary reason for diagnosing but not coding for HSDD for the profiles with comorbidities was the prioritization of treatment for comorbid conditions such as anxiety or depression (37%). Among the non-HSDD profiles, 16% were misdiagnosed and miscoded as HSDD, primarily due to a lack of understanding of different FSDs (51%).

CONCLUSIONS: Patients with HSDD and comorbidities are more likely to be misdiagnosed and miscoded due to confusion with comorbidities and other FSDs, uncertainty about diagnosis, and treatment prioritization of other comorbidities. More education is needed to help physicians better identify HSDD symptoms, and appropriately diagnose and code the condition.

EVALUATION OF A NATIONAL CARE COORDINATION PROGRAM TO REDUCE UTILIZATION AMONG HIGH-COST, HIGH-NEED MEDICAID BENEFICIARIES WITH DIABETES

O. Kenrik Duru[1]; Jessica Harwood[1]; Tannaz Moin[2]; Nicholas Jackson[3]; Susan Ettner[1]; Carol Mangione[1]. [1]GIM/HSR, UCLA, Los Angeles, CA; [2]Medicine, UCLA/VA Greater Los Angeles, Los Angeles, CA; [3]Medicine, University of California, Los Angeles, Los Angeles, CA. (Control ID #3389821)

BACKGROUND: Medical, behavioral, and social determinants of health are each associated with high levels of emergency department (ED) visits and hospitalizations. There is no consensus on the optimal interventions to address medical, behavioral, and social determinants of health among high-cost, high-need patients. In this project, we planned to evaluate a care coordination program designed to provide combined "whole-person care," integrating medical, behavioral and social support for high-cost, high-need Medicaid beneficiaries by targeting access barriers and social determinants.

METHODS: We conducted an individual-level interrupted time series with a comparator group, using person-month as the analysis unit. Our patient population included 42,214 UnitedHealthcare Medicaid beneficiaries (194,834 person-months) age >21 with diabetes, with Temporary Assistance to Needy Families, Medicaid expansion, SSI without Medicare, or dual Medicaid/Medicare in 15 states. Beneficiaries were eligible for the care coordination program if they were 1) identified as high-cost, high-need (i.e., in the top 5% of Medicaid spend) based on utilization over a rolling 12-month window and predicted to be in the top 5% of spend in the following 12 months by a risk model developed by the health insurer, or 2) admitted to the hospital and flagged to be at high risk for 30-day readmission. Our outcome measures were any hospitalizations and any ED visits in a given month. Covariates of interest included an indicator for intervention versus comparator group, and the interactions of the time period dummy and linear time trend with the intervention indicator.

RESULTS: Overall, six of the eight comparisons were not statistically significant. Among SSI beneficiaries, we observed a larger projected decrease in ED visit risk among the intervention sample versus the comparator sample at 12 months post enrollment compared to pre-enrollment (difference-in-difference/DID: -6.6%; 95% CI: -11.2%, -2.1%). Among expansion beneficiaries, we observed a greater decrease in hospitalization risk among the intervention sample versus the

comparator sample at 12 months post enrollment (DID: -5.8%; 95% CI: -11.4%, -0.2%).

CONCLUSIONS: A care coordination program designed to reduce utilization among high-cost, high-need Medicaid beneficiaries was associated with fewer ED visits and hospitalizations for patients with diabetes in selected Medicaid programs but not others; however, there was no strong, consistent pattern of reduction in high-cost health events across all outcomes and populations. Our results suggest that identification and enrollment of high-cost, high-need Medicaid beneficiaries into a care coordination program may not always be sufficient to result in change in ED and hospital utilization.

EVALUATION OF A PEER COACH-LED INTERVENTION TO IMPROVE PAIN SYMPTOMS (ECLIPSE)

Marianne S. Matthias[1]; Matthew J. Bair[2]; Susan Ofner[6]; Michele Heisler[3]; Marina Kukla[4]; Alan B. McGuire[5]; Joanne Daggy[6]. [1]HSR&D, Roudebush VAMC, Indianapolis, IN; [2]Medicine, Center for Health Information and Communication, Indianapolis, IN; [3]Ann Arbor VA/University of Michigan, Ann Arbor, MI; [4]Richard L. Roudebush VA Medical Center, Indianapolis, IN; [5]Richard L Roudebush VAMC, Indianapolis, IN; [6]Indiana University, Indianapolis, IN. (Control ID #3381217)

BACKGROUND: Chronic pain requires consistent self-management. Patients have identified the importance of encouragement, accountability, and motivation to continue in daily self-management. Given that clinicians are not always available to provide such support, placing a peer coach in a similar role might lead to similar benefits. Using peer coaches is an innovative approach to increasing the reach and adoption of pain self-management, potentially benefitting more patients. While peer support has been shown to be effective in other chronic conditions, research has largely neglected peer support for chronic pain management. ECLIPSE was a randomized controlled trial to test the effects of peer supported pain self- management on pain and other outcomes.

METHODS: ECLIPSE compared a 6-month peer coaching self-management intervention to a control group (2h pain self-management class). Intervention patients were paired with a peer coach for 6 months; pairs were asked to talk 2x/month. Coaches had prior self-management training or were recommended by their providers, and all attended a training session. The primary outcome was total pain, measured by the Brief Pain Inventory. Secondary outcomes included anxiety, depression, pain catastrophizing, patient activation, self-efficacy, social support, health-related quality of life, and healthcare utilization, including opioid prescriptions. Primary analyses employed linear mixed models fit to all time points with appropriate random effects. Exploratory analyses included examining whether discontinuing opioids during the study was a moderator of intervention effects.

RESULTS: 215 patients enrolled: 120 intervention, 95 control group. 63% of patients met 5 or fewer times (out of the 12 prescribed) during the 6-month intervention. There was not a statistically significant difference between groups on pain or any secondary outcomes at 6 or 9 months. Opioid discontinuation appeared to moderate intervention effects: Intervention patients whose opioids were discontinued during the study experienced statistically significant improvements in pain, self-efficacy, physical function, and pain catastrophizing.

CONCLUSIONS: Peer coaching did not result in improvements in pain and related outcomes compared to the control group. Intervention adherence helps to explain this lack of effect, with 63% having less than half the recommended contacts. ECLIPSE was intentionally a volunteer coaching model. However, it is possible that using a more "professionalized" model of peer coaching, in which coaches are hired as members of the healthcare team, might lead to higher adherence and better outcomes. It is notable that intervention patients whose opioids were discontinued during the study benefited from the intervention. This suggests that peer coaching might be a useful strategy to include in opioid tapering programs.

EVALUATION OF A STUDENT-CREATED SOCIAL DETERMINANTS OF HEALTH CURRICULUM

Dana Goplerud, Ruoxi Yu, Danielle Amundsen, Macy Early, Shanna Yue, Insia Zufer, Colleen Christmas. Johns Hopkins University School of Medicine, Baltimore, MD. (Control ID #3388370)

BACKGROUND: Social determinants of health (SDH) play a key role in health outcomes. Medical schools have increasingly incorporated SDH into their curriculums. However, these efforts often focus on teaching epidemiology rather than application, resulting in many students feeling underprepared to respond to SDH in clinical settings. We developed and evaluated a guide and training session for students to identify and address SDH on clerkships.

METHODS: A needs assessment was performed with upper-year medical students to inform the creation of an SDH guide. All students received this guide, which included screening questions and local resources for housing, food, utilities, transportation, and intimate partner violence. We conducted 2 optional 1.5-hour case- based sessions for pre-clerkship students to practice using the guide for screening and referral. Students were surveyed before, after, and 6 months later. Friedman tests were used to compare Likert scale scores, and Wilcoxon signed-rank tests with continuity correction were used for post-hoc analyses. Qualitative responses to case scenarios were analyzed to evaluate screening efficacy and identify themes.

RESULTS: More than one third of eligible students (41/120) attended the session. A total of 31 students (76%) completed both pre- and post-session surveys, and 12 students (29%) completed all three surveys. There was a significant difference in students' confidence in identifying patients with SDH needs (X^2_F (2) = 10.186, p = .006) and referring patients to appropriate resources (X^2_F (2) = 14.444, p = .001) before vs after the session. Confidence in identification of and referral for SDH increased both post-session and 6 months later, compared to pre-session. Qualitative analysis of the efficacy of student-generated screening questions was 67% (78/115) pre-session, 95% (60/63) post-session, and 79% (45/57) in the 6-month follow-up survey. Students valued case-based roleplays ("The scenarios … helped me figure out what I would say if I got pushback") and sharing screening strategies with others ("[I liked] debriefing scenarios to see how different people handled difficult discussions"). Students wanted more training on responding to SDH needs ("I feel somewhat prepared to ask about social determinants of health, but have very limited knowledge of resources to offer/when to refer to counselors/social work or what I personally can do").

CONCLUSIONS: Medical students who attended an optional SDH training session reported increased confidence in both identifying and referring for SDH needs. Students appreciated the role-play component of the session, and desired further information about how to respond to positive screens. Efficacy of screening questions increased post-session but decreased after 6 months, supporting need for spaced review. This case- based session is now required for all students prior to starting clinical clerkships with plans for further evaluation.

EVALUATION OF FIRST YEAR INTERNAL MEDICINE RESIDENTS' BASELINE HEALTH POLICY KNOWLEDGE

Tony Davis-Maxwell[1]; Peggy B. Hasley[1]; Scott Herrle[1]; Molly A. Fisher[2]. [1]Department of Internal Medicine, UPMC, Pittsburgh, PA; [2]Internal Medicine, Allegheny Health Network, Pittsburgh, PA. (Control ID #3370636)

BACKGROUND: Health policy in the United States is rapidly changing. Patients look to physicians for assistance in navigating the complex healthcare system, but not all physicians receive formal training in US health policy. Several professional groups, including ACGME, AMA, and ABIM have called for increasing physician education in this area. Some medical schools and residency programs have developed health policy curricula, yet the baseline knowledge of internal medicine residents in health policy is unknown. The aim of this study is to evaluate first-year internal medicine residents' baseline knowledge of health policy at the time of entry into residency.

METHODS: A 32-question multiple-choice examination was created and administered to residents during their internship orientation week. All 77 first-year internal medicine, transitional, and preliminary year interns at a single large academic center were considered eligible for participation. These interns come from a broad range of medical schools from the US and abroad. 74 interns (96%) completed the examination. The questions evaluated knowledge of specific content areas within health policy including Medicare, Medicaid, private insurance, social determinants of health, as well as health economics, cost, and quality. The social determinants of health questions were adapted from a previously validated survey tool used to evaluate resident's knowledge within that area. The test was administered on paper and data were then entered into RedCap software for analysis. Scores were compared using Tukey's method for multiple comparisons.

RESULTS: Interns scored an average of 65% on the exam. Interns scored statistically significantly higher on questions regarding health economics, cost, and quality (77%) and Medicaid (70%) compared to questions on Medicare (60%), private insurance (60%), and social determinants of health (58%). The 55% of interns who reported any prior health policy experience scored higher overall (69%) compared to interns without any past experience (59%), p=0.001. Interns who were born in the US scored significantly higher (68%) compared to those not born in the US (58%), p=0.002 for these US-centric questions. There was no difference in scores between categorical (66%) and preliminary- or transitional-year interns (64%), p=0.575.

CONCLUSIONS: Overall, we found that interns do not start their residency with high levels of health policy knowledge. Despite widespread recognition of the importance of education in this area, almost half (45%) of interns began their residency without any prior health policy experience or education. This highlights an area of opportunity for future educational focus. Special attention should be given to areas of struggle, including social determinants of health, the private insurance market, and Medicare.

EVALUATION OF GENERAL MEDICINE FACULTY FROM THE PERSPECTIVE OF THEIR PATIENTS AND RESIDENTS.

NiJuanna Irby-Johnson[1,3]; Laurence F. McMahon[2,1]; Sarah Hartley[3,1]; John Poe[3,1]; Giselle Uwera[3]. [1]Internal Medicine, Michigan Medicine, Belleville, MI; [2]Laurence McMahon, University of Michigan, Ann Arbor, MI; [3]Internal Medicine, University of Michigan, Superior Township, MI. (Control ID #3390841)

BACKGROUND: Academic generalist faculty routinely have their interpersonal qualities and knowledge/skills evaluated by patients and students. These ubiquitous ratings rely on patient-physician or physician-learner interactions in the forms of social media and formalized evaluations. We sought to assess whether there was an association between these different physician rating systems in order to determine if underlying physician characteristics transcend the rating method or venue.

METHODS: We identified General Medicine clinical faculty (n=46) who received 5 or more evaluations on any of 3 selected high volume social media physician rating websites, were evaluated by patients on the Clinician & Group Consumer Assessment of Healthcare Providers and Systems (CG-CAHPS) rating, and were recently evaluated by our resident physicians. To test for correlation, we rescaled the data, and used Box and Whisker plots to compare rescaled medians, 25th, and 75th percentiles of each set of evaluations and then utilized the re-scaled distributions to assess for associations between evaluation methods. To further test for correlation, we segmented the number of scores of each set of evaluations into terciles and compared each set of evaluations with agreement in the bottom, middle and top 3rd of the different tools.

RESULTS: Faculty scored the highest on evaluations completed by residents (med = 4.77) and had the lowest range between the upper and lower quartiles among responses. In contrast, Faculty scored the lowest on social media evaluations and the largest range between the upper and lower quartiles. In addition, in terms of agreement of tercile placement, the tools disagreed 74% and 85% percent of the time when comparing 2 and 3 categories respectively. The results showed no association with the relative ranking of faculty between evaluation methods.

CONCLUSIONS: The 3 tools compared different perspectives of General Medicine Faculty. We conclude that the tools are not able to highlight a uniform signal in faculty ratings across the types of evaluations. It is important to continue to evaluate faculty domains that include knowledge, interpersonal and professional skills. We need to develop a better understanding of the important patient and learner domains that are captured by the various evaluative tools currently used in practice to provide effective feedback to our faculty.

EVALUATION OF SKIN CANCER DIAGNOSIS FREQUENCY IN VA TELEDERMATOLOGY ENCOUNTERS

Aliya C. Hines[1,2]; Rebecca Lamkin[3]; Donglin Li[3]; David Mohr[3,7]; Allen L. Gifford[3,8]; Martin A. Weinstock[4,6]; Dennis Oh[4,5]. [1]VA Ann Arbor Health Care System, Ann Arbor, MI; [2]Institute of Health Policy and Innovation, University of Michigan, Ann Arbor, MI; [3]Center for Healthcare Organization and Implementation Research, VA Boston Healthcare System, Boston, MA; [4]VA Office of Connected Care, Washington, DC; [5]San Francisco VA Health Care System, San Francisco, CA; [6]Providence VA Medical Center, Providence, RI; [7]Boston University School of Public Health, Boston, MA; [8]Boston University, Boston, MA. (Control ID #3391932)

BACKGROUND: The Veterans Affairs (VA) Office of Rural Health (ORH) Enterprise Wide Initiative (EWI) was created in fiscal year (FY) 2017 to provide funding to increase rural veteran access to dermatology care through store- and-forward teledermatology (SFT). SFT allows primary care providers to digitally transmit patient clinical history and photographs to dermatologists at tertiary VA medical centers for evaluation, diagnosis and treatment recommendations. Little is known about the diagnostic outcomes of the national VA SFT program, and no previous studies have examined whether VA sites that receive EWI funding exhibit different diagnosis patterns compared to sites without EWI funding. The primary objectives of this study were to conduct the first national description of skin cancer diagnoses associated with teledermatology encounters in VA and compare SFT diagnosis patterns at EWI grantee sites to those at non-grantee sites.

METHODS: Diagnosis codes associated with SFT teledermatology encounters conducted between fiscal year (FY) 2016 and 2019 were obtained from the VA administrative records and a descriptive statistical analysis was conducted.

RESULTS: Nationwide, over FY16-19, a total of 388,045 unique veterans (91% male, mean age 65.9 years, 41.2% rural) had a VA teledermatology encounter, increasing from 90,450 in FY16 to 122,455 in FY19. Within this population, 445 (0.1%) had a teledermatology

diagnosis of melanoma and 11,822 (3.0%) had a diagnosis of keratinocyte carcinoma (KC). Neoplasm of uncertain behavior (NUB), a diagnosis commonly given to unbiopsied skin lesions suspicious for skin cancer, was the most common diagnosis in the study population, associated with 99,701 veterans (25.7%). Actinic keratosis (AK), a precancerous skin diagnosis, was the second most common diagnosis, given to 40,505 (10.4%) veterans. Grantee sites demonstrated patterns of teledermatology-associated skin cancer diagnoses that mirrored non-grantee sites and the national VA. Of the 132,735 veterans seen by teledermatology at grantee sites between FY16-19, 218 (0.2%) had an associated diagnosis of melanoma, 4,947 (3.7%) had a diagnosis of KC, 29,800 (22.4%) had a NUB diagnosis, and 14,465 (10.8%) had an AK diagnosis. The proportion of veterans with melanoma, KC, NUB and AK diagnoses remained stable each year from FY16 to FY19 nationally, at EWI grantee sites and non- grantee sites.

CONCLUSIONS: The national VA teledermatology program is being used to diagnose significant numbers of veterans with skin cancer, lesions suspicious for skin cancer and precancerous skin lesions. Future work will examine how often lesions diagnosed via teledermatology as NUB were subsequently biopsied and given a biopsy-proven skin cancer diagnosis. Diagnosis patterns at EWI grantee sites were similar to sites without EWI funding and the national VA over the entire study period, as well as year by year. Additional study is needed to better understand the impact of EWI grants on the diagnosis patterns seen at grantee sites.

EVALUATION OF SUSTAINED PRIMARY CARE PROVIDERS' ADOPTION OF AN ESTABLISHED ECONSULTS PROGRAM AT A TERTIARY PRIMARY CARE CENTER

Itohan Omorodion[1]; Kimberly Dowdell[2]. [1]General Internal Medicine, University of Virginia, Charlottesville, VA; [2]Medicine, UVA, Charlottesville, VA. (Control ID #3390348)

BACKGROUND: Electronic consultations (eConsults) were developed as a way to mitigate the increasing demand for specialists, which has negative cost consequences for patients and health systems. eConsults are an asynchronous documented form of communication that enable primary care providers (PCP) to seek advice from specialists. Most evaluations of eConsult programs focus on short-term program adoption after the initial implementation phase. As eConsult programs increase in popularity, it is essential to understand what facilitates program adoption. The focus of this study was to identify factors that promote the sustained use of long-established eConsult programs. This study examined PCP perceptions of a five-year eConsult program within a tertiary primary care center.

METHODS: This cross-sectional study surveyed PCP at a single U.S. based tertiary primary care center in July 2019. The survey collected information on providers' demographics and opinions regarding the aspects of the eConsults program. Bivariate analyses with the dependent variable as the frequency of use and the independent variables as demographics and opinions of the program were performed using the Chi-square or Fisher's Exact Test and Mann-Whitney U-Test for categorical and continuous variables, respectively.

RESULTS: 69 PCP responded to the survey. Attending physicians (67%) had the greatest representation among high frequency users. Most of the providers had positive sentiments regarding eConsults (70.4%). Key program facilitators that high frequency users strongly agreed with were the program's educational value ($p<0.001$), ability to reduce specialty visits ($p<0.005$), and capacity to improve their relationships with patients ($p<0.005$). The top barriers that low frequency users identified with were inadequate knowledge on how to use the templates ($p<0.001$) and disruption of workflow ($p<0.001$). Notably, the majority of PCP endorsed that requiring patient consent before performing an eConsult would be a barrier and this association did not vary significantly based on providers' frequency of using eConsults ($p=0.10$).

CONCLUSIONS: Our aim was to examine the factors that differentiate providers based on their usage patterns. We observed that program satisfaction among high utilizers may be attributed to their appreciation for the program's educational value and positive impact on patient care management. Future efforts to augment the adoption of eConsults would benefit from targeting technical support and workflow integration since low frequency users cited those as barriers. Reimbursement requirements to obtain patient consent prior to using eConsults may be a potential barrier. Overall, these findings highlight that eConsults are viewed favorably after long-term establishment. This research contributes to the field of telehealth by identifying common facilitators and barriers endorsed by providers that can help refine the implementation of eConsult programs within health systems.

EVALUATION OF THE ASSOCIATION BETWEEN 30-DAY READMISSIONS AND RECEIPT OF HOME HEALTH SERVICES IN GERIATRIC PATIENTS

Zoe d. Trutner[1]; Andrea Sorensen[2]; Chad Villaflores[2]; Jacob Komberg[1]; Sarah Meshkat[2]; Catherine Sarkisian[2]. [1]Geriatrics, UCLA, Los Angeles, CA; [2]Medicine, UCLA and Greater Los Angeles VA, Los Angeles, CA. (Control ID #3388450)

BACKGROUND: Due to focus on reducing readmissions, hospitals are incentivized to discharge high-risk patients to skilled nursing facilities (SNF) or offer skilled care such as home health services (HHS). HHS has favorable costs and patient satisfaction; however, outcomes are mixed. Existing studies compare HHS and SNF outcomes using national Medicare databases, but institution-level analses may better elucidate specific factors driving discharge practices and outcomes. Motivated by an observation that UCLA HHS expenditures in the Medicare Shared Savings Program are higher than a CMS-reported national average, we evaluate whether receipt of HHS is associated with lower likelihood of hospital readmission.

METHODS: This retrospective cohort study used electronic health records for older adults discharged from UCLA hospitals with HHS or "home with self-care" (HSC), from March 2017 to April 2018. We examined unadjusted sociodemographic and clinical correlates of discharge status (HHS vs HSC) and constructed a logistic regression model of readmissions adjusting for sex, age, surgical admitting service, race, and LACE+ score (readmission risk score assigned at discharge based on length of stay, admission acuity, comorbidities, 6-month ED visit count, and associated factors).

RESULTS: Of the 6,848 patients age >65 years discharged during the study period 45% (3,106) were HSC and 28% (1,923) were HHS. The remainder went to SNF (16%) or other (10%, including death, hospice). Compared to those discharged to HSC, patients with HHS were older (77.0 vs 74.4 years), more often female (29.4% vs 23.6%) and single (43.5% vs 37.4%), assigned higher average LACE+ scores (53 vs 51), and readmitted at a higher rate (13% vs 10%), $p<0.05$ for all. There was no difference between the groups in race/ethnicity. In adjusted analyses, patients discharged to HHS were more likely to be readmitted within 30 days compared to those discharged to HSC (OR=1.22, $p=0.034$). 54% of HHS discharges were not high-risk by LACE+.

CONCLUSIONS: Post-acute UCLA patients receiving home health services were more likely to be readmitted within 30 days compared to patients discharged home without HHS. Our analysis indicates that even within one institution or department, the population discharged to HHS is highly variable and the outcomes, as measured by 30-day readmissions, are worse compared to discharge home without HHS. Coupled with the observation that HHS at UCLA exceeds national averages, our findings

support the need for more specific guidelines to inform HHS referrals at discharge.

EVIDENCE REVIEW: IMPLEMENTATION OF CARE COORDINATION MODELS TO REDUCE HOSPITALIZATIONS AND EMERGENCY ROOM VISITS

Wei Duan-Porter[1,2]; Kristen Ullman[1]; Brittany Majeski[1]; Isomi Miake-Lye[3,4]; Susan Diem[1,2]; Nancy Greer[1]; Timothy Wilt[1,2]. [1]Center for Care Delivery Outcomes Research, Minneapolis VA Health Care System, Minneapolis, MN; [2]Medicine, University of Minnesota Medical School, Minneapolis, MN; [3]West Los Angeles VA Medical Center, Los Angeles, CA; [4]University of California Fielding School of Public Health, Los Angeles, CA. (Control ID #3391926)

BACKGROUND: Complexity in healthcare delivery and care fragmentation lead to adverse outcomes, particularly for certain vulnerable groups. However, it remains unclear whether care coordination (CC) interventions can address these issues and help reduce acute care utilization. We conducted an evidence review to better understand which CC models were effective and where they were implemented. We sought to summarize key elements of CC models, describe healthcare settings, and identify tools or approaches used to guide implementation and evaluation.

METHODS: To summarize the evidence addressing this broad topic area, we identified recent systematic reviews (SR) that examined the effect of CC interventions on hospitalizations and/or emergency room (ER) visits. We searched MEDLINE, CINAHL, Embase, Cochrane database, VA Evidence Synthesis Program, and AHRQ Evidence-based Practice Center reports from 2015-2019. Two individuals screened and conducted full-text review to identify eligible SR. All eligible SR underwent quality ratings using modified AMSTAR 2.

Data abstracted included: number and characteristic of included studies; target population(s); description of CC models; summary effects on hospitalizations, ER visits, and/or patient experience; and models or components reported as important for effectiveness. We undertook qualitative synthesis of SR results. Among primary studies included by eligible SR, we also abstracted data from relevant randomized controlled trials (RCT) and quasi-experimental observational studies conducted in the US.

RESULTS: Of 1589 unique citations, 16 eligible SRs were identified; fourteen examined care or case management, and two addressed models of intensive primary care. Twelve SR were high or medium quality, and all included US studies. SR included a wide variety of CC models, and those SR which classified interventions used broad definitions for categories or elements. No SR on case management found consistent reductions in hospitalizations or ER visits, although most described some studies that showed positive effects. SR on intensive models of primary care found that home based primary care reduced hospitalizations and ER visits, although the evidence was mostly from observational studies.

Eligible SR included 272 unique primary studies; we identified 18 RCT and 9 observational studies that were relevant. Among these, 4 RCT and 7 observational studies reported reductions in hospitalizations and/or ER visits. Studies were mostly conducted at large academic health systems (in urban settings) or public hospitals often serving poor and uninsured populations. Few studies reported on specific tools and approaches used to assess implementation.

CONCLUSIONS: CC models have inconsistent effects on reducing hospitalizations and ER visits. It remains unclear how CC models should be adapted to different healthcare settings and which tools or approaches are most helpful for implementation.

EXAMINATION OF PATIENT CHARACTERISTICS ASSOCIATED WITH READMISSION PRIOR TO POST-DISCHARGE FOLLOW-UP VISIT

Michael Sobieraj[1]; Mohammad Islam[1]; Sara Abrahams[1]; Jamil O. Alexis[1]; Alexander Khodak[1]; Kevin Coppa[2]; Jamie Hirsch[1]; Eun Ji Kim[3]. [1]Medicine, Northwell Health North Shore University Hospital, Glen Oaks, NY; [2]Department of Information Services, Northwell Health, Englewood, NJ; [3]General Internal Medicine, Northwell Hofstra School of Medicine, Lake Success, NY. (Control ID #3391856)

BACKGROUND: Post-discharge follow-up visits are designed to aid the transition to home or rehab facility after hospitalization and have been associated with decreased readmission. Despite scheduling post-discharge follow-up visits, we have identified patients who were readmitted prior to their follow-up visits. To better understand these early readmissions, we examined these patients' demographic characteristics, primary discharge diagnosis, LACE (Length of stay, Acuity of admission, Charleston comorbidity index, and Emergency department use in the prior 6 months) index, and reasons for readmission.

METHODS: We conducted a retrospective chart review on patients at a large metropolitan health system who were readmitted prior to their scheduled discharge follow-up appointment in 2018. First, we described patients' demographic characteristics (race, gender, age, and primary language), categorized the readmission risk based on the LACE index (0-4 = low, 5-9 = moderate, and >9 = high risk), and calculated the average number of days between index visit discharge and readmission. Next, we compared the primary diagnoses between the index hospitalization and readmission and assessed whether patients were readmitted for the same diagnosis and/or because their primary complaints were not adequately addressed during the index hospitalization using a chi-squared test.

RESULTS: This study included 162 patients who identified as 64% non-Hispanic White (n=104), 16% Black (n=26), 7% Asian (n=12), and 12% Other (n=20). Patients on average were readmitted within 7.3 days; 67% within 1 week and 86% within 2 weeks. The average LACE index was 11.2 with 4% low, 23% moderate, and 73% high risk. One-third (n=50, 31%) were readmitted with the same diagnosis as the index hospitalization and 22% (n=35) were readmitted due to inadequate management of the patients' primary complaint during the index hospitalization. A higher percentage of patients readmitted with the same diagnosis (48%, 24/50) were due to inadequate management of the primary complaint compared to those readmitted with a different diagnosis (10%, 11/112) ($p<0.001$). We also identified that having a non-English primary language (44% vs 19%; $p=0.02$) and being a racial minority (29.3% vs 17.3%; $p<0.001$) were associated with being readmitted due to inadequate management of primary complaint.

CONCLUSIONS: The majority of our study population had a high risk of readmission. While most post-discharge follow-up visits were scheduled within 2 weeks of discharge, the average time to readmission was only 7 days. We also found that patients were frequently readmitted for the same diagnosis as the index visit and identified associated factors (failure to address the patient's primary concern, limited English proficiency, and being racial minorities). Our study suggests that earlier post-discharge follow-up, addressing patients' complaint, and use of interpreters should be incorporated in discharge planning to reduce high readmission risks.

EXAMINATION OF POST-DISCHARGE FOLLOW-UP APPOINTMENT STATUS AND 30-DAY READMISSION

Kevin Coppa[1]; Eun Ji Kim[2,5]; Michael Oppenheim[1,3]; Kevin Bock[1]; Joseph Conigliaro[4,5]; Jamie Hirsch[1]. [1]Department of Information Services, Northwell Health, New Hyde Park, NY; [2]General Internal

Medicine, Northwell Hofstra School of Medicine, Lake Success, NY; [3]Department of Medicine, Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY; [4]Internal Medicine, Zucker School of Medicine, New Hyde Park, NY; [5]Institute of Health Innovations and Outcomes Research, Feinstein Institutes for Medical Research, Manhasset, NY. (Control ID #3391686)

BACKGROUND: Outpatient and ambulatory follow-up appointments are intended to evaluate and monitor patients' recovery following a hospitalization and adjust treatments that were commenced during hospitalization. Many studies examining post-discharge follow up visits and 30-day readmission, mainly using billing data, are only able to ascertain whether a patient arrived at a follow-up appointment or not. As patients who have a scheduled appointment may differ substantially from those with no appointment scheduled, this is an important element to consider in readmission risk assessments. The objective of this study is to examine the impact of having post-discharge follow-up appointment status, specifically, 1) having a scheduled appointment and 2) arriving to said appointment on 30-day readmission.

METHODS: This is a cross-sectional analysis of patients hospitalized at 13 hospitals in an Integrated Delivery Network in 2018 and their ambulatory appointments in that same network within 30 days of discharge. We included 50,772 patients who had both an inpatient admission and an outpatient appointment with the health system within 18 months prior to their admission. Primary outcome was readmission within 30-days post-discharge. We used the chi-squared test for categorical variables and Kruskal-Wallis for continuous variables across all groups to test for differences by appointment scheduled status and appointment arrival status. For comparing readmission risk of a patient's follow-up status, we used a Cox proportional hazard model to calculate the effect of appointment status on the time to 30-day readmission.

RESULTS: There were 32,108 (63.2%) patients with scheduled post-discharge follow-up appointments and 18,664 (36.8%) patients with no follow-up; 28,313 (88.2%) patients arrived, 3,149 (9.8%) missed, and 646 (2.0%) were readmitted prior to their scheduled appointments. Overall 30-day readmission rate was 7.3%; 6.0% [5.75-6.31] for those who arrived, 8.8% [8.44-9.25] for those without follow-up, and 10.3% [9.28-11.40] for those who missed a scheduled appointment ($p < 0.001$). After adjusting for covariates, patients who arrived at their appointment in the first week following hospital discharge were significantly less likely to be readmitted (HR 0.60 [0. 45 – 0.76], $p < 0.001$) compared with those not having any follow- up. However, this reduced risk was no longer significant at 14 days (1.11 [0.98 – 1.24], $p = 0.10$) and there was increased risk at 21 (HR 1.26 [1.12 – 1.40], $p < 0.001$) and 28 days (HR 1.37 [1.23 – 1.51], $p< 0.001$).

CONCLUSIONS: Patients who arrived at post-discharge appointments had a reduced risk of 30-day hospital readmission compared with patients who missed their follow-up visits or patients with no follow-up scheduled. This is only significant during first week post-discharge, suggesting that coordination of early care, preferably within one week of discharge, is critical in reducing 30-day readmissions.

EXAMINATION OF RESIDENTS' PERCEPTIONS OF CROSS-CULTURAL CARE AND THEIR CAREER INTEREST IN PRIMARY CARE OR COMMUNITY HEALTH

Sara Abrahams[1,3]; Eun Ji Kim[3,1]; Lyndonna Marrast[3,1]; Omolara T. Uwemedimo[2,1]; Joseph Conigliaro[3,1]; Johanna Martinez[3,1]. [1]Medical School, Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY; [2]Pediatrics, Zucker School of Medicine at Hofstra/ Northwell, New Hyde Park, NY; [3]Medicine, Northwell Health, Lake Success, NY. (Control ID #3390597)

BACKGROUND: The shortage of primary care physicians in the United States continues to grow with projections estimating a lack of 20,000-50,000 in the next decade. Resident physicians cite inability to address patients' social needs as one reason for not pursuing primary care. We investigated residents' career interest in primary care or community health and associations with their perceived preparedness to provide cross-cultural care and barriers they identify to cross-cultural care.

METHODS: We conducted a cross-sectional, retrospective analysis of a survey of internal medicine, pediatrics, and family medicine residents in the 2018-2019 academic year. Our primary outcome was resident career interest in primary care (PC) or community health (CH). We examined 8 domains of cross-cultural preparedness and 8 domains of perceived barriers to the provision of cross-cultural care. We described residents' sociodemographic and cultural characteristics by high career interest in PC or CH, defined as 80% or more on a continuous scale. Then, we examined correlations among high career interest in PC and CH and 1) preparedness and 2) barriers. Finally, we examined differences in perceived preparedness and barriers based on residents' characteristics and backgrounds.

RESULTS: The study population was diverse: 36.8% non-Hispanic White, 6.5% non-Hispanic Black, 7.7% Hispanic, 37.4% non-Hispanic Asian, and 11.6% Other. Of the 155 residents, 17 residents expressed high career interest in PC and 16 residents in CH. A quarter (27.7%) identified as coming from disadvantaged backgrounds, which was also associated with high career interest in CH ($p<0.01$). Racial/ethnic minorities, specifically non-Hispanic Blacks, were associated with high career interest in PC ($p<0.01$) and CH ($p<0.01$). Almost half (44.4%) of family medicine residents had high career interest in PC versus only 2.4% of internal medicine and 17.7% of pediatric residents (p-value<0.01). Preparedness to provide one domain of cross- cultural care correlated with preparedness to provide another (p-values<0.05). A higher percentage of residents coming from disadvantaged backgrounds identified training, lack of role models, and attitudes of attendings as barriers compared to those who were not (all p-values<0.05).

CONCLUSIONS: Resident characteristics, such as identifying as non-Hispanic Black or being a family medicine resident, were associated with high career interest in PC or CH. Perceived preparedness to provide one domain of cross-cultural care was correlated with being prepared in others, and this finding persisted for barriers to cross-cultural care. A higher proportion of residents from culturally diverse backgrounds identified barriers compared to their colleagues. With the majority of all health outcomes linked to social factors, preparing residents to provide cross-cultural care will be an important step towards addressing social determinants of health and reducing health disparities in the future.

EXAMINING MISSED APPOINTMENTS IN A STUDENT-RUN FREE CLINIC

Indrani Guzman Das[1]; Candace Chien[1]; Nicolas J. Blobel[1]; Asal Hejazi[1]; Jason Harris[2]; Elena Beideck[3]; Rhiannon C. Miller[1]; Alexandra H. Miller[4]; Ashita S. Batavia[5]; Pamela Charney[6]. [1]Weill Cornell Community Clinic, Weill Cornell Medicine, New York, NY; [2]Medical School, Weill Cornell Medicine, New York, NY; [3]Weill Cornell Community Clinic, Weill Cornell Medicine, New York, NY; [4]Medicine, Weill Cornell Medicine, New York, NY; [5]Medicine, Weill Cornell Medical College, Larchmont, NY; [6]Internal Medicine, Weill Cornell Medical College, New York City, NY. (Control ID #3392115)

BACKGROUND: Missed appointments hinder effective patient care. Nationally, missed appointment rates vary from 5-30%, and data from student-run free clinics is limited. The Weill Cornell Community Clinic (WCCC) is a student-run free clinic that provides comprehensive multidisciplinary care to uninsured patients. WCCC does not double-book

patients and volunteers provide reminder calls to all scheduled patients. Therefore, missed appointments limit the number of patients served and wastes resources. Here we explore factors associated with missed appointments.

METHODS: All patients with a scheduled appointment in 2019 were included. Missed appointments were defined as a no-show without advanced notice. Demographic information was collected for all patients with missed appointments (gender, age, distance from the clinic, language). Descriptive statistics were used to characterize patients with missed appointments during the study period.

RESULTS: The total number of scheduled appointments was 527. There were 134 missed appointments by 84 patients during the study period. Among patients with missed appointments, 46% (n=39) missed 1 appointment, 23% (n=19) missed 2 appointments and 31% (n=26) missed ≥3 appointments. Of the 26 patients who missed ≥3 appointments and were later unable to be reached by the clinic, 31% (n=8) received a notification letter from the WCCC (see Table 1.) All 8 patients were contacted over the phone (with translators if applicable). Of these, 3 patients contacted WCCC after receiving the notification letter, and 1 patient reestablished care at WCCC.

CONCLUSIONS: Our missed visit rates are similar to other primary care clinics at 25% vs. 5% to 30%, in spite of implementation of reminder calls and outreach after a missed visit. Despite multiple failed attempts at contacting patients via telephone, 3 patients were able to be contacted after sending a notification letter. Our study suggests that language barriers may be a driver of missed visits as 50% of the patients who received a notification letter do not speak English as their primary language vs. 26% of all WCCC patients. Further study is needed, but our limited sample size suggests patients with multiple comorbidities and comorbid mental illness are at risk of being lost to follow up.

EXAMINING NO-SHOW RATES IN AN URBAN PRIMARY CARE RESIDENCY CLINIC

Elizabeth Pines. Department of Medicine, Christiana Care Health System, Newark, DE. (Control ID #3378494)

BACKGROUND: No-show rates among resident primary care practices vary from 12.9% to 45%. No-shows have been associated with increased acute care utilization, reduced access for patients, worse health outcomes, decreased provider productivity, and missed educational opportunities for residents. Many reasons have been cited for missed appointments, but few studies investigate the barriers to attendance. This study examines the association between no-show rates at an urban internal medicine (IM) and family medicine (FM) residency continuity clinic based upon provider characteristics and appointment types as well as the barriers to attendance faced by patients.

METHODS: The project consisted of 1) a retrospective chart review including all scheduled adult appointments from July 1, 2016 and December 4, 2017 at our residency continuity clinic and 2) a prospective nine-item closed-ended telephone survey of sequential patients who no-showed from May 29, 2018 to June 29, 2018. Data extracted from the electronic medical record included demographic, geographic, and appointment details. Survey questions focused on transportation, financial, and scheduling concerns. Chi- square test was used to analyze no-show differences between IM and FM providers as well as to compare characteristics of survey responders vs. non-responders.

RESULTS: During the retrospective chart review, 47,753 discrete visits occurred. The overall no-show rate was 23.3% with IM residents having the highest no-show rate (29.0%) and IM attendings having the lowest (17.7%) ($p<0.01$). Regardless of specialty, hospital discharge appointments had the highest no-show rate (34.7% and 38.5%, respectively) while pre-operative appointments had the lowest (9.1% and 17.6%, respectively). During the survey study period, there were 422 no-show appointments for 391 patients. Of the 391 patients, 260 were contacted and 72 (27.7%) completed the survey. Responders were more likely to be female (80% vs. 51.6%), black (79.2% vs. 64.9%), have Medicare (30.6% vs. 23.4%), and be a patient of an attending (30.6% vs. 17.0%). The most common (54.1%) reason cited for no-show was forgetting. Over 60% of respondents did not cite any barriers to attendance. For those who experienced barriers, transportation ranked as the top three reasons for no-show. Furthermore, 60% preferred a cell phone call reminder and 55.6% wanted a text message while only 31.9% wanted a home phone call reminder, which during this study was the default.

CONCLUSIONS: This study identified significant differences in no-show rates between resident and attending practices as well as IM and FM residents. Hospital discharge appointments had the highest no-show rate, but follow-up appointments comprised the largest absolute number of no-shows. The survey revealed a surprisingly large percentage of patients denying any barrier to attendance. Those facing barriers cited difficulties with transportation and ineffective reminders as reasons for missed appointments.

EXAMINING THE ASSOCIATION OF INDIVIDUALS' BELIEFS ABOUT HYPERTENSION WITH BLOOD PRESSURE CONTROL AMONG AFRICAN AMERICANS WITH UNCONTROLLED HYPERTENSION LIVING IN THE RURAL SOUTH.

Anne Wagstaff[1]; Monika M. Safford[2]; Doyle Cummings[5]; Jacqueline Halladay[3]; Joanna Bryan[2]; Andrea L. Cherrington[4]. [1]Internal Medicine, University of Alabama at Birmingham, Birmingham, AL; [2]Department of Medicine, Weill Cornell Medical College, New York, NY; [3]Family Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC; [4]Department of Medicine, University of Alabama, Birmingham, AL; [5]East Carolina University, Greenville, NC. (Control ID #3392109)

BACKGROUND: Hypertension (HTN) is major risk factor for cardiovascular disease, and African Americans are known to have worse outcomes. Yet there is a relative paucity of literature studying HTN in southeastern, rural, African American communities. Patient beliefs surrounding HTN are varied and impact outcomes such that gaining a deeper understanding of the prevalence of beliefs is beneficial. This study examines the relationship between beliefs about HTN, lifestyle modification, and blood pressure (BP) control among African American adults living in rural AL and NC.

METHODS: This is a cross-sectional study of baseline survey data collected in a large cluster randomized trial of interventions to improve BP control for African Americans. HTN belief questions included: "How serious of a personal health concern has high blood pressure been?" and "Can changing your lifestyle help to lower your blood pressure?", responses were dichotomized into very/somewhat serious vs not. Our primary outcome was BP measured as a continuous variable. Secondary outcomes included medication adherence assessed by asking, "Do you sometimes stop taking your medicines for reasons other than forgetting?" and "Do you sometimes stop taking your medicine when your symptoms are under control?" - both answered yes/no. Covariates were age, sex, education, marital status, and depressive symptoms. Linear regression and robust Poisson regression were used to evaluate associations between HTN beliefs and outcomes.

RESULTS: Participants were African Americans with uncontrolled HTN who lived in rural AL or NC. Of the 1320 enrolled, 1238 had complete data. Characteristics included a mean age of 58 (± 12), 62% female, and a mean BP of 156 (±17)/90 (± 14) mmHg. Almost 95% (n = 1173) believed that BP was a very or somewhat serious concern and a similar percentage (96%; n = 1188) recognized lifestyle changes could help lower BP.

However, beliefs were not significantly associated with systolic or diastolic BP levels after controlling for covariates. Additionally, 1230 (99.4%) thought it was important to take medications. Despite this finding, only 37% (n = 457) reported not missing their medicines with no significant association between beliefs and taking medications consistently. Those that did not consider HTN as a serious concern and did not think lifestyle changes helped were more likely to be female, lack a high school degree, and be single.

CONCLUSIONS: The overwhelming majority of African Americans living in rural AL and NC believed HTN was a serious health concern and recognized the importance of lifestyle choices in HTN control. Despite these findings, there was no association between these beliefs and medication adherence or actual BP measurements. Importantly, these findings suggest that HTN outcomes are not due to lack of awareness. Rather other barriers to HTN control likely exist, and identifying and addressing these barriers will be essential to improving outcomes in this population.

EXAMINING THE ASSOCIATION OF SOCIAL RISK WITH THE RISK OF HEART FAILURE READMISSION IN THE VETERANS HEALTH ADMINISTRATION

Charlie M. Wray[1,2]; Marzieh Vali[3]; Louise Walter[4]; Lee Christensen[5]; Wendy Chapman[6]; Peter Austen[7]; Amy L. Byers[8]; Salomeh Keyhani[1]. [1]Department of Medicine, University of California, San Francisco, San Francisco, CA; [2]Section of Hospital Medicine, San Francisco VA Medical Center, San Francisco, CA; [3]Internal Medicine, NCIRE, San Francisco, CA; [4]Medicine, University of California, San Francisco, San Francisco, CA; [5]Biomedical Informatics, University of Utah, Salt Lake City, UT; [6]Centre for Digital Transformation of Health, University of Melbourne, Melbourne, UT; [7]Institute of Health Policy, Management and Evaluation, University of Toronto, Toronto, ON, Canada; [8]Psychiatry, UCSF/SFVAHCS, San Francisco, CA. (Control ID #3390546)

BACKGROUND: Previous research has found that social risk factors are associated with an increased risk of 30-day readmission. The impact of social risk factors on hospital readmissions following an episode of heart failure (HF) within the Veterans Health Affairs (VA) system has not been examined. Our objective was to assess the association of five social risk factors (living alone, lack of social support, marginal housing, substance abuse, and low income) with 30-day HF hospital readmissions within the VA.

METHODS: Using data from a national sample of Veterans from the VA Corporate Data Warehouse, we first identified 10,761 Veterans, aged 65 and older, who were hospitalized for HF in 2012. Patients were identified by a primary discharge diagnosis from VA administrative data using ICD-9 codes. We randomly selected 1,500 Veterans from this cohort for subsequent chart abstraction of social risk factors. We identified patient age and the 32 clinical variables that are utilized in the CMS HF readmission model for all-cause HF readmissions. All variables were identified in administrative data one year prior to the index admission.

Because administrative data lacks information on several common social risk variables, we utilized two methods to extract patients' social risk: (1) manual chart abstraction, and (2) administrative coding (e.g., ICD-9). Using chart review, we extracted data on three variables (social support, housing, and living situation [i.e., living alone]) with limited or no data in administrative datasets. We used ICD-9-CM diagnosis codes to assess for substance abuse (e.g., drug and alcohol abuse). To assess for low income status, we classified someone as low income if their VA co-payment was waived on the basis of their means test evaluation.

RESULTS: Prevalence of the five risk factors in readmitted and non-readmitted patients, respectively; low income (47% vs. 47%), lives alone (18% vs. 19%), substance abuse (14% vs. 16%), lacks social support (2% vs. <1%), and marginal housing (<1% vs. 3%). Controlling for clinical factors contained in the Centers for Medicare & Medicaid Services readmission models, a lack of social support was found to be associated with an increased risk of 30-day readmission (OR 4.8, 95%CI 1.35-17.88), while marginal housing was noted to decrease readmission risk (OR 0.21, 95%CI 0.03-0.87). Living alone (OR: 0.9, 95%CI 0.64-1.26), substance abuse (OR 0.91, 95%CI 0.67-1.22), and having low income (OR 1.01, 95%CI 1.01-1.31) had no association with HF readmissions.

CONCLUSIONS: While a lack of social support was associated with 30-day readmission in the VA, its prevalence was low. In an integrated healthcare system like the VA, social risk factors may have a limited effect on 30-day readmission outcomes.

EXAMINING USE OF URINE DRUG TESTING AMONG OPIOID-NAïVE AND LONG-TERM OPIOID MEDICAID BENEFICIARIES: A RETROSPECTIVE CROSS-SECTIONAL STUDY

Sarah A. Friedman[1]; Kirtan Patel[2]; Yan Liu[5]; Sarah Hartzell[3]; Michelle S. Keller[4]. [1]School of Community Health Sciences, UNR, Reno, NV; [2]Administration, Renown Health, Sparks, NV; [3]Public Health, University of Nevada, Reno, Reno, NV; [4]Medicine, Cedars-Sinai Medical Center, Los Angeles, CA; [5]Community Health Sciences, University of Nevada Reno, Reno, NV. (Control ID #3341647)

BACKGROUND: Given the rising number of deaths associated from prescription opioid use, the Centers for Disease Control and Prevention (CDC) and other guidelines recommend that clinicians use routine urine drug testing (UDT) to identify patients at risk for opioid misuse/abuse. Our objective was to identify whether Medicaid beneficiaries in Nevada at increased risk for opioid misuse/abuse received guideline-concordant UDT.

METHODS: We used Nevada Medicaid claims data from January 2017-April 2018 to describe patterns of UDT for adults with opioid prescriptions. We examined three cohorts of patients on opioids: opioid-naïve (N=11,326), opioid-naïve with a 2nd consecutive prescription (N= 8,605), and long-term opioid use (defined as 120 opioid days' supply within 6 months) (N=17,456). Our outcome was defined as UDT before an opioid prescription among the naïve cohorts, and UDT between 60 and 183 days following the initial prescription for the long term cohort, consistent with guidelines. We used two categories of predictors: diagnoses identified in the literature as putting patients at higher risk for opioid misuse/abuse (alcohol disorder, other substance disorders, nicotine dependence, mental health diagnoses, male gender, and age >35) and behaviors associated with opioid misuse/abuse (multiple providers, early refills). Diagnoses prior to testing were counted. For the naïve cohorts, we used logistic regression to estimate models calculating predicted probability of diagnosis predictors, controlling for gender, age, and timing of marijuana legalization. For the long-term cohort, we used Cox Proportional Hazard regression to examine hazard ratios (HRs) for risk of opioid misuse/abuse and behaviors associated with misuse/abuse.

RESULTS: Only a small percentage of patients received UDT within the expected timeframe: 2.5% for the naïve opioid cohort, 3.5% for the naïve with 2nd prescription cohort, and 9.9% for the long-term opioid cohort.

Those with alcohol disorders and other substance disorders had the highest predicted probabilities (PPs) of UDT, among both the naïve cohort (PPs: alcohol disorder; 3.9%; other substance disorder: 8.4%) and the naïve cohort with a 2nd prescription (PPs: alcohol disorder: 6.2%; other substance disorder: 6.4%). Other predictors with significantly higher odds of UDT compared to the reference groups included nicotine dependence, mental health disorders, and male gender in the naïve cohort, and nicotine dependence and age >35 in the naïve with a 2nd prescription cohort.

In the long term cohort, alcohol disorders (HR: 3.3) and other substance disorders HR: (7.4) were also most strongly associated with UDT; all predictors except for early refill, multiple providers, and male had HRs significantly higher than 1.

CONCLUSIONS: While only a small percentage of Nevada Medicaid adults with an opioid prescription received UDT, there was a strong association between having a risk factor for opioid misuse/abuse and receiving UDT, but not behaviors associated with misuse/abuse.

EXPERIENCE DOES NOT EQUAL EXPERTISE: NEW GRADUATES OUTPERFORM EXPERIENCED PROVIDERS ON AN EXPERIENTIAL FACULTY ONBOARDING EXPERIENCE

Kinga Eliasz, Mara McCrickard, Andrew Wallach, Katherine Hochman, Colleen Gillespie, Khemraj Hardowar, Sondra R. Zabar. New York University Grossman School of Medicine, New York, NY. (Control ID #3390542)

BACKGROUND: Newly-recruited providers have heterogeneous backgrounds and need an introduction to their new institution's patient communication, safety culture, and performance expectations. We designed an experiential onboarding simulation to set institutional standards for new providers who join our Division of General Medicine. To continue improving the program, we examined if providers with different levels of patient experience require different onboarding support.

METHODS: During the 2-hour onboarding, participants completed 3, 10-minute OSCE cases designed to assess how they addressed a medical error, managed the patient's discharge goals of care, and responded to a struggling learner. During each encounter, participants interacted with highly trained Standardized Patients (SPs) or Standardized Learners (SLs), who used behaviorally-anchored checklists to evaluate provider performance on communication and case-specific skills. Following each encounter, participants completed a self-assessment while SPs/SLs completed the checklist, then the 2 discussed the encounter and the SL/SP provided confidential and actionable feedback. At the end, participants completed a program evaluation, debriefed with experienced facilitators, and received their checklists and an institutional resource guide.

RESULTS: Over 3 years, 90 faculty members (70 MDs, 20 Advanced Practice Providers) from 11 clinical sites participated in the onboarding program. 55 were new graduates (no on-the-job patient experience) and 35 were experienced providers (>1 year in practice). Results are presented as the mean % of items well done (WD) on a scale of "not done," "partially done," or "well done." All participants scored >65% WD for communication across all cases; they all performed lower in the education and counseling subdomain (39-51%). T-tests, comparing outcomes between new graduates vs experienced providers, revealed that new grads significantly outperformed experienced providers in several domains: communication across cases (71 vs 59%, $p<0.01$), patient activation across the 2 patient cases (39 vs 23%, $p=0.01$), and case-specific skills (72 vs 46%, $p<0.01$ for med error case). SP/SL text comments about the experienced providers were more negative (eg 'said the right words, but I didn't feel heard/cared for'), describing them as 'confrontational,' having 'own agenda,' 'not listening,' and the encounters as 'rushed' and 'disconnected.' All 88 participants who completed the evaluation agreed/strongly agreed that the event was engaging (99%), gave a sense of institutional culture (97%), effectively reinforced good communication skills (98%), and 94% would recommend the program.

CONCLUSIONS: Our results show that an experiential onboarding program to set local standards is valuable to newly-hired providers of all experience levels. Our finding that new graduates outperformed experienced providers warrants further investigation and suggests a need for recalibration of experienced providers' core patient-centered care skills.

EXPERIENCE WITH PREP: SURVEY AMONG IM AND OB/GYN FACULTY AND RESIDENTS

Gina M. Simoncini[1]; David E. Koren[2]; Paul D'Avanzo[3]; Elijah Clayton[4]; Juan Diaz Quinones[5]; Jesse Brajuha[3]; Sarah B. Bass[3]. [1]Internal Medicine, Temple University, Philadelphia, PA; [2]Department of Pharmacy, Temple University Hospital, Philadelphia, PA; [3]College of Public Health, Temple University, Philadelphia, PA; [4]Lewis Katz School of Medicine at Temple University, Philadelphia, PA; [5]Obstetrics/Gynecology, Temple University, Philadelphia, PA. (Control ID #3344043)

BACKGROUND: Human immunodeficiency (HIV) disease prevention with pre-exposure prophylaxis (PrEP) is marred by lack of provider knowledge and health inequities. PrEP awareness, knowledge and adoption by primary care physicians (PCPs) including obstetrics and gynecology (Ob/Gyn) providers, is crucial to improve the health disparities that exist in HIV prevention with PrEP.

METHODS: We modified a previously validated PrEP provider survey and administered it to faculty and categorical residents in the Departments of Ob/Gyn and Internal Medicine (IM) of a large urban hospital. T-tests and chi-square tests were performed with an alpha significance value of 0.05.

RESULTS: Sixty-one surveys were completed (24 Ob/Gyn, 37 IM). No statistically significant differences were observed by age or race, however there were a higher proportion of female-identified providers in Ob/Gyn (87.5%) compared to IM (54.1%) (p=.01). There was a greater proportion of residents in the IM group (65% vs 35%) in the Ob/Gyn group (p=.023). Regarding the willingness to prescribe PrEP between the specialties based for certain risk factors, 76% of IM physicians were extremely willing to prescribe PrEP for a patient having sex with partners of unknown HIV status vs 24% of Ob/Gyn providers (p=.003). Faculty, regardless of specialty, were more likely to have had a patient conversation about PrEP (74% vs 30% of residents [p=.001]), prescribed PrEP to a patient (50% vs 10% of residents [p=.001]), and referred a patient for PrEP to another provider (54% vs 17% of residents [p=.003]).

CONCLUSIONS: Faculty discussed and prescribed PrEP at greater rates than residents. Curriculum development to improve resident awareness and knowledge of PrEP and other HIV prevention strategies could improve the health disparities that exist within HIV prevention and PrEP.

EXPLORING DECISIONAL NEEDS IN LUNG CANCER SCREENING ELIGIBLE INDIVIDUALS WITH COPD

Minal Kale, Warda Chaudhary, Eric Robinson, Julie Schnur. Icahn School of Medicine at Mount Sinai, New York, NY. (Control ID #3392587)

BACKGROUND: Smokers who are at high risk of lung cancer also have high rates of other tobacco-related comorbidities. Among the most common is chronic obstructive pulmonary disease (COPD), a occurring in ~ 35% of screening-eligible individuals. COPD increases the risk of complications related to work-up of positive LDCT, impacts lung cancer treatment selection and associated complications, leads to decreased quality of life, and a limited life expectancy, substantially altering the harm-benefit ratio of lung cancer screening. Lung cancer screening is currently the only cancer screening test in which shared decision making is a condition of reimbursement by Medicare. As such, it is imperative to examine the decisional needs of

patients with comorbidities, particularly in low-income, racially diverse populations poorly represented in clinical trials.

METHODS: We conducted semi-structured interviews with 9 lung cancer screening-eligible patients with COPD (mean age 66, 55% female, mean smoking pack-years=70). The goal of the interviews was to learn more about patients' reactions to the idea that they may have different harms and benefits from lung cancer screening because of their disease and that they possibly should not receive lung cancer screening in the context of severe COPD. Additionally, we were interested in learning more about how patients would prefer to be informed about the pros and cons of lung cancer screening in the context of COPD.

RESULTS: Regarding reactions to the notion of COPD may increase the harms from lung screening, we discovered 3 major themes: 1) "No idea the two were connected" – Here, participants reported surprise that COPD impacts lung cancer screening. 2) "Cancer beats all" – Here, patients discussed willingness to tolerate increased potential harms of screening because knowing whether they have cancer was considered more important. 3) "Knowledge for its own sake" – Here patients discussed how knowledge of having cancer in one's body was more important than whether that knowledge led to reduced mortality or longer life. Regarding communication preferences, we found 3 major themes including: 1) "Show and tell" – Here patients discussed a desire to learn specific harms and benefits using visual displays and printed materials in addition to discussions. 2) "Give it to me straight" – Here patients expressed a preference for non-"sugar- coated" wording regarding harms. 3) "Follow the doctor's orders" – Here patients discussed that ultimately they would have high trust in their doctor's advice if screening is discouraged.

CONCLUSIONS: These themes will be important for the design of effective communication tools, and elucidates some of the issues related to lung cancer screening informational needs. Future work will explore decisional needs of patients with other comorbidities (as we suspect that non-lung comorbidities that are possibly less symptomatic will be associated with different beliefs and expectations), and explore provider needs.

EXPLORING HIGH-NEED AMERICANS' SATISFACTION AND EXPERIENCES WITH PRIVATE HEALTH INSURANCE COVERAGE: A SCOPING REVIEW OF THE LITERATURE

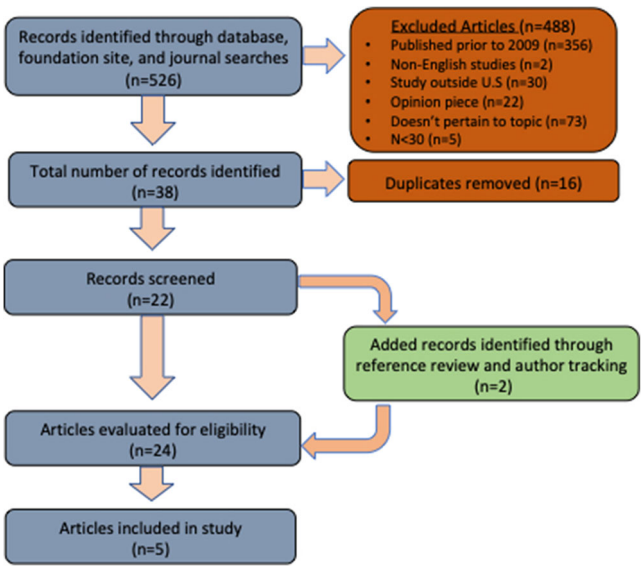
Charlie M. Wray[2,3]; Jordan Demos[2,4]; Madeleine Gerson[2,4]; Salomeh Keyhani[1,5]. [1]Department of Medicine, University of California, San Francisco, San Francisco, CA; [2]Northern California Institute of Research and Education, San Francisco, CA; [3]Section of Hospital Medicine, San Francisco VA Medical Center, San Francisco, CA; [4]San Francisco VA Medical Center, San Francisco, CA; [5]Section of General Internal Medicine, San Francisco VA Medical Center, San Francisco, CA. (Control ID #3390434)

BACKGROUND: The potential overhaul of the American health care system is a leading issue in the 2020 elections. It is often reported in the media that Americans are satisfied with their private health insurance, yet little is known about patients with high health care needs (>2 comorbidities). We conducted a systematic review of the medical and grey literature to understand the current evidence base on American's satisfaction and experience with private insurance, with a specific focus on those with high-needs.

METHODS: Using mesh terms: 'private insurance', 'patient satisfaction', 'opinion', and 'coverage' we identified studies of Americans' satisfaction with private health insurance using MEDLINE/PubMed, Kaiser Family Foundation (KFF), Robert Wood Johnson, Commonwealth Fund, and California Healthcare websites between November 2009 and November 2019. Two members of the team independently conducted the search and identified abstracts. Each abstract was independently reviewed by the team and evaluated for inclusion. All study designs were considered, including quantitative and qualitative methods, surveys, focus groups, literature reviews, and original research. We excluded consumer polls that lacked methodological details.

RESULTS: Of the 526 articles identified, 5 met search criteria to be included for manual review. Among these, several studies (Collins, Commonwealth; Pollitz, KFF, and Hamel, KFF) found that most people with private insurance were generally satisfied with their health plans - with experiences and attitudes differing based on cost and access to care. Only two studies commented on high-needs patients (>2 comorbidities). Ryan et al (Commonwealth) found that only 9% of high-needs patients had private insurance, while Hamel et al (KFF) found that patients with chronic medical conditions and private insurance reported more problems paying medical bills or affording out of pocket costs. Among the few high-needs patients surveyed, predominant themes were social isolation, unmet social needs, decreased access to care, and delays in care.

CONCLUSIONS: Among high-needs patients, limited data exists on satisfaction and experiences with private health insurance coverage. As the US debates health care reform, more information on high-needs patients' experiences with their health coverage will be needed to better inform policy makers and the voting public.



EXPLORING PATIENT INTEREST IN SOCIAL RISK ASSISTANCE FROM THEIR HEALTH CARE TEAMS

Emilia De Marchis[1]; Danielle Hessler[2]; Caroline Fichtenberg[3]; Elena Byhoff[4]; Cheryl R. Clark[5]; Alicia Cohen[6]; Eric Fleegler[7]; Amy G. Huebschmann[8]; Mark J. Ommerborn[9]; Laura M. Gottlieb[10]. [1]Family & Community Medicine, University of California, San Francisco, San Francisco, CA; [2]Family and Community Medicine, University of California, San Francisco, San Francisco, CA; [3]Center for Health and Community, UCSF, San Francisco, CA; [4]Medicine, Tufts Medical Center, Boston, MA; [5]General Medicine & Primary Care, Brigham and Women's Hospital, Boston, MA; [6]Primary Care, Providence VA Medical Center, Providence, RI; [7]Emergency Medicine, Boston Children's Hospital, Boston, MA; [8]Medicine, University of Colorado School of Medicine, Aurora, CO; [9]Brigham & Women's Hospital, Boston, MA; [10]Family and Community Medicine, UCSF, San Francisco, CA. (Control ID #3385966)

BACKGROUND: Health systems are increasingly incorporating social risk screening into patient care. Multiple recent studies have found that patients who screen positive for social risk factors (SRF) do not consistently report interest in receiving assistance with those risks. The objective

of this study was to evaluate the frequency of and factors associated with interest in social risk assistance by social risk screening results.

METHODS: Cross-sectional survey of a convenience sample of adult patients and caregivers of pediatric patients in 7 primary care and 4 emergency department (ED) settings in 9 US states. Surveys included multi- domain social risk screening questions on housing, food, transportation, utilities, and interpersonal violence. Additional questions assessed interest in assistance with social risks and perspectives on social risk screening. Respondents were randomized to two groups: one survey began with social risk screening questions and the other began with a question on interest in assistance. Multivariable logistic regressions evaluated co-variate associations with interest in assistance, stratified by social risk screening results.

RESULTS: Of 1,021 respondents, 353 screened positive for ≥1 SRF and were interested in assistance (34.6%); 309 screened positive and were not interested in assistance (30.3%); 328 screened negative for all SRF and were not interested in assistance (32.1%); and 31 screened negative for all SRF and were interested in assistance (3.0%). Among those who screened positive for ≥1 SRF, answering the survey question about interest in assistance before being screened for SRF (adjusted OR: 1.48 [95% CI: 1.05, 2.07]) was independently associated with higher odds of interest in assistance, as was screening positive for multiple SRF (2.40 [1.68, 3.42]), self-identifying as non-Hispanic Black race/ethnicity (2.22 [1.37-3.60]) and reporting lower income (7.78 [2.96, 20.4]). Among those who screened negative for all SRF, prior exposure to health care-based social risk screening (2.35 [1.47, 3.74]), higher perceived appropriateness of screening (3.69 [1.08, 12.5]), lower income (12.4 [2.94, 52.2]), poorer health (4.22 [1.09, 16.3]), and recruitment from an ED (4.27 [1.59, 11.4]) were independently associated with higher odds of interest in assistance.

CONCLUSIONS: Multiple factors were associated with patient interest in assistance with social risks. Regardless of social risk screening results, lower income patients had higher odds of interest in assistance. As the health care system's role in addressing social risk factors evolves, understanding patients' perspectives on social risk screening and desire for assistance will be critical to implementing patient-centered social care. To maximize uptake of social care interventions, clinical delivery systems should consider offering assistance prior to screening for specific risks. As social risk screening and intervention programs expand, interest in assistance is likely to increase.

EXPLORING SOCIAL DETERMINANTS AND AQP4 GENE EXPRESSION IN UVEAL MELANOMA: CORRELATION WITH SURVIVAL

Kelly Chen, Joseph Barney. Medicine, University of Alabama at Birmingham, Birmingham, AL. (Control ID #3376921)

BACKGROUND: Uveal melanoma (UVM) is the most common primary intraocular malignancy in adults. This aggressive cancer accounts for about 5–10% of all the melanomas, yet little is known about its genetic associations and risk factors for metastasis. Past reports found that median time to death after metastatic UVM diagnosis is six months. Aquaporin-4 (AQP4) is an integral membrane protein for maintaining water homeostasis within the central nervous system. Several studies have found AQP involvement in tumor cell metastasis. Additionally, loss of heterozygosity at the retinoblastoma (RB) locus has been found in UVM. We explored social determinants such as age, sex, etc, and their correlations with outcome. We also studied the relationships of gene expression levels of AQP4 and RB to UVM patient survival.

METHODS: We analyzed a publicly-available transcriptomic dataset from TCGA (The Cancer Genome Atlas). Using expression data from 80 patients with UVM, we explored the comparisons such as t statistics among variables of age, sex, and expression level of AQP4 and RB. Overall survival after UVM diagnosis was evaluated with Kaplan-Meier survival analysis methods including log-rank tests and Wilcoxon-Gehan tests.

RESULTS: Among the social determinants of health variables such as race, gender, and age, we did not find any correlations of patient survival. More specifically, no significant differences were observed in UVM survival related to sex (p=0.78) or RB2 level (p=0.29). We found, however, strong correlation between AQP4 expression level (p=0.03) with patient survival. There are no additive effects observed when both AQP4 and RB expressions were taken into consideration. These results suggest that higher levels of AQP4 expression can be protective to UVM patients. AQP4 expression level can also be used as an indicator of patient outcome for longer survival.

In addition, a trend was observed in UVM, which is related to old patients versus younger patients (p=0.06). **CONCLUSIONS:** There are no obvious correlations of social determinants with UVM patient outcome such as survival. AQP4 gene expression, however, was highly correlated to survival of UVM patients. This finding suggests a potential application of the gene as a positive predictor of survival after UVM diagnosis.

EXPLORING THE HEALTH INFORMATION-SEEKING EXPERIENCES OF A MULTILINGUAL, URBAN COHORT

Janet N. Chu, Elaine C. Khoong, Natalie Rivadeneira, Robert Hiatt, Urmimala Sarkar. Medicine, University of California, San Francisco, San Francisco, CA. (Control ID #3392141)

BACKGROUND: Negative health information-seeking experiences can worsen inequities in seeking health information and adversely impact health behaviors and outcomes. Prior studies have demonstrated disparities in health information-seeking experiences based on age, race/ethnicity, language, education, and income. Few studies have explored the impact of health literacy on health information-seeking, particularly among multilingual, diverse populations. This study examines the impact of language preference and limited health literacy (LHL) on self-reported health information-seeking experiences.

METHODS: We created a local survey by adding validated questions about health care access and health literacy to questions from the Health Information National Trends Survey. We administered this survey in English, Spanish, and Chinese to San Francisco residents, with oversampling for African Americans, from May to September 2017. We used weighted multivariable logistic regression analyses to assess the impact of language and LHL on health information-seeking experiences, adjusting for age, gender, race/ethnicity, education, usual place of care, and self-reported health status. We explored these four health information-seeking experiences: 1) confidence in getting health information, 2) frustration during information search 3) concern about quality of the information, and 4) finding information hard to understand.

RESULTS: The 1,027 survey participants included 50% of responses in English (n=514), 25% in Spanish (n=256), and 25% in Chinese (n=257). 82% of respondents reported at least one negative health information- seeking experience. In multivariate analysis, compared with English-language respondents, Chinese-language respondents had higher odds of low confidence (OR=3.25, 95% CI 1.62-6.55), feeling frustrated (OR=3.11, 95% CI 1.51-6.40), and found the information hard to understand (OR=2.50, 95% CI 1.25-5.00); Spanish- language respondents had higher odds of finding information was hard to understand (OR=2.22, 95% CI 1.28-3.84). Those who reported LHL had higher odds in all four negative information-seeking experience measures: lower confidence (OR=1.75, 95% CI 1.30-2.38), frustration (OR=2.16, 95% CI 1.61-2.92), concern about quality (OR=2.06, 95% CI 1.52-2.78), and difficulty understanding information (OR=2.60, 95% CI 1.92=3.51).

CONCLUSIONS: A majority of respondents reported at least one negative health information-seeking experience. Low health literacy and non-English language preference were associated with higher odds of negative health information-seeking experiences. This supports the American Medical Association's recommendations for health materials to be written at or below the 6th grade reading level. With a growing immigrant population, health systems need to consider linguistic diversity when creating health materials in order to mitigate inequities in seeking health information.

EXPLORING THE PIPELINE FOR DEAF AND HARD OF HEARING HEALTHCARE PROFESSIONALS: HOW THEY TRAIN AND WHO THEY SERVE.

Christopher Moreland[1]; Lisa Meeks[4]; Musarrat Nahid[2]; Tonya Fancher[3]. [1]Medicine, The University of Texas HSC - San Antonio, San Antonio, TX; [2]Medicine, Weill Cornell, New York City, NY; [3]University of California, Davis, Sacramento, CA; [4]Family Medicine, University of Michigan Ann Arbor, Ann Arbor, MI. (Control ID #3374075)

BACKGROUND: Deaf and hard of hearing (DHH) people (15% of U.S. population, an underserved health minority with documented disparities) are underrepresented among healthcare professionals. DHH physicians can provide communication-concordant primary care (PC) to DHH patients to improve healthcare access. No literature describes the DHH healthcare workforce or their accommodations or patients.

METHODS: We disseminated an online survey. Inclusion criteria were being DHH, having applied to a U.S. health professional school. Questions explored demographics, accommodations utilized and satisfaction, depression screening, patients served.

RESULTS: 150 respondents represented many professions, including medicine (36), nursing (25), audiology (17), dentistry (4). Training stages included students (47), residents/fellows (13), completed training (51).

Accommodation use varied widely by type, and overall decreased from education to employment. Respondents reported spending on average 2.1 hours weekly navigating school accommodations. Among those who transitioned directly from school to employment, accommodation satisfaction correlated with success in obtaining employment. This correlation was not present among those who entered residency.

Over 10% of respondents screened positive on the PHQ-2. Positive screens had a small and statistically significant association with less accommodation satisfaction in healthcare school. PHQ-2 score did not correlate with profession.

Of 105 people who reported current/planned medical specialty, 54 (51%) were categorized as PC, including 36 in medicine and 25 in nursing fields. Those in practice reported on average 33% of their patients were DHH. Those in school/training reported expecting on average 32% of future patients would be DHH.

CONCLUSIONS: Our study describes an under-recognized healthcare workforce segment: people with hearing loss. Our findings suggest that significant numbers of DHH students and professionals work in PC, or plan to, serving more DHH patients than non-DHH professionals. DHH healthcare professionals learn and serve across many specialties and utilize a wide range of accommodations. They commit significant personal resources to managing accommodations, which may be burdensome and lead to poorer wellbeing. Respondents seem more likely than the average health professional to serve DHH people, an underserved health minority. If school accommodation satisfaction predicts DHH students' wellness and employment likelihood, then effective accommodation provision during the educational pipeline is critical to maintaining the DHH workforce. This impacts the PC workforce's ability to reduce communication-discordant disparities, and serve an underserved minority population. Health professional schools, including medical schools, have opportunities to enhance the educational pipeline to a diverse workforce as well as reduce healthcare disparities by supporting effective accommodations for students and trainees with disabilities.

EXPLORING THE RELATIONSHIP BETWEEN CHURCH ENVIRONMENT AND CHANGE IN DIETARY HABITS AFTER A FAITH-BASED CARDIOVASCULAR DISEASE PREVENTION PROGRAM

Shanna A. Tucker[1]; Orysya Soroka[4]; Priscilla Amanquah[2]; Rosio Ramos[4]; Naa-solo Tettey[3]; Holly S. Andersen[4]; Erica Phillips[4]. [1]Internal Medicine, New York Presbyterian- Weill Cornell, New York City, NY; [2]Human Biology, CUNY Hunter College/ Weill Cornell, Brooklyn, NY; [3]Ronald O. Perelman Heart Institute, New York City, NY; [4]Medicine, Weill Cornell Medicine, New York City, NY. (Control ID #3391822)

BACKGROUND: Obesity prevalence and cardiovascular disease (CVD) risk factors disproportionately affect African Americans (AA). Multiple studies have shown that faith-based interventions can improve certain risk factors, including low fruit and vegetable (F&V) intake. In our previous study we developed and tested a novel quantitative measure of a healthy church environment termed the "Supportive Church Environment Score " (SCES). We found a strong correlation between baseline SCES and daily fruit intake, a moderate correlation between SCES and vegetable, and a weak correlation between SCES and ideal physical activity. Here, we compare churches' SCES to their members' fruit and vegetable intake before and 3- months after a faith-based CVD prevention program, to determine if there is a relationship between SCES and change in fruit and vegetable intake post-intervention. We hypothesized that a higher SCES would be associated with a greater increase in F&V intake at 3-months.

METHODS: Nine predominantly African-American churches were enrolled in a 10-week faith-based cardiovascular risk reduction program led by lay health-educators trained at each church. Program participants completed a written survey to assess cardiovascular risk behaviors and the church's health environment at baseline and 3-months. The SCES score was comprised of eleven activities that promote CVD health (i.e. healthy food options are provided at church events). Higher scores suggest greater CVD health promotion activities in the church. We calculated the R-coefficient of correlation to evaluate the relationship between participant's perception of their church environment (SCES) to change in fruit and vegetable intake between baseline and 3-months.

RESULTS: We calculated R- coefficients of -0.52 and -0.25 between median SCES and change in fruit and vegetable intake at 3-months, respectively.

CONCLUSIONS: A lower SCES at baseline was correlated with an increase in fruit and vegetable intake at 3-months. These findings suggest that, contrary to our hypothesis, our faith-based CVD prevention program is most effective in settings with low social support.

EXPLORING UNCERTAINTY AND THE GROWTH MINDSET AMONG SENIOR INTERNAL MEDICINE RESIDENTS

Marina Mutter[1,2]; Emmanuelle B. Yecies[1,3]; Deborah DiNardo[1,3]. [1]Internal Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA; [2]University of Pittsburgh Medical Center, Pittsburgh, PA; [3]VA Pittsburgh Healthcare System, Pittsburgh, PA. (Control ID #3391545)

BACKGROUND: Errors in medical decision making have been linked to adverse events and patient harm, particularly when diagnostic or therapeutic uncertainty exists. Prior research has attempted to categorize

uncertainty and to associate physicians' tolerance of uncertainty with various factors such as patient-provider communication and pursuit of diagnostic testing. The "growth mindset," or the perceived ability to change one's own intelligence level, has been well studied in other settings, but whether this mindset is associated with tolerance of uncertainty is unknown. In this study, we sought to explore senior internal medicine (IM) residents' reactions to uncertainty and to evaluate for associations between reactions to uncertainty and a measure of the growth mindset.

METHODS: Senior Internal Medicine residents at the University of Pittsburgh Medical Center rotating on inpatient night float from February through September 2019 were invited to participate in the study.

Participants completed a demographic survey, the Physicians' Reactions to Uncertainty (PRU) scale, and the Revised Implicit Theories of Intelligence or "growth mindset" scale. Spearman's Rho was calculated as a measure of association between scores on the two scales and the Wilcoxon rank-sum test was used to compare associations between demographic characteristics and scores on the PRU and "growth mindset" scales.

RESULTS: Between February and September 2019, 41 out of 45 (91%) eligible residents participated in the study. Residents scored an average of 18.4 out of 30 on the "anxiety due to uncertainty" PRU sub-scale, 9.3 out of 18 on "concern about bad outcomes," 19.1 out of 30 on "reluctance to disclose uncertainty to patients" and 4.7 out of 12 on "reluctance to disclose mistakes to physicians," with higher scores on these sub-scales suggesting greater affective responses to uncertainty (i.e. more anxiety or reluctance). Residents scored an average of 2.6 out of 6.0 on the "growth mindset" scale, with scores less than 3.3 on this scale suggesting the presence of a growth mindset. Resident demographic characteristics were not associated with PRU or growth mindset scores, with the exception of greater "concern about bad outcomes" among females than males. PRU scores and growth mindset scores were also not associated.

CONCLUSIONS: Our residents were moderately comfortable with uncertainty overall, and on average expressed a growth mindset. Relatively higher scores on the "reluctance to disclose uncertainty to patients" subscale (i.e. greater reluctance) suggest a need for enhanced training in skills for communicating uncertainty, which has the potential to impact both the quality of care delivered and patient satisfaction with that care. Finally, because most of our residents possessed a growth mindset, our ability to assess for an association between the growth mindset and tolerance of uncertainty was limited. Further exploration in different settings and populations is warranted.

EXTENDED HOURS PRIMARY CARE AND WAIT-TIMES IN VHA

Matthew R. Augustine[3,4]; Bjarni Haraldsson[5]; Karin M. Nelson[6,1]; Peter J. Kaboli[2,7]. [1]Department of Medicine, University of Washington, Seattle, WA; [2]Internal Medicine, Iowa City VAMC, Iowa City, IA; [3]Geriatric Research Education and Clinical Center (GRECC), Department of Veterans Affairs, Bronx, NY; [4]Department of Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; [5]Center for Access & Delivery Research and Evaluation (CADRE), Department of Veterans Affairs, Iowa City, IA; [6]VA Puget Sound Health Care System, Department of Veterans Affairs, Seattle, WA; [7]Carver College of Medicine, University of Iowa, Iowa City, IA. (Control ID #3390636)

BACKGROUND: The Veterans Health Administration (VHA) has required clinics offer appointments outside regular business hours. Impact of increasing after-hours availability upon wait-times remains unclear.

METHODS: We performed a longitudinal analysis of 609 primary care clinics within VHA with at least one full-time medical provider, and 2000 or more assigned primary care patients from July 2017 to October 2018. Using administrative data from the VHA Corporate Data Warehouse, we identified all primary care face-to- face visits completed during regular (8:00AM-4:30PM), morning (12:00AM-8:00AM), evening (4:30PM-12:00AM), and weekend hours by month. Outcomes included three wait-time measures: established patient wait-time, new patient wait-time, and third next available appointment extracted from Veterans Support Services Center (VSSC) by month. We controlled for clinic factors including clinic size and panel fullness based upon 1200 patients per full-time provider, and clinic-level aggregated patient factors including age, race/ethnicity, patient risk for higher healthcare costs (Nosos score), and rurality. We used negative binomial multilevel regression and applied between-within approach to determine the association of extended hours (morning, evening, weekends) primary care appointments with wait-times between and within VHA clinics.

RESULTS: Over the time period, 487 (80%) clinics that met inclusion criteria offered extended hour (EH) appointments with an average of 2.3% of all primary care encounters occurring in EH (IQR 0% to 3.2%) and standard deviation within clinics of 0.9% and between clinics of 2.9% over the 15 months of observation. Clinics delivering a greater percentage of EH appointments were more likely to be larger (Clinics in top quartile vs. bottom half of EH appointments: mean 6605 vs. 10,043 patients per clinic) and serve in urban population (76% vs. 62%) and minority population (Non-White, 25% vs. 21%). Over this timeframe, established patient wait-time (mean, 39.6 vs. 56.3 days; Adjusted, IRR 1.39, 95% CI 1.34-1.44, $p<0.001$) and time to third next available appointments increased (mean, 7.7 vs. 10.5 days; IRR 1.36, 95% CI 1.29-1.45, $p<0.001$), respectively, while new patient wait-time remained unchanged (mean, 21.0 vs. 20.2 days; IRR 1.06, 95% 0.93-1.22, $p=0.37$). The percentage of appointments in EH was not associated with new (Between clinics: IRR 1.00, 95% CI 0.99-1.01; Within clinics: IRR 1.01, 95% CI 0.99-1.02) or established patient wait- times (Between: IRR 1.00, 95% CI 0.98-1.01; Within: IRR 1.00, 95% CI 0.99-1.01) or time to TNA appointment (Between: IRR 1.00, 95% CI 0.98-1.02; Within: IRR 1.01, 95% CI 0.99-1.02).

CONCLUSIONS: Extending hours of primary care delivery within the VHA is not associated with change in wait-times to clinical appointments. Shifting primary care appointments after regular hours to accommodate patient or physician preferences may not compromise wait-times.

EXTENT OF EDUCATION IN NUTRITION AND TRAINING IN LIFESTYLE COUNSELLING IN INTERNAL MEDICINE RESIDENCY PROGRAMS IN U.S: A NATIONAL SURVEY OF RESIDENCY PROGRAM DIRECTORS.

Byung Jae Kim[3]; Michelle Hauser[2,4]; Rachel Stark[1]; Danny McCormick[3]. [1]Medicine, Cambridge Health Alliance, Lexington, MA; [2]Primary Care and Population Health, Stanford University School of Medicine, Palo Alto, CA; [3]Medicine, Cambridge Health Alliance / Harvard Medical School, Cambridge, MA, United States Minor Outlying Islands; [4]Obesity Medicine & Internal Medicine-Primary Care, Veterans Affairs Palo Alto Health Care System, Palo Alto, CA. (Control ID #3392254)

BACKGROUND: The primary intervention to prevent and treat the most common chronic diseases is making healthy lifestyle changes such as improving diet and exercise; yet, many patients fail to receive counselling on lifestyle. The extent of education and counselling training about nutrition and exercise in internal medicine (IM) residency programs is not known.

METHODS: We conducted an email-based survey of 477 U.S. program directors of internal medicine residency programs (RPD) between December 2019 and January 2020 to assess the quantity of curricular content on nutrition and training in counselling to improve diet and exercise as well as barriers to and attitudes about implementing these educational

activities in the residency programs they direct. We obtained a list of programs and their RPD's email from the website of the American College of Graduate Medical Education (ACGME). We developed and emailed a 14-item survey to RPDs with a request to complete the survey. No incentive was offered. We used descriptive statistics to analyze responses.

RESULTS: 48 RPDs returned the survey (to date); program types included categorical only programs (76.1%), categorical with a primary care track (17.3%) and primary care only programs (6.5%). The majority of RPDs (79.1%) believed that a nutrition curriculum should be an essential part of an IM residency program. Yet, the majority (77.0%) reported that their program lacked a nutrition curriculum. Among programs that did offer a nutrition curriculum, the mean number of hours of curricular time was 22.3 hours. Nearly all (93.6%) RPDs believed that the number of nutrition curricular hours in their program is inadequate for trainees who will enter primary care practice and most (74.4%) also believed it was inadequate for residents entering a sub-specialty practice. Most RPDs also reported that their program did not provide training in how to identify or address food insecurity (66.0%) nor instruction on how to counsel patients (using motivational interviewing techniques) about healthy dietary behavior changes (57.4%) However, 65.3% reported providing training in counseling to increase physical activity. Barriers to providing a nutrition curriculum included a lack of expert faculty (68.7%), competing curricular demands (68.2%), a lack of ACGME requirements for a nutrition curriculum (28%), a lack of resident interest in nutrition (20%), a lack of administrative support (19.1%), and a lack of faculty interest (19.1%).

CONCLUSIONS: The majority of IM residency programs in the US do not provide education in nutrition or instruction in counseling for diet change. Expanding the prevalence and intensity of such teaching in residency programs could better match residency training activities with clinical imperatives of internists to improve prevention and treatment of chronic diseases.

FACTORS AFFECTING DIABETES SELF MANAGEMENT AND CONTROL: COMPARING CHARACTERISTICS OF A POPULATION WITH BREAST CANCER + DIABETES WITH A POPULATION WITH DIABETES ALONE

Natalie Rodriguez[1]; Jax Witzig[1]; Jenny J. Lin[2]; Mita S. Goel[1]. [1]Internal Medicine, Northwestern University, Chicago, IL; [2]Medicine, Icahn School of Medicine at Mount Sinai, New York, NY. (Control ID #3391967)

BACKGROUND: Understanding factors that affect diabetes self-management behaviors among older women treated for breast cancer is important for reducing the cardiovascular mortality in this population; however, it is unclear whether this population faces unique challenges compared to the general diabetes population.

METHODS: We compared factors known to affect diabetes self-management behaviors and/or control between two populations: women with diabetes who had been previously treated for breast cancer and diabetic individuals with no known cancer history. Factors that were assessed included cognitive function, mental health, disease beliefs, and locus of control. The prevalence of these factors among women with breast cancer and diabetes was ascertained through in-person interviews at three sites as part of a larger study; the prevalence of factors among the general diabetes population was determined through a literature search to identify diabetes studies populations that most closely matched our sample's primary demographic characteristics. We measured cognitive functioning using the WMS Logical Memory I and II (WMS), the Digit Symbol Substitution Test (DSST), Trails A and B, Digit Span, and the Boston Naming Test (BNT); mental health using the Hospital Anxiety and Depression Scale (HADS);.disease beliefs using the Beliefs about Medicines Questionnaire (BMQ); and locus of control using the Treatment Self-Regulation Questionnaire (TSRQ). We performed t-tests for continuous values and chi-square tests for categorical values, with $p < 0.05$ considered as significant.

RESULTS: The sample population with breast cancer and diabetes included 101 multiethnic female subjects with a mean age of 65.6 years ± 7.16. We found that compared to the general diabetes population, those with diabetes and breast cancer had areas of cognitive function that were better as well as worse: those with breast cancer and diabetes exhibited poorer immediate and delayed recall on the WMS ($p<0.05$); similar associative learning on the DSST; better or poorer recall on the Digit Span test depending on the comparison population; and poorer confrontation naming on the BNT ($p<0.05$). There were no significant differences in performance on Trails A and B. Those with breast cancer and DM were less likely to experience anxiety or depression ($p<0.05$); were more likely to perceive their diabetes medications as a necessity ($p<0.05$); were likely to experience concerns about their diabetes medications ($p<0.05$); and less likely to experience controlled or autonomous motivation for treatment and medication adherence ($p<0.05$).

CONCLUSIONS: Interventions for women with Type II diabetes and breast cancer should take into consideration that this population may express greater concern about their diabetes medication usage, as well as a comparatively low sense of both external and internal loci of control. This population may also experience diminished cognitive functioning specific to immediate and delayed recall and confrontation naming.

FACTORS ASSOCIATED WITH HEPATITIS B AND C SCREENING IN A DIVERSE, MULTILINGUAL, URBAN COHORT

Janet N. Chu[1]; Tung T. Nguyen[1]; Natalie Rivadeneira[1]; Robert Hiatt[2]; Urmimala Sarkar[1]. [1]Medicine, University of California, San Francisco, San Francisco, CA; [2]Epidemiology & Biostatistics, UCSF, San Francisco, CA. (Control ID #3390662)

BACKGROUND: Immigrants and racial/ethnic minorities bear a disproportionate burden of hepatitis B virus (HBV) and hepatitis C virus (HCV)-related disease. Few studies have evaluated barriers to HBV and HCV screening in a diverse, multilingual population. We examined the impact of race/ethnicity, language, and healthcare access on rates of HBV and HCV screening in a multilingual, urban cohort.

METHODS: We used questions from the Health Information National Trends Survey and added validated questions about healthcare access and health literacy. From May to September 2017, we administered this survey to English, Spanish, and Chinese-speaking participants, with oversampling for African Americans, in San Francisco County, CA. We used weighted multivariable regression analyses to examine factors associated with self-report of screening for HBV and HCV.

RESULTS: The mean age of the 1,027 participants was 47 years (SD ±16.7), 52% were women, 24% African American, 31% Hispanic, and 36% Asian. Half completed the survey in English, 25% in Spanish, and 25% in Chinese (Cantonese or Mandarin). Half (50%) of all participants reported having been screened for HBV, 32% had never been screened, and 18% didn't know or refused to answer. The proportions for HCV screening were 52%, 30%, and 18%, respectively.

In multivariate analysis, African Americans (odds ratio (OR)=0.19, 95% CI 0.07-0.53) and Asians (OR=0.35, 95% CI 0.12-0.99) had lower odds of HBV screening compared to non-Hispanic whites. Spanish-language respondents had higher odds of HBV screening (OR=1.83, 95% CI 1.01-3.33). Education, being born outside of the U.S., and limited health literacy were not associated with HBV screening, but having at least one usual place of care was (OR=1.72, 95% CI 1.06, 2.80).

Women (OR=0.52, 95% CI 0.37-0.74) had lower odds of HCV screening compared to men. Lower educational attainment was associated with lower rates of HCV screening. Compared to English-language respondents, Spanish- and Chinese-language respondents were less likely to have had HCV screening (OR=0.53, 95% CI 0.28-0.99 for Spanish-speakers; and OR=0.28, 95% CI 0.12-0.6 for Chinese-speakers).

CONCLUSIONS: Self-reported screening rates for HBV and HCV were low in this diverse, multilingual, urban cohort. Factors associated with screening for HBV and HCV differed; interventions targeting barriers to screening must address each separately. Efforts to address HBV screening should focus on African Americans and Asians, while efforts to address HCV screening should focus on women and Spanish and Chinese speakers.

FACTORS ASSOCIATED WITH INCARCERATION IN OLDER HOMELESS ADULTS: RESULTS FROM THE HOPE HOME STUDY

Ilana Garcia-Grossman[1]; Lauren M. Kaplan[2,3]; Karen Valle[2,3]; David Guzman[2,3]; Pamela Olsen[2,3]; Brie Williams[4]; Margot Kushel[2,3]. [1]Department of Medicine, University of California, San Francisco, San Francisco, CA; [2]UCSF Center for Vulnerable Populations, Zuckerberg San Francisco General Hospital and Trauma Center, San Francisco, CA; [3]Division of General Internal Medicine, University of California, San Francisco and Zuckerberg San Francisco General, San Francisco, CA; [4]Division of Geriatrics, University of California, San Francisco, San Francisco, CA. (Control ID #3384483)

BACKGROUND: Little is known about the risk factors for incarceration among older homeless adults. In a cohort of older adults homeless at study entry, we examined factors associated with incarceration. We hypothesized that being unsheltered, substance use, mental health problems, and cognitive impairment would be associated with incarceration over the study period.

METHODS: The Health Outcomes in People Experiencing Homelessness in Older Middle Age (HOPE HOME) study is a longitudinal study of adults aged ≥50 who were homeless at study entry. Staff interviewed participants at baseline and every 6 months. We excluded participants who died or were lost to follow-up before the first 6 month visit. We assessed jail or prison over the follow-up period based on interview and administrative data, defining incarceration as any stay in jail or prison over the follow-up period. We defined unsheltered homelessness as reporting, in a residential calendar, spending any nights either unsheltered or in an emergency shelter in the prior 6 months. Participants reported the total length of time they had experienced homelessness as an adult. We defined binge drinking as ≥6 or more drinks at least monthly, and moderate-to-severe risk illicit drug use (opioids, amphetamines, or cocaine) as a score ≥4 on the Alcohol, Smoking, and Substance Involvement Screening Test. We assessed cognitive function with the Modified Mini-Mental State (3MS). Using logistic regression, we analyzed associations between baseline variables and incarceration; we used backward stepwise elimination, retaining all independent variables with p-value ≤0.20.

RESULTS: Of 450 HOPE HOME participants, we included n=397 in this analysis. Participants had a median age of 58 years, were predominantly men (75%) and African American (82%). They spent an average 83 nights unsheltered in the 6 months prior to study enrollment. Overall, 17% had cognitive impairment, 12% reported binge drinking and 41% moderate-to-severe risk illicit drug use. The majority had a lifetime history of jail (84%) or prison stays (37%); 15% were on probation or parole at baseline. During a median follow-up of 52 months (range 6-72 months), 25% spent time in jail or prison. In multivariable models, men had increased odds of incarceration (AOR 2.27, 95% CI 1.06-4.84). Individuals with moderate-to-severe risk drug use had increased odds (AOR 3.57, 95% CI 1.97-6.46), as did those on parole or probation (AOR 3.36, 95% CI 1.67-6.78). Individuals who spent any nights unsheltered had increased odds of incarceration (AOR 4.50, 95% CI 1.63-12.44). Cognitive impairment was not associated.

CONCLUSIONS: Older homeless adults have a high risk of incarceration. Expanding access to housing, substance use treatment and reforming parole and probation programs may reduce incarceration among older homeless adults.

FACTORS INFLUENCING PRIMARY CARE PROVIDERS' WILLINGNESS TO DISCONTINUE UNNECESSARY MEDICATIONS

Heather Davila[1]; Kelly Stolzmann[1]; Amy Rosen[1]; Libin Zhang[1]; Amy Linsky[1,2]. [1]VA Boston Healthcare System, Boston, MA; [2]Boston University School of Medicine, Boston, MA. (Control ID #3392404)

BACKGROUND: Polypharmacy (often defined as ≥5 medications) is common and associated with increased adverse drug events, mortality, and healthcare costs. Despite known concerns with polypharmacy, there are multiple barriers to discontinuing medications that have potential for harm or that fail to provide benefits outweighing their risks ("deprescribing"). Therefore, we examined the factors that influenced providers' recommendation to discontinue potentially unnecessary medications.

METHODS: We randomly sampled 2,475 providers with prescribing privileges in Veterans Affairs primary care clinics nationally to complete a survey assessing providers' beliefs, attitudes, and experiences regarding medication discontinuation. Our primary outcome was response to an item asking providers to indicate the proportion of patients for whom they recommended discontinuing a medication among those they identified as taking a potentially unnecessary medication. Predictors of interest included patient characteristics; workplace characteristics; and providers' demographics, attitudes, beliefs, and prior experiences with discontinuing medications. We used multivariable logistic regression to assess the factors associated with highest likelihood (≥80%) of recommending discontinuation.

RESULTS: We received 411 responses (response rate: 17%; 304 physicians, 68 nurse practitioners and physician assistants, and 39 clinical pharmacy specialists). More than half were female (52%), age ≥50 (62%), and had been practicing in their current roles for ≥10 years (54%). After excluding respondents with missing data for key variables, our total sample for modeling analysis was 273. Most respondents (78%) indicated that ≥20% of their patients were candidates for discontinuing medications. However, only 30% reported recommending discontinuation to ≥80% of candidate patients. Factors associated with increased likelihood to recommend discontinuation included providers' self-rated comfort with discontinuing medications (odds ratio [OR] 1.50; 95% confidence interval [CI] 1.23-1.84); having support to monitor the patient after discontinuation (OR 1.59; 95% CI 1.04-2.43); and having more patients who asked for information about medications (OR, 1.35; 95% CI, 1.04-1.76). Although not statistically significant, results suggest that when the indication for a medication was unclear, providers were less likely to recommend discontinuation (OR 0.65; 95% CI 0.39-1.06).

CONCLUSIONS: Although most providers indicate they have patients taking potentially unnecessary medications, they do not consistently recommend discontinuation to these candidate patients. Having additional support in place to monitor patients who discontinue medications and strengthening providers' comfort with deprescribing may promote

discontinuation. Educating patients about their medications may also help reduce barriers to deprescribing. Taken together, these strategies may reduce use of potentially low- value or harmful medications.

FACULTY OPINION ON FACULTY DEVELOPMENT: HOW AND HOW MUCH?

Jennifer jeremiah, Kelly McGarry, dominick tammaro. Internal Medicine, Brown Alpert Medical School, Providence, RI. (Control ID #3389737)

BACKGROUND: GME programs rely on faculty to teach, supervise, evaluate and guide trainees in their progression from student to independent practitioners. Regular feedback aligned with educational goals is essential. Nevertheless, learners often report receiving inadequate evaluation and feedback. Faculty report inadequate training and desire faculty development but cite multiple challenges including lack of time, lack of skill, inadequate learner insight, and discomfort with providing constructive criticism to residents. Given reported barriers to faculty development despite recognizing the need, targeted methods to meet needs, overcome barriers and respond to faculty's sources of motivation are necessary. The purpose of this study is to assess preferences for faculty development on evaluation and feedback at an academic institution.

METHODS: 251 teaching faculty who completed evaluations during the 2018 academic year were surveyed. The multiple choice survey assessed demographics, interest in and barriers to participating in faculty development sessions in evaluation and feedback, perceived satisfaction with their evaluation and feedback abilities, willingness to be observed and what types of faculty development activities they desired. Faculty were also asked their preferred methods for faculty development from a list which included teaching tweets, half day workshops outside of work week, half day workshops during work week, webinars, ongoing longitudinal series, online self-directed modules, and short electronic audio slide shows. Analyses were performed using SAS[1] software. Chi-square and Fisher exact tests were performed.

RESULTS: The response rate was 58%. 98% felt that evaluating and providing feedback was an important part of their job, yet 30% of faculty were not satisfied with their evaluation abilities and 41% were not satisfied with their feedback abilities. Gender, time from training, or whether subspecialty or non-specialty physician did not affect satisfaction with evaluation skills. Significantly more male (42%) than female (15%) faculty were not interested in faculty development (p-value=0.0008). Subspecialty faculty reported less interest (61%) when compared with non-specialty (79%), p-value=0.02. Significantly fewer subspecialty faculty (41%) compared with non-specialty faculty (50%) were interested in being observed (p- value=0.01). Short electronic audio slideshows were the most preferred faculty devleopment method. **CONCLUSIONS:** For faculty development to be successful, faculty must want to participate, have the time to participate, and receive effective training. Creating faculty development that is effective and acceptable to most faculty should be the aim of GME programs. Although this study was limited to a single institution and a single specialty, dissatisfaction with feedback is a pervasive issue in medical education. Assessing the needs of diverse faculty may allow for the development of programs that will appeal to the mix of faculty found at most institutions.

FALLING THROUGH THE CRACKS – TRACKING PATIENTS CARE TASKS IN RESIDENT CLINICS

Rachel snyder[1]; David Do[4]; David A. Asch[3]; Marc Shalaby[2]; Deepa R. Nandiwada[1]. [1]Internal Medicine, University of Pennsylvania, Ardmore, PA; [2]Medicine, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA; [3]Medicine, University of Pennsylvania, Philadelphia, PA; [4]Neurology, University of Pennsylvania, Philadelphia, PA. (Control ID #3391937)

BACKGROUND: A lot of important patient care happens between office visits. We call this intervisit care. Although we have access to a patient's entire history via the EMR, current systems are not ideal for providing proactive care and managing follow up tasks. In resident clinics it can be especially challenging given the limited time residents are in clinic and the frequent hand offs between providers as residents rotate between inpatient and outpatient in a block system. A literature review demonstrated that attending physicians have similar concerns, and many have not developed a streamlined way to organize these intervisit tasks.

METHODS: We developed a survey to assess different resident practices to track tasks of mid level urgency requiring follow up, their confidence in their personal tracking systems, the time intensity of the tracking system, and their level of worry about tasks getting lost to follow up. From February to May 2019 we surveyed 16 primary care residents in an academic primary care track.

RESULTS: Our survey found that residents worried that care would get lost to follow up after the visit (median = 4, 1 = strongly disagree and 5 = strongly agree). While most residents had a system to track and sign out intervisit tasks, there were at least 4 different systems used. Some residents used multiple systems. This suggested that there was not a standardized nor consistent process between providers. Further, residents agreed that their systems were time consuming (median score = 4). They were neutral that their systems were effective (median score = 3). This suggests that we need better systems to support intervisit care management.

CONCLUSIONS: Our data suggests that we need better systems to support intervisit care management. This includes tasks like a repeat BMP after medication initiation and repeat imaging for abnormal findings. To address these concerns we worked with the Penn Center for Innovation to create a live dot phrase that automatically inputs patient information, tasks and orders directly into a task management dashboard from the patient note the dot phrase was used in. The dashboard is shareable between clinicians, allows for updates to tasks, and pulls data from the EMR into the dashboard based on orders placed during an encounter. This *Tickler Agent Dashboard* is a compiled patient list of tasks including labs, follow up, consults, patient updates and imaging. Of 23 clinicians, 9 residents piloted the *Tickler*. We categorized the tasks that residents demarcated as needing intervisit follow up. Labs and return visits were equal for the most documented tasks (63), followed by imaging (59), consults (45) and updates (28), respectively. The goal is that as the dashboard and process gets fine-tuned, this intervisit care model will create a standardized workflow, consequently limiting tasks lost to follow up, helping facilitate sign out and reducing stress between outpatient providers.

FAMILY MEMBER INCARCERATION AND WELLBEING: A NATIONAL CROSS-SECTIONAL STUDY

Ram Sundaresh[1]; Youngmin Yi[2]; Brita Roy[1]; Carley Riley[3,4]; Tyler D. Harvey[5]; Hedwig Lee[6]; Christopher Wildeman[2]; Emily A. Wang[1]. [1]Yale School of Medicine, New Haven, CT; [2]Cornell University, Ithaca, NY; [3]Department of Pediatrics, University of Cincinnati College of Medicine, Cincinnati, OH; [4]Division of Critical Care, Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [5]Yale School of Public Health, New Haven, CT; [6]Washington University in St. Louis, St. Louis, MO. (Control ID #3390064)

BACKGROUND: The mass incarceration of over 2 million Americans has potentially far-reaching effects on the families of incarcerated individuals. However, the impact of family member incarceration on overall wellbeing has not been studied. The aim of this study is to estimate associations between family member incarceration and wellbeing.

METHODS: We used data from the 2018 FamHIS, a cross-sectional survey of family incarceration (FI) (N=2,815) that is nationally representative of US household adults. Immediate FI included the incarceration of a parent, sibling, romantic partner, or child, and extended FI encompassed that of other familial relations. We measured wellbeing using the validated 100 Million Healthier Lives Adult Wellbeing Assessment, which includes self-reported life evaluation as a measure of overall wellbeing. Life evaluation is categorized as thriving, surviving, or suffering, which we also use to estimate life expectancy. Using logistic regression, we compare wellbeing across levels of immediate and extended FI exposure, controlling for sociodemographics and predictors of family incarceration.

RESULTS: We estimate that 45% of Americans have had any immediate FI, and 35% have had any extended FI. Compared with White respondents, Black respondents were 1.5 and 1.6 times more likely to have any immediate or extended FI, respectively. Any FI (immediate or extended, N=1,956) was associated with lower rates of thriving (70% vs 58%) and higher rates of surviving or suffering (30% vs 42%) (p<0.001, Table), which is estimated to be associated with 3.2 years shorter life expectancy compared with those without FI (N=643). With greater numbers of family members ever incarcerated, proportions thriving declined (Table). These trends persisted in adjusted models, with lower odds of a thriving life evaluation among those with any immediate (Adjusted Odds Ratio (AOR) 0.71, 95% CI 0.56 – 0.89) or any extended FI (AOR 0.77, 95% CI 0.60 – 0.99), compared with those without FI experience.

CONCLUSIONS: Having had a greater number of family members incarcerated is associated with a dose- dependent decrease in wellbeing. This suggests that clinical jail diversion and other decarceration efforts could have broader population health implications by minimizing detrimental effects of incarceration on non- incarcerated family members.

Table: Unadjusted trends in wellbeing by family member incarceration (FI)

	Life Evaluation				
FI Experience	Thriving (%)	Surviving (%)	Suffering (%)	N	P-for-trend
Overall	63.3	34.1	2.7	2755	
No FI	69.5	27.9	2.6	643	<0.001
Any FI	58.4	38.9	2.7	1956	
Any Immediate FI	56.9	40.7	2.5	1007	
1 immediate	60.2	37.8	2.0	844	
2-3 immediate	57.3	40.0	2.7	614	<0.001
>3 immediate	47.7	49.2	3.1	319	
Any Extended FI	57.7	39.0	3.3	955	
1 extended	67.9	29.6	2.4	198	
2-3 extended	61.3	33.1	5.5	325	<0.001
>3 extended	49.3	48.7	2.0	432	
Both Extended and Immediate FI	53.8	43.1	3.2	776	

FAMILY VERSUS HOME HEALTH AGENCY CAREGIVERS: A CROSS SECTIONAL ANALYSIS OF MANAGED CARE PARTICIPANTS AND COST OUTCOMES

Clark A. Veet[1]; Mary Winger[2]; Suzanne Kinsky[2]. [1]Internal Medicine, UPMC, Pittsburgh, PA; [2]UPMC, Pittsburgh, PA. (Control ID #3385639)

BACKGROUND: As Americans age and chronic disease management evolves, more care is being provided within the home as opposed to institutions. Long-term services and supports (LTSS) address health and social needs to promote optimal functioning of individuals with disabilities and accounted for $112 billion in US spending in 2015. LTSS includes caregivers who may be hired from community agencies or may be "self- appointed" by the participant and can include family or friends who receive payment for services. As the practice of self-appointing expands in the US, we sought to elucidate the demographic characteristics and total cost of care between participants choosing agency or self-appointed caregivers.

METHODS: Study participants were UPMC Community HealthChoices (CHC) members enrolled in Southwestern Pennsylvania with physical health coverage through UPMC Medicaid and Medicare using personal caregiver services in 2018. We excluded participants living in nursing facilities or receiving physical health coverage from an outside insurer. We compared baseline characteristics using one-way Analysis of Variance (ANOVA) for continuous, normally distributed variables, Kruskal-Wallis tests for non-normally distributed variables, and Chi-square tests for proportions. We separated the primary outcome, total cost of care, by LTSS, physical health, pharmacy, dental, and vision costs and analyzed outcomes according to caregiver status.

RESULTS: 9,013 participants were identified for consideration in the sample and 3,232 met inclusion criteria. Of the 3,232 participants using home caregivers, 69% (N=2,217) had an agency caregiver, 23% (N=752) had a self-appointed caregiver, and 8% (N=263) had a combination of both. Agency-only groups were older (mean 62.0 vs 55.0 years), more likely to be female (69.0% vs 62.8%), and had higher baseline health needs (UPMC Need Index 3.24 vs 2.96). Total cost was higher in agency-only participants (median $55,837 vs $45,324/year). When separated, LTSS (median $37,953 vs $31,136/year) and physical health (median $6,858 vs $5,385/year) costs were higher in agency-only groups, whereas pharmacy, dental, and vision costs were similar.

CONCLUSIONS: Among dually-eligible Medicare and Medicaid beneficiaries receiving caregiver services in their home, participants receiving care from agencies were older, more likely to be female, and had higher total cost of care. Older participants may be less likely to have reliable family or friends to appoint for care provision. Gender roles may inform the female predominance, as the majority of existing unpaid caregivers are women and provide disproportionately more services than men. Higher costs, driven by LTSS and physical health, may be due to higher baseline comorbidity and increased service needs. These findings have important implications for policymakers and insurers in helping to govern community LTSS while supporting member autonomy. Future work aims to identify the adjusted association among caregiver status, utilization, and cost.

FEASIBILITY OF A SUBSIDIZED FARM SHARE PROGRAM IN PRIMARY CARE PRACTICES

Victoria L. Mayer[1]; Richa Deshpande[1]; Daphne Brown[1]; Dennis Derryck[5]; Erica Christensen[6]; Emily Hanlen-Rosado[7]; Carol R. Horowitz[4]; Emily Goodman[3]; Leora Mogilner[2]. [1]Population Health Science and Policy, Icahn School of Medicine at Mount Sinai, Brooklyn, NY; [2]Department of Pediatrics, Icahn School of Medicine at Mount Sinai, New York, NY; [3]Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; [4]Population Health Science and Policy, Mount Sinai School of Medicine, New York, NY; [5]Milano School of International Affairs, Management and Urban Policy, New School University, New York, NY; [6]NA, Corbin Hill Food Project, New York, NY; [7]Department of Population Health Science, Duke University, Durham, NC. (Control ID #3390502)

BACKGROUND: Food insecurity is associated with adverse health outcomes in adults and children. Produce incentives may alleviate food insecurity and improve diet quality. A farm share subsidy program may provide families with an affordable option for healthy food choices. Our objective was to assess the feasibility of a subsidized farm share program in urban primary care clinics.

METHODS: We recruited participants from internal medicine or pediatric primary care clinics. The health system team partnered with a community fresh produce distributor, a local food pantry, and a national nonprofit. We block randomized participants to two groups. The immediate intervention group received 6 months of bi-weekly subsidized farm shares starting at enrollment, and the comparison group received the same

intervention but starting 6 months later (delayed intervention group). All participants received information about local emergency food resources at enrollment. Inclusion criteria included: 1) food insecurity (as measured by the 2-item Hager screen) and/or receipt of SNAP and/or WIC and 2) age 5-11 years with obesity or age >/= 18 years with uncontrolled diabetes. Farm share pickup occurred in the hospital lobby. We measured frequency of farm share pickup and participant feedback (using closed- and open-ended questions). Descriptive statistics and mixed methods were used.

RESULTS: We enrolled 95 participants, 50 adults and 45 children with their parents or guardians. The group was 57% Hispanic and 36% Black; 52% were female. 72% had annual income < $30,000. Adult participants picked up an average of 4.7 farm shares (range 0-12, SD 3.7) and pediatric participants picked up an average of 4.1 farm shares (range 0-12, SD 3.8). 95.5% of participants were likely or very likely to recommend the program to a friend. Participants stated the program helped with: 1) exposure to new foods and a variety of fruits and vegetables, 2) increased access and affordability, 3) improved knowledge of how to eat and cook healthy foods, and 4) improved diet and enhanced ability to maintain a healthy diet. Reasons participants gave for not picking up farm shares included: was away (12.5%), not enough money (12.5%), didn't like what I was getting (12.5%) and forgot (9.7%). When asked what they would change, participants stated: 1) more choice/variety of items, 2) more pickup times, more locations, and home delivery, 3) lower price, greater quantity of items (especially fruits), 4) greater ease in payment method, and 5) more cooking instructions and recipes.

CONCLUSIONS: Our findings of moderate pickup rate and strong positive feedback support the feasibility of a subsidized farm share program embedded within urban primary care clinics. Future research is needed on how changes to pricing, logistics, and additional supportive programming can optimize participation and bring such programs to scale.

FEASIBILITY OF ONLINE SELF-MANAGEMENT SUPPORT WITH MINDFULNESS FOR TREATING BLOOD PRESSURE

Kathleen M. McTigue[1]; Jonathan Yabes[1]; Carol Greco[2]; zachary Marcum[3]; Ruth Wolever[4]; Natalia Morone[5]. [1]Medicine, University of Pittsburgh, Pittsburgh, PA; [2]Psychiatry, University of Pittsburgh, Pittsburgh, PA; [3]School of Pharmacy, University of Washington, Seattle, WA; [4]Physical Medicine & Rehabilitation, Vanderbilt University, Nashville, TN; [5]Boston Medical Center, Boston, MA. (Control ID #3392560)

BACKGROUND: Although numerous efficacious hypertension therapies exist, 40% of treated patients do not meet blood pressure (BP) goals. This likely reflects low levels of adherence to lifestyle recommendations and medication regimens. Furthermore, stress-reduction has been identified as potentially useful for reducing blood pressure but is not typically utilized in treatment regimens.

METHODS: We developed a 17-week online behavioral support intervention for BP that includes interactive lessons to support healthier diet, physical activity choices and medication adherence, self-monitoring tools and e-coaching. The intervention can be delivered with or without a mindfulness curriculum for stress reduction [Minding GOALS-BP (MGBP) and GOALS-BP (GBP)]. Adult volunteers with uncontrolled hypertension from UPMC primary care were randomized to MGBP versus GBP to assess the feasibility of recruitment, intervention adherence and intervention delivery. Feasibility outcomes (Timely Enrollment, Intervention Delivery and Completion of Assessments), BP and other measures were obtained at baseline, 4-months and 6- to 12-months after program enrollment. Descriptive statistics were reported for feasibility outcomes and predicted means at baseline (T1), 4-months (T2, program completion) and 12 months (T3) were calculated using linear mixed models for clinical outcomes.

RESULTS: Eligibility was assessed for 644 people and 76 were randomized over 54 weeks. At baseline, MGBP (n=37) and GBP (n=39) participants, on average, had hypertension (149.1/88.4 and 147.2/90.3 mm Hg), obesity (33.5 and 33.8 kg/m^2), took 2.0 medications daily for hypertension and had few comorbidities (Charlson Comorbidity Index < 1.0). Outcomes were assessed for 86% (n=65) at T2 and 82% (n=62) at T3. MGBP and GBP groups completed a similar number of lessons [mdn= 7 (IQR 5-10) vs 8 (IQR 4-11)] and logins [20 (IQR 16-39) vs 23 (IQR 12.0-40.0) respectively] over 6 months, though completion of 80% of lessons was slightly higher for the MGBP group (89 vs 77%). MGBP participants generally showed slightly higher rates of self-monitoring than did GBP. Based on a linear mixed model, systolic BP declined from T1 to T3, though the trend was similar between MGBP [T1 estimate (95% confidence interval): 145.8 (141.3-150.3), T2: 139.8 (136.2-143.5); T3: 127.9 (121.9-133.9)] or GBP [T1: 145.2 (140.8-149.6), T2: 140.1 (136.5-143.8), T3: 130.0 (123.7-136.3)]. Similarly, diastolic BP declined in both groups [MGBP T1: 85.8 (82.2-89.3), T2: 83.5 (80.4-86.6), T3: 79.0 (74.6-83.3) versus GBP T1: 88.4 (84.9-91.8), T2: 85.6 (82.5-88.7), T3: 80.1 (75.5-84.7)].

CONCLUSIONS: An online tool to support self-management of blood pressure can be implemented and evaluated in coordination with primary care. Interactive mindfulness resources may enhance program engagement but did not show improved blood pressure in this pilot evaluation.

FEATURES OF NEW DRUG INDICATIONS NOT APPROVED BY THE FOOD AND DRUG ADMINISTRATION, 2008-2017

Audrey D. Zhang[3]; Jason L. Schwartz[2]; Joseph S. Ross[1]. [1]Internal Medicine, Yale University School of Medicine, Woodbridge, CT; [2]Health Policy & Management, Yale School of Public Health, New Haven, CT; [3]Medicine, New York University School of Medicine, New York, NY. (Control ID #3391226)

BACKGROUND: The US Food and Drug Administration (FDA) is responsible for approving new indications for drugs through the Supplemental New Drug Application (sNDA) process. Such approvals require sponsors to submit new supportive data for their products, typically clinical trials. FDA reviews of this data become publicly available on approval, but data supporting unapproved uses remains confidential. The FDA thus holds data about the efficacy and safety of numerous off-label indications that nonetheless may be clinically relevant. Using publicly-available advisory committee records, this study examined features of new indications reviewed and not approved by the FDA over 10 years.

METHODS: We performed a systematic review of all FDA advisory committee meetings voting on a proposed new indication for an approved drug from January 2008 through December 2017. Using the public Drugs@FDA database, we characterized the indications and determined their approval status, including those indications not approved by the FDA for our study. We performed document content analysis on the advisory committee transcripts, using the constant comparative method to generate and illustrate a single set of themes that represented committee members' rationales for approval or non-approval of the new indications.

RESULTS: 54 advisory committee meetings discussing sNDAs were held from 2008-2017, which discussed approvals for 69 separate indications. Of these, 30 (38.4%) proposed indications remained unapproved, representing 23 unique drugs submitted for 29 unique new indications. The most common type of unapproved new indication was a new efficacy claim (n=20, 66.7%), followed by an expanded population (n=6, 20.0%) and modified efficacy claim (n=4, 13.3%).

Efficacy and safety concerns were cited by committee members as a basis for every non-approval. These ranged in degree from failures to meet standards for substantial evidence of efficacy (n=9, 30.0%) and/or safety (n=5, 16.7%), to having insufficient or inconsistent data for risk-benefit determination (n=21, 70.0%).

Contextual concerns, such as unmet need (n=5, 16.7%), existing market experience (n=6, 20.0%), future prescribing patterns (n=10, 33.3%), and long-term impacts on drug development (n=3, 10.0%), were also common and modulated the effects of efficacy and safety concerns.

CONCLUSIONS: Efficacy and safety concerns are major contributors to the non-approval of new indications of drugs by the FDA, with contextual concerns playing an effect-modifying role. Transparency of information held by the FDA about the efficacy and safety of new uses of drugs has the potential to inform and improve clinical practice.

FIB-4 SCORES IN PRIMARY CARE PATIENTS WITH ABNORMAL LIVER TESTS

Andrew Schreiner[1]; Jingwen Zhang[2]; Valerie Durkalski-Mauldin[1]; Sherry Livingston[3]; Justin Marsden[1]; Patrick D. Mauldin[3]; William P. Moran[1]; Don Rockey[3]. [1]General Internal Medicine, Medical University of South Carolina, Charleston, SC; [2]Medicine, MUSC, Charleston, SC; [3]Medicine, Medical University of South Carolina, Charleston, SC. (Control ID #3391326)

BACKGROUND: Liver fibrosis severity is an important predictor of outcome in patients with a variety of liver diseases. The Fibrosis-4 (FIB-4) Index, a non-invasive test of liver fibrosis combining commonly available lab results and age, may play a role in improving the diagnosis and management of non-alcoholic fatty liver disease (NAFLD) in primary care patients at risk. We examined FIB-4 score and its relationship with clinical components of metabolic syndrome (MetS) in a primary care population with abnormal liver tests and no other identified liver disease diagnoses.

METHODS: A retrospective study of electronic record data from a primary care clinic from 2007 - 2018 identified adult patients with abnormal liver tests and evaluated patient-level FIB-4 scores, the proportion of patients with values concerning for liver fibrosis (FIB-4>1.3) and cirrhosis (FIB-4>2.67), and the demographic and clinical factors associated with an elevated FIB-4 score. We developed multivariable logistic regression models for the dependent variables of mean FIB-4>1.3 and mean FIB-4>2.67. Objective measures of MetS components served as independent variables: BMI (continuous), A1c>6.5%, triglycerides>150 mg/dL, HDL<50 mg/dL for women (<40 mg/dL for men), and blood pressure (BP)>130/85 mm Hg.

RESULTS: 9,657 patients with 116,237 FIB-4 scores were included, with mean of 12 (SD: 17.4) and a median of 7 (IQR: 3-14) values per patient, respectively. Of these patients, 97% had at least one component of MetS, 8% had all five components, and only 1% carried an ICD-9/10 diagnosis code for NAFLD. Using patient-level mean FIB-4 scores, 3,547 (37%) patients had values > 1.3, and 564 (6%) > 2.67 (Table 1). The logistic regression model identified elevated BP (OR 1.73, 95% CI 1.49-2.01), hyperglycemia (OR 1.26, 95% CI 1.13-1.40), hypertriglyceridemia (OR 1.16, 95% CI 1.06-1.28), Black race (OR 1.28, 95% CI 1.17-1.40), and male gender (OR 1.71, 95% CI 1.57-1.86), as positively associated with a mean FIB-4 score consistent with advanced fibrosis.

CONCLUSIONS: A large proportion of primary care patients with risk factors and clinical signals of NAFLD have FIB-4 scores concerning for advanced fibrosis. Future work is needed to validate the performance of FIB-4 in this setting.

FINANCIAL HARDSHIPS AMONG UGANDANS SEEKING HEALTH CARE: FINDINGS FROM A 2019 NATIONAL SURVEY

June-Ho Kim[1,2]; Griffith A. Bell[2]; Hannah Ratcliffe[2]; Simon P. Kibira[3]; Elizabeth Nabiwemba[3]; Fredrick Makumbi[3]; Fred Wabwire-Mangen[3]; Jessica Wiken[2]; Stuart R. Lipsitz[1,2]; Asaf Bitton[1,2]; Lisa R. Hirschhorn[4,2]; Dan Schwarz[2]. [1]Division of General Internal Medicine and Primary Care, Brigham and Women's Hospital, Boston, MA; [2]Ariadne Labs, Boston, MA; [3]Makerere University School of Public Health, Kampala, Uganda; [4]Northwestern University Feinberg School of Medicine, Chicago, IL. (Control ID #3392212)

BACKGROUND: Globally, countries are aiming for universal health coverage—access to quality care without financial hardship. This has been elusive for Uganda where individual out-of-pocket (OOP) costs comprise over 40% of total annual health expenditures, contributing to financial challenges. We assessed the national prevalence and correlates of financial hardship and OOP costs in accessing health care.

METHODS: We analyzed a household survey conducted in Uganda in 2019 by the Performance Monitoring and Accountability 2020 (PMA2020) program, which collected data from a nationally representative sample of women and men ages 15+ in Uganda in 2019. We defined financial hardship as having had to borrow money or sell a possession in order to afford a visit to a health care facility. We used descriptive statistics with survey weights to estimate the national prevalence of financial hardship and distribution of OOP costs; multivariable logistic and linear regression models to identify significant predictors of financial hardship and higher OOP costs; and multivariable logistic regression models to assess the association between financial hardship and excellent or very good ratings of patient experience.

RESULTS: In 2019, less than 1% of the population reported having any form of health insurance while 44.3% of Ugandan people seeking care reported experiencing financial hardship. Among those experiencing financial hardship, the mean OOP cost was 88,404 Ugandan shillings, about USD$24, compared to 49,351 shillings for those who did not report financial hardship. In a multivariable model, characteristics associated with higher odds of financial hardship were being in the poorest wealth quintile compared to the richest (adjusted odds ratio, aOR, 6.54, 95% CI 3.93-10.9); poor self-reported overall health vs excellent (aOR 5.09, 95% CI 2.08-12.5); rural-dwelling vs urban (aOR 1.68, 95% CI 1.17-2.43); going to a public facility vs private (aOR 1.52, 95% CI 1.03-2.24); and seeking care for acute reasons vs chronic/preventive reasons (aOR 1.86, 95% CI 1.06-3.27). For OOP costs, being in the highest wealth quintile, living in a rural area, and bypassing the closest facility to seek care elsewhere were associated with higher expenses. People reporting financial hardship had worse ratings of patient experience, though this relationship was not significant when adjusted for covariates such as wealth.

CONCLUSIONS: There is a large burden of financial hardship in Uganda that disproportionately affects the poor, sick, acute care-seeking, and rural-dwelling population and is associated with higher out-of-pocket costs. Given the high proportion of financial hardship and its impact on subpopulations that may be at higher risk of catastrophic expenditures, there is a significant need for health insurance coverage, particularly with a severe lack of available financial protection. These findings are highly relevant to the current ongoing legislative process in Uganda to pass a national health insurance bill.

FINANCIAL IMPLICATIONS TO PRIMARY CARE PRACTICES OF ALTERNATIVE BUPRENORPHINE-BASED OPIOID ADDICTION TREATMENT STRATEGIES: A MICROSIMULATION MODEL

Jonathan E. Fried[1]; Sanjay Basu[1,2]; Russell Phillips[1,3]; Bruce E. Landon[1,3]. [1]Center for Primary Care, Harvard Medical School, Boston, MA; [2]Collective Health, San Francisco, CA; [3]Division of General Internal Medicine and Primary Care, Beth Israel Deaconess Medical Center, Boston, MA. (Control ID #3383229)

BACKGROUND: Buprenorphine therapy has been limited in supply in high need areas, in part due to uncertainty about how instituting a buprenorphine treatment program may impact practice finances. While buprenorphine treatment is cost-effective in terms of improving quality-adjusted life-years in the population relative to the cost of the drug, whether it is financially beneficial to practices to invest in the training, infrastructure, workforce, and time to deliver buprenorphine remains uncertain.

METHODS: We interviewed twenty practice managers and identified four approaches to delivering buprenorphine-based treatment through primary care practices, which differed in physician and nurse responsibilities. We then used a microsimulation model to estimate how practice variations in patient types, payers, revenues, and costs across primary care practices nationwide would affect cost and revenue implications of each approach, for four types of practices: federally-qualified health centers (FHQCs), non- FQHCs in urban high-poverty areas, non-FQHCs in rural high-poverty areas, and practices outside of high- poverty areas.

RESULTS: Four approaches to buprenorphine-based treatment included: physician-led visits with nurse-led logistical support; nurse-led visits with physician oversight; shared visits; and solo prescribing by physicians alone. Net practice revenues would be expected to increase after introduction of any of the four approaches, by between $18,000 and $70,000 per full-time physician in the first year across practice types. Yet physician- led visits and shared medical appointments–both of which relied upon nurse care managers–consistently produced the greatest net revenues ($29,000 to $70,000 per physician in the first year). To ensure positive net revenues in any approach, providers would need to maintain at least nine patients in treatment and no-show rates <34%.

CONCLUSIONS: Many types of primary care practices could financially sustain buprenorphine-based treatment if demand and no-show rate requirements were met, but a nurse care manager-based approach may be most sustainable.

FINANCIAL STRAIN AMONG LOW, MIDDLE, AND HIGH-INCOME ADULTS WITH EMPLOYER-SPONSORED INSURANCE IN THE UNITED STATES

Janine R. Petito[1,3]; Adam Tapley[1,3]; Soumya Narayan[1,3]; Shinn-Te Chou[1,3]; Andrew Glick[1,3]; Byung Jae Kim[1,3]; David F. Lee[1,3]; Jay Luthar[1,3]; Adam Gaffney[2,3]; Danny McCormick[1,3]. [1]Internal Medicine, Cambridge Health Alliance, Somerville, MA; [2]Pulmonary & Critical Care, Cambridge Health Alliance, Cambridge, MA; [3]Harvard Medical School, Boston, MA. (Control ID #3391622)

BACKGROUND: Some proposed health care reforms would take the controversial step of eliminating employer-sponsored insurance (ESI). Little information is available on the extent to which ESI protects families, particularly those with low incomes, from high health care costs.

METHODS: We analyzed 4 years of data (2014-2017) from the Medical Expenditure Panel Survey on non- elderly adults (age 18–64) covered by ESI. We examined 4 indicators of financial strain: 1. Difficulty paying medical bills; 2. Currently paying medical bills over time; 3. High-burden medical spending (family out of pocket medical (OOP) spending >10% of family income); and 4. Catastrophic medical spending (family OOP spending and premium contributions >40% of income). We examined outcomes among 3 groups based on family income: Low (0–250% of the federal poverty level [FPL]), middle (251-400% FPL) and high (>400% FPL) income. We used logistic regression and predictive margins to estimate percentage point differences between Low and High, and between Middle and High income groups, controlling for age, gender, race/ethnicity, marital status, educational attainment, employment status, self-reported health status, number of chronic health conditions, and measures of health care utilization. Analyses were replicated for a subgroup of enrollees with 1 or more chronic conditions and for those with each chronic condition individually.

RESULTS: The study sample included 34,655 non-elderly adults with ESI. Low income enrollees were more likely than high income enrollees to report difficulty paying medical bills (14.9% vs 4.6%; adjusted percentage point difference [AD], [95% CI], 9.1 [7.4-10.8]) and to report paying medical bills over time (27.3% vs 15.7%; AD, 10.4 [8.2-12.6]). Low income enrollees were also more likely than high income enrollees to experience high burden spending (9.1% vs 1.0%; AD, 8.9 [7.5-10.2]) and catastrophic spending (6.7% vs 0.0%; AD, 6.7 [5.4-8.3]). Among individuals with 1 or more chronic medical conditions, low income enrollees were also more likely than high income enrollees to report difficulty paying medical bills (19.2% vs 6.0%; AD, 11.0 [8.0-14.0]), paying medical bills over time (31.6% vs 19.0%; AD, 10.2 [6.7-13.8]), and experience high burden spending (14.0% vs 1.4%; AD, 12.2 [9.6-14.7]) and catastrophic spending (8.2 vs. 0.0%; AD, 7.8 [5.8-9.8]). Spending disparities were particularly large among persons with cancer: more low- than high-income enrollees experienced high burden (23.1% vs 1.4%; AD, 21.8 [14.2-29.2]) and catastrophic spending (12.2% vs 0%; AD, 12.1 [9.3-15.3]). Middle- vs high-income comparisons yielded somewhat smaller differences.

CONCLUSIONS: Many persons with ESI, particularly those with low incomes, experience serious financial strain due to medical costs.

FLUID RESUSCITATION AND CLINICAL OUTCOMES IS SEPSIS PATIENTS WITH AND WITHOUT CONGESTIVE HEART FAILURE (CHF)

Destiny Roseman[3]; Alexander J. Beagle[1]; Priya A. Prasad[2]; Yumiko Abe-Jones[3]; Kathleen D. Liu[3]; Kirsten Kangelaris[3]. [1]School of Medicine, University of California, San Francisco, San Francisco, CA; [2]Division of General Internal Medicine, Department of Epidemiology and Biostatistics, UCSF, San Francisco, CA; [3]Medicine, Division of Hospital Medicine, University of California at San Francisco, San Francisco, CA. (Control ID #3388324)

BACKGROUND: The Surviving Sepsis guidelines suggest that patients meeting severe sepsis criteria should be administered fluids for initial management; however, data is lacking for patients with congestive heart failure (CHF) where pulmonary edema is a concern. We aim to identify the association between initial volume of fluid administered and clinical outcomes among septic patients with and without CHF.

METHODS: In this retrospective cohort study, we extracted Electronic Health Record (EHR) data on adults presenting to an academic emergency department (ED) from 2012-2018 who met validated Sepsis-III EHR criteria and had a lactate ≥2 mmol/L. CHF patients were identified by ICD-10 codes. Fluids given in the first 24 hours following ED presentation were summed. Multivariable logistic regression was used to estimate adjusted associations with mortality and mechanical ventilation (MV) across quintiles of volume received, stratified by CHF diagnosis. There

was an interaction between CHF status and fluid quintile on mortality (P=0.02), but not MV (P>0.20).

RESULTS: Patients with CHF received less fluid overall (CHF mean 1.8 ± 1.9L vs. no CHF 2.9L ± 1.9L, P<0.001). In multivariable analysis, there was a stepwise decrease in odds of morality with increasing fluid quintiles (P=<0.001-0.04, Table). Among CHF patients, the association was more attenuated, but there was a trend towards decreased mortality with increasing fluid quintile (quintile 4, P=0.02, Table). There was no association between fluid quintile and need for MV in either CHF or non-CHF patients.

CONCLUSIONS: Clinicians administer less fluid to septic patients with CHF. Increased fluid administration was associated with a mortality benefit in patients without CHF; an association not clearly observed in CHF. Fluids were not associated with MV for either group. While CHF patients may not benefit from increased fluids as much as patients without CHF, they were not at higher risk of MV after adjustment for potential confounders. More investigation is needed to determine the optimal fluid resuscitation strategy in patients with CHF.

Associations between fluid volume in the first 24 hours and death or mechanical ventilation in multivariable models stratified by CHF status

Multivariable logistic regressions adjusted for the following variables: illness severity (Sequential Organ Failure Assessment score), demographic characteristics (age, gender, race/ethnicity, limited english proficiency), comorbidities (hypertension, diabetes, renal disease, liver disease, cancer, substance use, mental health conditions), triage vitals (Glasgow Coma Scale, temperature, heart rate, mean arterial pressure, respiratory rate, SpO2:FiO2 ratio), initial labs (lactate, leukocytes, platelets, creatinine).

FOR OLDER HOMELESS ADULTS, HOUSING INSTABILITY AND MENTAL HEALTH HOSPITALIZATIONS ARE ASSOCIATED WITH UNMET CAREGIVING NEED: FINDINGS FROM THE HOPE HOME STUDY

Wagahta Semere[1]; Lauren M. Kaplan[2]; Karen Valle[1]; David Guzman[2]; Margot Kushel[1]. [1]Department of Medicine, Division of General Internal Medicine and Center for Vulnerable Populations, University of California San Francisco, Zuckerberg San Francisco General, San Francisco, CA; [2]Department of Medicine, Division of General Internal Medicine and Center for Vulnerable Populations, University of California, San Francisco, Zuckerberg San Francisco General, San Francisco, CA. (Control ID #3390538)

BACKGROUND: Adults ≥50 comprise approximately 50% of the individual adult homeless population. They experience high rates of chronic illness and early onset of disabilities that can increase acute care utilization and need for costly long-term care placement. "Aging in place" with the support of caregivers and community-based programs can yield significant savings. Yet, the current state of caregiving and caregiving need among older homeless-experienced adults is not well understood. In this study, we aim to (1) describe the characteristics of older homeless-experienced adults with caregiving need and (2) determine factors associated with unmet need.

METHODS: The sample is drawn from the Health Outcomes in People Experiencing Homelessness in Older Middle Age (HOPE HOME) study, an ongoing longitudinal study of health, life course events, and functional status among older adults homeless at study entry. Between July 2013 and June 2014, we recruited adults over age 50 in Oakland, CA and re-interviewed them every 6 months regardless of housing status. In this study, we included a cross-sectional sample of participants who completed a caregiving questionnaire at their most recent interview. We defined caregiving need as having difficulty with any Activities of Daily Living (ADLs), Independent Activities of Daily Living (IADLs), falls, Short physical Performance Battery (SPPB) score <10, or Modified Mini-Mental State (3MS) exam impairment. We defined unmet need as having caregiving need but not having caregiving assistance in the last 6 months. Using logistic regression, we analyzed associations between respondent characteristics (i.e. housing type, social support, health status, substance use, and mental health hospitalization) and having unmet caregiving need.

RESULTS: Among 345 participants, over 80% met the definition for caregiving need. Among those with need, the median age was 62 years (IQR 58-66) with over 80% African American. Nearly 85% of participants were single and 44% remained homeless. About half reported having 2 or more chronic conditions;78% rated their health as fair or poor. Twelve percent reported being hospitalized for a mental health problem. Of those with caregiving need, nearly 80% had unmet need. Mental health hospitalization (AOR 3.75, CI [1.46-9.67], p<0.01) was associated with higher odds of having unmet need; residing in an institutional setting (i.e. hospital, prison, skilled nursing facility, or other rehab institution) (AOR 0.26, CI [0.07-0.92], p<0.05) and permanent supportive housing (AOR 0.26, CI [0.07-0.97], p<0.05) were associated with lower odds versus being unsheltered or in emergency shelter.

CONCLUSIONS: Older homeless adults have high prevalence of unmet caregiving need. Targeted interventions to support stable housing and address severe mental health problems may improve the ability to meet caregiving needs, avoiding costly consequences of disability and supporting this population to age in place.

FRAILTY IS STRONGLY ASSOCIATED WITH SELF-REPORTED SYMPTOM BURDEN IN PATIENTS WITH CIRRHOSIS

Lisa X. Deng, Kara Bischoff, Dorothea S. Kent, David L. O'Riordan, Steven Z. Pantilat, Jennifer C. Lai. Medicine, University of California, San Francisco, San Francisco, CA. (Control ID #3346748)

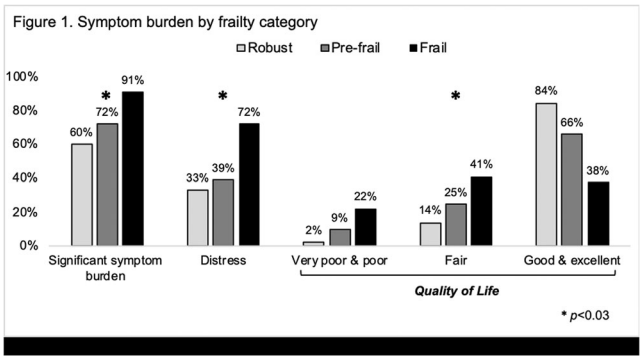
BACKGROUND: Among patients with cirrhosis, frailty has most commonly been measured using instruments that focus on malnutrition, muscle wasting, and functional impairment. Little is known about how these frailty domains correlate with patient-reported symptoms.

METHODS: Adult patients with cirrhosis undergoing outpatient evaluation for liver transplantation from 7/1/19-9/30/19 were eligible for inclusion. Frailty was assessed using the Liver Frailty Index (LFI; grip strength, chair stands, and balance) and categorized as robust (< 3.2), pre-frail (3.2-4.4), and frail (≥ 4.5). Symptom burden was assessed using the Palliative Care Quality Network Symptom and Well-being Survey, a composite of validated measures including the Edmonton Symptom Assessment Scale (ESAS), National Comprehensive Cancer Network Distress Thermometer, and a single-item quality of life measure. We defined a significant symptom burden as a score on the ESAS of ≥ 4 (moderate or severe) in at least one of nine symptoms.

RESULTS: Of 233 patients (median age 61 years, 43% female, 82% white), median LFI was 3.8 (IQR 3.3-4.2); 22% were robust, 64% pre-

frail, and 14% frail. Overall, 72% of patients had a significant symptom burden. Higher frailty categories were associated with increased prevalence of pain, dyspnea, fatigue, nausea, drowsiness, depression, and poor wellbeing (test for trend, all $p<0.03$). Frail patients were also more likely to report distress and poor quality of life (Figure 1). In univariate analysis, each 0.5 increase in LFI was associated with 35% increased odds of experiencing significant symptom burden (95% CI: 1.1-1.6, $p=0.001$), which persisted (OR 1.3, 95% CI: 1.0-1.5, $p=0.04$) even after adjusting for MELD, ascites, hepatic encephalopathy, and dialysis.

CONCLUSIONS: In patients with cirrhosis, frailty is strongly associated with physical/psychologic symptoms including pain and depression, in addition to poor quality of life; 91% of patients who were frail reported significant symptom burden and 72% reported significant distress. Frail patients with cirrhosis may benefit from palliative care referral to address symptoms and improve quality of life.



FREQUENCY AND CONTENT OF HYPOGLYCEMIA DISCUSSIONS IN PRIMARY CARE VISITS FOR PATIENTS WITH DIABETES

Scott J. Pilla[1]; Jenny Park[2]; Jessica L. Schwartz[3]; Patti Ephraim[4]; L. Ebony Boulware[5]; Nestoras N. Mathioudakis[6]; Nisa Maruthur[7]; Mary Catherine Beach[2]; Raquel Greer[1]. [1]General Internal Medicine, Johns Hopkins University, Baltimore, MD; [2]Medicine, Johns Hopkins University, Baltimore, MD; [3]General Internal Medicine, Johns Hopkins School of Medicine, Baltimore, MD; [4]Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [5]Medicine, Duke University, Durham, MD; [6]Endocrinology, Johns Hopkins University, Baltimore, MD; [7]Medicine, Johns Hopkins University School of Medicine, Baltimore, MD. (Control ID #3390996)

BACKGROUND: Hypoglycemia is the most common serious adverse effect of diabetes treatment, and occurs more often among racial/ethnic minorities. Most hypoglycemia is caused by sulfonylureas or insulin. Diabetes guidelines recommend that patients using these medications be asked about hypoglycemic events at each clinical encounter and be provided anticipatory guidance for hypoglycemia prevention. No prior studies have examined whether and how these hypoglycemia discussions occur in clinical practice.

METHODS: We performed a mixed methods study to determine the frequency and content of hypoglycemia discussions during primary care visits. We included patients with diabetes using sulfonylureas or insulin who participated in the Achieving Blood Pressure Control Together (ACT) study, a randomized controlled trial to study the effectiveness of hypertension behavioral self-management interventions among African Americans with uncontrolled hypertension receiving primary care in Baltimore, MD. During the 12-month study period, all participant's routine primary care visits were audio-recorded; we transcribed verbatim the first three visits for each participant. Three investigators abstracted discussions of hypoglycemia or blood glucose to develop a coding framework to classify the type and content of communicative acts related to hypoglycemia. We defined assessment for hypoglycemia as any discussion of hypoglycemic events, symptoms, or review of glucose readings during the clinical encounter.

RESULTS: We examined 84 visits occurring from 2013-2015 representing 33 unique patients and 8 providers. Participants at baseline were mean age 61 years, 67% female, 97% had type 2 diabetes and 61% used insulin. Diabetes was listed as a problem in the visit plan for 99% of visits. Assessment for hypoglycemia occurred in 33% of visits which was similar for insulin users and non-users (33% vs. 34%, p=0.53). Clinicians mostly assessed hypoglycemia by asking about home glucose readings or reviewing glucose logs (21% of visits) rather than asking about hypoglycemic events directly (13%) or symptoms (7%). In 12% of visits, patients reported hypoglycemic events without clinician prompting. Clinicians asked for additional detail around hypoglycemic events in 15% of visits, which was mostly related to the context of the event rather than event frequency or severity. Anticipatory guidance for hypoglycemia was discussed in 12% of visits, which consisted mainly of behavioral modification for hypoglycemia prevention; hypoglycemia treatment was discussed in 1% of visits.

CONCLUSIONS: In this high hypoglycemia risk population from one primary care clinic, assessment for hypoglycemia occurred in a minority of visits. Hypoglycemia discussions focused on glucose values, lacked key details of hypoglycemia frequency and severity, and rarely included anticipatory guidance. Research is needed to identify efficient ways to assess for hypoglycemia and counsel for hypoglycemia prevention in primary care.

FURTHER VALIDATION OF THE INFLUENCE AND MOTIVATION FOR PATIENT ACTIVATION IN DIABETES CARE (IMPACT-D) AMONG DIVERSE PRIMARY CARE SETTINGS

Guisselle Wismer[1]; Stephanie Batio[1]; Lauren Opsasnick[1]; Marina Arvanitis[1]; Stacy Bailey[1]; Alex Federman[2]; Michael S. Wolf[1]. [1]General Internal Medicine and Geriatrics, Northwestern University, Chicago, IL; [2]Medicine, Icahn School of Medicine at Mount Sinai, New York, NY. (Control ID #3391685)

BACKGROUND: Although there has been increasing interest in patient activation, the most widely used measure, the Patient Activation measure (PAM), is a generic assessment and not unique to a specific condition, such as type 2 diabetes (T2DM). As a result, there have been inconsistent associations reported with the PAM and T2DM-related outcomes. The Influence and Motivation for Patient ACTivation in Diabetes Care (IMPACT-D) is a valid and easily administered tool that can be used to assess patient activation among a diverse population of adults with T2DM. The objective of this study was to further validate the newly available IMPACT-D in a more diverse setting.

METHODS: We used data from an ongoing randomized controlled trial of community dwelling adults with T2DM. 490 patients who had been prescribed 5+ medications were recruited in outpatient primary care practices in New York City, NY and Chicago, IL. Outcomes included regimen adherence (ASK-12), depression (PROMIS), self-reported overall health (SROH), and preliminary clinical values (blood pressure (N=490), HbA1c (n=139), cholesterol (n=83). Health literacy was assessed via the Newest Vital Sign (NVS). Item performance was analyzed (cronbach's alpha, principal components analysis, construct validation with Consumer Health Activation Index (CHAI)). To confirm IMPACT-D associations with health outcomes, we ran correlations between the IMPACT-D and regimen adherence, depression, overall health, and clinical values (blood pressure, HbA1C, and cholesterol).

RESULTS: The mean age of participants was 61 years; two thirds were women; 63% had received a high school education or less; 43% reported

an annual household income of less than $20,000; over half (54%) were African-American. A third (36%) of participants had limited health literacy. The IMACT-D showed good internal consistency (alpha =0.69); the six items included in the IMPACT-D loaded onto a single factor (Eigenvalue: 1.70, factor loadings ranged 0.33-0.68). In terms of construct validity, a higher IMPACT-D score was associated with higher CHAI scores (r=0.49, p<0.0001), greater medication adherence (r=-0.43, p<0.001), fewer depressive symptoms (r=-0.-34, p<0.0001), and better overall health status (r=0.26, p<0.0001). No significant differences were noted by blood pressure (r=0.02, p=0.62), HbA1c (r=-0.08, p=0.32), or cholesterol (r=-0.20, p<0.06).

CONCLUSIONS: The IMPACT-D tool is a reliable, valid measure of patient activation in diabetes care that demonstrated good psychometric performance. IMPACT-D scores were associated with patient-reported outcomes and greater medication adherence, while not being associated with intermediary clinical outcomes due to limited data. These results suggest the IMPACT-D should still be considered as a diabetes-specific alternative to existing patient activation measures.

GASTRIC ANTRAL VASCULAR ECTASIA (GAVE): A FREQUENTLY MISSED DIAGNOSIS

Ravi Jariwala[1]; Basem Alkurdi[2]; Peng Li[3]; Sujan Ravi[4]; Shajan Peter[4]; Theresa Hydes[4]; Mohamed Shoreibah[4]. [1]Internal Medicine, University of Alabama at Birmingham (UAB), Birmingham, AL; [2]Hepatology, Largo Medical Center, Largo, FL; [3]School of Nursing, University of Alabama at Birmingham, Birmingham, AL; [4]Hepatology and Gastroenterology, University of Alabama at Birmingham, Birmingham, AL. (Control ID #3361482)

BACKGROUND: Gastric antral vascular ectasia (GAVE) accounts for 4% of non-variceal upper gastrointestinal bleeds and is associated with significant morbidity. A diagnosis of GAVE is made primarily at endoscopy supplemented by histology where available. The endoscopic pattern of GAVE is characterized as "watermelon," "honeycombing" and "nodular" and is not exclusive to the antrum. Treatment of GAVE is dependent on an accurate diagnosis. The aim of this study was to evaluate the accuracy with which an endoscopic diagnosis of GAVE was made in a large tertiary referral center.

METHODS: A retrospective analysis of esophagogastroduodenoscopies (EGD) was performed for patients diagnosed with GAVE in a tertiary care center over a 16 year period. Charts were reviewed for an endoscopic diagnosis of GAVE including location and subtype, treatment delivered, number of EGD's performed, training of the endoscopist and pathology results. The level of concordance between different endoscopists and histology was examined.

RESULTS: In total, 110 patients received a diagnosis of GAVE at some point during the study period and 184 EGDs were performed overall. Eighty-five patients (77%) had GAVE isolated to antrum while the rest had GAVE in the antrum as well as the body (2.7%), cardia (2.7%), duodenum (9.1%), pylorus (1.8%), and multiple locations (5.5%). Sixty-four (58%) patients had unclassified GAVE, while the rest were defined as nodular (19%), watermelon (15.5%), honeycomb (3%) and mixed (3.6%). Band ligation (BL) was performed only among those with nodular GAVE and those that were unclassified. Even among patients with nodular GAVE only 42.9% underwent BL. One hundred and twenty five (68%) of the endoscopies were performed by hepatologists.

CONCLUSIONS: GAVE was mislabeled as erythema, ulceration, polyps and gastritis in 74 (40%) patients. Among the 110 patients, 26.4% of them required more than one procedure to reach GAVE diagnosis. The misdiagnosis rates for gastroenterologists and hepatologists were similar (46.6% vs 36.8%, p=0.22). For the 60 patients who also received a biopsy, there was a discordance rate of 30% (K=0.35) in comparison to an endoscopy. In addition the subtype of GAVE was documented in less than half of cases. This study highlights GAVE as a disease which can be frequently misdiagnosed at endoscopy and should be made a focus for trainees and current practitioners.

GENDER DIFFERENCES IN BURNOUT: HOW PREVALENCE OF CONTRIBUTING FACTORS MAY CREATE DISCREPANCIES BETWEEN MEN AND WOMEN.

Lauren Peccoralo[1]; Carly Kaplan[1]; Jonathan Ripp[2]. [1]Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; [2]Department of Medicine, Icahn School of Medicine at Mount Sinai, New York, NY. (Control ID #3391515)

BACKGROUND: Physician burnout threatens professional satisfaction, mental health outcomes and likelihood to continue practice. Though many studies report gender-based differences in burnout prevalence, few have examined how and why certain factors may differentially contribute to these differences. We conducted an institution-wide survey at an academic medical center to explore how some professional and personal characteristics vary by gender and may in turn influence gender-based differences in well-being.

METHODS: We administered a web-based anonymous cross-sectional survey to all clinical and non-clinical faculty at the Mount Sinai Health System (MSHS) from 11/2018 to 2/2019. The survey was comprised of validated instruments to measure burnout (Maslach Burnout Inventory-MBI-2, Well-being Index-WBI), depression (PHQ-2) and items to assess professional roles, workplace culture, and demographics. Data analysis involved dichotomization of Likert scale variables and t-test and chi-square bivariate analyses. We excluded non-binary and other gender responses due to small sample size.

RESULTS: Of 4156 faculty, 1781 (43%) participated in the survey. We included 1497 who identified as male (753) or female (744). Women were significantly more likely to be younger, work fewer hours per week, be junior in academic rank and disagree that work leaves enough time for family. Women were more likely to experience gender discrimination (25.2% vs. 2.2%; p<0.001), sexual harassment (13.1% vs. 2.3%; p<0.001) at work and feel unsatisfied with their current job (18.8% vs. 13.0%; p=0.006). Women were significantly more likely than men to be burned out (WBI - 39.2% vs. 27.4%; p<0.001; MBI - 30.9% vs 23.3%; p=0.002), to screen positively for depression (25.9% vs. 18.2%; p=0.002) and believe they would benefit from mental healthcare in the prior year (40.8% vs. 23.5%; p<0.001). We found no gender-based difference in likelihood to have a professional mentor (28.3% vs 27.1%; p=0.62), and satisfaction with their leaders (64.5% vs 69.7%; p=0.12). Experience of gender discrimination, younger age, and dissatisfaction with supervisor were significantly associated with burnout in both genders. However, lack of a mentor (OR 1.96; p=0.003) was associated with MBI burnout in men, not women. Higher numbers of hours worked per week was associated with increased MBI burnout in women; peaking at 51% burnout in women working 71-80 hours per week (p= 0.002), an association not seen in men (p=0.34).

CONCLUSIONS: Many factors contribute to burnout in both genders, such as gender discrimination, younger age and lower faculty level; however, some factors affect women (i.e. gender discrimination) more and thus may be a greater contributor to gender differences in burnout prevalence. This study is limited by its cross-sectional design at one institution and its assessment of only some factors contribuiting to burnout. Nonetheless, gender differences in factors contributing to physician burnout should inform novel intervention strategies.

GENDER DIFFERENCES IN EXPERIENCED BULLYING AMONG INTERNAL MEDICINE RESIDENTS

Manasa Ayyala[1]; Rebeca Rios[3]; Scott Wright[2]. [1]Medicine, Rutgers New Jersey Medical School, Newark, NJ; [2]medicine, jhusom, Baltimore, MD; [3]Georgetown University School of Medicine, Washington, DC. (Control ID #3390533)

BACKGROUND: Bullying is a significant problem in medical education and it results in a wide-range of negative consequences for those who are bullied. Preliminary analyses from this national study characterized the precise prevalence of bullying among internal medicine (IM) trainees at 1 in 7 residents, 14%. In further exploring the data, we wanted to discern whether there were gender differences across types of bullying endorsed (including verbal, physical, and sexual) and the personal consequences of this bullying. Based on research from other fields, we hypothesized that female residents would experience more detrimental consequences from being bullied.

METHODS: This cross-sectional survey exploring bullying included all IM residents in the US who were eligible to take the IM In-Training Exam (ITE) in 2016. Bullying was defined as: "harassment that occurs repeatedly by an individual in a position of greater power." Among the 2,875 trainee respondents who endorsed having been bullied (14%), the survey inquired about the types of bullying experienced during residency training, and the perceived resulting personal consequences. Descriptive and inferential statistics were computed and gender differences were tested using Pearson's chi-squared tests.

RESULTS: Among those who endorsed being bullied, 47% were female and 53% were male. Most respondents (n=2506, 87%) experienced one type of bullying during residency, and 13% (n=369) declared to have endured two or more types of bullying. Female respondents were more likely to have endorsed experiencing verbal (OR=1.5, p<.05) and sexual harassment (OR=2.7, p<.05), while male respondents were more likely to endorse experiencing physical (OR=1.4, p<.05), and "other" (OR=1.3, p<.05) forms of harassment.The two most commonly reported personal consequences of bullying were feeling burned out (57%), and a decline in performance (39%). A quarter of trainees reported no personal consequences attributable to bullying, and 6% endorsed a resultant improvement in their performance. Female respondents were significantly more likely to endorse experiencing burnout, depression, and weight change, while male respondents were more likely to endorse improved performance or no personal consequences resulting from bullying (all p<.05). Among those whose bullying involved sexual harassment, men were more likely to use illicit drugs, and women more likely to report burnout (both p<.05). Among those that endorsed more than one type of bullying, all detrimental personal effects were endorsed at equal rates across genders.

CONCLUSIONS: Bullying has significant negative sequelae on both male and female IM residents, but overall the impact is disproportionately larger on women. The reason for this differential impact is unclear and may relate to a vulnerability or to more intense bullying of female trainees. Bullying in medical education must be eliminated.

GENDER DIFFERENCES IN MEDICARE BENEFICIARIES' PERCEPTIONS OF INTEGRATED CARE

Jodi So, Sara Singer. School of Medicine, Stanford University, Palo Alto, CA. (Control ID #3388339)

BACKGROUND: Prior research has identified numerous disparities between male and female patients. However, gender differences in patient perceptions of integrated care (PPIC) have not been characterized. Understanding variation in PPIC is critical, as these differences may further exacerbate disparities in patient experiences and outcomes. This study sought to investigate differences in PPIC across providers, settings, and over time between male and female Medicare beneficiaries.

METHODS: We explored gender differences in PPIC using the 2015 Medicare Current Beneficiary Survey (MCBS) for 8 PPIC domains: provider (PRK), specialist (SPK), and staff (STK) knowledge of the patient, provider support for self-directed care (SDC), medication/home-health management (MHH), and following hospitalization (HOS), test result communication (TRC), and outside-of-visit organization (OVO). To evaluate PPIC responses, we constructed linear regression models for each of the eight PPIC domains, treating PPIC score as a continuous outcome and respondent gender (male/female) as the independent variable of interest. Each model controlled for patient demographics, activation, and optimism. Sensitivity analyses controlled for level of health need and self-reported health status. We used Chi-squared tests to evaluate question-level differences between men and women. Our sample included 11,978 respondents (5,494 male, 6,484 female) who completed a community interview for the 2015 MCBS.

RESULTS: Men perceived significantly higher levels of integrated care compared to women for 6 of the 8 PPIC domains: STK, SDC ($p<0.05$); and PRK, SPK, TRC, OVO ($p<0.01$). Results persisted after adjusting for level of health need or self-reported health status.

CONCLUSIONS: Compared to men, women consistently reported lower levels of PPIC even after controlling for patient demographics, activation, optimism, level of health need, and self-reported health status, suggesting disparities in PPIC between men and women. These observed disparities may be due to actual differences in care experienced by men and women or to differences in values or expectations about care. Additional research is needed to further understand the sources of these discrepancies. For example, female patients may value detailed discussions with providers about their medical conditions and treatments more than men do. If so, then given the same level of detail, a female patient could perceive the discussion as inadequately integrating information about her medical conditions, while a male patient could be satisfied. Interventions targeting different aspects of PPIC offer a unique starting point for providers or policymakers seeking to improve patient experiences and outcomes.

GENDER DYSPHORIA: DIAGNOSIS AND ETHICAL TRADEOFFS

Zackary Berger[1]; Paula Neira[2,3]. [1]General Internal Medicine, Johns Hopkins School of Medicine, Baltimore, MD; [2]John Hopkins Center for Transgender Health, Baltimore, MD; [3]Plastic and Reconstructive Surgery, Johns Hopkins School of Medicine, Baltimore, MD. (Control ID #3390045)

BACKGROUND: Diagnosis is contingent on a patient's clinical presentation, the relationship with the provider, and the historical, societal, economic, and political context of the encounter. Assigning a diagnosis can present an ethical dilemma for clinicians, particularly when caring for transgender patients. For example, a 21-year-old presents for gender-affirming treatment. To authorize treatment, their insurance company demands a diagnosis of "gender dysphoria." What are the ethical tradeoffs in such a diagnosis? What can the clinician do? What should they do?

METHODS: We perform an ethical analysis of the use of this diagnosis considering medical indications, patient factors, quality of life, and contextual factors. These dimensions reflect the bioethical principles of benevolence, non-maleficence, autonomy, and justice. We also consider the ways in which patient autonomy influences diagnosis through acceptance of, collaboration with, and opposition to dictates of the health care system.

RESULTS: A straightforward application of the diagnosis occurs when patients endorse dysphoria with their sex assigned at birth (exercising autonomy), and diagnosis makes treatment financially possible. A potentially more complex situation arises when patients do not experience dysphoria, yet are making an informed decision to live as their authentic self, in alignment with their gender identity, and in the context of their own assessment of their quality of life. Labeling their decision as dysphoric might stigmatize gender identification and trans identity more generally, leading to QOL consequences for individual patients and systemic harms to the trans population. Even for those patients who do endorse gender dysphoria, making use of this diagnosis furthers stigmatization and the continued medicalization of transgender identity. We note that the ICD-11 removes gender dysphoria as a diagnosis (in favor of gender incongruence), moving the new diagnosis to sexual health. Finally, social contexts (e.g. the unequitable US health care system) require that practitioners and patients consider inequalities in how gender dysphoria might be screened for and received, especially for non-white and other disadvantaged populations whose negative emotions are often subject to epistemic injustice. A practitioner's approach to the use of gender dysphoria thus depends on the patient's willingness to accept the diagnosis, with all its potential deleterious effects, and the clinician's willingness to accede to the status quo rather than supporting positive formulations of trans identity (acknowledging negative implications for the patient needing treatment in the moment).

CONCLUSIONS: Gender dysphoria, like other diagnoses, demands consideration of the individual patient, their decisions and self-assessment, as well as the clinician's role within the system, in political and social context. Alternatives to such diagnoses, and to larger medicalizing frameworks, should be considered in the care of transgender patients.

GENDER VARIATIONS IN GUIDELINE-CONCORDANT CERVICAL CANCER SCREENING IN RESIDENT-PRECEPTOR DYADS

Payel J. Roy[1]; Shwetha S. Sequeira[5]; Juhee McDougal[4]; Christine Prifti[3]; Rebecca Green[3]; Sarah Fulco[6]; Mara Eyllon[2]. [1]Medicine, UPMC/University of Pittsburgh, Pittsburgh, PA; [2]Department of Medicine, Boston University School of Medicine, Somerville, MA; [3]Medicine, Boston Medical Center, Boston, MA; [4]Medicine, Boston University Medical School, Boston, MA; [5]General Internal Medicine, Boston University Medical Center, Boston, MA; [6]Internal Medicine, Boston Medical Center, Boston, MA. (Control ID #3360606)

BACKGROUND: Prior research has shown that male healthcare providers complete guideline-based cervical cancer screening at lower rates than female providers after completing post-graduate training. This study compared the rates of guideline-concordant cervical cancer screening performed by male and female internal medicine residents among eligible patients in an outpatient general medicine clinic. We then examined whether attending preceptor gender moderated cervical cancer screening completion in these encounters.

METHODS: This study was a retrospective chart review conducted on patients seen during an 18-month period at an academic, internal medicine primary care clinic at a safety-net hospital in Boston, Massachusetts. The participants were cisgender female patients between the ages of 24 and 65 who had completed a primary care clinic encounter with an internal medicine resident physician between July 1, 2017 and December 31, 2018. We excluded patients who did not have a cervix. The exposure of interest was male resident gender and the comparator was female resident gender. The outcome of interest was odds of receiving guideline- concordant cervical cancer screening. Data were analyzed using multivariable logistic regression, where we adjusted for patient smoking status, insurance status, and race/ethnicity. In order to understand whether screening varied across preceptor gender, the analyses were stratified by preceptor gender.

RESULTS: A total of 3,022 patients were included for analysis; 996 were seen by a male resident (33%), of which 357 (36%) were precepted by a male physician. There were no statistically significant differences in the odds of receiving guideline-concordant cervical cancer screening by resident gender. Patients seen by male residents who were precepted by male physicians had 1.54 times the odds of having past-due cervical cancer screening (95% CI 0.83-2.85). When precepted by female physicians, patients of male residents had 0.75 times the odds of past-due cervical cancer screening (95% CI 0.46-1.23). These findings were not statistically significant.

CONCLUSIONS: We identified lower odds for cervical cancer screening among cisgender female patients who were seen by male residents with male preceptors compared to male residents with female preceptors. However, the difference was not statistically significant. Our study was limited by statistical power. The identified trend may have implications for the health of female patients cared for by male residents and preceptors. Future directions include increasing the sample size to improve the study's power and conducting qualitative studies to understand potential reasons for this discrepancy.

GENERALIZED RISK PREDICTION FOR CARDIOVASCULAR EVENTS WITHIN VA HEALTHCARE

Jeremy Sussman[1,2]; David Ratz[2]; Janelle Keusch[5]; Bradley Youles[3]; TImothy Hofer[4]; Wyndy L. Wiitala[5]; Rodney A. Hayward[6]. [1]Internal Medicine, University of MIchigan, Ann Arbor, MI; [2]CCMR, Veterans Affairs, Ann Arbor, MI; [3]Health Services Research & Development, Department of Veterans Affairs, Ann Arbor, MI; [4]Medicine, University of Michigan, Ann Arbor, MI; [5]HSR&D/Center for Clinical Management Research, VA Medical Center, Ann Arbor, MI; [6]Internal Medicine, U. Michigan, Ann Arbor, MI. (Control ID #3392631)

BACKGROUND: Traditionally, prediction of cardiovascular disease (CVD) events, has been separated into primary prevention and secondary prevention. Many patients fit poorly in either of these groups, such as patients with a history of cardiovascular procedures (such as bypass surgery or stents) or heart failure. We hypothesized that the division between primary and secondary prevention conceals patient variation in risk both within and between these risk groups.

METHODS: Participants: Everyone aged 45-80 who used VA outpatient services in 2009.

Outcomes: Acute myocardial infarction, stroke, or cardiovascular death between 2010 and 2014 in VA electronic health records, Medicare billing data, or National Death Index.

Variables: Up to 100 variables that are based on existing cardiovascular disease risk factors, procedures, events, labs, and medicines with some two-way interactions. Patients were classified in three prevention groups: Primary, secondary (history of heart attack or stroke), and other, which was defined as no history of heart attack or stroke, but having other very high risk features, including a history of stent placement or bypass, or a diagnosis or heart failure or atrial fibrillation.

Models: Logistic regression with elastic net regularization was used to fit the model utilizing an 80%/20% split for training and test data. Reported results are all based off of the test data.

RESULTS: 67% of patients were primary prevention, 16% were secondary prevention, 17% were "other", primarily due to heart failure or having a history of cardiovascular procedures. The combined CVD prediction model had an ROC of 0.78, with a Brier score of 0.10 and generally good calibration. Primary prevention had an average 5-year event rate of 7.2%,

secondary prevention 30.4%. The other group had a rate of 22.8%. However, there was tremendous range within each group. The 10th percentile of risk for primary prevention had a 2% 5-year event rate and the 90th percentile had a 14% event rate. This was higher than the 10th percentile event rate for secondary prevention, of 13%. The 90th percentile of secondary prevention had a 53% estimated event rate. The risk for the other group was nearly always almost as high as the secondary prevention group.

CONCLUSIONS: While dividing patients into primary and secondary prevention has many clinical benefits, it obscures overlap in CVD risk between and among those groups and leaves a large number of patients who are both very high risk, but not clearly in either group.

GETTING AHEAD OF BIAS: QUALITATIVE PRE-WORK FOR DEVELOPING AI CAPTURE OF PALLIATIVE AND END-OF-LIFE QUALITY MEASURES

Karleen Giannitrapani[1,2]; Anne M. Walling[3,4]; Raziel Gamboa[1]; Claire E. O'Hanlon[3]; Canning Mark[3]; Charlotta Lindvall[5,6]; Karl Lorenz[1,2]. [1]U.S. Department of Veterans Affairs Palo Alto Healthcare System, Menlo Park, CA; [2]Division of Primary Care and Population Health, Stanford University School of Medicine, Stanford, CA; [3]U.S. Department of Veterans Affairs Greater Los Angeles Healthcare System, Los Angeles, CA; [4]General Internal Medicine, University of California, Los Angeles, Los Angeles, CA; [5]Dana-Farber Cancer Center, Harvard Medical School, Boston, MA; [6]U.S. Department of Veterans Affairs Boston Healthcare System, Boston, MA. (Control ID #3389680)

BACKGROUND: Artificial intelligence (AI) may enable the widespread adoption of palliative care quality measures enhancing feasibility of patient population management. How do we choose what measures to use to train algorithms? The VA IMPACS Study elicited national expert stakeholder input on prioritizing patient- caregiver input in cancer palliative and end-of-life care quality measurement, with the goal of identifying measures to implement using computational methods.

METHODS: Using a purposive sampling approach we recruited 15 palliative care key-stakeholders with backgrounds and national leadership positions in primary care, palliative care, pain management, oncology, social work, nursing, and medical ethics. A semi-structured interview guide elucidated provider perspectives of measure selection and prioritization as well as introduction of potential bias. We analyzed audio recordings from phone interviews (20-65 minutes) and produced mutually agreed upon themes.

RESULTS: Theme 1: In terms of measuring palliative care quality, AI algorithms are limited, and only going to be as relevant as the measures they are trained to capture. Theme 2: The field of palliative quality measurement, though it has over 226 individual process quality measures, is perceived as nascent in terms of provider, patient, and caregiver measure and concept prioritization. Theme 3: providers question if the quality measures developed for the middle 80% are relevant for the 20% tail populations? Populations that may need to be considered when determining if existing quality measures represent all patients may include gender, race, age, sexual orientation, cis/trans gender, significant social disadvantages (e.g. homelessness), serious mental illness, cognitive impairment, or *"patients who can't verbalize or speak for themselves or who have delirium, we don't have measure for any of those groups*." Theme 4: Existing quality measures may not comprehensively capture the constructs that are important to palliative patients/caregivers. *"The things they [Patients] think are really important and frankly the things we spent a lot of time on is like trust and rapport, and listening, coordination of care, and addressing caregiver needs, and we just have this zero caregiver needs assessment in quality measures."*

CONCLUSIONS: Computational approaches may improve feasibility of population assessment, but are limited by missing concepts, and their potential to improve population reach may be undermined by inherent biases. Our results advocate for soliciting field expert input prior to implementing measures with AI approaches. To ensure measures implemented are relevant in "tail" populations and capture the constructs most relevant to patients we will repeat this process with patient stakeholders. We will also conduct Delphi consensus panels with providers and patients.

HARNESSING ELECTRONIC HEALTH RECORD INTEROPERABILITY TO IMPROVE INTER- HOSPITAL TRANSFER COMMUNICATION: A RANDOMIZED STEPPED WEDGE INTERVENTION

Michael Usher[1]; Michael Rhodes[2]; Jonathan D. Kirsch[3]; Cheryl Bloom[5]; Karyn Baum[4]. [1]Department of Medicine/Division of General Internal Medicine, University of Minnesota Medical School, Minneapolis, MN; [2]Department of Medicine, University of Minnesota, Minneapolis, MN; [3]Internal Medicine, University of Minnesota, Minneapolis, MN; [4]Medicine, University of Minnesota, Minneapolis, MN; [5]MHealth - Fairview, Minneapolis, MN. (Control ID #3392061)

BACKGROUND: Patients transferred between hospitals undergo a high-risk transition of care, where communication is asynchronous, information is commonly lost, and mortality is disproportionately high. The lack of interoperability of electronic health records (EHR) is a barrier to high quality hand-off in this high- risk transition of car. Improving the flow of information such as regional participation of health information exchanges (HIE) has the potential to improve the cost and outcomes of this vulnerable population, but this remains to be tested in practice. The impact of interoperability has yet to be tested in prospective interventional trials.

METHODS: We conducted a prospective randomized stepped wedge interventional trial to leverage the high regional prevalence of epic care everywhere of non-emergent transfers to a representative tertiary care center. All inpatient services i randomized into one of 4 blocks which determined order of implementation. A multi- disciplinary intervention including (1) Epic Care-everywhere informed consent was signed (2) images were requested to be electronically "pushed" (3) an encounter was generated, and (4) time was allowed to review records prior to verbal hand off and structured with a note. The intervention was staggered in 3 month periods to each of the four blocks. The primary outcomes was inpatient mortality after transfer, secondary measures included length of stay, return transfer, escalation of care after transfer, and provider satisfaction. Differences- in-differences (DiD) analysis was used comparing outcomes against a 1 year prospectively collected baseline using differences in differences analysis.

RESULTS: Following intervention we compared the outcomes of 1110 patients following intervention against 2221 controls. 92% of transfers had information made available prior to hand off. We observed no significant improvement in inpatient mortality ($p = 0.53$), nor length of stay ($p = 0.58$). We observed a significant reduction in rate of escalation of care within 24 hours (1.8% to 1.2%, DiD coef, p=0.012). Before and after the intervention providers remained positive regarding the potential for HIE to improve inter- hospital transfers; however, there was a decline in the belief that access was practical during routine care particularly among services that lacked 24-hour in-house call.

CONCLUSIONS: In this single center interventional study, we find that integrating EHR interoperability into the hand off process did not improve mortality or length of stay, but did reduce early escalation of care. Many providers found a more involved transfer process disruptive to normal workflow and patient care. We conclude that interoperability efforts are a necessary step toward improved communication, however not sufficient in the absence of dedicated staff allowing sufficient time to review records and images during the transfer process.

HEALTH AND HOUSING: A COMPREHENSIVE COMMUNITY HEALTH NEEDS ASSESSMENT OF LOW-INCOME COMMUNITIES IN PUEBLA, MEXICO

Timothy Mercer[1]; Veronica Remmert[2]; Luis Hernandez[3]; Eder Hernandez[3]; Christina Ciaburri[2]; Andrea Flores[2]; Stephenson Claire[2]; Alfonso Rojas[2]; Peter Ward[2]; Ricardo Ainslie[2]. [1]Population Health, The University of Texas at Austin Dell Medical School, Austin, TX; [2]The University of Texas at Austin, Austin, TX; [3]Benemerita Universidad Autonoma de Puebla, Puebla, Mexico. (Control ID #3392278)

BACKGROUND: In Mexico and the U.S., those living in poverty suffer disproportionately from chronic diseases and face barriers accessing care. In order to improve population health we must start with a detailed understanding of community health needs, as well as the underlying social determinants of health related to poverty. A comprehensive health needs assessment in four low-income communities in Puebla, Mexico was designed with the following objectives:

1. Understand the perceptions and priorities of the health needs of families
2. Characterize health behaviors, risk factors, utilization patterns and access issues
3. Describe the intersection between the built environment and health through an exploration of housing, water, and air quality

METHODS: A mixed-methods approach was used to assess community health needs and explore social determinants of health. This included semi-quantitative household surveys (n=242), key informant qualitative interviews (n=4), focus group discussions (n=6), intensive case studies of dwelling units (n=5), and technical air and water quality sampling of each household. The household surveys covered demographics and economic indicators, perceived health challenges, health care utilization, access, and quality of care, women's health, nutrition, mental health, health risk behaviors, water quality, cooking practices, air quality, and housing conditions.

RESULTS: Low-income communities in Puebla, Mexico face multiple health challenges at both the individual and health system levels, but also due to underlying social determinants of health. Diabetes is widely thought to be the major health problem affecting these communities and nutritional practices are poor. There are many barriers to accessing health care, including geographic isolation as well as health system quality issues. Despite a policy of universal health coverage, there is high use of the private sector for primary care (38% of households surveyed) associated with having to pay out-of-pocket costs and travel longer distances to access care. Trauma related to the 2017 earthquake in Mexico is still pervasive, with over 80% of respondents reporting persistent symptoms of earthquake-related trauma. Indoor air pollution was a problem, with mean CO2 and PM2.5 concentrations being above the recommended thresholds on average in all community households. A detailed analysis showed that the housing environment poses health risks related to hygiene, mobility, and safety.

CONCLUSIONS: These findings illustrate the importance of engaging with communities to develop a deep understanding of their needs and priorities. Addressing these needs will require a combination of further research, education, clinical care, public health interventions, and new policy proposals. This community health needs assessment galvanized the start of an academic global health partnership between UT and BUAP that will work with communities and public-sector health care delivery systems to improve population health.

HEALTH BEHAVIORS OF AN IMMIGRANT SOUTH ASIAN, INDO-CARIBBEAN POPULATION IN A PRIMARY CARE CLINIC IN QUEENS, NEW YORK: A PILOT STUDY

Lyndonna M. Marrast[1]; Alana Doonachar[2]; Zaid Tahir[3]; Nilifa Desilva[4]; Alison Karasz[4]. [1]General Internal Medicine, Zucker School of Medicine at Hofstra/Northwell, Kew Gardens, NY; [2]Health Professions, Hofsta University, Long Beach, NY; [3]Ambulatory Care Unit, Feinstein Institute, Elmont, NY; [4]Family and Social Medicine, Albert Einstein College of Medicine, Bronx, NY. (Control ID #3391829)

BACKGROUND: South Asians are a fast- growing minority group in the US with a high prevalence of chronic conditions. Many community-based studies exist, but few studies look at immigrant South Asians in a primary care setting. We conducted a pilot study of patients originally from countries in South Asia and the Caribbean to assess dietary and physical activity behaviors, health seeking behaviors and acceptability of text message use for nutritional advice. The goal is to develop future interventions that are most applicable to this population.

METHODS: We approached patients in the Ambulatory Care Unit of a large academic medical center in Queens, NY. Inclusion criteria included individuals originally from South Asian and the Indo-Caribbean countries of Guyana and Trinidad, aged 18 to 84. Patients were approached in the waiting area or examination room. Informed consent was obtained followed by administration of a 15-minute paper survey. Participants received a $5 gift card for participation. We performed descriptive statistics on the data.

RESULTS: We approached 80 patients and completed 69 surveys. Thus, our response rate was 86%. The population was 52% female; 43.5% Muslim and 34% Hindu, largely from Bangladesh (34%) and Guyana (30%) with 12% from India. While 61.2% rated their health as "excellent/very good/good," 38.8% reported a "fair/poor" health status. Chronic conditions are prevalent: 66.7%, 62.3%, 71% reported being told they have high cholesterol, hypertension and diabetes, respectively. The majority consumed 1 to 2 serving of fruits and vegetables daily. While over 90% reported no daily intake of soda, 44% drank 1-2 sweetened beverages per day. During the past month, 56% participated in a physical activity like jogging or walking. Preferred sources of health information about eating healthy included internet (51%), doctors (38%) and family/friends (28%). Over 60% would be willing to receive text messages about healthy eating.

CONCLUSIONS: Chronic conditions are common among this immigrant population of South Asian and Indo Caribbean patients. Though the sample reported their health positively, many had diabetes, hypertension or high cholesterol. Future interventions about eating healthy can come from multiple sources such as the internet and health providers. Limitations include English-speaking research assistants and an English language consent form, resulting in a largely English speaking sample which excluded a large amount of non- English speaking South Asian immigrants. In addition, over the study period, the clinic scheduled a reduced number of patients in preparation for relocation to a new site. Nevertheless, this study will inform future interventions around diet and nutrition for immigrant South Asian and Indo Caribbean patients.

HEALTHCARE ACCESS AND HEALTH RISK BEHAVIORS AS MEDIATORS FOR THE RELATIONSHIP BETWEEN TRANSGENDER IDENTITY AND NEGATIVE HEALTH OUTCOMES: EVIDENCE FROM THE BRFSS (2017)

Natalie LaBossier[1,2]; Randi L. Garcia[2]. [1]Medicine, Boston University School of Medicine, Boston, MA; [2]Statistics and Data Sciences, Smith College, Northampton, MA. (Control ID #3382509)

BACKGROUND: New guidelines from the American College of Physicians recognize internists as the first line of care for transgender individuals. It is critical that internists, most of whom are already treating gender diverse patients, understand the unique health needs of this medically vulnerable population. Transgender individuals have worse health outcomes than their cisgender peers, and health outcomes vary within the transgender community. It is also known that transgender individuals are less likely to have health insurance or a personal health provider. Previous work, however, has been unable to determine causal relationships between these factors and the negative health outcomes seen in this population. An understanding of these relationships would allow us to better target interventions to support the wellbeing of our transgender patients.

METHODS: In order to demonstrate potential causal pathways between transgender identity, factors influencing health, and health outcomes, factor analysis and structural equation modeling (SEM) were used. Using a large national sample from the Behavioral Risk Factor Surveillance System, we were able to account for many factors, including proxies for mental and physical health, healthcare access, chronic illness, health risk behaviors, and many demographic factors. An initial measurement model was fit to the data and subsequently adjusted. A SEM was then fit to the data and found to have good overall fit. Finally, the Sobel Test was used to test for multiple mediation.

RESULTS: In the final model, transgender identity was a significant negative indicator of healthcare access and a significant positive indicator of negative health behaviors, but it was not associated with chronic health conditions. Healthcare access and health behaviors significantly mediated the relationship between transgender identity and health outcomes. When transgender groups were disaggregated, the same mediation relationships held true for male-to-female transgender individuals, while access was the only significant mediator for female-to-male individuals, and health behaviors was the only significant mediator for gender non-conforming individuals. Socioeconomic status also significantly mediated the relationship between transgender identity and healthcare access.

CONCLUSIONS: This study adds a crucial missing piece to the literature by focusing on the pathways that drive health outcomes for transgender individuals. We were able to demonstrate that healthcare access and negative health behaviors mediate the relationship between transgender identity and negative health outcomes. Findings have implications for policy aiming to improve insurance access and programs aiming to address negative health behaviors. Providers may play a role in ameliorating these factors by becoming more educated on transgender care, screening for and addressing negative health behaviors with their patients, and referring patients to services that address their social determinants of health.

HEALTH CARE CONSUMERISM IN A MEDICAID EXPANSION PROGRAM TO ENCOURAGE COST-CONSCIOUSNESS AMONG BENEFICIARIES

Jeffrey T. Kullgren[1]; Renuka Tipirneni[2]; Matthias Kirch[2]; Erica Solway[2]; Erin Beathard[3]; Sarah J. Clark[4]; Minal Patel[5]; Edith C. Kieffer[6]; Tammy Chang[2]; Adrianne N. Haggins[7]; Sunghee Lee[2]; John Z. Ayanian[8]; Susan D. Goold[9]. [1]VA Center for Clinical Management Research and Department of Internal Medicine, Ann Arbor VA Healthcare System and University of Michigan, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI; [3]Institute for Healthcare Policy & Innovation, University of Michigan, Ann Arbor, MI; [4]Pediatrics, University of Michigan, Ann Arbor, MI; [5]Health Behavior & Health Education, University of Michigan, Ann Arbor, MI; [6]School of Social Work, University of Michigan, Ann Arbor, MI; [7]Emergency Medicine, University of Michigan, Ann Arbor, MI; [8]Institute for Healthcare Policy and Innovation, University of Michigan, Ann Arbor, MI; [9]Internal Medicine/IHPI, University of Michigan, Ann Arbor, MI. (Control ID #3391692)

BACKGROUND: State Medicaid programs are increasingly using cost-sharing, premiums, and cost information to encourage health care consumerism. In Michigan's Medicaid expansion, Healthy Michigan Plan (HMP) beneficiaries have MI Health Accounts (MIHAs) into which they pay copays after services and, for those with incomes 100-133% of the Federal Poverty Level, premium contributions equal to 2% of their income. Quarterly MIHA statements tell beneficiaries what they owe and what their managed care plan paid for services. Little is known about engagement in consumer behaviors among beneficiaries subject to these policies.

METHODS: We used data from a longitudinal telephone survey in which 1,489 HMP beneficiaries age 19-64 were surveyed at least 36 months after enrollment. Beneficiaries were asked if in the last 12 months they had carefully reviewed their MIHA statements; checked how much they would have to pay for a service before they received care; asked a provider to recommend a less costly prescription drug; talked with a provider about how much a service would cost out-of-pocket (OOP); or compared quality ratings for services. We used 5 multivariable mixed-effects regression models to estimate associations between engagement in each consumer behavior and demographic characteristics, income, chronic conditions, health status, literacy, perceived affordability of HMP payments, previous forgone care due to cost, and previous OOP spending. All models incorporated weights to adjust for probabilities of sampling.

RESULTS: In the last 12 months, 87.5% of enrollees who recalled receiving a MIHA statement carefully reviewed their statements; 21.0% checked how much they would have to pay for a service before they received care; 20.6% asked a provider to recommend a less costly prescription drug; 15.5% talked with a provider about how much a service would cost OOP; and 12.5% compared quality ratings. Compared to being age 19-34, being age 51-64 was associated with carefully reviewing MIHA statements [odds ratio (OR) 1.82]. Female gender was associated with checking costs before receiving care (OR 1.85), asking for a less costly prescription drug (OR 2.42), and comparing quality ratings (OR 2.61). Compared to a high school education or less, having at least a bachelor's degree was associated with checking costs before receiving care (OR 2.54), talking with a provider about OOP costs (OR 1.89), and comparing quality ratings (OR 3.30). Compared to < $50 in OOP costs in the previous year, $101-$500 in OOP costs was associated with checking costs before receiving care (OR 1.90), asking for a less costly prescription drug (OR 1.90), and talking with a provider about OOP costs (OR 2.45).

CONCLUSIONS: Medicaid beneficiaries often carefully review quarterly statements with cost information, but in a setting of relatively low cost-sharing may not engage in other consumer behaviors at high rates without additional strategies to support decision-making.

HEALTHCARE DELIVERY INTERVENTIONS TO IMPROVE HYPERTENSION MANAGEMENT IN COMMUNITY HEALTH SETTINGS: A SYSTEMATIC-REVIEW

Maarya Pasha[1]; Susie Sennhauser[2]; M. Hassan Murad[3]. [1]General Internal Medicine, Mayo Clinic, Apple Valley, MN; [2]Cardiovascular Disease, Mayo Clinic College of Medicine, Jacksonville, FL; [3]Preventative Medicine, Mayo Clinic, Rochester, MN. (Control ID #3390807)

BACKGROUND: The high prevalence of uncontrolled hypertension in underserved patient populations is a major cause of health disparities in the United States and treatment of hypertension has a significant impact

on reducing cardiovascular disease mortality. Evaluating practice based change models for underserved patients with a high burden of uncontrolled hypertension is important and emphasized by the Institute of Medicine report in 2010 on population-based policy and systems change approaches to prevent and control hypertension. Healthcare delivery interventions to improve blood pressure control are particularly challenging in low resource settings, such as community health centers (CHCs).

METHODS: We conducted a systematic review of randomized controlled trials (RCTs) and comparative observational studies examining the effectiveness of systems change and quality improvement interventions aimed at improving blood pressure control in community health settings published from 2010 to 2019. The broader purpose was to identify intervention characteristics associated with the most success serving a low- income, underserved population with high rates of uncontrolled blood pressure. Inclusion criteria were studies of multi-component practice improvement interventions conducted in North America at FQHCs, CHCs, and safety-net practices, reporting blood pressure as the primary outcome of interest (either as proportion of patients with controlled blood pressure or reduction in systolic and diastolic blood pressure) with pre and post measurements.

RESULTS: Of the 400 articles screened, 25 studies with 31,744 hypertensive patients were included. Studies had a high proportion of patients with a low-income, racial/ethnic minorities, and comorbidities. Of these, 5 studies demonstrated effectiveness of integrating pharmacists into community health centers for blood pressure management using medication therapy management. Four studies involved community health workers and led to improved blood pressure control, and importantly reported high patient satisfaction with this model. Close and regular follow-up with patients was shown to be an important part of improved blood pressure control. One study evaluated financial incentives to clinics for uninsured patients and Medicaid patients meeting performance criteria, resulting in improved blood pressure control in those clinics. Studies involving combined physician and patient education were generally successful in improving blood pressure, but not any more than other interventions. Very few studies discussed patient-reported outcomes and side effects. The majority of the studies in this systematic review showed improvement in blood pressure; which may suggest publication bias.

CONCLUSIONS: Multi-component practice improvement interventions conducted in North America at FQHCs, CHCs, and safety-net practices are effective in lowering blood pressure. Several components of the interventions were identified as being associated with higher efficacy.

HEALTHCARE FRAGMENTATION AND BLOOD PRESSURE CONTROL AND APPARENT TREATMENT-RESISTANT HYPERTENSION AMONG BLACK AND WHITE ADULTS WITH HYPERTENSION.

Calvin Colvin[1]; Mangala Rajan[2]; Joanna Bryan[2]; Monika M. Safford[3]; Paul Muntner[1]; Lisandro Colantonio[1]; Lisa M. Kern[4]. [1]Epidemiology, University of Alabama at Birmingham, Birmingham, AL; [2]Department of Medicine, Weill Cornell Medicine, New York, NY; [3]Department of Medicine, Weill Cornell Medical College, New York, NY; [4]Healthcare Policy and Research, Weill Cornell Medical College, New York, NY. (Control ID #3388295)

BACKGROUND: Black adults have higher blood pressure (BP) and are more likely to have apparent treatment-resistant hypertension (aTRH) versus white adults. Prior studies suggest that fragmented ambulatory healthcare may be associated with poor BP control. It is not known whether the associations between healthcare fragmentation and BP control and aTRH differ among black versus white adults.

METHODS: We analyzed data from black and white participants ≥66 years of age in the REasons for Geographic and Racial Disparities in Stroke (REGARDS) study who attended an in-home study visit between 2013 and 2016, had hypertension, were taking antihypertensive medication, and had continuous Medicare fee-for-service healthcare insurance coverage and ≥4 ambulatory care visits in the year prior to their study visit. Healthcare fragmentation was measured using Medicare claims for ambulatory visits in the year prior to the study visit. High healthcare fragmentation was defined as a reversed Bice-Boxerman Index ≥75th percentile of the distribution. BP control was defined as having a systolic/diastolic BP of <140/90 mm Hg. aTRH was defined as having uncontrolled BP while taking ≥3 antihypertensive medications or taking ≥4 antihypertensive medications regardless of BP.

RESULTS: Among 2,897 participants (mean age 76 years, 69% female, 31% black), BP control was 80.8% and 81.9% in those with and without high healthcare fragmentation, respectively. After multivariable adjustment, the prevalence ratio (PR) for BP control associated with high healthcare fragmentation was 0.98 (95% CI 0.94, 1.02). The prevalence of aTRH was 17.7% and 15.9% among participants with and without high healthcare fragmentation, respectively. The PR for aTRH associated with high healthcare fragmentation was 1.15 (95% CI 0.97, 1.37). In race-stratified analyses, high healthcare fragmentation was associated with a higher prevalence of aTRH among black but not among white participants (Table).

CONCLUSIONS: Healthcare fragmentation was not associated with BP control in this population of black and white adults with hypertension. However, healthcare fragmentation may be associated with a higher risk for aTRH in black adults.

HEALTHCARE FRAGMENTATION AND CARDIOVASCULAR RISK CONTROL AMONG CANCER SURVIVORS IN THE REASONS FOR GEOGRAPHIC AND RACIAL DIFFERENCES IN STROKE (REGARDS) STUDY

Laura C. Pinheiro, Evgeniya Reshetnyak, David Nanus, Monika M. Safford, Lisa M. Kern. Department of Medicine, Weill Cornell Medical College, New York, NY. (Control ID #3384187)

BACKGROUND: Cardiovascular disease (CVD), not cancer, is the #1 cause of death among 5-year cancer survivors. The reasons for this are not well established. A possible explanation is that because cancer survivors see many different providers after cancer care, lack of coordination among those providers may contribute to poor CVD risk factor control. Our objective was to determine, among cancer survivors, if more fragmented ambulatory care (i.e., receipt of care from multiple providers without a dominant provider) is associated with worse CVD risk factor control. We also examined findings stratified by health status, as in our prior work the association between fragmentation and CVD outcomes varied by health status.

METHODS: This study included participants in the nationwide REGARDS cohort study with linked Medicare claims data who: 1) were aged 66+ years; 2) reported a history of cancer (that did not receive treatment in the past two years); 3) had diabetes, hypertension, or hyperlipidemia; and 4) had continuous Part A and B Medicare coverage for the 12 months prior to baseline. Fragmentation of ambulatory care in the 12 months before baseline was calculated from Medicare claims using the reversed Bice-Boxerman Index (rBBI). Higher scores reflect more fragmentation. We determined associations between fragmentation and CVD risk factor control using separate logit models for each risk factor, defining "good control" as fasting glucose<126/non-fasting glucose<200 for diabetes, blood pressure <140/90 mm Hg for hypertension, and TC<240 or LDL<160 or HDL>40 for hyperlipidemia. We examined results overall and stratified by self- reported excellent, very good/good, and fair/poor health, adjusting for demographics, comorbidities, and health status.

RESULTS: The 1,002 cancer survivors had mean age of 75 years at baseline, 39% were women, and 23% were Black. Survivors had a median of 10 visits (IQR 7-15) with 5 providers (rBBI 0.80) and 43% of visits were with their most frequently seen provider. Among individuals with diabetes (N=225), hypertension (N=660), and hyperlipidemia (N=516), separately, 61% had diabetes control, 59% had hypertension control, and 60% had hyperlipidemia control, respectively. Fragmentation was not associated with CVD risk factor control in the overall sample (RR 1.03 (0.99, 1.08), p=0.12). However, among cancer survivors who reported very good r good health, more fragmentation (every 0.1-unit increase in rBBI) was associated with a 36% decrease in the likelihood of diabetes control (95% CI 0.46-0.89), adjusting for potential confounders. We did not observe this pattern for hypertension or hyperlipidemia control.

CONCLUSIONS: More fragmentation of ambulatory care was associated with worse glycemic control among cancer survivors with diabetes who self-reported very good or good health, concordant with our past findings. Fragmentation was not associated with hypertension or lipid (control for any health status.

HEALTHCARE FRAGMENTATION AND INCIDENT ACUTE CORONARY HEART DISEASE EVENTS

Lisa M. Kern[1]; Mangala Rajan[1]; Joanna Bryan[1]; Lisandro Colantonio[2]; Paul Muntner[2]; Lawrence P. Casalino[1]; Michael Pesko[3]; Evgeniya Reshetnyak[1]; Laura C. Pinheiro[1]; Monika M. Safford[1]. [1]Weill Cornell Medicine, New York, NY; [2]University of Alabama at Birmingham, Birmingham, AL; [3]Georgia State University, Atlanta, GA. (Control ID #3386614)

BACKGROUND: Highly fragmented ambulatory care (i.e., care spread across many providers without a dominant provider) has been associated with excess tests, procedures, emergency department visits, and hospitalizations. Whether fragmented care is associated with worse health outcomes, or whether any association varies with health status, is unknown. We sought to determine whether fragmented care is associated with the risk of incident coronary heart disease (CHD) events (definite or probable fatal or non- fatal myocardial infarction or CHD death), overall and stratified by self-reported general health.

METHODS: We conducted a secondary analysis of the nationwide prospective REasons for Geographic And Racial Differences in Stroke (REGARDS) cohort study (2003-2016). We included participants who were ≥65 years old, had linked Medicare fee-for-service claims, and had no history of CHD (N = 10,556). We measured fragmentation with the reversed Bice-Boxerman Index (rBBI), with high fragmentation defined as scores greater than or equal to 0.85 (on a scale from 0.00 to 1.00). We used Cox proportional hazards models to determine the association between fragmentation as a time-varying exposure and adjudicated CHD events in the 3 months following each exposure period. We considered 32 potential confounders, including demographic characteristics, medical conditions, medications, health behaviors, psychosocial variables, and physiological variables.

RESULTS: The mean age was 70 years; 57% were women, and 34% were African-American. Overall, 18% of the sample had excellent self-reported health, 67% had very good or good self-reported health, and 14% had fair or poor self-reported health. During the first year of observation, those with high fragmentation had on average 29% of their ambulatory visits with the most frequently seen provider (rBBI 0.91), compared to those with low fragmentation, who had on average 58% of their ambulatory visits with the most frequently seen provider (rBBI 0.63) ($p < 0.001$ for each comparison). Over 11.8 years of follow-up, 569 participants had CHD events. Overall, the adjusted hazard ratio (HR) for the association between high fragmentation and CHD events was 1.14 (95% confidence interval [CI] 0.92, 1.39). Among those with very good or good self-reported health, high fragmentation was associated with an increased hazard of CHD events (adjusted HR 1.35; 95% CI 1.06, 1.73; p = 0.01). Among those with fair or poor self-reported health, high fragmentation was associated with a trend toward a decreased hazard of CHD events (adjusted HR 0.54; 95% CI 0.29, 1.01; p = 0.052). There was no association among those with excellent self-reported health.

CONCLUSIONS: High fragmentation was associated with an increased independent risk of acute incident CHD events among those with very good or good self-reported health, which was the majority of the sample, adjusting for known cardiac risk factors.

HEALTHCARE UTILIZATION AND PATIENT AND PROVIDER EXPERIENCE WITH A HOME VISIT PROGRAM FOR PATIENTS DISCHARGED FROM THE HOSPITAL AT HIGH RISK FOR READMISSION: A MIXED METHODS STUDY

Anita D. Misra-Hebert[1]; Michael B. Rothberg[1]; Jacqueline Fox[2]; Xinge Ji[3]; Bo Hu[3]; Alex Milinovich[3]; William Zafirau[2]; Anthony Onuzuruike[4]; Kurt C. Stange[5]. [1]Internal Medicine, Cleveland Clinic, Cleveland, OH; [2]Medicine Institute, Cleveland clinic, Cleveland, OH; [3]QUANTITATIVE HEALTH SCIENCES, Cleveland Clinic, Cleveland, OH; [4]Cleveland Clinic Lerner College of Medicine, Cleveland, OH; [5]Family Medicine & Community Health, Case Western Reserve University, Cleveland, OH. (Control ID #3372435)

BACKGROUND: We recently implemented a home visit program delivered after discharge by advanced practice nurses (APRN) and paramedics for patients at high risk for readmission. We aimed to assess the effect of the program on health care utilization and mortality and to examine provider and patient experience.

METHODS: Utilizing a convergent, mixed methods design, we studied adult patients discharged to home from a medicine service in the Cleveland Clinic Health System (CCHS) from November 2017-September 2019 with a CCHS primary care physician (PCP). Patients receiving home visits for 4 weeks after discharge were matched 1:3 using coarsened exact matching to a comparison group discharged in the same period by age, gender, race, insurance, median income, an internal CCHS readmission risk score, and number of admissions and primary care visits in 180 days prior to admission. Outcomes at 30, 90, and 180 days, including hospital admission, emergency department(ED) use, and death, were analyzed in two time periods- Phase 1(5 months, APRN or paramedic delivered home visits based upon geographic location) and Phase 2 (6 months, APRNs and paramedics both delivered visits to the same patient). Mixed effect models adjusted for patients with multiple discharges. Patients declining home visits and those accepting were also compared. Semi-structured audiorecorded interviews were conducted with home visit patients, APRNs, paramedics, PCPs, and primary care nurse care coordinators (CC). Interviews were transcribed and coded, then, using an editing analysis, emergent themes identified.

RESULTS: In Phase 1, 144 home visit patients were matched to 432 comparison patients. There were no differences in readmissions, ED visits, or death at 30, 90, and 180 days. In Phase 2, 197 home visit patients matched to 591 comparison patients had fewer 30-day readmissions (21.8% vs. 31.5%, p 0.013) and no differences in the other outcomes. Compared with patients declining home visits, patients accepting had lower odds of 30 day readmissions: Phase 1(Odds ratio (OR) 0.89, p 0.013), Phase 2(OR 0.882, p 0.001). Forty-four interviews were conducted (22 patients, 7 CC, 9 PCPs, 3 paramedics, 3 APRNs). Themes of lack of understanding medications (APRN: "a lot of times you find that they didn't pick up a prescription or … didn't know it was decreased or increased "), health literacy, need for education, patient complexity(PCP: "The support needed for those really sick-sick patients to get them their meds, to assist them with their daily needs …They're exhausted,)"

financial barriers, need for social support, and patient reassurance after discharge (Patient: "… knowing that she's coming out … makes me feel better") emerged.

CONCLUSIONS: A post-discharge home visit program delivered by APRNs and paramedics to patients at high risk for readmission was associated with reduced 30 day readmissions. Barriers to remaining healthy at home related to medication understanding, health complexity, financial issues, and need for social support.

HEART FAILURE DISEASE MANAGEMENT VERSUS USUAL CARE IN PATIENTS WITH A PRIMARY DIAGNOSIS OF HEART FAILURE IN SKILLED NURSING FACILITIES

Himali Weerahandi[1]; Erin Chaussee[2]; John Dodson[1]; Mary A. Dolansky[3]; Rebecca Boxer[4]. [1]NYU School of Medicine, New York, NY; [2]University of Colorado School of Medicine, Aurora, CO; [3]Nursing, Case Western Reserve University, Cleveland, OH; [4]Medicine, University of Colorado, AURORA, CO. (Control ID #3341316)

BACKGROUND: Skilled nursing facilities (SNFs) are common destinations after hospitalization for patients with heart failure (HF). However, readmissions from SNFs and immediately after SNF discharge are common. In this study, we examined whether patients with a primary hospital discharge diagnosis of HF may benefit from a HF disease management program (HF-DMP) while undergoing post-acute rehabilitation in SNFs.

METHODS: This is a sub-group analysis of a cluster-randomized controlled trial of HF-DMP vs usual care (UC) for patients in SNF (n=671) with a HF diagnosis, regardless of ejection fraction (EF), conducted in 47 SNFs in the Denver-metropolitan area. The HF-DMP standardized SNF HF care using HF practice guidelines and performance measures and was delivered by a HF nurse advocate (HFNA). The HFNA directed a 7-component intervention focused on optimizing HF disease management through the following: documentation of EF, symptom and activity assessment, weights 3 times a week with dietary surveillance, recommendations for medication titration, patient/caregiver education, discharge instructions, and 7-day post- SNF discharge follow-up.

This sub-group analysis examined patients discharged from hospital to SNF with a primary hospital discharge diagnosis of HF (n=125). The primary outcome was a composite of all-cause hospitalization, emergency department visits, and mortality at 60 days post-SNF admission. The etiology (HF related, non-HF cardiovascular (CV) related, or "other") of the first event was adjudicated by a Clinical Endpoints committee that was blinded to treatment group. Secondary outcomes were the composite outcome at 30 days, and change in health status and self-management from baseline to 60 days measured by the Kansas City Cardiomyopathy Questionnaire (KCCQ) and the Self-care of HF Index (SCHFI).

RESULTS: Of the 125 patients with a primary hospital discharge diagnosis of HF, 50 were in the HF-DMP and 75 in UC. Overall mean age was 79±10, 53% were women, mean EF was 46±15%. At 60 days, the rate of the composite outcome was lower in the HF-DMP group (30%) compared to UC (52%) (p=0.02). Adjudicated events in the HF-DMP group revealed one HF related event, one CV related event, and 12 events classified as "other" within 60 days. In contrast, the UC group had 12 HF related events, 5 CV related events, and 19 events classified as "other" within 60 days. The rate of the composite outcome at 30 days for the HF-DMP group was 18% versus 31% in the UC group (p=0.11). Change in KCCQ and SCHFI measures were not significantly different between groups at 60 days.

CONCLUSIONS: Patients with a primary hospital discharge diagnosis of HF who received HF-DMP while receiving rehabilitation in a SNF had lower rates of the composite outcome at 60 days and less HF related events. Standardized HF management during SNF stays may be particularly important for patients with a primary discharge diagnosis of HF.

HEART FAILURE TRAINING AND JOB SATISFACTION: A SURVEY OF HOME CARE WORKERS CARING FOR ADULTS WITH HEART FAILURE IN NEW YORK CITY

Madeline R. Sterling, Jacklyn Cho, Joanna Bryan. Weill Cornell Medicine, New York, NY. (Control ID #3385669)

BACKGROUND: Home care workers (HCWs), which include home health aides and personal care attendants, frequently care for adults with heart failure (HF). Despite being heavily involved in HF patients' care, prior qualitative studies have found that HCWs lack training and confidence, which creates challenges for this workforce and potentially for patient care. As the foundation for future interventions, we aimed to: 1) Quantify the prevalence of HF training and confidence among HCWs providing HF care; 2) Determine the association between HF training and job satisfaction.

METHODS: We conducted a cross-sectional survey of HCWs caring for HF patients from August 2018 - May 2019. Using purposeful sampling, we recruited English-speaking HCWs employed by home care agencies across NYC. The survey was comprised of 64-items including a demographic questionnaire and novel and validated instruments on HF caregiving. HF training was assessed with a 1-item question, *"Have you received prior HF training?"* Job satisfaction was assessed with a 1-item question, *"How satisfied are you with your job?"* The association between HF training and job satisfaction was determined with robust poisson regression adjusting for agency, participant demographics and heart failure care characteristics.

RESULTS: 323 HCWs from 23 home care agencies participated. They had a median (IQR) age of 50 (37,58) years, 94% were women, 44% were Non-Hispanic Black, 23% were Hispanic, 78% completed ≥ high school education, and 72% were foreign-born. They had a median (IQR) of 8.5 (4,15) years of caregiving experience, and the majority (73%) had cared for 1-5 HF patients. While 63% of HCWs contributed adequately to HF maintenance tasks, only 23% contributed adequately to HF management tasks; 44% did not feel confident with HF caregiving. Overall, 66% of HCWs reported receiving none or a little HF training. 82% of HCWs reported feeling satisfied with their job. Compared to those with none or a little HF training, HCWs with some or a lot of HF training had 14% higher job satisfaction, after adjusting for demographic characteristics, agency size, years as a HCW, and number of prior HF patients (PR 1.14; 95% CI 1.03-1.27; p-value 0.014).

CONCLUSIONS: Despite contributing to HF self-care, the majority of HCWs received none or a little HF training and lacked confidence providing care to HF patients. In this diverse sample of HCWs, HF training was associated with higher job satisfaction. Our findings suggest that HF training programs may improve HCWs' experience caring for this patient population.

HELP ME WITH THAT URINE TOXICOLOGY RESULT: INSIGHTS AND CHALLENGES TO PROVIDING LABORATORY-GENERATED INTERPRETATIONS FOR PATIENTS RECEIVING CHRONIC OPIOID THERAPY

Isaac S. Chua[1,4]; Olga Ehrlich[2]; Jaime Ransohoff[3]; Athena Petrides[3,4]; Maram Khazen[1,4]; Stacy Melanson[3,4]; Gordon D. Schiff[5,4]. [1]General Internal Medicine, Brigham and Women's Hospital, Boston, MA; [2]Phyllis Cantor Center for Research in Nursing and Patient Care Services, Dana Farber Cancer Institute, BOSTON, MA; [3]Pathology, Brigham and

Women's Hospital, Boston, MA; [4]Harvard Medical School, Boston, MA; [5]Center for Patient Safety Research, Brigham and Women's Hospital, Boston, MA. (Control ID #3391106)

BACKGROUND: Urine drug testing (UDT) is commonly used to monitor opioid misuse for patients on chronic opioid therapy (COT). Our prior study showed that nearly 30% of UDT results at an academic hospital using liquid chromatography-tandem mass spectrometry were misinterpreted by clinicians. Therefore, clinicians may benefit from receiving expert UDT interpretations from the laboratory.

METHODS: This mixed methods study is part of an effectiveness and implementation evaluation (Type II hybrid design) of a laboratory-generated interpretation of UDT results to reduce misinterpretation while improving documentation and decision-making for clinicians managing patients on COT. Participants completed a survey adapted from the Technology Acceptance Model Questionnaire at baseline, 3 months and 6 months and participated in focus groups at the end of the study to: a) evaluate the usability of laboratory- generated interpretations; b) identify barriers to implementation; and c) assess impact on workflow, communication, and patient care. We evaluated clinician experience and responses at 4 ambulatory clinics (primary care [2], palliative care, and pain management) at a U.S. academic medical center.

RESULTS: A total of 8 clinicians (7 physicians and 1 nurse practitioner; 2 [25%] women) participated: 4 primary care, 2 palliative care, and 2 chronic pain management clinicians. Their mean age (SD) was 57.1 (9.8). On a 5-point Likert scale, participants' scores improved from baseline to 6 months in the following areas: results comprehension (3.3 to 5, respectively); interpretation accuracy (4 to 5); interpretation speed (2.7 to 4.7); and interpretation confidence (3.1 to 4.8). During focus group discussions, six themes emerged: layout and language of interpretive reports; utility in aiding clinical decision-making and overcoming knowledge deficits; impacts on clinician-patient relationships and communication; interplay of human factors, systems, and workflow considerations; effects of external factors on interpretive report utility; and impact on interprofessional communication. Clinicians found the interpretive reports concisely summarized toxicology results, serving as an accessible, reliable reference when clinicians had knowledge deficits regarding the opioid metabolite findings. They also described ways lab-generated interpretations prevented near misses by flagging aberrant results and enhanced clinician confidence when communicating aberrant results to patients. Cited areas for lab-generated report improvements included a preference for descriptive accuracy while maintaining non-judgmental language; accuracy of patient medication lists referenced for the UDT interpretations; and timeliness of receiving reports.

CONCLUSIONS: Clinicians receiving laboratory-generated UDT interpretations reported multiple benefits from this intervention, identified limitations, and suggested improvements.

HETEROGENEITY IN TRUST OF CANCER INFORMATION AMONG HISPANICS IN THE UNITED STATES

Christopher J. Gonzalez[1]; Kelly D. Blake[3]; Rose Calixte[2]; Marlene Camacho-Rivera[4]. [1]Internal Medicine, Weill Cornell Medicine, New York, NY; [2]Department of Community Health and Social Medicine, CUNY School of Medicine, New York, NY; [3]Health Communication and Informatics Research Branch, National Cancer Institute, Bathesda, MD; [4]Department of Community Health Sciences, SUNY Downstate Health Sciences University, School of Public Health, New York, NY. (Control ID #3390602)

BACKGROUND: Cancer is the leading cause of death among Hispanics in the United States (US), but subgroups of the population are heterogenously burdened by inequities in cancer outcomes. Increasing cancer knowledge among Hispanics may aid in reducing these inequities, but little is known about how Hispanics differentially trust varying sources of health information. The objective of this study was to examine heterogeneity in trust of cancer information from various sources among US Hispanic adults.

METHODS: We analyzed data on self-identified Hispanic respondents of the Health Information National Trends Survey (HINTS), a nationally representative self-administered survey. Using data from HINTS 4, Cycles 2 and 4, and HINTS 5, Cycle 2, we examined 9 trust questions: doctor/healthcare providers, government health organizations, charitable organizations, media (print, television, radio and internet), family/friends and religious organizations. Multivariable logistic regression models identified independent predictors of high or low levels trust in cancer information, using jackknife replicate weights for accurate standard errors. Independent variables examined were gender, Hispanic ethnic categories (Mexican American, Cuban/Puerto Rican, and other Hispanics), age, education, income, English proficiency, nativity and length of time residing in the US, adjusting for smoking status, personal cancer history, family cancer history, and HINTS cycle.

RESULTS: Among 1,512 Hispanic respondents, trust in sources of information ranged from 27% for radio to 91% for doctors. Multivariable models showed that Cuban/Puerto Rican respondents were nearly twice as likely to report high levels of trust in cancer information from print media when compared to Mexican/Mexican American participants [OR 1.95 95% CI 1.12-3.41]. Participants who did not speak English were 55% less likely to report a high level of trust in cancer information from print media relative to those who spoke English very well [0.22-0.92]. Participants living in the U.S. <10 years were more likely to trust information from government health agencies (OR 8.66 [2.74–27.38]) when compared to those living in the U.S. >10 years. Hispanic women were 59% more likely to trust cancer information from the internet compared to men [CI 1.10-2.32] and Hispanics >50 years old were more likely to trust cancer information from religious organizations relative to those aged 18-34 (50-64 years old, OR 1.68 [1.04-2.70]).

CONCLUSIONS: Sub-group variability in trust of health information sources may be masked by broad racial and ethnic categories, particularly for the heterogenous Hispanic population. There is significant variation by ethnicity and other socio-demographics in trust of sources of cancer information across multiple constructs, with notable implications for disseminating cancer information.

HETEROGENEOUS CHANGES IN INPATIENT CARE UTILIZATION ASSOCIATED WITH 2014 AFFORDABLE CARE ACT REFORMS

Amresh D. Hanchate[4,2]; Michael Paasche-Orlow[2]; Karen E. Lasser[3]; Shuting Wang[1]; Meng-Yun Lin[2,4]. [1]General Internal Medicine, Boston University School of Medicine, Boston, MA; [2]Boston Medical Center, Boston, MA; [3]Medicine, Boston Medical Center, Boston, MA; [4]Social Sciences and Health Policy, Wake Forest School of Medicine, Winston Salem, NC. (Control ID #3375531)

BACKGROUND: Prior research on the impact of the 2014 Affordable Care Act (ACA) on inpatient care utilization has largely focused on evaluation of Medicaid expansion, and concluded unequivocally that expansion was associated with no change in inpatient care use. There has been little work examining potential heterogeneity of ACA effects, particularly across geographic regions by baseline uninsured rates, and whether the changes varied across expansion and non-expansion states.

METHODS: We used all-payer inpatient discharge data (2012-2016) from 12 Medicaid expansion states (AR AZ CA CO IA IL KY MA NJ NY OR PA) and six non-expansion states (FL GA NC TX VA WI), which together account for 65 percent of the national population. We stratified all hospitalizations by patient residence zip code into five groups (regions) of

zip code-level baseline (2012) uninsured rates: ≤ 10%; 10% to 20%; 20% to 35%; 35% to 45%; >45%. The main outcome was the quarterly count of all hospitalizations ("hospitalization volume") from each zip code of patients aged 26-64 stratified by age (four groups) and sex cohorts (N=9,281 zip codes and 1,410,712 cohort observations). Secondary outcomes included volumes of hospitalizations with and without ED admission. Using a quasi-experimental difference-in-differences study design and Poisson regression models, we estimated changes in hospitalization volume, by baseline uninsured rate regions, arising from (a) all 2014 ACA reforms, separately for expansion and non-expansion states and (b) Medicaid expansion alone. All regression models used zip code-level fixed effects with standard errors clustered at the state level.

RESULTS: Study data included 62.3 million and 38.9 million hospitalizations from the expansion and non-expansion states, respectively. Highest baseline uninsured rate zip codes (>45%) were concentrated in TX, CA and FL, with a sizable share of other higher uninsured rate groups across all states. The pattern of longitudinal changes in hospitalization volumes varied by uninsured rate zip codes. In expansion states, relative to lowest uninsured rate region (reference), hospitalization volume increased in higher uninsured rate regions with a change of 7.2% (95% CI, 5.2% to 9.3%) in the highest uninsured rate region. In the non-expansion states, volume increases were observed in some of the higher uninsured rate regions (2.1% [95% CI, 0.6% to 3.7%] in regions with 35% to 45% uninsured rate). Medicaid expansion alone was associated with a larger increase in hospitalization volume (relative to reference region), with a change of 5.0% (95% CI, 1.8% to 8.3%) in the highest uninsured rate region. Similar patterns were found for ED and non-ED hospitalizations.

CONCLUSIONS: Regions with higher baseline uninsured rates experienced a higher increase in inpatient care utilization relative to the lowest uninsured rate regions. The increases were larger in states with Medicaid expansion. Our findings likely represent pent-up demand for health care.

HIGH-DISPARITY CAUSES OF PREMATURE MORTALITY AMONG RACIAL/ETHNIC MINORITY VETERANS IN THE VETERANS HEALTH ADMINISTRATION

Donna L. Washington[1,3]; W. N. Steers[1,3]; Boback Ziaeian[1,3]; Michelle S. Wong[1]; Katherine J. Hoggatt[2]. [1]VA HSR&D Center for the Study of Healthcare Innovation, Implementation & Policy (CSHIIP), VA Greater Los Angeles Healthcare System, Los Angeles, CA; [2]Research, VA San Francisco Health Care System, Sepulveda, CA; [3]Medicine, University of California Los Angeles, Los Angeles, CA. (Control ID #3390244)

BACKGROUND: Recent evaluation of racial/ethnic variations in all-cause mortality among Veterans using Veterans Health Administration (VA) healthcare identified disparities for Black and American Indian/Alaska Native (AIAN) Veterans, relative to non-Hispanic Whites; decreased mortality for Asians and Hispanics; and similar mortality for Native Hawaiian/Other Pacific Islanders (NHOPIs). Identifying causes of death (CODs) disproportionately contributing to premature mortality can inform actions needed to close racial/ethnic disparities in life expectancy. Our objective was to identify CODs resulting in disproportionate premature mortality in racial/ethnic minority VA users.

METHODS: Linking VA records for a national cohort of Veterans using VA care 10/2008–9/2009, with CDC National Death Index records through 12/2016, we assessed cause-specific mortality for 5,032,009 Veterans. We calculated years of potential life lost before age 75 (YPLL) as the difference between 75 and age of death for those who died before age 75, and zero for all others. We used the direct standardization method to compute joint age/sex-standardized mortality rate ratios (SRRs) by race/ethnicity compared to Whites for the overall top 20 CODs. For each racial/ethnic group, we first summed YPLL for CODs with SRRs >= 1.2 (and $p < 0.05$; high disparity CODs); next, we calculated the percentage of total YPLL that high disparity CODs accounted for using the formula (YPLL from high disparity CODs / YPLL from all causes) * 100%; then, we contrasted this percentage to the corresponding percentage for the same CODs in Whites.

RESULTS: Nine CODs were high disparity CODs (% of overall YPLL: A-cerebrovascular disease=2.6%; B-accidents=8.5%; C-diabetes=4.2%; D-nephritis=1.4%; E-septicemia=1.4%; F-chronic liver disease/cirrhosis=3.7%; G-hypertension/hypertensive renal disease=0.8%; H-assault/homicide=0.7%; I-HIV disease=0.7%). High disparity CODs by race/ethnicity were: BCFI for AIANs; ACDEGHI for Blacks; CEFGHI for Hispanics; D for NHOPIs; none for Asians. High disparity CODs accounted for 24.2% of YPLL for AIANs (vs 16.7% for Whites), 17.5% for Blacks (vs 10.0%), 18.1% for Hispanics (vs 10.3%), and 1.6% for NHOPIs (vs 1.1%).

CONCLUSIONS: Diabetes and HIV disease contributed to premature mortality disparities in AIANs, Blacks, and Hispanics. Seven additional high disparity CODs had more heterogeneous effects. Four CODs disproportionately affected AIANs. The "Hispanic paradox" of decreased all-cause mortality masks increased Hispanic premature mortality for 6 CODs. Several common CODs (e.g., heart disease, cancer, and suicide) were not high disparity CODs. Several CODs contributing to Veteran racial/ethnic mortality disparities are for conditions that may be prevented or controlled with guideline-adherent healthcare. Further work is needed to identify tailored best practices within VA for achieving equity in control of chronic conditions (e.g., hypertension, diabetes, HIV) and addressing behavioral risk factors.

HIGH-DOSE INFLUENZA VACCINE AND LIVE ATTENUATED INFLUENZA VACCINE DELIVERY PRACTICES AMONG US PRIMARY CARE PROVIDERS (2016-17 AND 2018-19 INFLUENZA SEASONS)

Jessica R. Cataldi[2,4]; Laura P. Hurley[1,2]; Megan C. Lindley[3]; Sean T. O'Leary[2,4]; Michaela Brtnikova[5,4]; Carol Gorman[2]; Brenda Beaty[2]; Lori A. Crane[2,6]; David Shay[3]; Allison Kempe[2,4]. [1]Denver Health, Division of General Internal Medicine, Denver, CO; [2]Adult and Child Consortium for Health Outcomes Research and Delivery Science, University of Colorado Anschutz Medical Campus and Children's Hospital Colorado, Aurora, CO, AURORA, CO; [3]Immunization Services Division, Centers for Disease Control and Prevention, Atlanta, GA; [4]Pediatrics, University of Colorado Anschutz Medical Campus, Aurora, CO; [5]Children's Outcomes Research Program, Aurora, CO; [6]Department of Community and Behavioral Health, Colorado School of Public Health, University of Colorado Anschutz Medical Campus, Aurora, CO, AURORA, CO. (Control ID #3387355)

BACKGROUND: As nine types of influenza vaccine are licensed for use in adults, primary care physicians may not be fully cognizant of Advisory Committee on Immunization Practices (ACIP) current recommendations for their use. High-dose inactivated influenza vaccine (HD-IIV) is licensed for use in adults ≥65 years based on improved immunogenicity data. ACIP has not preferentially recommended HD-IIV over other vaccines. ACIP recommended against use of live-attenuated influenza vaccine (LAIV) for the 2016-17 season based on lower vaccine effectiveness; in 2018-19, it was again recommended after presentation of new data.

METHODS: Surveys were conducted in 2017 and 2019 among nationally representative samples of FPs and GIMs.

RESULTS: Response rates were 67% (620/930) in 2017 and 69% (642/926) in 2019. Many providers reported the belief that HD-IIV is more effective than standard-dose IIV in patients ≥65 years (76%) or that their patients ≥65 years believe they need HD-IIV rather than standard-dose IIV (67%). Incorrectly, most respondents thought ACIP preferentially

recommended HD-IIV for adults ≥65 years (89%). 66% 'almost always/always' recommended HD-IIV for adults ≥65 years. Some providers incorrectly reported that ACIP preferentially recommended HD-IIV for adults <65 years with cardiopulmonary disease (38%) or immunosuppression (48%), and some respondents recommended HD-IIV for these groups of patients (25% and 28% respectively). In 2017, 88% of respondents knew that ACIP recommended against use of LAIV during the 2016-17 influenza season, and 4% recommended LAIV to patients. In 2019, 63% knew that ACIP recommended that LAIV could be used during the 2018-19 influenza season, and 9% recommended LAIV.

CONCLUSIONS: Many physicians incorrectly thought ACIP had preferential recommendations for HD- IIV. Any age-appropriate influenza vaccine can be used in adults ≥65 years since no preferential recommendation exists.

HIGHER IMPACT ON CLINICAL OUTCOMES FROM DELAYS IN COLORECTAL CANCER SCREENING WITH THE FECAL IMMUNOCHEMICAL TEST VS MULTITARGET STOOL DNA: CRC-AIM MICROSIMULATION MODEL RESULTS

Paul Limburg[1]; Leila Saoud[2]; Bijan J. Borah[3]; A. Mark Fendrick[4]; Kristen Hassmiller Lich[5]; Andrew Piscitello[6]; Michael Matney[2]; A. Burak Ozbay[2]; Marcus Parton[2]. [1]Gastroenterology, Mayo Clinic, Rochester, MN; [2]Exact Sciences Corporation, Madison, WI; [3]Health Services Research, Mayo Clinic, Rochester, MN; [4]Division of Gastroenterology, University of Michigan, Ann Arbor, MI; [5]Health Policy & Management, Gillings School of Global Public Health, University of North Carolina at Chapel Hill, Chapel Hill, NC; [6]EmpiriQA, LLC, Long Grove, IL. (Control ID #3389688)

BACKGROUND: Patients may delay colorectal cancer (CRC) screening beyond the recommended age for initiation or repeat testing. The impact of delayed adherence on subsequent CRC outcomes is not fully understood. The CRC-AIM microsimulation model was used to estimate the impact of delays in recommended triennial multitarget stool DNA (mt-sDNA) or annual fecal immunochemical test (FIT) screening strategies on resulting CRC outcomes.

METHODS: CRC-AIM contains natural history and screening components and has been cross-validated against the Cancer Intervention and Surveillance Modeling Network models. Sensitivity and specificity from DeeP-C trial data were used for screening inputs. Predicted outcomes for mt-sDNA and FIT screening strategies were simulated for 40-year-olds born in 1975 free of diagnosed CRC and screened between ages 45–75 or 50–75. For this analysis, it was assumed that recommended triennial mt-sDNA or annual FIT was delayed by 12, 18, or 24 months every time screening was due. For example, with a 12-month delay for triennial mt-sDNA, an individual would take their first test at age 51 instead of 50 and their second test at age 55 instead of 53 (age 51 + 3-year interval + 12 months delay=age 55). Outcomes are reported per 1000 individuals vs no screening.

RESULTS: For individuals screened between ages 50–75, the predicted life-years gained (LYG) and reductions in CRC-related incidence and mortality were highest for triennial mt-sDNA and FIT when there was no delay vs the delayed adherence scenarios. The LYG with a 12, 18, and 24-month delay was greater with triennial mt-sDNA (278, 262, and 247 LYG, respectively) than annual FIT (271, 245, and 226 LYG). The reduction in CRC-related incidence with a 12, 18, and 24-month delay was greater with triennial mt- sDNA (59.7%, 57.0%, and 52.7%, respectively) than annual FIT (54.8%, 49.6%, and 44.4%). The reduction in CRC-related mortality with a 12, 18, and 24-month delay was greater with triennial mt-sDNA (67.5%, 64.1%, and 59.8%, respectively) than annual FIT (64.9%, 58.5%, and 53.6%). Similar results were obtained when screening ages were between 45–75. With no delay, FIT provides an additional 1 LYG per additional 4.7 colonoscopies (COL) but requires 10,244 more stool-tests vs mt-sDNA. This relationship reverses with screening delays; with a 12, 18, and 24-month delay, mt-sDNA provides an additional 1 LYG per 35 additional COL, 18 additional COL, and 13 additional COL, respectively, but with 4456, 3099, and 2415 fewer stool tests, respectively, vs FIT.

CONCLUSIONS: Delays in screening adherence resulted in less favorable outcomes vs no delay for each of the modeled CRC screening strategies, although even delayed screening provides substantial clinical benefit. The relative efficacy of mt-sDNA was better than FIT when clinically realistic delayed screening adherence scenarios were considered.

HIGH RATES OF ORAL ANTICOAGULATION IN ATRIAL FIBRILLATION PATIENTS AT A SAFETY NET INSTITUTION

Benjamin Leon[2]; Carolyn A. Valdez[3]; Rebecca Hanratty[1]. [1]General Internal Medicine, Denver Health, Denver, CO; [2]Internal Medicine, Colorado University School of Medicine, Denver, CO; [3]Patient Safety and Quality, Denver Health, Denver, CO. (Control ID #3389509)

BACKGROUND: Atrial fibrillation (a-fib) is associated with significant morbidity and mortality. This risk can be mitigated by the use of oral anticoagulation (OAC). The use of OAC remains underutilized, as nearly 45% of eligible patients are not on OAC. These rates are even worse among certain sub-populations, including racially diverse and underserved groups. The objective of this evaluation is to assess utilization of OAC among patients with a-fib in a safety net health system.

METHODS: International Classification of Diseases, Tenth Revision (ICD-10) codes were used to identify patients with a-fib and at least one visit with a primary care provider from April 2016 through November 2018. CHADs2VASc and modified HAS-BLED scores were calculated using ICD-10 codes, medication lists, recent vital signs and demographics. Patients eligible for guideline appropriate OAC were then identified using a CHADs2VASc score > 1. Among patients eligible for OAC, overall rates of OAC was calculated and clinical characteristics of those not on OAC were compared to those who were on OAC in a cross sectional design.

RESULTS: A total of 1669 patients with a-fib were identified, a large proportion of whom were at high risk for stroke with a CHADs2VASc score > 1 (78% of total a-fib population). Nearly one-third of this population was of non-white race, and 97% of the group was on either government issued or financially assisted insurance. Of this high-risk group, 64% of patients were on OAC. When comparing the high-risk groups based on OAC status, there was no significant difference between the two groups based on many baseline characteristics. Those on OAC had higher average CHADs2VASc scores, and the rates of OAC increased with stroke risk. Those on OAC also had higher rates of heart failure, diabetes, stroke, and vascular disease, HAS-BLED scores and were more likely to have been seen by cardiology. Those not on OAC had significantly higher rates of falls and dementia.

CONCLUSIONS: We demonstrated that a safety net institution can have rates of OAC that is better than the national average for high risk a-fib patients. Systems level factors that may have contributed to these rates of OAC include: an integrated health system including specialists, primary care and a hospital all on the same electronic medical record; clinic-based clinical pharmacists to manage the population on OAC; and a long standing inpatient-outpatient anticoagulation work group that works on care standards and transitions between settings. While a third of those eligible were not on OAC, that may in part be intentional and rational prescribing behavior as those not on OAC had significantly higher rates of dementia and falls. There may be additional unmeasured factors that

explain why these patients were not on OAC, which could guide future interventions to further improve guideline adherence.

HOME IS WHERE THE MOLD GROWS: USING UNANNOUNCED STANDARDIZED PATIENTS TO UNDERSTAND CLINICAL REASONING AND SOCIAL DETERMINANTS OF HEALTH

Jeffrey Wilhite, Sondra R. Zabar, Khemraj Hardowar, Harriet Fisher, Lisa Altshuler, Amanda Mari, Fariha Ansari, Barbara Porter, Andrew Wallach, Kathleen Hanley, Colleen Gillespie. Division of General Internal Medicine, New York University School of Medicine, New York, NY. (Control ID #3391839)

BACKGROUND: The importance of addressing patients' social determinants of health (SDoH) is widely recognized, but less is known about how physicians specifically elicit, respond to, and document these determinants. We sought to describe resident practices when caring for a patient whose SDoH is integral to accurate diagnosis and treatment using Unannounced Standardized Patients (USPs).

METHODS: USPs were used (n=68) to assess how medicine residents responded to the consistent portrayal of a patient with asthma exacerbation and concern that her living situation (moldy, dilapidated housing) might be contributing to her symptoms. USPs, or "secret shoppers", were sent to two of New York's safety-net hospitals. Resident practices were assessed by the USP during a post-visit behaviorally-anchored checklist (7 items) and through a systematic chart review (3 items). Checklist items included whether or not a provider explored and fully elicited the USPs concerns, how they responded once shared, and what the provider actually did in response. Chart review items included whether or not a provider documented their patient's housing concerns in the history of present illness (HPI), problem list, or through use of a billing-related Z-code.

RESULTS: 68/79 consented residents participated: 11 PGY1 (16%), 31 PGY2 (46%), and 26 PGY3 (38%). 65% (44/68) of residents elicited the patient's housing SDoH and of those, 75% (33/44) responded by acknowledging/exploring and providing notes/practical support. 30% (10/33) connected the patient to informative resources or direct referral. Less than half (14/33; 42%) of those who acknowledge/explored documented appropriately in the EMR. No residents documented housing in the problem list or with a housing-related ICD10 Z-code. Of the 14 high performers, 6 successfully elicited, acknowledged, and documented housing concerns for one of our other five SDoH cases. More than half (55%) of the residents who elicited housing information connected the mold to the asthma exacerbation as a possible trigger, either during clinical interaction or in documentation. All but one (93%) of those who elicited, acknowledged, and documented made this connection.

CONCLUSIONS: Using USPs to directly observe resident practice behaviors in gathering information about, documenting and taking action on a consistently portrayed SDoH case closely linked to clinical symptoms is the first piece of the puzzle needed to better understand education and training that prepares physicians to address SDoH. Our study identifies practice gaps at all stages – adequately collecting information, understanding the clinical/treatment consequences of, effectively responding to needs, and in documentation of SDoH. Future research should explore the influence of the clinical microsystem (e.g., SDoH screening tools, available resources and referrals, and workflows) on physician SDoH-related practices.

HOME TELEHEALTH IN THE VETERANS HEALTH ADMINISTRATION: PREDICTORS AND TRENDS IN ENROLLMENT FROM 2010-2017

Lee W. Eschenroeder[1]; Eric Gunnink[2]; John Geyer[3]; Karin M. Nelson[2,3]; Ashok Reddy[2,4]. [1]Internal Medicine, University of Washington, Seattle, WA; [2]VA Puget Sound Health Care System, Department of Veterans Affairs, Seattle, WA; [3]General Internal Medicine, University of Washington, Seattle, WA; [4]Medicine, University of Washington School of Medicine, Seattle, WA. (Control ID #3389900)

BACKGROUND: Remote monitoring of chronic illness may facilitate patient self-management and has generated increasing interest among patients, clinicians, and payers. The Veterans' Health Administration's (VHA) Home Telehealth (HT) program was created in 2003 to improve chronic disease management for Veteran patients. Prior evaluations of the program have been limited, and the program has expanded rapidly since 2010. Our primary objective was to describe this expansion and identify patient characteristics associated with HT enrollment from 2010 through 2017.

METHODS: This was a retrospective cohort study. Primary sources of data were the VHA Corporate Data Warehouse (CDW) for administrative data and the VHA Support Service Center (VSSC) Capital Assets Databases for enrollment data. The longest enrollment period of each HT patient was identified and examined using specific codes for telehealth services in the VHA.

Two authors (LE, AR) categorized all disease management protocols according to Agency for Healthcare Research and Quality criteria. CDW data was used to define patient characteristics including age, sex, race, patient comorbidity index (Gagne), drive time to the nearest VHA, urban/rural, and neighborhood socioeconomic status. We used Chi-square tests to compare categorical variables and Kruskal-Wallis to compare continuous variables. Tests of significance were two-tailed (alpha level of 0.05). Univariate and multivariate survival analyses described the relationship between these variables and length of enrollment in HT services.

RESULTS: Enrollment in HT expanded from 30,000 patients in 2010 to nearly 85,000 patients in 2015, and the program continues to enroll over 60,000 patients per year (2017). For the 427,461 patients who were enrolled between 2010-17, patient's average age was 63.6 years (SD 12.9), and the majority were male (91%) and white (67%). Most patients lived urban areas (61.3%) and had an average drive time of 22.3 minutes to the nearest VA clinic (SD 24.4). The 3 most common conditions treated were hypertension (27.1%), obesity (22.5%), and diabetes (16%). The median length of enrollment in the HT program was approximately 8.4 months (IQR 1.45 years). Patient characteristics associated with continued enrollment at 90 days included male gender, rural residence, and low income.

CONCLUSIONS: In this descriptive study, we highlight the rapid expansion of HT services from 2010 through 2017 in the VHA. A majority of patients enroll for common primary care related conditions. Moreover, patients living in more rural areas and low income are continuing to engage in these services after 90 days. Future work will examine the impact of HT services on clinical quality and outcomes.

HOSPITALIST YEARS OF EXPERIENCE AND ASSOCIATION WITH INPATIENT LABORATORY TESTING

Shradha Kulkarni, Wendi Zhao, Margaret Fang. Department of Medicine, University of California, San Francisco, San Francisco, CA. (Control ID #3389482)

BACKGROUND: Thoughtful laboratory testing is a key component of high-value and cost-effective patient care. Studies estimate that nearly half of laboratory tests may be unnecessary in certain patient populations. The drivers of observed variation in laboratory testing are not clearly established; our study aims to examine whether testing varies by hospitalist years of experience.

METHODS: We conducted a retrospective study of a direct-care physician-staffed hospitalist service at a tertiary-referral academic medical center from July 2018 to June 2019. Data on hospitalist characteristics, including years of experience (defined as years since initial American Board of Internal Medicine certification) were obtained for all providers. We identified all orders for complete blood count (CBC), basic metabolic panel (BMP), prothrombin time, serum albumin, serum magnesium, and serum phosphorus from the electronic health record. Using multivariable linear regression, we then tested the association of years of experience with the mean total laboratory tests per patient-day, adjusted for physician gender and patient characteristics (demographics, comorbidity index, length-of-stay).

RESULTS: Over the study period, 81 hospitalists (47 women and 34 men) with years of experience ranging from 0 to 26 years (mean: 5.6 years) on the direct-care service ordered a total of 47268 laboratory tests over 16045 patient-days. For the entire study population, the average number of laboratory tests per patient-day was 2.95. The most common test was a CBC, with or without differential (0.81 per patient-day), followed by a BMP (0.73 per patient-day). For every year of experience, there was a decrease in 0.03 laboratory tests per patient-day (95% confidence interval [CI] -0.05 to -0.002, p = 0.03). First-year hospitalists (n = 11) ordered significantly more laboratory tests than all others (n = 70) with 3.53 laboratory tests per patient-day vs 2.90 (p = 0.002). Early-career hospitalists (0-3 years of experience, n=32) ordered more laboratory tests than mid- career hospitalists (4-7 years of experience, n=30) (3.19 vs 2.80, p = 0.01) and later-career hospitalists (9 or more years of experience, n=19) (3.19 vs 2.87, p = 0.04). Physician gender was not significantly associated with laboratory testing.

CONCLUSIONS: Our study found an inverse association with hospitalist years of experience and laboratory testing. Early-career hospitalists ordered on average more tests per patient day than did mid- or later-career hospitalists. Hospitalists in their first year of practice ordered over 20% more laboratory tests than all other hospitalists. Efforts to promote high-value care should examine physician experience as a potential contributor to utilization.

HOSPITALIZATIONS WITHIN 6 MONTHS AFTER INDEX ADMISSIONS: IMPACT OF THE HOSPITAL READMISSIONS REDUCTION PROGRAM

Jennifer Meddings[2,1]; David Ratz[2]; Shawna N. Smith[1,3]; John Poe[1]; Jessica Ameling[1]; Laurence F. McMahon[1,4]. [1]Internal Medicine, University of Michigan, Ann Arbor, MI; [2]Center for Clinical Management Research, Veterans Affairs (VA) Ann Arbor Healthcare System, Ann Arbor, MI; [3]Institute for Social Research, University of Michigan, Ann Arbor, MI; [4]Department of Health Management and Policy, University of Michigan School of Public Health, Ann Arbor, MI. (Control ID #3391316)

BACKGROUND: The Hospital Readmissions Reduction Program (HRRP) penalizes hospitals based on readmissions within 30 days after index admissions for specific conditions such as heart failure (HF), pneumonia (PNA), acute myocardial infarction (AMI), and chronic obstructive pulmonary disease (COPD). While prior work has associated HRRP with reductions in 30-day readmissions for some conditions, little work has examined whether this policy has resulted in improvement of care that could reduce admissions beyond this short-term window. Our objective was to assess if this policy, focused on 30-day readmissions, was associated with reductions in hospitalizations within 6 months of an index admission.

METHODS: Retrospective cohort study of Medicare beneficiaries in New York (NY) and Florida (FL) age 65 and older who had an index admission for HF, PNA, AMI, or COPD, using 2008-2014 Healthcare Cost and Utilization Project discharge claims data before and after the October 2012 implementation of HRRP. We predicted the total unplanned hospitalizations within 180 days after index admissions for HF, PNA, AMI, COPD in each state after HRRP implementation (October 2012-June 2014) based on hospitalization rates prior to implementation (October 2008-June 2012). For each state, we used piecewise Poisson regression to assess the difference in the predicted versus observed hospitalizations per year, which was then used to estimate the number of hospitalizations within 6 months of a patient's HRRP-qualifying index admission. Subsequent hospitalizations were reported as a percentage of predicted hospitalizations, as well as the median number of estimated "saved" hospitalizations per hospital.

RESULTS: The expected reduction or 'savings' in hospitalizations (number, % of predicted hospitalizations, and median hospitalizations saved per hospital) within 6 months of qualifying index admissions overall averaged 2.6% of predicted hospitalizations, but varied by state and index admission. NY hospitals experienced greater savings than FL for each condition:

1. HF (NY: 1929, 3.5%, 4 per hospital; FL: 1303, 1.9%, 3 per hospital)
2. PNA (NY: 874, 3.4%, 2 per hospital; FL: -22, 0%, 0 per hospital)
3. AMI (NY: 643, 4.5%, 1 per hospital; FL: 540, 2.6%, 1 per hospital)
4. COPD (NY: 1789, 4.8%, 5 per hospital; FL: 826, 1.6%, 2 per hospital)

CONCLUSIONS: HRRP only resulted in median reduction of 0-5 hospitalizations per hospital over a 6-month period for patients with an HRRP-qualifying index admission, a small percentage of total hospitalizations over the same period. HRRP was designed to reduce readmissions and Medicare cost ostensibly by improving quality of care. True improvements in quality and associated cost should extend beyond the 30-day policy period. Our results show that the median hospital saw minimal reductions in 6-month re-hospitalizations for patients with HRRP index admissions. Further, for many hospitals, cost savings from "saved" hospitalizations are likely more than offset by costs related to HRRP implementation.

HOW ARE THE ARTS AND HUMANITIES USED IN MEDICAL EDUCATION? A SCOPING REVIEW OF THE LITERATURE.

Paul Haidet[1]; Tracy Moniz[3]; Maryam Golafshani[2]; Nancy Adams[1]; Javeed Sukhera[4]; Carolyn Gaspar[5]; Rebecca Volpe[6]; Claire De Boer[6]; Shannon Arntfield[4]; Tavis Apramian[4]; Lorelei Lingard[4]. [1]Medicine, Penn State College of Medicine, Hershey, PA; [2]University of Toronto, Toronto, ON, Canada; [3]Mount Saint Vincent University, Halifax, NS, Canada; [4]Schulich School of Medicine and Dentistry, Western University, London, ON, Canada; [5]Dalhousie University, Halifax, NS, Canada; [6]Humanities, Penn State College of Medicine, Hershey, PA. (Control ID #3391742)

BACKGROUND: Research increasingly suggests that integrating the arts and humanities (A&H) into medical education may lead to important learning outcomes. The range of A&H that can inform medical learning and, ultimately, patient care is vast—from literature and reflective writing to visual arts and philosophy. As part of an Association of American Medical Colleges initiative (https://www.aamc.org/what-we-do/mission-

areas/medical-education/humanities), we conducted a scoping review to identify how and why the A&H are being used to educate physicians and interprofessional learners across the spectrum from premed to CME.

METHODS: We followed Arksey & O'Malley's (2005) five scoping review stages and included the sixth stage of stakeholder consultations suggested by Levac (2010). We developed a search strategy that a health sciences librarian implemented across seven databases in May and June 2019, locating 21,988 citations. Five authors independently screened all titles and abstracts and six reviewers screened the full text of 4,652 records. At both stages, each record was screened by two trained reviewers, and discrepancies were resolved by a third reviewer. In the end, 772 citations met inclusion criteria. We collected descriptive data such as learner level, setting, and type of A&H. Using frameworks by Dennhardt et al (2016), we performed a conceptual analysis of epistemic function (e.g., assumptions about how teaching and learning with the A&H occurs) and a discursive analysis of how the A&H are positioned (e.g., as intrinsic, additive, or curative) in relation to medicine. Stakeholder interviews included leading voices in the literature, institutional administrators, teachers, learners, and patients.

RESULTS: This literature is diverse and dominated by: a) conceptual works that either call for the use of A&H in general or critically engage with its ideas and methods, b) works that describe implementations of A&H, and c) empirical works, mostly qualitative studies that evaluate A&H-based interventions. Absent in the literature are the voices of medical students, patients, and artist- and community-based educators as well as robust engagement with A&H in interprofessional, pre-medical, and continuing medical education contexts. Conceptual analysis demonstrates the A&H being seen to function foremost as a means for learners to develop skills or expertise, or to engage learners in dialogue and perspective taking. Less commonly, A&H are seen to function as a medium for personal growth or activism/advocacy. In the discursive analysis, the A&H were positioned as additive most of the time (498 records) as opposed to intrinsic (36 records) or curative (128 records).

CONCLUSIONS: The literature is complex, and can inform local and national discussions. To the extent that the literature reflects on-the-ground discussions, the position and perceived function of the A&H has important implications for how they are implemented, and ultimately, how successful they can be in medical education.

HOW DO CLINICIANS RESPOND TO ELEVATED HOME BLOOD PRESSURE READINGS FOR PATIENTS WITH HYPERTENSION?

Natalie S. Lee[1]; Rebecca E. Anastos-Wallen[3]; Krisda H. Chaiyachati[2]; David A. Asch[4]; Shivan Mehta[1]; Catherine Reitz[1]. [1]University of Pennsylvania, Philadelphia, PA; [2]Division of General Internal Medicine, The University of Pennsylvania, Philadelphia, PA; [3]Internal Medicine, University of Pennsylvania, Philadelphia, PA; [4]Medicine, University of Pennsylvania, Philadelphila, PA. (Control ID #3387456)

BACKGROUND: Remote blood pressure monitoring (RBPM) is a common strategy for managing hypertension, but how clinicians respond to elevated readings is poorly described. To understand how such programs might be improved and scaled, we characterized and quantified the spectrum of clinician actions in response to elevated readings during a trial of automated RBPM.

METHODS: We analyzed data from a 16-week randomized clinical trial, SupportBP. 201 patients randomized to the intervention arms received automated text message prompts to submit home readings. Clinicians were notified in the electronic health record (EHR) for elevated readings, defined as: (a) 3 of the last 10 readings ≥140/90; or (b) single reading ≥180/110. Notifications contained the elevated readings plus 5-10 recent readings.

Of 201 patients, 165 (82%) met criteria for escalation at least once during the trial. The remaining 36 did not participate (n=4) or did not meet escalation criteria. For this analysis, two internists reviewed charts first collaboratively to code categories of clinician action, then independently. In the final analysis, inter-reviewer correlation will be calculated and differences resolved through discussion.

RESULTS: Preliminary review of 55 patients revealed 189 escalations (mean 3.4, SD 1.6). Most commonly, alerts did not change practice (47%, n=89). Of these, clinicians documented receipt of the alert in the EHR for 19% (n=17), while 76% (n=68) were not acknowledged. The independent reviewers judged it was clinically reasonable not to act on 40% (n=36) of these alerts because BP values were borderline; however, they judged that 53% (n=47) warranted action.

For almost 31% of escalations, clinicians instructed the patient to schedule an appointment, yet only 15% of encounters resulted in an office visit. Less than 20% of encounters resulted in a medication change.

At a patient level, a mean of 1.8 actions (SD 1.3) were taken by the clinicians over 16 weeks. Among the 55 patients reviewed, 84% had at least one escalation that resulted in no action; for 7 patients (13%), all escalations resulted in no action. Attempts to schedule the patient, medication changes, and clinic visits were the most common actions at both patient and encounter levels.

CONCLUSIONS: Limited clinician responses to elevated blood pressure alerts in a remote monitoring program demonstrates a level of inertia to overcome prior to changing medications in this setting, as less than half of all patients received medication changes. Additionally, most clinicians preferred to schedule patients for an in-person evaluation, suggesting that these programs build new infrastructure and practice culture to support RBPM. Finally, some alerts justifiably did not change practice, implying opportunity to improve the clinical utility of alerts to clinicians.

HOW DOES GENDER IMPACT CLINICAL PERFORMANCE ASSESSMENT IN CORE CLERKSHIPS?

Abigail Bennett[2]; Winter Williams[1]. [1]Medicine, UAB, Birmingham, AL; [2]UAB School of Medicine, Birmingham, AL. (Control ID #3389691)

BACKGROUND: Clinical performance assessment is an inherent part of undergraduate medical education (UME) to show competency and achievement of milestones. Assessment of clinical performance, however, has shown variability and poor reliability across clerkships yet remains a central tenet of clerkship grading. Variability of student and assessor characteristics and structural clerkship components introduce subjectivity into clinical grading. The impact of gender on assessment has been limited predominantly to faculty opinion and behavior on scripted vignettes with little empirical data available. This study aimed to examine how gender affects performance assessment within core clinical clerkships.

METHODS: A single institution, retrospective review was performed on all completed clinical evaluations of clerkship students during the 2017-18 academic year across seven core clerkships at the UAB School of Medicine, Birmingham campus. Data consisted of numerical scores on 11 items with a 4-point ordinal scale indicating student performance within each domain (e.g. exam skills), structural components (e.g. contact time), and a yes/no designation of clinical honors. Self-identified gender was obtained from UME and GME databases. The data was examined at the level of individual evaluations and organized by evaluator-evaluatee gender concordance or discordance (MM, FF, MF, FM). Analysis used Chi-square and Fisher's exact test to assess how gender affected clinical performance rating and likelihood of clinical honors. Logistic regression determined odds ratios (OR) of honors recommendation by gender concordance or discordance for each clerkship.

RESULTS: 4,362 evaluations of 187 medical students (100 M, 87 F) were analyzed and revealed a statistically significant impact of gender upon honors recommendation for four of the seven clerkships: family medicine (p=0.008), internal medicine (p<0.001), neurology (p<0.001), and surgery (p=0.009). The impact of gender did not reach statistical significance for OBGYN, pediatrics, or psychiatry. Within internal medicine, gender discordance (M:F or F:M) increased likelihood of an honors recommendation (p=0.012) compared to gender concordance, OR 1.43 (95% CI=1.09-1.88). Gender concordance was marginally significant for surgery (p=0.048), OR 0.77 (95% CI 0.586-0.998). Concordance was not significant for any of the other five clerkships. Additionally, direct observation of clinical skills and contact time (hours per week and number of weeks) significantly increased likelihood of honors recommendation (p<0.0001).

CONCLUSIONS: Gender of evaluators and students impacted clinical performance assessment across several clerkships in our study; however, our findings question the prevailing notion that gender concordance inflates assessment. On the contrary, within internal medicine gender discordance conferred a higher likelihood of honors. Structural factors such as direct observation and contact time also increased likelihood of honors recommendation.

HOW DOES SELF-WEIGHING IMPROVE WEIGHT CONTROL: ANALYSIS FROM A RANDOMIZED BEHAVIORAL WEIGHT LOSS INTERVENTION.

Carolyn Bramante[1]; Aaron Kelley[1]; Claudia Fox[1]; Nancy Sherwood[2]. [1]Internal Medicine & Pediatrics, University of Minnesota, Minneapolis, MN; [2]Epidemiology, University of Minnesota, Minneapolis, MN. (Control ID #3392158)

BACKGROUND: Daily self-weighing promotes weight loss and weight loss maintenance and has been shown to improve the ability to refrain from excess caloric intake. Behavior change theory states that self- observation improves self-efficacy, but the mechanisms by which self-weighing improves weight is not fully known. Therefore, we explored longitudinal associations between self-weighing and both self-control attributes (e.g., cognitive restraint, uncontrolled eating) and weight loss efficacy (e.g., emotional eating, social eating) in the BestFIT behavioral weight loss randomized controlled trial.

METHODS: BestFIT was a two-stage sequential multiple assignment randomized trial for adults with body mass index (BMI) between 30 and 45kg/m^2. All participants received standard behavioral weight loss treatment (SBT) that included advice to self-weigh daily. Patients were randomized to a response assessment at either 3 weeks or 7 weeks, and non-responders were then re-randomized to either augmenting SBT with portion-controlled meals or switching to an acceptance-based enhanced version of SBT. Measures included self-reported self-weighing frequency, collected at 0, 6, 12, and 18 months, and Power of Food Scale (PFS), Three-Factor Eating Questionnaire (TFE), and the Weight Efficacy Lifestyle (WEL) surveys, each collected at 0, 6, and 18 months. Relationships between self-weighing pattern and longitudinal changes in weight, PFS, TFE, and WEL were examined using mixed-effects models adjusted for treatment assignment.

RESULTS: Overall 468 participants were enrolled, mean age 49y, mean BMI 36 kg/m^2, 76% women. Three distinct temporal patterns of self-weighing frequency were identified using latent class analysis: low frequency (n=52), moderate frequency (n=228), and high frequency (n=188). The high frequency group achieved the most weight loss at 6, 12, and 18 months (p<0.05). Mean weight loss at 18 months was 1.6kg, 3.6kg, and 8.3kg in the low-, moderate- and high-frequency groups (p<0.05), respectively. There were statistically significant associations (p<0.05) between self-weighing patterns and improvements in the following measures, with high frequency weighers showing the greatest improvements: PFS overall, PFS present domain; TFE cognitive restraint, TFE uncontrolled eating, TFE emotional eating; WEL total and the following domains: emotion, availability, social, physical, and addictive.

CONCLUSIONS: This analysis offers unique insight into behaviors and attributes that might explain the mechanisms through which self-weighing improves weight control. While causality cannot be determined, more frequent self-weighing was associated with improvement in measures of the psychologic impact of living in a food abundant environment, self-efficacy, cognitive restraint, uncontrolled eating, and emotional eating. These associations warrant further exploration because better understanding of these relationships may offer insight into more effective tailoring of behavioral weight loss treatment.

HOW GOOD IS THE SUPPLIED CRYSTAL BALL? EVALUATION OF AN ELECTRONIC HEALTH RECORD (EHR) NO-SHOW (NS) PREDICTION MODE

Ling Chu[1]; Vaishnavi Kannan[2]; Christoph Lehmann[2]; Mujeeb Basit[2]; Seth M. Toomay[2]; Yin Xi[2]; Duwayne L. Willett[2]. [1]General Internal Medicine, UT Southwestern, Dallas, TX; [2]Internal Medicine, University of Texas Southwestern Medical Center, Dallas, TX. (Control ID #3391784)

BACKGROUND: Studies analyzing appointment data from EHRs demonstrated certain social determinants contribute to no-show (NS). The large amount of data collected in EHRs allows for the application of artificial intelligence (AI). However, knowledge gained from AI may contain potential biases. The objective of our study is to evaluate the accuracy of our NS prediction model adopted from vendor with local modification and to explore potential bias for patient subgroups. In our academic primary care setting, we compared the EHR vendor generated NS prediction rate to the actual NS rate. We further analyzed data from patient subgroups to investigate the possibility of potential bias.

METHODS: We analyzed appointment data from our EHR for the last 3 years. We included 38,443 active patients who had completed an encounter in the last 3 years and were alive on the day of the analysis. No-shows were defined as an appointment where the patient did not show or did not cancel in time. Reports for all appointments including all NS were generated within the EHR and exported to Excel for further analysis. Sub-analysis of NS prediction and actual rates included the following factors: gender, patient portal activation, depression PHQ9 scores, smoking status, insurance and marital status.

RESULTS: In our population, the NS prediction model overestimated actual NS by 1.9% absolute percentage points (37% relative) on average. The overall NS prediction was 7.3% compared to actual NS rate of 5.4%. NS overestimation in women was 2.1% vs men 1.8%. Patients who did not activate their patient portal were more likely to NS (actual rate of 8.6% vs 5.1% for those with portal activation). Male patients who did not activate their portals were most likely to NS and best predicted in that subgroup. In all patients with depression, not only did the prediction match the actual NS rate better than in the general patient population, but the more severe the depression, the more accurate the prediction. Similar to established literature, our analysis showed that smokers are more likely to no show compared to nonsmokers (9.8% vs 6.15%). Our observation also suggests that patients who are identified as self-pay are more likely to no show when compared to Medicare (7.3% vs 5.5%). However, patients with Medicare or with managed care showed an underestimation of NS by the prediction model (delta of 1.4% and 1.5% respectively). Single patients are more likely to have an overestimated NS rate compared to the general population (delta of 5.6% vs 1.9%).

CONCLUSIONS: Our study found overestimation of NS rates by the vendor provided prediction model. In our subgroup analysis, patients without portal use and with depression were found to have more accurate NS prediction rates. In patients with Medicaid or managed care, the prediction model underestimated the NS rates. Organizations may consider examining the performance of risk models and their potential biases prior to their implementation and with continued monitoring throughout their use.

HOW PAYERS ARE LEVERAGING OPPORTUNITIES TO PAY FOR BENEFITS TO ADDRESS SOCIAL RISK FACTORS? A QUALITATIVE STUDY OF EXPANDING SUPPLEMENTAL BENEFITS AMONG MEDICARE ADVANTAGE PLANS

Michelle Tong[1]; Laura Shields-Zeeman[2]; Laura M. Gottlieb[2]. [1]School of Medicine, University of California, San Francisco, San Francisco, CA; [2]Family and Community Medicine, UCSF, San Francisco, CA. (Control ID #3389789)

BACKGROUND: Health care payers are increasingly experimenting with interventions to address social risk factors. Recent federal policy changes (the Bipartisan Budget Act's CHRONIC Care Act of 2019) allowed for greater flexibility in the definition of supplemental benefits, creating opportunities for plans to adjust organizational approaches to social risk-related programming. Despite this, few plans have increased offerings of supplemental benefits addressing non-medical needs. An understanding of implementation challenges and opportunities health plans currently face will allow adjustment of future policy decisions to maximize avenues for MA plans to advance social care initiatives.

METHODS: In this qualitative study, we interviewed executive leadership representatives from a nationally-representative sample of Medicare Advantage plans (n=25 across 14 plans) to assess plan motivations to offer social-risk related interventions and challenges plan face in decisions to expand benefits. Plans were selected to be representative based on the following criteria: geographic coverage (regional, state, and national), Special-Needs plans vs. Special-Needs plans, tax status (non-profit vs. for-profit), and plan type (HMO, PPO, and PFFS).

RESULTS: Results suggest that plans have interest addressing members' social risk factors through supplemental benefits, but most have not widely expanded the scope of their supplemental benefits due to internal and external factors. Plans that expanded or offered new benefits most commonly reported expansion of meal programs and transportation benefits.

Internal factors influencing plan motivations to address social needs included (1) plan missions and values drive decisions to change benefit offerings over considerations about return on investment (2) provider-driven initiatives and (3) member needs. External factors influencing plan decisions included evidence of positive returns on investment (ROI), improved health care costs and outcomes, and competition with other plans covering a similar beneficiary population.

Plans face several challenges that influence decisions to address social risk factors via supplemental benefits: difficulty in selecting and designing interventions during tight bid cycles, resource allocation challenges, lack of operational research of benefits implementation, and limited evidence of uptake of new benefits.

CONCLUSIONS: This study elucidates some of the drivers for MA Plans to address social determinants of health of their enrollees and highlights the challenges plans face in doing so. As Medicare Advantage continues to grow, increasingly more Medicare beneficiaries will be affected by changes in the MA program. Increased opportunity to address adverse social determinants of health constitutes a major change in Medicare Advantage. Future efforts should monitor the implementation of new or expanded benefits in considerations for future policy directions for Medicare Advantage.

HOW WE LEARN: A NATIONWIDE SURVEY OF THE USE AND PERCEIVED VALUE OF NOVEL AND TRADITIONAL EDUCATIONAL RESOURCES AMONG INTERNAL MEDICINE RESIDENTS.

Nakul Bhardwaj[1]; Eden Bernstein[1]; Elizabeth Pfoh[2]; Eric Yudelevich[3]. [1]Internal Medicine, Cleveland Clinic Foundation, Cleveland, OH; [2]Medicine, Cleveland Clinic, Cleveland, OH; [3]General Internal Medicine, Cleveland Clinic Foundation, Beachwood, OH. (Control ID #3392229)

BACKGROUND: Medical residents have access to novel educational resources including podcasts, YouTube, and Twitter. These resources are largely unregulated and non-peer reviewed and they have direct implications for medical education. We sought to describe the use and perceived value of novel and traditional educational resources among internal medicine (IM) residents.

METHODS: This was a cross-sectional survey of IM residents in January 2020. Residency programs were contacted via email and sent a SurveyMonkey link to distribute to residents. Residents were asked to check which resources they used at least once in the past three months for attaining general medical knowledge and for point-of-care decision making. They rated the helpfulness of each resource using a 5 point Likert scale and identified their "go-to" resource in each category. We categorized Twitter, YouTube, online blogs, podcasts, and Wikipedia as "novel resources" since they are non-peer reviewed, and less characterized in the literature. Traditional resources included textbooks, pocketbooks, peer-reviewed digital media (Up-to-date, DynaMed), professional guidelines, clinical experience, peer-reviewed articles, residency curriculum and board-review guidebooks (MKSAP). Questions were field tested for content and face validity. Resources were considered valuable if identified as "very helpful" or "helpful". We collected demographics, commute time, and type of program (academic or community). A logistic regression model was used to identify the association between these variables and the odds of using a novel resource.

RESULTS: We received 439 responses from PGY1-3 residents from 32 different programs across 19 states. Average age of the resident was 29 and 45% were female. The most common resource was independent reading of peer-reviewed digital media for both general (46%) and point-of-care (87%) knowledge. On average, residents used 7 (out of 8) traditional resources and 2 (out of 5) novel resources. The most commonly used novel resource was podcasts (58%) followed by YouTube (57%) and these were used by more residents than textbooks (54%). The majority of residents who used YouTube rated it valuable (83%), and 73% of residents who used podcasts rated them valuable. Regarding traditional resources, 94% of residents who used a peer-reviewed digital clinical resource rated it valuable, and 70% of residents who used textbooks rated them valuable. There was no association between demographics, commute, or the type of program on odds of using a novel resource ($p>0.05$).

CONCLUSIONS: We found that residents use novel resources frequently and that their use is not associated with age, gender, commute time or PG year. Textbooks (both print and digital), once the centerpiece of medical knowledge acquisition, are no longer used by almost half of the residents surveyed. Despite not being systemically peer-reviewed, novel resources are rated as valuable by residents and may influence clinical decisions and patient care.

HYPERTENSION MANAGEMENT IN AN INTERNAL MEDICINE RESIDENT CLINIC: A QUALITY IMPROVEMENT PROJECT UPDATE

Charlotte Lin[1]; Vanessa-Giselle Peschard[1]; Vijay Kannuthurai[1]; Tanya Walker[2]; Christine Moorehead[2]; Emily D. Fondahn[3]. [1]Medicine, Washington University, St. Louis, MO; [2]Ambulatory Services, Barnes Jewish Hospital, Smithton, IL; [3]Department of Medical Education, Washington University, St Louis, MO. (Control ID #3384263)

BACKGROUND: The Barnes-Jewish Hospital Primary Care Medicine Clinic is an academic internal medicine resident clinic with an average of 1960 patient visits per month; 62% of our patients have a diagnosis of hypertension (HTN). We started a quality improvement project in August 2018 with the aim of improving the percentage of hypertensive patients with controlled blood pressure (defined as <140/90) from a baseline of 65.8% to 80.0%. We established a multi-disciplinary nurse HTN clinic, in which patients are scheduled with a nurse, who measures blood pressure, consults with a resident for medication changes if blood pressure is uncontrolled, and educates patients regarding lifestyle and blood pressure goals. Patients can follow up regularly until they have reached their goal blood pressure. The first PDSA cycle involved changing the nurse HTN clinic referral process from paper-based to electronic to increase use of this resource by residents. While this improved referral rates to this clinic, it did not affect overall blood pressure control. After tracking referral rates and no-show rates to the nurse HTN clinic visits, we found that a high no-show rate limited the effectiveness of this clinic.

METHODS: The next PDSA cycle focused on addressing the no-show rate by assigning one specially- trained nurse to be responsible for the nurse HTN clinic for improved continuity. Other changes included reminder phone calls prior to appointments and enhancement of patient education efforts. In the most recent PDSA cycle, we obtained blood pressure monitors to give to patients free of charge to facilitate patient engagement in HTN management.

RESULTS: The percentage of patients with controlled HTN decreased from baseline of 65.8% (June to September 2018) to 62.5% in November 2018, then increased to 68.6% in May 2019 but decreased again from October 2019 onward. There were 1243 completed visits in the nurse HTN clinic from August 2018 to December 2019, serving 717 unique patients. The no-show rate decreased from 50% to 34%. From August 2019 through December 2019, 131 blood pressure monitors were distributed to selected patients.

CONCLUSIONS: By using reminder phone calls, our clinic was able to decrease the no-show rate for patients in the nurse HTN clinic. With ongoing interventions, the percentage of hypertensive patients with controlled blood pressure steadily improved from December 2018 to May 2019. Blood pressure control worsened in the fall and winter of 2019. Possible reasons for this include staff turnover, and dietary indiscretions during the holidays. Sustained improvement may be difficult to appreciate because the interventions only directly affect a small subset of patients with HTN. We attribute our successes and momentum to our multidisciplinary team, including physicians, nursing, pharmacy, and information technology. Future PDSA cycles include developing resident HTN management guidelines, improving HTN documentation in the electronic medical record, and patient engagement.

IDENTIFYING BARRIERS TO PHYSICIAN ENGAGEMENT AMONG COMMUNITY-BASED PHYSICIANS IN A LARGE ACADEMIC HEALTH SYSTEM

Daniel J. Coletti[1,3]; Kayla Finuf[1]; Thomas McGinn[2,3]. [1]Medicine, Northwell Health, Great Neck, NY; [2]Medicine, Northwell Health, New York, NY; [3]The Donald and Barbara Zucker School of Medicine at Hofstra Northwell, Hempstead, NY. (Control ID #3388251)

BACKGROUND: Prior research has documented the impact of healthcare delivery and financing changes on physician perceptions of their work and personal wellbeing. Engaging physicians in practice re-design and management has been identified as a protective factor for burnout, and high-performing health systems make extensive efforts to listen to provider experiences before engaging in practice transformation. Less known are the specific ways systems can enhance provider engagement and reduce burnout. This investigation sought to identify drivers of provider dissatisfaction in preparation for a comprehensive physician wellbeing initiative.

METHODS: Randomly selected practice-based physicians completed an anonymous online survey to obtain perceptions of (a) the electronic health record (EHR); (b) practice based workflows, scheduling, staffing, and quality improvement (QI); (c) the effectiveness of health system marketing support; (d) opportunities for professional development; and (e) general satisfaction with health system affiliation. Physicians responded to questions using a 100-point visual analog scale (VAS), and were also asked to provide open-ended explanations for their answers.

RESULTS: We obtained surveys from 161 of 230 physicians. Frequently cited reasons for provider dissatisfaction included inefficiencies in EHR documentation and task management, with older respondents endorsing greater difficulty with the EHR than younger physicians ($P<.05$). Management of patient phone calls was also of concern, with greater dissatisfaction identified among providers using an external call center ($P<.001$). Overall pride in health system affiliation was high. Providers working in practices with a greater number of allied health professionals (e.g., nurses, social workers, psychologists, etc.) had more positive attitudes to QI standards ($P<.001$) and greater overall pride in health system affiliation ($P<.05$). Across content areas (i.e., call management, marketing, QI, and work-life balance) physicians reported more positive attitudes when they felt involved in problem-solving and connected to other colleagues rather than when tasks were removed from their local environment or practice's set of responsibilities.

CONCLUSIONS: We obtained baseline data upon which to establish benchmarks and targets for improvement, and inform a new provider wellness program. Results describing ways the EHR and call management problems exacerbate time and staff-related pressures are broadly consistent with prior research. Interestingly, commitment to QI and overall satisfaction were higher in practices with more interprofessional support, suggesting a tangible physician-reported benefit of working within a Patient Centered Medical Home (PCMH). Results also suggest that provider wellness initiatives must balance efforts at promoting self-care and work-life balance with tangible efforts to improve practices with extensive involvement of physicians at all levels of training and experience.

IDENTIFYING CULTURAL AND SOCIO-ECONOMIC BARRIERS IN LONG TERM CARE PLANNING

Christine Cummings[2]; Caren Steinway[1]; Sophia Jan[1]. [1]Pediatrics, Cohen Children's Medical Center of Northwell Health, New Hyde Park, NY; [2]Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY. (Control ID #3389747)

BACKGROUND: The lives of individuals with intellectual/developmental disabilities (IDD) continue to extend into adulthood as medicine continues to advance. Many components of long term care (LTC) are neglected due to a lack of knowledge or resources which then cause uncertainty in the health, financial, and legal welfare of individuals with IDD. Furthermore, resources available to families to help LTC are not individualized to a family's values, culture, and socio-economic status. The aim of this study was to gain a better understanding of the cultural and socio-economic barriers families face when considering next steps for LTC planning.

METHODS: Semi-structured in-depth interviews were conducted with families, siblings, and individuals with IDD. Before each interview, participants were asked to browse through an existing web-based resource for LTC planning. Participants were also asked to report current socio-economic status, education level, and race/ethnicity. Previous semi-structured interviews with this population identified the following domains of LTC planning: caregiving, transportation, housing, health management, financial management, and legal management. Participants were asked to expand on barriers to planning any of these domains. Participants were prompted to follow-up questions regarding their cultures, values, and finances. Additionally, they were asked to compile a comprehensive "wish list" for LTC in an ideal setting.

RESULTS: From October-December 2019, ten in-depth interviews were conducted. Each participant identified with at least one of the following: non-white (4,40%), English as a second language (1,10%), education equivalent to or less than a high school diploma (2,20%), or income less than $50,000 annually (7,70%). Interviews revealed a web-based tool would help facilitate planning if viewers felt there were photos of individuals of diverse backgrounds and disease states; availability in multiple languages; and peer collaboration. Participants states financial security in the short term (i.e. social security assistance), but lack of LTC in most of the domains, particularly legal and financial management.

CONCLUSIONS: LTC planning is a challenging process for families with children with IDD. Cultural and socio-economic factors play a large role in a family's ability to be receptive to the resources provided.

IDENTIFYING DISTINCT SUBGROUPS OF HIGH-NEED, HIGH-COST VETERANS USING MACHINE LEARNING CLUSTERING METHODS

Ravi Parikh[3,1]; Kristin Linn[4]; Jiali Yan[5]; Ann-Marie Rosland[6]; Matthew Maciejewski[7]; Peter W. Groeneveld[8]; Kevin G. Volpp[2]; Amol S. Navathe[3,2]. [1]Leonard Davis Institue of Health Economics, Philadelphia, PA; [2]Department of Medical Ethics and Health Policy, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [3]Corporal Michel J. Cresencz VA Medical Center, Philadelphia, PA; [4]Department of Biostatistics, Epidemiology, and Informatics, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [5]Department of Medicine, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [6]University of Pittsburgh School of Medicine, Pittsburgh, PA; [7]Durham VA Medical Center, Durham, NC; [8]PVAMC, University of Pennsylvania, Philadelphia, PA. (Control ID #3390613)

BACKGROUND: To improve care management for high-need, high-cost (HNHC) Veterans, the Veterans Health Administration (VA) developed the Care Assessment Needs (CAN) score, a model that predicts a patient's percentile risk of hospitalization and/or death at one year. We used machine learning (ML) clustering methods to examine subgroups of HNHC Veterans with combined one-year CAN scores ≥75th percentile.

METHODS: In this cross-sectional study of 110,000 Veterans, we used data from the VA Corporate Data Warehouse (CDW). We categorized 2014 data into 119 independent variables, grouped into 6 categories: demographics, comorbidities, pharmacy, vital signs, labs, and prior utilization. We applied a validated density-based clustering algorithm to ten randomly selected training sets of 10,000 Veterans to optimize model hyperparameters; then applied our optimized algorithm to a holdout set of 10,000 Veterans to generate clusters. To label each cluster, we used ridge regressions to compare estimated coefficients for each independent variable within and across clusters. For each cluster, we calculated average two-year utilization and mortality.

RESULTS: We identified 30 subgroups of HNHC Veterans ranging from 50-2,446 patients (see table). Elixhauser comorbidities and pharmacy information had greater importance for subgroup identification than vital signs and demographics. Mean CAN score ranged from 72.4-90.3 among subgroups. Two-year mortality ranged from 0.9%-45.6% and was highest in the home-based care subgroup. Mean inpatient days ranged from 1.4-30.5 and were highest in the post-surgical infection subgroup. Mean emergency room visits ranged from 1.0-4.3 and were highest in the sedative use subgroup. Mean outpatient visits ranged from 22.9-119.1 and were highest in the home-based care subgroup.

CONCLUSIONS: HNHC Veterans are a heterogeneous population consisting of 30 subgroups with distinct utilization and outcome patterns. Distinct HNHC subgroups may benefit from individualized interventions that address their unique needs.

IDENTIFYING PATIENTS' UNMET HEALTH-RELATED SOCIAL NEEDS IN AN ACADEMIC PRIMARY CARE PRACTICE IN SAN FRANCISCO, CA

Antony H. Nguyen[2]; Jasmin Woo[2]; Jennifer Fung[2]; Liliana Chacon[6]; Jennifer Morrish[3]; Nikko Gonzales[4]; Irena Stijacic Cenzer[5]; Joselvin Galeas[2]; Jane Jih[1]. [1]Medicine, General Internal Medicine, UCSF, San Francisco, CA; [2]General Internal Medicine, University of California San Francisco, San Francisco, CA; [3]UCSF Health, San Francisco, CA; [4]School of Medicine, UCSF, San Francisco, CA; [5]Geriatrics, UCSF, San Francisco, CA; [6]Division of General Internal Medicine, University of California, San Francisco, San Francisco, CA. (Control ID #3391712)

BACKGROUND: Unmet health-related social needs may lead to negative health outcomes and increase healthcare utilization by patients. There is growing interest in integrating social needs care into healthcare to reduce disparities and promote health equity. We conducted a needs assessment of unmet health-related social needs in a diverse, urban academic primary care practice to help prioritize strategies to integrate social needs care.

METHODS: We recruited a convenience sample of patients from clinic waiting rooms in a three-site academic primary care practice to complete a self-administered anonymous paper survey from February to October 2019. The survey was available in English, Chinese and Spanish. We

used questions from the Accountable Health Communities Health-Related Social Needs Screening Tool from Centers for Medicare and Medicaid Services covering these domains: food insecurity, housing instability, transportation problems, utility health needs, interpersonal safety, financial strain, and family and community support. We also collected age, gender and zip code of residence. Participants received a $5 gift card incentive and a 4-page in- language printed resource guide for these health-related social needs. Survey responses were recorded in REDCap. We used STATA for bivariate analyses.

RESULTS: 679 patients completed the survey. Participants were 56% female with a mean age of 58±18 years old (range 18-101). 5% of respondents completed the survey in Spanish while 10% completed the survey in Chinese. The table presents the prevalence of each health-related social need for the total study population and then separately stratified by gender, age (<65 vs 65+), and language of completed survey. Presentation of needs assessment findings to key stakeholders including the practice's Patient Advisory Council, clinicians, clinical team members, and clinical and administrative leadership is ongoing.

CONCLUSIONS: In a convenience sample of patients from an academic primary care practice, the burden of unmet health-related social needs was not insignificant. Food insecurity (23%), housing-related problems (27%) and financial strain (34%) were the most prevalent social needs overall. These survey findings, paired with planned geographic-based data visualization, can help inform development of a clinical infrastructure and population health approach to support health-related social needs screening and care within the primary care practice.

IDENTIFYING THE SICKEST ON TRIAGE: TEST CHARACTERISTICS OF POINT-OF-CARE SEVERITY SCORES FOR PREDICTING PROGNOSIS IN EMERGENCY DEPARTMENT PATIENTS PRESENTING WITH SUSPECTED SEPSIS

Priya A. Prasad, Margaret Fang, Kathleen D. Liu, Kirsten Kangelaris. Medicine, University of California, San Francisco, San Francisco, CA. (Control ID #3385909)

BACKGROUND: Early risk stratification and treatment is critical in sepsis. Sepsis-3 introduced the quick Sequential Organ Failure Assessment (qSOFA) score to determine patient risk at bedside. Other point-of-care prognostic scores are available, such as the easy to calculate Shock Index (SI) and the more difficult to derive National Early Warning Score-2 (NEWS2) adopted by the NHS, but the comparative performance of these scores has not been evaluated in patients presenting with suspected sepsis. Our objective was to compare how well qSOFA, SI, and NEWS2 calculated at emergency department (ED) triage predicted in-hospital mortality and ED-to-intensive care unit (ICU) admission in patients with suspected sepsis.

METHODS: We identified adults who presented to an academic ED between June 1, 2012 and December 31, 2018 with suspected sepsis, defined as having blood cultures ordered and intravenous antibiotics received within 72 hours of ED presentation. Discharge disposition, demographics, laboratory studies, vital signs, and medication administrations were collected. Patients were considered at increased risk of poor outcomes using a qSOFA score ≥2, an SI value of <0.5 or >0.7, or a NEWS2 score ≥7 based on their first ED triage vitals, all standard abnormal cutoffs. We calculated test characteristics for each score to predict in-hospital mortality and ED-to-ICU admission.

RESULTS: There were 26,079 ED patients that met inclusion criteria. At ED triage, 2,053 (8%) were at increased risk of poor outcomes by qSOFA, 5,206 (20%) by SI, and 5,324 (20%) by NEWS2. There were 1,594 (6%) deaths and 3,483 (13%) ED-to-ICU admissions. All scores had high specificities and negative predictive values. Sensitivities and positive predictive values were similar for SI and NEWS2, but lower for qSOFA (Table).

CONCLUSIONS: All scores were notable for high specificity and high negative predictive value, which may provide reassurance for prognosis when negative in the general ED population with suspected sepsis. If selecting a point-of-care bedside risk stratification score based on sensitivity, the SI is simple to calculate and has similar test characteristics to NEWS2.

Mortality				
	Sensitivity	Specificity	Positive Predictive Value	Negative Predictive Value
qSOFA	29.8% (CI 27.6-32.1%)	93.6% (CI 93.2-93.9%)	23.1% (CI 21.6-24.8%)	95.3% (CI 95.2-95.5%)
SI	47.0% (CI 44.5-49.5%)	81.8% (CI 81.3-82.3%)	14.4% (CI 13.7-15.1%)	96.0% (CI 95.8-96.1%)
NEWS2	47.9% (CI 45.5-50.4%)	81.4% (CI 80.9-81.9%)	14.4% (CI 13.7-15.1%)	96.0% (CI 95.8-96.2%)
ED-to-ICU Admission				
	Sensitivity	Specificity	Positive Predictive Value	Negative Predictive Value
qSOFA	28.8% (CI 27.3-30.3%)	95.4% (CI 95.1-95.6%)	48.8% (CI 46.8-50.8%)	89.7% (CI 89.5-89.9%)
SI	54.1% (CI 52.4-55.7%)	85.3% (CI 84.8-85.8%)	36.2% (CI 35.2-37.2%)	92.3% (CI 92.1-92.6%)
NEWS2	50.0% (CI 48.3-51.6%)	84.1% (CI 83.7-84.6%)	32.7% (CI 31.7-33.7%)	91.6% (CI 91.3-91.9%)

CI: 95% confidence interval; qSOFA components: respiratory rate, systolic blood pressure, altered mental status; SI components: heart rate, systolic blood pressure; NEWS2 components: respiratory rate, oxygen saturation (Scale 1), use of supplemental oxygen, heart rate, temperature, systolic blood pressure, altered mental status

IMAGING FOR LOW BACK PAIN IN THE URGENT CARE SETTING: DOES AN EDUCATIONAL INTERVENTION FOR INTERNS CHANGE RADIOLOGIC MANAGEMENT?

Julia B. Nath[1]; Jessica Telleria[3]; Erin Y. Rieger[5]; Annie Rhee[4]; Carina W. Yang[3]; Joyce W. Tang[2]. [1]Internal Medicine, University of Chicago, Chicago, IL; [2]Division of General Internal Medicine, University of Chicago, Chicago, IL; [3]Radiology, University of Chicago, Chicago, IL; [4]Pritzker School of Medicine, University of Chicago, Chicago, IL; [5]Pritzker School of Medicine, The University of Chicago, Chicago, IL. (Control ID #3388520)

BACKGROUND: Low back pain (LBP) is among the most common presenting symptoms in a primary care clinic, and up to a quarter of those visits result in imaging. However, imaging for simple lumbago without red flag symptoms has not been shown to provide clinical benefit, and rather increases costs, anxiety, and radiation exposure. As a result, LBP has been a substantial focus in health services research in an effort to reduce waste and expenses, with several guidelines on appropriate image ordering. We sought to determine the patterns of LBP imaging in an academic urgent care setting and assess the impact of an educational intervention on appropriate image ordering practices among internal medicine (IM) residents.

METHODS: An interactive lecture series ("Imaging Wisely") was developed for the University of Chicago's IM interns for the 2017-2018 academic year. The curriculum aimed to guide evidence-based imaging by introducing the American College of Radiology's (ACR) Appropriateness Criteria through two lectures and interactive, case-based, Radiology-TEACHES assignments between lectures. Previous research found that the program improved knowledge and intention to change imaging practices. The purpose of this study was to assess for behavior change by focusing on rates of radiologic mismanagement of LBP pre- and post-intervention. An electronic medical record query was conducted of all urgent care visits with diagnoses related to LBP among interns (n=27) who participated in the Imaging Wisely lectures. Patient encounters were reviewed and coded for diagnosis, red

flag symptoms, type of imaging ordered, and appropriateness of imaging ordered.

RESULTS: A total of 219 urgent care encounters for LBP were reviewed. Nineteen percent (n=41) of encounters involved a red flag symptom (duration >6 weeks and failed conservative therapy; concern for cancer, infection, cord compression, or fracture; progressive neurologic symptoms; history of lumbar surgery). Among LBP visits, radiologic mismanagement was noted in 10% of cases (n= 22). This mismanagement was equally attributable to over- and under-imaging. Rates of radiologic mismanagement did not change after interns participated in the Imaging Wisely sessions (χ^2 p =0.67; 11.3% incorrect imaging pre-intervention vs. 9.5% post-intervention). Controlling for resident and attending fixed effects increased the odds of correct imaging after the intervention but remained statistically insignificant (OR=3.87 [0.77-19.4]).

CONCLUSIONS: The Imaging Wisely lecture series did not lead to a statistically or clinically significant decrease in radiologic mismanagement of low back pain in the urgent care setting by the participating interns. Notably, radiologic mismanagement was attributable to equal amounts of under- and over-imaging. This suggests that curricula should not only focus on decreasing excessive image ordering but also reinforce situations in which imaging is indicated.

IMAGINING THE FUTURE OF PRIMARY CARE – A GLOBAL LOOK AT INNOVATIVE HEALTHCARE DELIVERY

Pratik Doshi[1,2]; Satasuk J. Bhosai[3,2]; Krishna Udayakumar[2,1]. [1]School of Medicine, Duke University, Durham, NC; [2]Global Health Innovation Center, Duke University, Durham, NC; [3]Clinical Research Institute, Duke University, Durham, NC. (Control ID #3344561)

BACKGROUND: Given the exponentially growing burden of noncommunicable diseases (NCDs) combined with the national shortage in primary care providers who are best able to target and treat NCDs, there is a need for strong primary healthcare (PHC) delivery models within the USA. Concurrently, there has been an increasing number of global PHC models that have created novel methods for chronic disease management. By identifying and investigating these global "exemplars" of innovative PHC delivery, we can inform future priorities by learning from today's most promising models of primary care.

METHODS: Our team at Innovations in Healthcare (IiH) has curated a network of 92 innovators across nearly 90 countries to evaluate multimodal approaches to identify innovative primary healthcare models. These innovations were characterized by archetype and evaluated by a Delphi Method of expert interviews to select the four most innovative primary care models to investigate thoroughly using stakeholder analysis and company interviews.

RESULTS: Of the 92 innovators in our network, we selected four that were considered most innovative by our panel of experts within Duke Global Health Innovation Center and the Bill and Melinda Gates Foundation. These four "exemplars" are: CASALUD (Mexico), North Star Alliance (Sub-Saharan Africa), Possible (Nepal), OneFamilyHealth (Rwanda).

CONCLUSIONS: CASALUD in Mexico created a suite of digital health technologies to help patients and providers continuously manage NCDs. As of May 2018, they had spread to 12,400 clinics, providing NCD monitoring and management for over 2 million people. North Star Alliance (NSA) operates in 13 countries throughout Sub-Saharan Africa focused on delivering care to mobile workers in the region. Since their founding in 2006 as a public-private partnership between the World Food Programme and TNT, NSA has opened 90 roadside clinics, serving nearly 200,000 patients including truck drivers, sex workers, and local communities per year, with a total revenue of about $6 million per year. Possible, based in Nepal, uses an integrated care approach based on community health workers and government-owned facilities to provide comprehensive care. They are able to operate with annual expenses at less than $25 per capita and demonstrate a reduction in under 2 mortality from 36.9 in 2015 to 18.5 as of 2017, and a tripling of the institutional birth rate from 30% in 2012 to 96% in 2017. OneFamilyHealth is a franchising primary health clinic system based in Rwanda. They are in 110 clinics across 14 districts and have 1.5 million registered patients as of 2018. Their model has averted nearly 1000 deaths and saved upwards of 84,000 DALYs. These models all integrate digital health technologies to expand their reach to patients, select business models that align with patient behaviors, standardize operating procedures, and unlock the power of data to deliver high- value, high-quality primary care to millions of people

IMPACT OF A PREP CHAMPION BASED INTERVENTION ON QUALITY OF HIV PRE- EXPOSURE PROPHYLAXIS (PREP) CARE IN AN URBAN, SAFETY-NET, HOSPITAL-BASED PRIMARY CARE PRACTICE

Kristen Nocka[1]; Jessica Stewart[2]; Alexandra Heinz[3]; Kristen S. Lee[4]; Jessica Taylor[5]. [1]Health Law, Policy, and Management, Boston University School of Public Health, Boston, MA; [2]Boston Medical Center, Boston, MA; [3]Infectious Disease, Boston Medical Center, Boston, MA; [4]Department of Medicine, Boston University School of Medicine, Boston, MA; [5]General Internal Medicine, Boston Medical Center, Boston, MA. (Control ID #3389352)

BACKGROUND: New HIV infections continue to number 40,000 per year in the United States (US). HIV pre-exposure prophylaxis (PrEP) with daily oral tenofovir disoproxil fumarate/emtricitabine (TDF/FTC) reduces HIV incidence by more than 90% in people at risk for sexual transmission, and by more than 74% in those with injection-related risk. The Centers for Disease Control and Prevention (CDC) and the US Preventive Services Task Force recommend PrEP for people at risk; however, PrEP uptake remains low and significant racial and ethnic disparities in access persist. The goal of this work is to describe the impact of a novel "PrEP Champion" based intervention on the quality of PrEP care within an urban, hospital-based primary care practice.

METHODS: The intervention was launched on 1/1/2017 within the General Internal Medicine (GIM) primary care practice at Boston Medical Center in Boston, MA, which serves 37,000 diverse patients. Program components included a GIM faculty PrEP champion, who supported colleagues and reviewed charts for quality, a PrEP program navigator, and an infectious disease physician available for consultation. Quality metrics included meeting recommended intervals for HIV, creatinine, hepatitis B virus (HBV), and bacterial STI (bSTI) screening according to 2014 CDC PrEP guidelines. Program volume (the number of PrEP patients), and quality data were abstracted on a per month basis from 1/1/2016-12/31/2017. Interrupted time- series (ITS) models analyzed the program's short-term and sustained impact on program volume and quality of care.

RESULTS: Ninety-one patients with a GIM primary care provider received a PrEP prescription, the majority of whom were male (76.9%), white (50.6%), and non-Hispanic (68.1%). Although the number of patients on PrEP rose steadily during the study period, the program did not have a significant effect on patient volume. The PrEP program led to a significant short-term (coefficient= 6.03; p=0.0081) and sustained (coefficient=1.11; p=0.0004) increase in the percent of individuals up to date on gonorrhea and chlamydia screening. The program was also associated with a short-term decrease in the percent of patients with up-to- date creatinine screening (coefficient=-2.98; p=0.0071), though no sustained change was observed. Lastly, the PrEP program led to a significant short-term increase in the percent of PrEP users with up-to-date HBV screening,

though it was associated with a sustained decrease over time (coefficient=-1.70 p<0.0001). Intervention effects on HIV and syphilis screening were not seen.

CONCLUSIONS: Implementation of a "PrEP Champion" model in an urban, safety-net, primary care clinic was associated with improved gonorrhea and chlamydia screening among patients on PrEP. Given rising bSTI rates in Massachusetts during the study period, this likely conferred individual and public health benefits. Comprehensive PrEP programs that include internal champions and navigation support show promise for increasing the quality of PrEP care.

IMPACT OF A SUBSIDIZED FARM SHARE PROGRAM ON DIET AND FOOD SECURITY: RESULTS OF A PILOT RANDOMIZED CONTROLLED TRIAL

Victoria L. Mayer[2]; Richa Deshpande[2]; Daphne Brown[2]; Dennis Derryck[3]; Erica Christensen[4]; Emily Hanlen-Rosado[1]; Carol R. Horowitz[5]; Emily Goodman[6]; Leora Mogilner[7]. [1]Department of Population Health Science, Duke University, Durham, NC; [2]Department of Population Health Science and Policy, Icahn School of Medicine at Mount Sinai, New York, NY; [3]Milano School of International Affairs, Management and Urban Policy, New School University, New York, NY; [4]NA, Corbin Hill Food Project, New York, NY; [5]Population Health Science and Policy, Mount Sinai School of Medicine, New York, NY; [6]Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; [7]Department of Pediatrics, Icahn School of Medicine at Mount Sinai, New York, NY. (Control ID #3391615)

BACKGROUND: Food insecurity has an adverse effect on diet quality and is associated with multiple negative outcomes. Fruit and vegetable subsidy programs may address food insecurity and improve diet and health, but the impacts have not been fully investigated. Our objective was to assess impact of an RCT farm share subsidy program on diet quality and food insecurity.

METHODS: We recruited participants from internal medicine or pediatric primary care clinics. The health system team partnered with a community fresh produce distributor, a local food pantry, and a national non- profit. We block randomized participants to two groups. The immediate intervention group (treatment group) received 6 months of bi-weekly subsidized farm shares starting at enrollment, and the comparison group received the same intervention but starting 6 months later (delayed intervention group). All participants received information about local emergency food resources at enrollment. Inclusion criteria included: 1) food insecurity (as measured by the 2-item Hager screen) and/or receipt of SNAP and/or WIC and 2) age 5-11 years with obesity or age >/= 18 years with uncontrolled diabetes. Data collected at baseline, 6 months, and 12 months included: socio-demographics, the 18-item USDA food security survey (categorizing 4 levels of FI), and diet recall (ASA-24, used to derive Healthy Eating Index). Descriptive statistics, chi-squared and Fisher's Exact tests, mixed effects, and generalized estimating equation models were used.

RESULTS: We enrolled 95 participants, 50 adults and 45 children with their parents or guardians. The group was 57% Hispanic and 36% Black; 52% were female. 72% had income < $30,000. At baseline, the treatment and comparison groups were similar with respect to age, gender, race, education, employment, food security status and Healthy Eating Index, but differed with respect to ethnicity. There was no significant difference between the two groups with respect to change in Healthy Eating Index at 6 months (p=0.3). At month 6, the estimated odds of high or marginal food security (versus low or very low food security) was 3.5 times higher in the treatment versus the comparison group (95% CI 1.3-9.6, p=0.014).

CONCLUSIONS: While a change in diet quality was not seen in this RCT, we did see an improvement in food security status associated with the intervention. The results of this pilot study indicate the impacts of subsidy interventions are likely multifaceted, and may improve household finances even in the absence of effects on diet. Research on how to ensure these programs optimize diet quality is needed.

IMPACT OF CALIFORNIA'S GLOBAL PAYMENT PROGRAM ON BEHAVIORAL HEALTH SERVICES UTILIZATION

Maria DeYoreo[2]; Justin W. Timbie[3]; Jodi Liu[2]; Denise Quigley[3]; Katherine L. Kahn[1,2]. [1]Medicine, David Geffen School of Medicine at UCLA, Los Angeles, CA; [2]RAND Corporation, Santa Monica, CA; [3]RAND Health, RAND, Arlington, VA. (Control ID #3392258)

BACKGROUND: The goal of California's Global Payment Program (GPP) is to provide more effective and higher-value care to uninsured individuals through the delivery of care in more appropriate settings. GPP aims to accomplish this by establishing a point system that allows payments for services including outpatient non-emergent, emergent, residential, and acute inpatient health services. We assess changes in overall utilization of behavioral health (BH) services between 2015-2016 and 2017-2018 and shifts in utilization between low-intensity clinical and substance use (SU) outpatient, and high-intensity emergency department (ED), inpatient, and residential services.

METHODS: We analyzed data on service utilization by uninsured patients that were submitted by GPP's 12 participating public health care systems (PHCS). Using a pre-post design, we compared utilization in service categories between program years 1 and 3. We also administered surveys and interviews to leaders of participating PHCS to understand strategies used to facilitate change and to assess progress in meeting GPP goals.

RESULTS: Overall, across all PHCS, the number of points earned for BH services declined slightly, by 0.3% across the three years. An overall increase in the percentage of points earned was observed for SU visits (15%), methadone treatments (11%), sobering center (46%), and mental health inpatient stays (21%). A decrease in the percentage of points earned was observed for mental health outpatient visits (-6%), mental health ER and crisis stabilization (-14%), and mental health/SU residential stays (-18%). BH utilization trends within PHCS demonstrated declines in BH service use for most PHCS, but there was substantial variability by service and PHCS. Declines in outpatient service use were observed in nine PHCS (changes in percentage of points earned ranged from -44% to +12% across the 12 PHCS). Declines were observed for BH ER services in seven PHCS (range -86% to +218%), and for BH inpatient services in seven PHCS (range -84% to +153%). Five PHCS saw notable increases in BH inpatient service use.

Analyses of surveys and interviews with PHCS leaders indicated important changes in coding of mental health conditions and services as well as ongoing efforts to integrate BH outpatient and traditional primary care settings, as contributing to observed BH utilization changes.

CONCLUSIONS: Utilization changes across the GPP's initial implementation years reflected a decrease in points for BH outpatient, ED, and residential visits but an increase in SU, sobering center, and inpatient points. Declines in outpatient BH points might reflect a shift from ambulatory care in BH to primary care settings where group visits, health coaching and behaviorists are becoming integrated. Observed changes in GPP's BH services likely reflect the delivery and integration of non-BH and BH care in the ambulatory, ED, inpatient, and community settings, as well as coding practices.

IMPACT OF CALIFORNIA'S GLOBAL PAYMENT PROGRAM ON THE BREADTH AND UTILIZATION OF NONTRADITIONAL (NT) SERVICES FOR UNINSURED INDIVIDUALS

Jodi Liu[2]; Justin W. Timbie[3]; Maria DeYoreo[2]; Denise Quigley[2]; Katherine L. Kahn[1,2]. [1]Medicine, David Geffen School of Medicine at UCLA, Los Angeles, CA; [2]RAND Corporation, Santa Monica, CA; [3]RAND Health, RAND, Arlington, VA. (Control ID #3392272)

BACKGROUND: The goal of California's Global Payment Program (GPP) is to provide higher-value care to uninsured individuals. The GPP aims to accomplish this by establishing a point system that allows payments for a variety of services including non-traditional (NT) services, which typically have not been paid for under programs like Medi-Cal. NT services may entail the involvement of NT providers on care teams and NT settings such as mobile clinic visits and telehealth. Of the 50 services that earn points in the GPP, 33 are NT, including: outpatient services provided by non-physicians (RNs, PharmDs, and care managers); prevention and patient support services (e.g., case management, health education); chronic and integrative services (e.g., group medical visits); community-based encounters (e.g., home nursing visits); technology-based services (e.g., email, text, eConsults, telehealth); as well as residential services for sobering center care and recuperative and respite care.

METHODS: We analyzed the utilization of services by individuals uninsured for each service using data submitted by all 12 public health care systems (PHCS) participating in the GPP. Using a pre-post design, we compared utilization between program years 1 and 3 in different service categories.

RESULTS: Overall, from year 1 to 3, points earned increased by 42% for NT outpatient services and 79% for NT residential services. Rates of NT service per uninsured patient served increased by 28%. The ratio of NT services to traditional primary, specialty, and other non-emergent care increased by 40%, suggesting a shift towards more use of NT versus traditional services. The most frequently provided NT services were eConsults, RN-only visits, and case management, which collectively accounted for 59-66% of points earned for all NT services in any given year. Over the 3 program years, large increases occurred for PharmD visits (418% increase), real-time telephone consults (382% increase), paramedic treat and release (120% increase), mobile clinic visits (106% increase), and recuperative and respite care days (86% increase). Based on interviews with PHCS leaders, the PHCSs generally viewed NT services as a way to expand access to services by uninsured patients while improving health system efficiency.

CONCLUSIONS: The GPP point system that awards points to NT services was accompanied by increased utilization of NT services from program year 1 to 3, potentially providing the uninsured with increased access to a wider range of preventive, diagnostic, and therapeutic services. The share of NT services may grow as PHCS further test and scale up those services that are most effective in meeting their goals of delivering higher-value care in more appropriate settings. NT services may be especially effective in improving outcomes for uninsured patients who often face challenges in obtaining traditional care, or experience gaps in care as they navigate multiple providers, settings, and treatments.

IMPACT OF DIGITALLY ACQUIRED INPUT FROM PEERS ON CLINICIAN DIAGNOSTIC CONFIDENCE IN REAL-LIFE OUTPATIENT CASES: A PRAGMATIC RANDOMIZED TRIAL

Elaine C. Khoong[1,2]; Valy Fontil[1,2]; Natalie Rivadeneira[1,2]; Mekhala Hoskote[3]; Shantanu Nundy[4,5]; Courtney Lyles[1,2]; Urmimala Sarkar[1,2]. [1]Division of General Internal Medicine at Zuckerberg San Francisco General Hospital, University of California - San Francisco, San Francisco, CA; [2]UCSF Center for Vulnerable Populations, San Francisco, CA; [3]UC Berkeley - UC San Francisco Joint Medical Program, Berkeley, CA; [4]Milken Institute School of Public Health, George Washington University, Washington, DC; [5]Accolade, Inc, Plymouth Meeting, PA. (Control ID #3387526)

BACKGROUND: Each year 1 in 20 adults experiences a diagnostic error in outpatient care. Clinician confidence impacts errors. Overconfidence results in inadequate work-up while underconfidence is associated with use of unnecessary tests. Peer input on decision-making may reduce errors by affecting confidence to ensure appropriate work-up. Few have explored interventions on the diagnostic process in real-life cases, particularly in general outpatient medicine. We sought to assess if peer input on real-life outpatient cases impacted diagnostic confidence

METHODS: This pragmatic randomized trial of a peer input intervention occurred among 28 primary care providers (PCPs) with randomization at a case level. Physician scribes reviewed PCPs' encounters and identified cases with new/unresolved complaints. Case information (one-line summary and relevant history, exam, and tests) was entered into a digital tool, where input from other clinicians was collected. After 3+ clinicians provided input, their feedback was collated into a collective opinion about the diagnosis and plan, which was provided to PCPs for intervention cases. The primary outcome was high vs low diagnostic confidence, collected via survey after PCPs provided baseline perceptions about case uncertainty. Our primary analyses assessed for differences in rates of high confidence between the control and intervention group; we also a priori planned a stratified analysis by baseline uncertainty.

RESULTS: From the 28 outpatient clinicians, we identified 519 cases (257 control; 259 intervention), of which 127 (24%) were thought to have higher uncertainty. Intervention vs control cases had similar level of difficulty, patient characteristics, and clinician traits ($p>0.05$). The rate of high confidence was 46% (119/257) in control vs 54% (140/259) in intervention cases with a trend towards higher confidence in intervention cases ($p=0.078$). Baseline case uncertainty was associated with higher confidence ($p<0.05$). In analyses stratified by baseline diagnostic uncertainty, the intervention was associated with high confidence in high uncertainty cases [9% (6/65) in control vs 23% (14/62) in intervention cases ($p=0.039$)] but not low uncertainty cases [59% (113/192) in control vs 64% (126/197) in intervention cases ($p=0.301$)].

CONCLUSIONS: Outpatient clinicians report high uncertainty in ~25% of interactions with new/unresolved complaints. Peer input on clinical decision-making increased diagnostic confidence only in cases when clinicians felt high uncertainty, consistent with findings that clinicians seek input primarily for cases with continued uncertainty. Since uncertainty is associated with increased use of resources, increasing confidence in high uncertainty cases may reduce resource allocation. Next steps include exploring how digitally facilitated peer input on cases can be implemented in real-time in diverse settings and assessing impact on outcomes, such as time to diagnosis, diagnostic accuracy, or tests/referrals ordered.

IMPACT OF ELECTRONIC PRIOR AUTHORIZATION ON MEDICATION FILLING

Michael A. Fischer[1]; Mengdong He[1]; Satish Mudiganti[2]; Xiaowei Yan[2]; Lisa Dean-Gilley[2]; Cheryl D. Stults[2]. [1]Pharmacoepidemiology and Pharmacoeconomics, Brigham and Women's Hospital/Harvard Medical School, Boston, MA; [2]Center for Health System Research, Sutter Health, Walnut Creek, CA. (Control ID #3383963)

BACKGROUND: Medications frequently require prior authorization (PA) from payors before reimbursement is authorized. Obtaining PA creates delays in filling prescriptions and may reduce patient adherence.

Electronic PA (EPA), based in the electronic health record (EHR), can remove some of these barriers. We evaluated the impact of implementation of an EPA system on prescription filling.

METHODS: The study took place at an integrated health care system in California. EPA was implemented in a 2-phase process in 2018, so that some areas of the system began using EPA in 9/2018 while other began in 11/2018, allowing use of the later-implementing sites as a concurrent control group. We obtained data from the EHR that included all prescriptions written during the study period, patient health insurance (which determines whether PA is required for a given medication), all occasions on which the EPA intervention appeared, and information on whether the prescriptions were filled, which the EHR obtains from the medication history function.

We reviewed EPA records and retained those for which the EPA request was approved. We identified as a control group matched prescriptions for the same medications to the same patients with the same drug benefits in the months prior to EPA implementation. We linked the prescribed medications to the medications history to calculate the proportion of prescriptions filled within 30 days after being written.

RESULTS: We identified 74,546 prescriptions that triggered EPA during the study period. Of that total, 19,167 (26%) were approved and were candidates for the study cohort, 11,097 (15%) were denied and 44,282 (59%) did not have a resolved status. Of the approved EPAs, 4,475 occurred for patient/medication/benefit combinations that also appeared in the pre-EPA control period.

The Table shows that in the early adoption sites the filling rate after EPA implementation increased by 3% compared to baseline, while filling at that time in the later adopting sites that did not yet have EPA decreased by 4%, a difference-in-differences of 7%. When the later adopting sites implemented EPA the filling rate decreased by 1%, compared to a decrease of 7% over that time period in the early adopting sites.

CONCLUSIONS: Adoption of EPA was associated with a small increase in the prescription filling rate in the early adopting sites, while there was a small decrease in filling at the later adopting sites. Limitations include challenges with EPA implementation, since 59% of EPAs did not result in either approved or denied status, and potential changes in which medications required PA, which could affect the control group. Additional analyses of larger samples of EPAs will be needed to determine whether these preliminary effects are sustained.

IMPACT OF EXECUTIVE ORDER 13769 IMMIGRATION BAN ON HEALTHCARE UTILIZATION AND STRESS RELATED DIAGNOSES IN MINNEAPOLIS-ST. PAUL, MN

Aarti Bhatt[1,2]; Elizabeth Samuels[3]; Altaf Saadi[4]; Lillia Orr[5]; Elizabeth White[6]; Aasim Padela[7]; Michael Westerhaus[1,8]; Pooja Agrawal[5]; Dennis Wang[9]; Gregg Gonsalves[5]. [1]Internal Medicine, University of Minnesota, Minneapolis, MN; [2]Community University Health Care Center, University of Minnesota, Minneapolis, MN; [3]Alpert Medical School, Providence, RI; [4]Harvard Medical School, Boston, MA; [5]Yale University, New Haven, CT; [6]School of Public Health, Yale University, New Haven, CT; [7]University of Chicago, Chicago, IL; [8]Health Partners, Saint Paul, MN; [9]School of Medicine, Yale University, New Haven, CT. (Control ID #3390843)

BACKGROUND: On January 27, 2017, President Trump issued Executive Order (EO) 13769, "Protecting the Nation from Foreign Terrorist Entry into the United States," which banned citizens from 7 Muslim majority countries (Iraq, Syria, Iran, Libya, Somalia, Sudan, and Yemen) from entering the US, suspended the US refugee program, and banned Syrian refugee US resettlement. Stress due to discrimination and Islamophobia has been previously associated with negative health outcomes among Muslim and Arab Americans. The impact of restrictive immigration policies on Muslim refugee and immigrant populations is less known.

METHODS: We performed an observational, retrospective study evaluating changes in health care use by people from EO 13769 targeted nations one year before and after issuance of EO 13769 using EHR data from HealthPartners clinics and emergency departments (EDs). Using a differences-in-differences analysis, we compared healthcare utilization between patients whose nation of origin was one of seven countries named in EO 13769 to non-Latino U.S.-born citizens during the pre-EO period (January 1, 2016 - January 26, 2017) and the hpost-EO period (January 27, 2017 - December 31, 2017). We defined stress related diagnoses using ICD10 codes. Comparisons made included changes in visits overall, stress-related clinic and ED diagnoses, missed appointments, and ED visits for ambulatory sensitive conditions. We estimated the effect at increasing time intervals, beginning with 30 days pre- and post-intervention and increasing in 30-day increments up to 360 days pre- and post-intervention.

RESULTS: Of the 252,594 patients included in this analysis, 5,667 were from one of the seven countries named in EO 13769 and 245,673 were non-Latino US-born citizens. There was no statistically significant change in healthcare utilization rates. Within the EO group we observed a trend toward increasing clinic visits for stress related diagnoses. However, the effect was only slightly more than zero and only in the last 180 days. There was an initial rise in the point estimate for ED visits for stress related diagnoses and ambulatory sensitive conditions, but this was not statistically significant. Overall, there was no statistically significant difference observed between stress responsive diagnoses in the ambulatory setting or in the ED.

CONCLUSIONS: Our analysis found no significant change in healthcare utilization or stress related diagnoses among this sample of individuals from EO 13769 targeted nations in Minneapolis-St.Paul, MN. However, among ambulatory patients, stress related diagnoses became more common over time. This is suggestive of an emerging trend within outpatients following EO 13769. This study advances health research exploring the relationship between Islamophobia and healthcare utilization. The health consequences of immigration policy may not impact populations equally. Further research is needed to identify sub- populations more vulnerable to social stressors from restrictive immigration policies.

IMPACT OF GLOBAL PAYMENTS FOR UNINSURED UNCOMPENSATED CARE: EVALUATING CALIFORNIA'S GLOBAL PAYMENT PROGRAM (GPP)

Justin W. Timbie[3]; Jodi Liu[2]; Maria DeYoreo[2]; Denise Quigley[2]; lesley baseman[2]; Katherine L. Kahn[1,2]. [1]Medicine, David Geffen School of Medicine at UCLA, Los Angeles, CA; [2]RAND Corporation, Santa Monica, CA; [3]RAND Health, RAND, Arlington, VA. (Control ID #3392230)

BACKGROUND: California's Medi-Cal 2020 waiver authorized a new payment model, the Global Payment Program (GPP), for reimbursing services provided to the state's remaining uninsured. Under GPP, which included California's 12 county-based public healthcare systems (PHCS), the state gained unprecedented flexibility to use its federal Medicaid Disproportionate Share Hospital (DSH) allotment to make prospective payments for services provided to the uninsured in hospital, clinic, and community settings. Historically, DSH funding has been used to retrospectively finance only hospital-based care. GPP was designed to encourage participating PHCS to invest in infrastructure and processes that could better tailor care to patients' needs and expand the delivery of preventive

services. We assessed changes in service utilization through GPPs's first 3 years.

METHODS: We used aggregate service utilization data submitted by each of the 12 county-based PHCS that collectively served most of the state's uninsured (nearly 3 million annually). We compared changes in utilization by type of service during the demonstration's first 3 years (through June 2018). The study population comprised uninsured California residents receiving care from participating PHCS.

RESULTS: The number of uninsured served by PHCS increased 6 percent over the 3 years. For physical health services, use of outpatient non-emergent services increased by 12 percent while use of emergency room (ER) and inpatient services decreased by 14 and 15 percent, respectively. Outpatient mental health and substance abuse treatment services decreased by 4 percent; ER and crisis stabilization services decreased by 14 percent; and mental health inpatient service use increased by 21 percent. The decreases in outpatient behavioral health service utilization are consistent with shifts in delivery of these services to primary care settings, while increases in inpatient services are consistent with progress in addressing unmet needs through increased access to high-intensity care. Non-traditional service use increased by 10 percent driven by greater use of case management, mobile clinic visits, PharmD visits, eConsults, and store-and-forward telehealth. PHCS varied widely in their relative use of physical, behavioral, and non-traditional services and trends over time in these services.

CONCLUSIONS: These results suggest that it is feasible to implement global payments for the uninsured, although the long-term effects of the observed changes in utilization on health outcomes and expenditures must also be assessed. Other states might consider using Section 1115 waiver authority to test similar value- based payment programs that can make more efficient use of available Medicaid DSH funding. Such strategies are particularly important in light of the recent growth in the uninsured that followed repeal of the individual mandate's tax penalty and as the first of $43 billion in Medicaid DSH funding cuts begin in 2020.

IMPACT OF HIGH-DEDUCTIBLE HEALTH PLAN ENROLLMENT ON THE TIMING OF RETINOPATHY CARE AND VISION LOSS DIAGNOSIS

James F. Wharam[1]; Fang Zhang[2]; Christine Lu[7]; Tomasz Stryjewski[3]; Jamie Wallace[4]; Joseph P. Newhouse[5]; Dennis Ross-Degnan[6]. [1]Population Medicine, Harvard Medical School and Harvard Pilgrim Healthcare, Boston, MA; [2]Department of Population Medicine, Harvard Pilgrim Health care Institute, Boston, MA; [3]Ophthalmology, Massachusetts Eye and Ear, Boston, MA; [4]Health Policy and Insurance Research, Harvard Pilgrim Health Care Institute, Boston, MA; [5]Health Care Policy, Harvard Medical School, Boston, MA; [6]Population Medicine, Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, MA; [7]Department of Population Medicine, Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, MA. (Control ID #3379834)

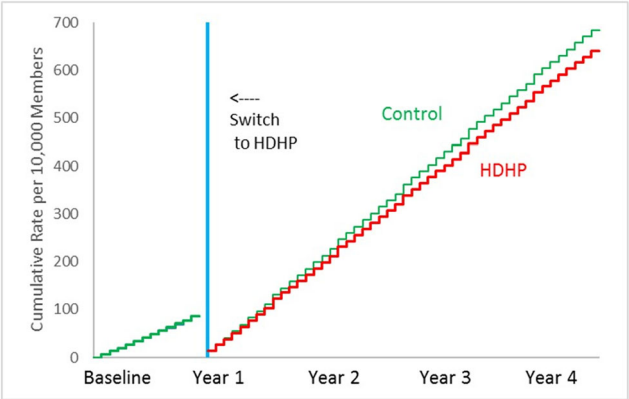
BACKGROUND: Diabetes patients require timely care to prevent retinopathy progression and blindness. High-deductible health plans (HDHP) require large out-of-pocket payments for most health services including retinopathy screening and ophthalmologist visits. We sought to determine the effect of HDHPs on the timing of retinopathy screening, retinopathy diagnosis, and vision loss diagnosis.

METHODS: We studied 2004-2014 data in a large commercial and Medicare Advantage claims database. We included a national sample of 39,798 HDHP members with diabetes enrolled for 1 year in a low deductible (≤$500) plan followed by up to 4 years in a HDHP (≥$1000) after an employer-mandated switch. We matched HDHP patients to 305,852 contemporaneous controls whose employers offered only low-deductible plans. Outcomes included time to first: (a) retinopathy screening, (b) diagnosis of mild-to- moderate and (c) severe retinopathy, and (d) vision loss diagnosis. We used Cox proportional hazards models adjusted for multiple baseline characteristics to estimate baseline and follow-up hazard ratios.

RESULTS: At baseline, adjusted hazard ratios (aHRs) between HDHP members and controls were not statistically different. At follow up, HDHP members experienced delays in first retinopathy screening (aHR: 0.89 [085, 0.92]), diagnosis of mild-to-moderate retinopathy (aHR: 0.82 [0.76, 0.89]), diagnosis of severe retinopathy (aHR: 0.90 [0.81, 1.00]), and vision loss diagnosis (aHR: 0.93 [0.88, 0.99], Figure).

CONCLUSIONS: HDHP members with diabetes experienced delayed retinopathy screening, retinopathy diagnosis, and vision loss diagnosis compared with similar patients in more generous health plans. Reducing financial barriers to care might improve retinopathy outcomes.

Figure 1. Time to first vision loss diagnosis.



IMPACT OF HOSPITALIST TEAM STRUCTURE ON PATIENT REPORTED SATISFACTION WITH PHYSICIAN PERFORMANCE

Katie Lappe[1,2]; Sonja Raaum[1,2]; Claire Ciarkowski[3]; Santosh Reddy[1]; Stacy A. Johnson[4]. [1]Internal Medicine, University of Utah, Salt Lake City, UT; [2]Internal Medicine, George E Wahlen Veteran Affairs Hospital, Salt Lake City, UT; [3]Internal Medicine, University of Utah, Salt Lake, UT; [4]Internal Medicine, University of Utah School of Medicine, Salt Lake City, UT. (Control ID #3390778)

BACKGROUND: Patient experience is valuable because it reflects how patients perceive the care they receive within the healthcare system and is associated with clinical outcomes.[1–3] In addition, as part of the Hospital Value-Based Purchasing (HVBP) program, the Center for Medicare and Medicaid Services (CMS) rewards hospitals with financial incentives for patient experience.[4] It is unclear how the addition of residents and advanced practice clinicians (APCs) to hospitalist-led inpatient teams affects patient satisfaction. This study compares patient satisfaction scores reported on the HCAHPS and Press Ganey physician performance survey domains between resident, APC and solo hospitalist teams.

METHODS: We conducted a retrospective cohort study at the University of Utah Medical Center for all inpatients discharged from the Internal Medicine service between July 1, 2015 and July 1, 2018. The post-discharge patient experience survey was distributed to all eligible patients by Press Ganey, Inc., and included the HCAHPS 29-question survey instrument and an additional 45 questions developed by Press Ganey, Inc. Patients were stratified into one of three cohorts: 1) "Resident team" comprised of one senior resident and 1-2 medical students, or one senior

resident, two interns, and 1-2 medical students supervised by a hospitalist physician; 2) "APC team" comprised of 1-2 APCs supervised by a hospitalist physician; and 3) "Solo Hospitalist" comprised of one hospitalist physician. Hospitalist physicians work on all three team types at our institution.

Patient responses were compared for both the HCAHPS and Press Ganey physician performance survey domains for the corresponding admission. Responses for HCAHPS questions were converted to binary responses with only a response of "Always" receiving credit as only "top box" scores meet the CMS incentive funding requirement. Press Ganey survey responses were evaluated on a Likert scale (1-very poor, 2-poor, 3-fair, 4-good, 5-very good). Responses were adjusted for differences in age, gender, Charlson Comorbidity Index, and time of admission.

RESULTS: No differences were observed in the selection of "top box" scores on the HCAHPS physician performance domain between resident, APC and solo hospitalist team. Compared with resident teams, solo hospitalist teams had significantly higher scores on the Press Ganey physician performance domain survey in three areas: time physician spent with you (4.58 vs. 4.38, p=0.050); physician kept you informed (4.63 vs. 4.43, p=0.047); and physician skill (4.80 vs. 4.63, p=0.027). Solo hospitalists were also perceived to have higher physician skill in comparison to APC teams (4.80 vs. 4.69, p=0.042).

CONCLUSIONS: While Press Ganey survey results suggest that patients have greater satisfaction with physicians on solo hospitalist teams, these differences are not seen on the HCAHPS physician performance survey domain, suggesting team structure should not impact HVBP incentive payments.

IMPACT OF IMPLEMENTATION OF COMPREHENSIVE, LANGUAGE-CONCORDANT DISCHARGE INSTRUCTIONS ON RATES OF PATIENT CONCERNS ABOUT DISCHARGE MEDICATIONS OR DISCHARGE INSTRUCTIONS

Elaine C. Khoong[1,2]; Sachin J. Shah[3]; Michelle Mourad[3]; Raman Khanna[3]. [1]Division of General Internal Medicine at Zuckerberg San Francisco General Hospital, UCSF, San Francisco, CA; [2]UCSF Center for Vulnerable Populations, San Francisco, CA; [3]Division of Hospital Medicine, Department of Medicine, University of California, San Francisco, San Francisco, CA. (Control ID #3390931)

BACKGROUND: One in five patients experiences an adverse drug event after discharge. Comprehensive discharge instructions improve transitions by communicating critical information, such as med changes, but there is large variation in instructions; moreover, patients with limited English proficiency (LEP) rarely receive instructions in their preferred language creating increased vulnerabilities. We assessed if language- concordant written instructions improve patient understanding.

METHODS: On the hospital medicine service in an academic center, we assessed two discharge instruction interventions. In 11/2017, we adopted a new after visit summary (AVS) that included some text in non-English languages. We also implemented standardized instructions (created with patient & clinician stakeholders) in English (3/2018) and in Spanish and Chinese (8/2018). Our two outcomes were rates of questions about instructions or medications collected from 11/1/2016–4/30/2019 via automated post- discharge phone calls conducted in English, Spanish, or Cantonese. We assessed interventions using interrupted time series analyses (ITSA) stratified by language status.

RESULTS: *Questions about dc instructions*: Among English-speakers, similar rates of patients had questions about discharge instructions at baseline, post-AVS, and post-standard instructions (6.3% vs 7.4% vs 6.5%); after adjusting for secular trends (i.e., ITSA), we found decreases in rates of questions at time of both AVS (p=0.023) and standardized instruction implementation (p=0.007). In contrast, among LEP patients, both interventions seemed to decrease questions: 46.4% baseline, 28.8% post-AVS, 14.7% post-standard instructions (X^2, p<0.05), but this was not significant after considering secular trends. *Questions about meds* (Table): In English-speakers, neither intervention impacted med-related questions. Among LEP patients, there were differences between rates at baseline and post-standard instruction implementation (18.4% vs 12.0%, p=0.024). After considering secular trends, only the AVS decreased rates of questions (p=0.036).

CONCLUSIONS: Modifying written discharge instructions impacts patients' rates of questions about discharge medications and instructions. Providing written instructions in their preferred language to LEP patients can reduce medication-related questions post-discharge.

Table. Rate of medication-related questions

Baseline	Post AVS	Post Standard Instructions
English-speaking Patients		
302/2679 (11.27%)	91/768 (11.85%)	282 / 2463 (11.45%)
Limited English Proficient (LEP) Patients		
64 / 347 (18.44%)	50 / 295 (16.94%)	36 / 300 (12.00%)

P>0.05 for all pairwise comparisons except between rates at baseline and post-standard instructions in LEP patients

IMPACT OF INTEGRATED MENTAL HEALTH SERVICES ON DIABETES AND HYPERTENSION CONTROL AMONG VA PRIMARY CARE PATIENTS

Lucinda B. Leung[1]; Lisa V. Rubenstein[5]; Erin L. Jaske[3]; Leslie Taylor[3]; Edward P. Post[4]; Karin M. Nelson[2,5]; Ann-Marie Rosland[7,6]. [1]Division of General Internal Medicine, UCLA David Geffen School of Medicine & West LA VA Medical Center, Los Angeles, CA; [2]PACT Demonstration Laboratory Initiative, Department of Veteran Affairs, Seattle, WA; [3]Health Services Research and Development, VA Puget Sound, Seattle, WA; [4]Internal Medicine, VA Ann Arbor Healthcare System and University of Michigan, Ann Arbor, MI; [5]Department of Medicine, University of Washington, Seattle, WA; [6]Internal Medicine, University of Michigan, Ann Arbor, MI; [7]VA Pittsburgh Healthcare System, VA Center for Health Equity Research and Promotion, Pittsburgh, PA. (Control ID #3390410)

BACKGROUND: Increasing evidence supports the effectiveness of collaborative care management for co- occurring mental and physical health conditions. Over the past decade, the Veterans Health Administration (VA) transformed primary care practices into team-based patient centered medical home models nationally through Patient Aligned Care Teams (PACT) initiative with embedded mental health care through Primary Care–Mental Health Integration (PC-MHI, i.e., collaborative care model). Models included increased staff and resources to support primary care teams in treating mental health conditions and addressing health behaviors (e.g., sleep, pain coping), alongside chronic medical disease management. While the original goal of PC-MHI was to improve mental health care access, this study explored whether addressing mental health issues through these collaborative primary care models resulted in downstream improvements to Veteran's chronic medical disease management and physical health.

METHODS: Our retrospective longitudinal study examined 828,050 primary care patients in 396 VA clinics mandated to offer integrated

mental health services nationally (October 1, 2013 to September 30, 2016).

Robustness of each clinic's mental health integration was approximated via the proportion of primary care patients seen by PC-MHI providers annually (median=6.3%). As part of VA's quality monitoring program, chart abstractors rated established diabetes and cardiovascular measures among an approximately 5% random sample of each clinics' patient health records. In multilevel regressions, we examined how clinic level of mental health integration predicted patient odds of meeting each quality measure, controlling for year, region, clinic characteristics (e.g., size, medical home implementation), and patient characteristics (e.g., age, gender).

RESULTS: Nearly 1 in 5 Veterans with diabetes had poor glycemic control (hemoglobin A1c greater than 9) and 5% had severely elevated blood pressures (greater than 160/100, or not recorded). Among Veterans with diabetes, each two-fold increase in proportion of clinic patients seen by PC-MHI providers was associated with, on average, 2% lower odds of poor glycemic control (95% Confidence Interval [CI]=.96-.99; p=.01) and 3% lower odds of severely elevated blood pressure (CI=.94-0.998; p=.04). While there was no observed effect among all Veterans with diagnosed hypertension, we noted 5% lower average odds of severely elevated blood pressures among Veterans without diagnosed hypertension (CI=.92-.99; p=.01).

CONCLUSIONS: Patients cared for in primary care clinics with increased access to collaborative mental health care had significantly better physical health quality. Healthcare system-wide policies to improve access to mental health collaborative care may lead to improved overall chronic disease health. Increasing reach of integrated mental health services across all health system clinics could help maximize chronic disease quality of care.

IMPACT OF LONGITUDINAL VIRTUAL PRIMARY CARE ON DIABETES QUALITY OF CARE

Amy D. Lu[1,2]; Elise Gunzburger[4]; Thomas J. Glorioso[4]; William B. Smith[1,2]; Mary Whooley[1,2]; Michael Ho[3,4]. [1]Medicine, San Francisco VA Health Care System, San Francisco, CA; [2]Medicine, University of California San Francisco, San Francisco, CA; [3]Cardiology, Eastern Colorado Health Care System, Denver, CO; [4]Denver Center of Innovation for Veteran Centered and Value Driven Care, Denver VA Medical Center, Aurora, CO. (Control ID #3388441)

BACKGROUND: Individuals living in rural areas experience a higher prevalence of diabetes and diabetes- related morbidity than their urban counterparts due to socioeconomic challenges and limited access to care. In randomized controlled trials, use of telemedicine has been effective in increasing access to care and lowering hemoglobin A1C levels in diabetic patients, but whether these results can be generalized to real-world primary care settings remains unknown. The Virtual Integrated Multisite Patient Aligned Care Team (V- IMPACT) is a novel primary care delivery model implemented by the Department of Veterans Affairs (VA) that utilizes video visits to provide longitudinal primary care services in rural areas. We compare diabetes quality of care among veterans who received V-IMPACT versus those who received traditional in-person care.

METHODS: We conducted a retrospective quasi-experimental study utilizing difference-in-differences analysis to evaluate diabetes quality of care before and after implementation of V-IMPACT in participating primary care clinics from January 1, 2016 through December 31, 2019 with staggered V-IMPACT implementation across clinics occurring in 2018. We identified 64,639 veterans with type 2 diabetes receiving care in 44 participating VA primary care clinics. Patients were eligible for analysis if they had at least one primary care encounter and one documented hemoglobin A1C level available during the observation period. We excluded patients younger than 18 years old and those with metastatic cancer. Propensity score matching was used to construct a matched-pair cohort of patients with balanced demographics and comorbidities who did and did not receive V-IMPACT services. Our primary outcome of interest was change in hemoglobin A1C (HbA1C) before and after implementation of V-IMPACT. Secondary outcomes included the proportion who received urine microalbuminuria screening and were prescribed statins, ACE or ARBs.

RESULTS: Our propensity-matched cohort included 9,150 veterans split evenly between those who participated in V-IMPACT and those who remained in usual care. Mean HbA1C decreased from 7.35% to 7.29% among diabetics who were exposed to V-IMPACT and from 7.29% to 7.23% among those receiving traditional in-person care before and after V-IMPACT implementation. No significant difference was found in the change in HbA1C between groups (difference-in-differences estimate, 0.0035%; -0.034 to 0.041%). We observed a 4.1% (95% CI 1.4-6.8%) greater absolute increase in the proportion of diabetic Veterans prescribed statins in the V-IMPACT group compared to the control group, and a 5.7% greater increase in the proportion prescribed ACE/ARBs. V-IMPACT implementation was not associated with significant changes in the proportion of veterans receiving urine microalbuminuria screening (-0.06%, 95% CI -2.9 to 2.8).

CONCLUSIONS: The quality of diabetes care delivered by a longitudinal virtual primary care model was similar if not better than traditional in-person care.

IMPACT OF MASSACHUSETTS' AMBULANCE DIVERSION BAN ON ED DESTINATION PATTERNS BY RACE/ETHNICITY

Amresh D. Hanchate[1]; Michael Paasche-Orlow[2]; William E. Baker[3]; Meng-Yun Lin[1,4]; James Feldman[5]. [1]Social Sciences and Health Policy, Wake Forest School of Medicine, Winston-Salem, NC; [2]General Internal Medicine, Boston Medical Center Corporation, Boston, MA; [3]Emergency Medicine, Boston University, Boston, MA; [4]Section of General Internal Medicine, Boston Meidcal Center, Boston, MA; [5]Emergency Medicine, Boston University School of Medicine, Boston, MA. (Control ID #3375156)

BACKGROUND: The impact of ambulance diversion (AD) in response to ED crowding and AD bans is largely unknown despite decades of AD and growing experience with AD bans. We aimed to examine the association between AD and destination ED patterns incorporating Massachusetts' 2009 AD ban as a quasi- natural experiment. Our focus was on concordance in destination ED across patients of different race/ethnicity from the same geographic location, since prior literature indicates that disparities in patient outcomes are associated with which EDs/hospitals patients are treated in.

METHODS: Using administrative data for a national sample of Medicare enrollees (2007-2012) aged 66 and older, we selected all zip codes with at least 10 Hispanic, 10 (non-Hispanic) black and 10 (non-Hispanic) white enrollees and obtained data on all EMS transports to ED before and after the ban. We identified the most frequent ED destination of white transported patients as the reference ED (RefED) and defined a dichotomous indicator (0/1) of whether each EMS transport in each zip code was to the respective RefED as the main outcome. We treated Massachusetts residents as the target population of the ban and residents of 18 other states as the comparison population. Based on a difference-in-differences specification of a linear probability regression model, with zip code fixed effects, and adjusting for patient demographics, ED diagnosis and comorbidities, we estimated the change in the proportion of transports to the RefED associated with the ban. We also examined transportation to a safety-net ED.

RESULTS: In our study cohort of 843,247 enrollees from 3,354 selected zip codes, there were 361,006 EMS transports to an ED. At baseline the proportion of transports to the RefED was 61.0 percent overall, and lower among blacks (46.1 percent) and Hispanics (53.0 percent) relative to whites (64.2 percent; all p-values < 0.01). The ban was associated with a 2.7 percentage point reduction in the proportion transported to RefED among Massachusetts patients (95% CI, 0.8% to 4.6%), with no difference by race/ethnicity. At baseline, the proportion transported to a safety-net ED was higher among blacks (28.4 percent) and Hispanics (26.1 percent) relative to whites (16.1; all p-values < 0.01). Among white patients, the ban was associated with a 1.2 percentage point reduction in transportation to a safety-net ED (95% CI, 0.2% to 2.2%). The corresponding change among blacks was similar, but among Hispanics there was a 3.0 percentage point increase in transportation to a safety net (95% CI, 0.3% to 5.7%).

CONCLUSIONS: Black and Hispanic EMS patients were less likely to be transported to the RefED as compared to their white counterparts from the same zip code location. The AD ban in Massachusetts was associated with a reduction in transportation to the RefED among all groups. As RefED is usually the nearest facility, a plausible implication of our findings is that destination ED is influenced by patient preference.

IMPACT OF MEDICAID EXPANSION ON MOUD TREATMENT ACCESS FOR OPIOID USERS EXPERIENCING HOMELESSNESS

Natalie Swartz[3]; Avik Chatterjee[1,2]; David M. Cutler[4]. [1]Internal Medicine, Boston University School of Medicine, Boston, MA; [2]Boston Health Care for the Homeless Program, Boston, MA; [3]Health and Society, Harvard College, Cambridge, MA; [4]Economics, Harvard University, Cambridge, MA. (Control ID #3390619)

BACKGROUND: State Medicaid expansions under the 2010 Affordable Care Act increased access to medications for opioid use disorder (MOUD) in the general population. No studies have examined how Medicaid expansion affected MOUD access for people experiencing homelessness, who face higher opioid mortality than individuals who are housed. People experiencing homelessness face challenges with coordination of care and stigma that we hypothesized may reduce their MOUD access gains after expansion.

METHODS: Data were obtained from the Treatment Episodes Data Set-Admissions for 2000-2017. The sample consisted of 7,245,956 admissions for which opioid use was the primary substance. The primary outcome variable indicated whether admission treatment plans included MOUD. The first regression specification used difference-in-differences to evaluate whether Medicaid expansion's effect on the proportion of treatment admissions including MOUD differed between housed and homeless clients. The second regression specification examined whether this effect was differential for outpatient admissions, given that outpatient episodes administer MOUD more frequently and that people experiencing homelessness are less likely to receive outpatient treatment. Controls were included for socio-economic demographics, referral source, and clinical severity.

RESULTS: Across states, people experiencing homeless made up a mean (SD) of 13.9% (5.2%) of admissions. The mean proportion of admissions with planned MOUD was 33.5% (18.1%) for housed clients and 17.1% (10.2%) for homeless clients.

Medicaid expansion was associated with a 10.5 (95% CI, 3.3 to 17.8) percentage point increase in the proportion of MOUD-inclusive treatment plans. The effect of the intervention on people experiencing homelessness was not statistically different (95% CI, -9.4 to 3.6). People experiencing homelessness, however, were overall 12.4 (95% CI, -18.0 to -6.8) percentage points less likely to have MOUD treatment plans.

After adding a treatment setting interaction term, expansion was only associated with an MOUD increase in outpatient settings, with a 13.0 (95% CI, 3.7 to 22.3) percentage point increase in MOUD likelihood. This increase was not statistically different for homeless clients in outpatient settings in expansion states. People experiencing homelessness, however, were 25.9 (95% CI, -29.6 to -22.2) percentage points less likely to access treatment in an outpatient setting.

CONCLUSIONS: State Medicaid expansion increased the likelihood of planned MOUD among housed and homeless clients alike at substance use treatment centers. Yet, the pre-existing disparity in access between the groups persisted, indicating that barriers beyond insurance reduce the likelihood of planned MOUD for this vulnerable population.

IMPACT OF MEDICAID EXPANSION ON THE HOSPITAL USE PATTERNS OF SUPER- UTILIZERS

Zach Kaltenborn[2]; Brian Hilliard[3]; Jonathan D. Kirsch[2]; Michael Rhodes[6]; Koushik Paul[4]; Elizabeth A. Rogers[5]; Michael Usher[1]. [1]Department of Medicine/Division of General Internal Medicine, University of Minnesota Medical School, Minneapolis, MN; [2]Internal Medicine, University of Minnesota, Minneapolis, MN; [3]Internal Medicine and Pediatrics, University of Minnesota, Minneapolis, MN; [4]College of Pharmacy, University of Minnesota-Duluth, Burnsville, MN; [5]General Internal Medicine, University of Minnesota, Minneapolis, MN; [6]Department of Medicine, University of Minnesota, Minneapolis, MN. (Control ID #3392050)

BACKGROUND: Care fragmentation is associated with a number of clinical and socio-demographic features which have been thought to increase hospital utilization as well as morbidity and mortality. Patients who receive fragmented care at the hospital level are often underinsured and uninsured. It is unclear to what degree lack of insurance and subsequently lack of continuous preventive care drives fragmentation and high hospital use. In this study we aim to determine if Medicaid expansion was effective in improving insurance rates in this challenging population and improve hospital continuity and utilization.

METHODS: We identified high-utilizing patients within the Health Care Utilization Project's State Inpatient Dataset from 6 states: 3 that expanded Medicaid (IA, VT, NY) and 3 that did not (GA, FL, and UT) from 2011 - 2015. Super-utilizers were identified if they had 4 or more hospitalizations in 1 year. We determined the efficacy of medicaid expansion in reducing the rate of uninsured using differences-in-differences (DiD) analysis using non-expansion states as a control following the first quarter of 2014. Then we then used DiD to test the association between Medicaid expansion and the number of different hospitals visited, number of encounters, total length of stay, diagnosis rates, and charges of high utilizing patients.

RESULTS: Medicaid expansion was associated with a reduction in the number of uninsured encounters (OR 0.24, 95% CI 0.23 - 0.25, p <0.001) and specifically better for patients with fragmented care (p<0.001 for interaction). Medicaid expansion was specifically successful in reducing the rate of uninsured of patients with care fragmentation (p <0.001 for interaction). Medicaid expansion was associated with a lower degree of fragmentation as measured by number of different hospitals visited in 1 year (coef -0.025, p<0.001), lower number of encounters (coef -0.03, p<0.001), lower total charges (coef -0.249, p<0.001), but higher total length of stay, (coef 0.106, p<0.001). Hospital reported mortality and chronic diagnosis rates did not change.

CONCLUSIONS: Medicaid expansion was effective in reducing the rate of uninsured patients with care fragmentation, particularly in patients that lack continuity. We also found reductions in the degree of fragmentation, and lower hospitalization rates; however, this did not translate to a

reduction in the total number of days hospitalized nor mortality. We conclude that while improving insurance coverage improved continuity to a small degree, more work is needed to specifically address drivers of fragmentation and hospital utilization.

IMPACT OF MEDICAL SCRIBES ON CLINICAL EFFICIENCY IN ACADEMIC PRIMARY CARE

Anastasia Pozdnyakova[1]; Sandra Ham[2]; Neda Laiteerapong[3]; Wei Wei Lee[3]. [1]Pritzker School of Medicine, University of Chicago, Chicago, IL; [2]University of Chicago, Chicago, IL; [3]Medicine, University of Chicago, Chicago, IL. (Control ID #3386800)

BACKGROUND: Medical scribes are increasingly being used to assist physicians with Electronic Health Record (EHR) documentation. However, little is known about the impact of scribes on clinical efficiency in primary care. We assessed the impact of scribes on clinical efficiency in an academic internal medicine practice.

METHODS: We piloted a 3-month scribe program at an academic general internal medicine clinic with six faculty and one full-time medical scribe. The scribe drafted EHR notes that faculty reviewed and signed. Patient visits for 3 months prior to the intervention (baseline control), unscribed physician-only visits during the intervention period (concurrent control), and physician-scribe (intervention) visits were included in the study. The main clinical efficiency measures included number of patients seen per clinic session, physician time to close encounter, and patient time to check-out. Secondary measures included physician review of the problem list, immunizations, and medications. Generalized linear mixed models were used to determine the effect of scribe presence on the outcome measures. Physicians were treated as a random effect. For time to close encounter, patient visits were nested within physicians and modeled using repeated measures.

RESULTS: A total of 789 baseline control, 605 concurrent control, and 579 intervention patient visits were used for data analysis. Overall, 949 (48.8%) visits were by patients over 65 years old and 1,234 (62.5%) of visits were by women. Median physician time to close encounter (Interquartile Range [IQR]) decreased from 1.2 (5.9) and 2.9 (5.4) days for baseline and concurrent control respectively, to 0.4 (4.8) days for intervention visits ($p<0.05$ for both). Scribe presence did not affect the number of patients seen per clinic session or patient time to check-out. Compared with baseline control visits, the problem list was more likely to be reviewed during intervention visits (OR, 1.85, 95% CI 1.23-2.77, p=0.003). Similarly, current medications were more likely to be reviewed during intervention vs. baseline control visits (OR, 1.70, 95% CI 1.22-2.35, p=0.002). However, immunizations were less likely to be reviewed during intervention visits compared to baseline control visits (OR 0.55, 95% CI 0.38-0.79, p=0.002).

CONCLUSIONS: In this short pilot, we found evidence of decreased provider time to close encounter associated with scribe presence. However, the effect of scribe presence on other clinical efficiency measures was mixed. These findings suggest that hiring scribes may improve some aspects of clinical efficiency in primary care. Additional research is needed on which physicians may benefit greatest from medical scribes.

IMPACT OF NEW ONSET ATRIAL FIBRILLATION IN PATIENTS HOSPITALIZED WITH PNEUMONIA

Eric Mortensen, Nkiruka Atuegwu. Medicine, UConn Health, Farmington, CT. (Control ID #3390477)

BACKGROUND: There is little information on the incidence of atrial fibrillation ("a-fib") in patients hospitalized with pneumonia. Our aim was to assess the incidence of atrial fibrillation after hospitalization for pneumonia and the impact of a-fib on 30-day mortality.

METHODS: We conducted a retrospective cohort study using United States Department of Veterans Affairs (VA) national data including patients >65 years hospitalized with pneumonia in fiscal years 2002-2007 that did not have a prior diagnosis of a-fib. We included only the first pneumonia-related hospitalization. We identified patients who had a new diagnosis of a-fib within 30-days of admission. The primary outcome was all-cause 30-day mortality. Our primary analysis was a multilevel regression model, adjusting for >40 potential confounders including sociodemographics, health care utilization, comorbidities, medications, and severity of illness.

RESULTS: We identified 38,679 patients who met the inclusion criteria. Of these, 2,690 (7%) had a new diagnosis of a-fib within 30-days of admission. In the univariate analysis, a-fib was associated with increased 30-day mortality (20.1% vs. 13.2%, P<0.0001). In the multivariable regression model, incident a-fib was significantly associated with increased 30-day mortality (odds ratio 1.32, 95% confidence interval 1.18-1.47).

CONCLUSIONS: A clinically significant number of patients hospitalized for pneumonia have new onset a-fib and it is associated with increased 30-day mortality. Additional research is needed to identify the potential causes of a-fib as well as to determine the ideal way to manage these patients.

IMPACT OF PRIMARY AND RECURRENT CLOSTRIDIOIDES DIFFICILE INFECTION ON PATIENT QUALITY OF LIFE

Zheyi Han[1]; Abhishek Deshpande[2]. [1]Lerner College of Medicine, Cleveland Clinic, Cleveland, OH; [2]Medicine, Cleveland Clinic, Cleveland, OH. (Control ID #3363361)

BACKGROUND: *Clostridiodes difficile* infection (CDI) is associated with significant morbidity and mortality and places a huge burden on our healthcare system. Patients with CDI experience significant decrements in quality of life (QoL), but evidence for these decrements is limited. Here, we assessed the impact of CDI on QoL using the recently developed, disease specific, health-related quality-of-life questionnaire, Cdiff32 in a cohort of hospitalized patients.

METHODS: We surveyed adults who were hospitalized at Cleveland Clinic main campus from July to December 2019 and were diagnosed with CDI. Patients were identified as having CDI if they were symptomatic (≥3 episodes of diarrhea in 24 hours) and had a positive laboratory test positive for *C. difficile* (toxin gene PCR and/or toxin EIA). Patients were consented and completed both the CDI-specific Cdiff32 questionnaire and the generic Patient-Reported Outcomes Measurement Information System – Global Health (PROMIS-GH) questionnaire at bedside. We collected demographic and relevant clinical data from the electronic health records (EHR), including CDI severity and past history of CDI. The Cdiff32 scores were converted from a 5-point Likert scale to a 100-point scale, with 100 representing the best QoL. Overall and subdomain (physical, mental, social) QoL scores were calculated from Cdiff32 and PROMIS-GH responses. PROMIS-GH scores from our cohort were compared to the general population T-score of 50 using one- sample t-tests. We performed univariate analysis for potential predictors of Cdiff32 scores (age ≥65 or <65, sex, recurrent CDI, CDI severity, and presence of immunosuppression) using two-sample t-tests. Finally, we constructed a multiple linear regression model to identify predictors for Cdiff32 scores.

RESULTS: A total of 92 inpatients (mean age =58.4 years, 52.2% male, 88% white) diagnosed with CDI completed the QoL questionnaire survey. Mean length of stay at the time of survey was 11.6 days. Most patients experienced primary vs recurrent CDI (88% vs 12%), and most cases of

CDI were either non-severe (44.6%) or severe (50%), with only 5 cases (5.4%) being fulminant. Mean Cdiff32 score was 48.7±15.5. Cdiff32 subdomain scores for the physical, mental and social health subdomains were 51.5±17.5, 44.4±16.8 and 58.1±22.2, respectively. PROMIS-GH physical ($T = 37.2$, $p<.001$) and mental ($T = 43.7$, $p<.001$) health domain scores were lower compared to the general population. On univariate analysis, CDI recurrence status and CDI severity were associated with lower Cdiff32 scores (primary vs recurrent, 49.8 vs 40.1, p=.046; non-severe vs severe, 52.6 vs 46.1, p =.048). The multiple linear regression model did not identify any independent predictors influencing the Cdiff32 scores.

CONCLUSIONS: CDI is associated with significantly decreased QoL in multiple health domains. The Cdiff32 questionnaire is sensitive to decreases in QoL experienced by patients with CDI, particularly those with recurrent disease.

IMPACT OF REDUCED MEDICATION OUT-OF-POCKET COSTS ON ACUTE DIABETES COMPLICATIONS AND HIGH-ACUITY OUTCOMES: A NATURAL EXPERIMENTS FOR TRANSLATION IN DIABETES (NEXT-D2) STUDY

James F. Wharam[1]; Jamie Wallace[2]; Matthew Lakoma[3]; Christine Lu[3]; Fang Zhang[4]; Stephen B. Soumerai[5]; Dennis Ross-Degnan[6]. [1]Population Medicine, Harvard Medical School and Harvard Pilgrim Healthcare, Boston, MA; [2]Health Policy and Insurance Research, Harvard Pilgrim Health Care Institute, Boston, MA; [3]Department of Population Medicine, Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, MA; [4]Department of Population Medicine, Harvard Pilgrim Health care Institute, Boston, MA; [5]Department of Population Medicine, Harvard Medical School, Boston, MA; [6]Population Medicine, Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, MA. (Control ID #3391301)

BACKGROUND: In an attempt to improve diabetes outcomes, some employers and insurers have adopted Preventive Drug Lists (PDLs) that reduce out-of-pocket costs for antidiabetic and cardioprotective medications to $0. We sought to determine whether shifts to PDL coverage reduce acute diabetes complications and high-acuity outcomes among commercially insured patients with diabetes.

METHODS: Our study design was a natural experiment comparing changes in outcomes 1 year before and after the PDL switch in matched study groups. This study was completed using a national commercial and Medicare Advantage health insurance claims database. The Intervention group included 16,174 commercially-insured diabetes patients age 12-64 switched by their employers to PDL coverage; the Control group included 711,085 coarsened exact-matched contemporaneous patients whose employers offered no PDL. We conducted similar analyses in a subset of low-income members switched to PDL plans and their matched controls. Outcomes were acute diabetes complication visits, high-severity emergency department visits, and hospitalization days.

RESULTS: Transition to the PDL was associated with a relative pre-post change of 1.6% (95% confidence interval, -7.2% to 10.3%) in acute diabetes complication visits, -3.2% (-14.4% to 8.1%) in high-severity emergency department visits, and 2.2% (-9.8% to 14.1%) in hospitalization days. Findings were similar in the low-income subgroup.

CONCLUSIONS: We did not find detectable changes in acute diabetes complication visits and high-acuity outcomes among diabetes patients switched to low drug cost sharing health plans. Further research should assess longer-term outcomes and examine effects of reducing financial barriers to outpatient and emergency department care.

IMPACT OF THE 2009 U.S. PREVENTIVE SERVICES TASK FORCE MAMMOGRAPHY SCREENING RECOMMENDATIONS: ARE PHYSICIANS ENGAGING IN SHARED DECISION MAKING?

Kathryn A. Martinez, Abhishek Deshpande, Michael B. Rothberg. Center for Value-Based Care Research, Cleveland Clinic, Cleveland, OH. (Control ID #3387485)

BACKGROUND: In 2009 the U.S. Preventive Services Task Force (USPSTF) recommended against routine mammography in average risk women aged 40-49 years, instead recommending shared decision making (SDM). Population-based studies show screening rates have remained static since 2009, suggesting SDM is not taking place. Yet nothing is known about how individual physicians altered their screening behavior after 2009.

METHODS: We performed a retrospective cohort study in the Cleveland Clinic Health System. Physicians were included if they had ≥20 encounters with eligible women in the period before (2006-2008) and after (2011-2015) the USPSTF guideline change. Eligible women were mammography-naïve, aged 40 to 49 years with no personal history of breast cancer or biopsy. We assessed screening rates overall in the pre-2009 and post-2009 periods and assessed changes in individual physicians' screening rates over time, defining a 10% change as meaningful. We also assessed the screening rate among patients seen by physicians new to the health system after 2009. Multivariable mixed effects logistic regression was used to assess the odds of a woman receiving screening post 2009, accounting for clustering by physician. We included each physician's pre-2009 screening rate decile as a predictor in the model, as individual screening rates should change after 2009 if they were engaging in SDM. Patient characteristics included race, marital status, insurance type and median household income. Physician characteristics included gender, age, specialty and practice location.

RESULTS: In the pre-2009 period, the 112 study-eligible physicians saw 20,781 study-eligible patients, 50% of whom received mammography. In the post-2009 period, these physicians saw 15,630 patients, 45% of whom received mammography. For patients seen by physicians new to the health system after 2009, the mammography rate was 33%. More than two-thirds (68%) of study-eligible physicians had post-2009 screening rates within 10% of their pre-2009 rate, while 18% had screening rates that were at least 10% higher. In the mixed effects model of the odds of a patient receiving mammography post 2009, the strongest predictor of mammography receipt was their physician's pre-2009 screening rate (aOR:2.90 per decile;95%CI:1.68-4.98). Compared to having a male physician, having a female physician was associated with higher odds of screening (aOR:1.35:95%CI: 1.14-1.58). Black patients were more likely to get screened than white patients (aOR:1.49; 95%CI:1.30-1.71).

CONCLUSIONS: For patients, the strongest predictor of mammography receipt after 2009 was their physicians' pre-2009 screening rate. Physicians were therefore not individualizing screening decisions by routinely engaging patients in SDM. The screening rate was lower for physicians new to the system after 2009. Interventions aimed at increasing SDM should focus on physicians who practiced before 2009, as longstanding screening behaviors may be harder to change.

IMPACT OF THE YALE INTERNAL MEDICINE CLINICIAN-EDUCATOR DISTINCTION PATHWAY ON INTERNAL MEDICINE RESIDENCY GRADUATES

Yihan Yang[1]; Katherine A. Gielissen[2]; Donna Windish[3]. [1]Internal Medicine, Yale, New Haven, CT; [2]Internal Medicine - Pediatrics, Yale-New Haven Hospital, New Haven, CT; [3]Internal Medicine, Yale University, Cheshire, CT. (Control ID #3391850)

BACKGROUND: Many residency programs offer curricula to prepare trainees to thrive as clinical- educators. Little is known, however, about the impact of these programs on resident participants. In 2016, Yale's Internal Medicine Residency Programs launched the Clinician-Educator Distinction (CED), a 2-year certificate program aimed to help residents gain proficiency in teaching, curriculum design, and medical education scholarship. We aimed to determine: 1) why residents enroll in the CED, 2) the impact of the CED, and 3) the strengths and limitations of the CED.

METHODS: Between 2016-2019, 4 cohorts of residents enrolled in the CED (n=65), with 23 of 29 graduates completing the Distinction. We conducted a qualitative study of the graduates who had enrolled in the CED using purposive sampling, representing participants across a variety of career paths and including graduates who enrolled but did not complete the CED. Individual, in-person or telephone interviews were conducted using a semi-structured interview guide. Interview transcripts were analyzed and coded using thematic analysis. A coding structure was developed using an iterative, constant comparative method of analysis. Interviews were conducted until thematic saturation was reached.

RESULTS: Of 16 participants sampled, 3 did not complete the CED, 10 graduated in 2019, and 11 are currently in academic medicine. Motivations for applying to the CED included improving teaching skills, proving or exploring interest in medical education, filling a gap in skillset, as well as fear of "missing out." Regardless of CED completion, participants reported positive impacts from the CED, such as building a foundation in educator skills, career development, membership in a medical educator community, and motivation to "go the extra mile." A common theme of unexpected professional identity formation also emerged: most residents enrolled in the CED focused exclusively on teaching but realized through the CED that "successful" clinician-educator careers are quite diverse and often require competencies aside from teaching. Effective components of the CED included relevance of curricular topics, flexibility of requirements, small group interactive didactics, direct observation with feedback, and exposure to dedicated faculty. Areas of improvement included increasing medical education scholarship mentoring, accessibility of didactics, clarity of requirement logging, and availability of funding.

CONCLUSIONS: A longitudinal clinician-educator curriculum comprised of flexible requirements, small group-based didactic sessions, observed teaching with feedback, and a mentored project helps residents develop educator skillsets and broadens participants' understanding of clinician-educator careers. Results from our study can help other internal medicine residency programs develop or enhance their clinician- educator training curricula. Future studies will need to assess the long-term impacts of CED participation.

IMPLEMENTATION AND EFFECTIVENESS OF RHEUMATOLOGY E-CONSULTS INTERVENTION TO REDUCE SPECIALIST WAIT TIMES

Elizabeth Malcolm[1]; Zachary Brandon[2]; John Paul Shoup[4]; Lauren Wilson[2]; Heather King[2]; Allison Lewinski[2]; Melissa Greiner[2]; shauna malone[2]; Julie Miller[2]; Teresa K. Tarrant[2]; Robert Keenan[2]; Alex H. Cho[2]; Donna Phinney[3]; Megan Oakes[2]; Kevin Shah[2]. [1]General Internal Medicine, Duke University School of Medicine, Durham, NC; [2]School of Medicine, Duke University, Durham, NC; [3]Medicine, Duke University, Durham, NC; [4]BJC Healthcare, Wentzville, MO. (Control ID #3391547)

BACKGROUND: US health systems have adopted e-consults to extend the specialist workforce and improve care efficiency. Though studies have demonstrated a range of benefits for e-consults, few incorporate comparison groups, focus on rheumatology, or supply understanding of factors influencing primary care provider's adoption of e-consults for rheumatology care. We sought to assess the impact of a mandatory rheumatology e-consult program on specialty appointment wait times and to understand factors influencing providers' e-consult adoption.

METHODS: We implemented e-consults in four clinics in our network of 33 community-based primary care clinics in an academic health system. We retrospectively assessed the implementation and effectiveness of the pilot comparing four matched clinics not offered the intervention. Our primary outcome was wait time from e-consult or traditional referral to first scheduled specialty appointment 1-year pre- and post- implementation. We conducted multivariable adjusted quantile regression testing for differences in median wait times and a differences- in-differences analysis. We abstracted EHR data to assess provider adoption and rheumatologist recommendations. We conducted semi-structured telephone interviews with a purposeful sample of 11 primary care providers (PCP) in the four pilot clinics and one in-person focus group of 8 rheumatologists. We used applied thematic analysis based on an a priori framework to analyze qualitative data.

RESULTS: 809 patients had scheduled appointments across the pre- and post- implementation periods in 4 implementation and 4 comparison clinics. There was a significant difference in the appointment wait time pre- to post- implementation across all clinics (-25.1 days, 95%CI -40.9- -9.3, $p<0.001$). We observed a trend towards decreased median wait times (-17.1 days, 95%CI -39.1- +4.8, $p= 0.12$) among the e-consult clinics (adjusted for age, race, clinic pair, and primary payer). The trend persisted in a sensitivity analysis adjusting for within-clinic similarities. Key implementation themes included: meeting patient needs, primary care provider task-technology fit, specialist task-technology fit, virtual team care, and technology features. Primary care providers perceived e-consults to be most helpful for initial diagnostic work-up of patients with suspected rheumatologic disease, and least helpful in cases such as fibromyalgia, where there is no clear specialty "home" for the condition. Interesting subthemes emerged around "virtual team care" including the need for better role clarity and a mechanism for iterative communication over time.

CONCLUSIONS: Our work demonstrates the impact of rheumatology e-consults implementation in community primary care practices in our large academic health system. Implications for practice include an enhanced focus on role clarity, communication, and task-technology fit in e-consult implementation. Further research could focus on features of high quality virtual team care

IMPLEMENTATION OF AN ELECTRONIC MEDICAL RECORD PRACTICE ALERT TO IDENTIFY PATIENTS FOR ADVANCE CARE PLANNING FOR THE META-LARC ACP STUDY

Jessica Ma[1]; Jared Lowe[2]; Callie Berkowitz[2]; Azalea Kim[2]; Ira Togo[4]; R. Clayton Musser[2]; Nikita Shah[7]; Jonathan Fischer[5,6]; Annette M. Totten[3]; Rowena Dolor[2]. [1]Durham Center of Innovation to Accelerate Discovery and Practice Transformation, Durham VA Health Care System, Durham, NC; [2]Department of Medicine, Duke University School of Medicine, Durham, NC; [3]DMICE, OHSU, Milwaukie, OR; [4]Duke Office of Clinical Research (DOCR), Duke University, Durham, NC; [5]Department of Community & Family Medicine, Duke University, Durham, NC; [6]Duke Palliative Care, Duke University, Durham, NC; [7]Duke Clinical & Translational Science Institute, Duke University School of Medicine, Durham, NC. (Control ID #3390063)

BACKGROUND: Only a quarter of Americans have a documented advance directive and almost three- quarters of elderly patients at high risk of dying have not discussed their medical treatment preferences with their physician. Health data science and information technology can overcome barriers in identifying appropriate patients for Advance Care Planning (ACP) discussions at the point of care and facilitate the workflow within Primary Care (PC) settings. We developed a novel point-of-care alert to increase patient identification and referral of patients

eligible for ACP discussions within Duke PC clinics participating in the Meta-LARC ACP study.

METHODS: An algorithm within the Epic Electronic Health Record (EHR) at Duke was developed to identify patients who may benefit from ACP for the Meta-LARC ACP study, a US-Canadian multi-site cluster randomized trial comparing clinician-focused or team-based implementation of the Serious Illness Care Planning (SICP) toolkit. This algorithm identified patients who would likely benefit from ACP (age 70 or greater, with 3 or more of a specific list of co-morbidities, or with 2 or more hospitalizations in the past year) with a Best Practice Advisory (BPA) alert in the EHR. The alert reminded clinicians to have an ACP discussion and refer patients who had a conversation to the study team. Alerts and user actions in response to them were followed and measured.

RESULTS: Within 6 Duke PC clinics, 41 clinicians and 2 nurses have been trained to use the SICP toolkit, view the ACP score and receive the Meta-LARC study alert. Within the first 6 months (June – Nov 2019), 1,775 patients were identified by the ACP algorithm. Patients had a mean age of 78 (SD 9) years and were 59% female and 65% Caucasian. The alert occurred a median 137 (IQR 32 - 225) times per provider, an average of 2.8 (SD 1.0) times per patient. Top reason for alert dismissal was timing-related factors (e.g. plan for future visit, acute care visit). 172 patients were referred to the study via the alert. The referral rate per patient was 3.1% (IQR 0 – 20.7) in the team-based implementation arm and 4.6% (IQR 0.1 – 11.2) in the clinician-focused implementation arm.

CONCLUSIONS: This EHR-based algorithm with a point-of-care alert has streamlined patient identification and referral of patients undergoing ACP (SICP) discussions in primary care clinics at Duke. Further analyses will be conducted to understand whether alert-based identification results in higher rates of ACP documentation within the EHR. At the end of the study, providers will be surveyed about the usefulness and their experience with the study-related alert, plus whether they would recommend ongoing use of the alert in their clinic as part of routine care. Knowledge of provider utilization and interaction with alerts can help us understand how this innovation can be employed at other institutions to facilitate ACP discussions and referral to research studies.

IMPLEMENTATION OF A PHYSICIAN ACCEPT NOTE TO IMPROVE INTERHOSPITAL TRANSFER DOCUMENTATION ON GENERAL MEDICINE SERVICES: A QUALITY IMPROVEMENT (QI) PROJECT

Marc Heincelman. Internal Medicine, Medical University of South Carolina, Charleston, SC. (Control ID #3390360)

BACKGROUND: Several population wide studies have demonstrated worse outcomes for patients admitted to hospitals following interhospital transfer compared to patients admitted directly through the emergency department (ED); specifically increased risk-adjusted mortality, adverse events, and length of stay. One proposed etiology for the worse outcomes includes the transfer process itself leads to discontinuity of care. Based on a 2018 survey of internal medicine residents and hospitalists at the Medical University of South Carolina (MUSC), 74% of providers responded that interhospital transfer patients always/frequently arrive without necessary transfer records and 69% responded that a physician accept note was rarely/never available at the time of transfer. Interhospital transfer instruments, based on the transfer phone call, have demonstrated improved outcomes related to transfers. The objective of this study is to standardize interhospital transfer documentation on general medicine services by implementation of a physician accept note into the electronic health record (EHR) at the time of the transfer.

METHODS: In April 2019, baseline data regarding physician documentation of the interhospital transfer phone conversation into the EHR was obtained for patients transferred to general medicine services at MUSC. The QI intervention included creation of a physician accept note, implementation of the note into the electronic health record, and physician education. New patients without a medical record number (MRN) at the time of transfer request were excluded as physicians were unable to document in the electronic health record until an MRN was created. In August 2019, the QI intervention was implemented. The primary outcome was utilization of the physician accept note. Secondary outcomes included transfer to the intensive care (ICU) within six hours of admission as well a change in provider perception related to interhospital transfers. Pearson's chi-square test was performed to determine difference in proportions between the pre/post-intervention outcomes.

RESULTS: Baseline data obtained in April 2019 revealed only 2% of interhospital transfer patients had any physician documentation of the phone call between the outside hospital physician and the MUSC accepting physician. After implementation of the QI intervention, a 5 month post-intervention chart review performed in December 2019 demonstrated 75% of interhospital transfer patients had documentation of a physician accept note ($p<0.001$). Please note, 8 months of data will be available at the time of the SGIM presentation in May. Regarding secondary outcomes, the proportion of patients transferred to the ICU within six hours of admission and a post-intervention survey of provider perception of the interhospital transfer process will be performed in April, as not all residents have been exposed to the intervention at this time, with results available at the time of SGIM.

CONCLUSIONS: Implementation of a physician accept note into the EHR is one way to improve communication and documentation of interhospital transfer patients to general medicine services. Secondary outcomes will determine whether the physician accept note leads to decreased transfer to the ICU within six hours and improved perceptions related to the interhospital transfer process.

IMPLEMENTATION OF DEPRESSION SCREENING AT A STUDENT-RUN FREE CLINIC UNCOVERS HIGH RATES OF DEPRESSION

Yu Han Chen[1]; Evan Balmuth[1]; Brian LaGrant[1]; Lillye P. Anderson[1]; Nicolas J. Blobel[1]; Alexandra H. Miller[2]; Ashita S. Batavia[3]; Pamela Charney[4]. [1]Weill Cornell Community Clinic, Weill Cornell Medicine, New York, NY; [2]Medicine, Weill Cornell Medicine, New York, NY; [3]Medicine, Weill Cornell Medical College, Larchmont, NY; [4]Internal Medicine, Weill Cornell Medical College, New York City, NY. (Control ID #3391862)

BACKGROUND: Nearly 1 in 10 uninsured New Yorkers experience symptoms of depression, yet there is limited information on depression screening rates in free clinics. The Weill Cornell Community Clinic (WCCC) is a student-run free clinic that provides comprehensive multidisciplinary care to uninsured New Yorkers. The WCCC currently screens all patients for depression using the Patient Health Questionnaire (PHQ). The PHQ is verbally administered in the patient's primary language. If the initial 2-item screen (PHQ2) is positive, an additional 9-items (PHQ9) are used to estimate the severity of depression. Here we report the utility of PHQ in screening for depression in a student-run free clinic and the rate of follow-up at the WCCC mental health clinic, which is staffed by a board-certified psychiatrist.

METHODS: All WCCC patients seen between April 2017 and September 2019 were verbally screened for depression by a trained medical student using the PHQ2 (n=138) and, if positive, the PHQ9. Score on the PHQ9 range from 0 to 27, and correlate with depression severity. Patient demographics, PHQ scores, and referral to the WCCC mental health clinic were assessed using descriptive statistics.

RESULTS: 39.1% (N=54) of WCCC patients had a positive PHQ2 depression screen. Of these patients, 75.9% (N=41) had a positive

depression screen with the PHQ9 and were referred to the WCCC mental health clinic. Among patients that screened positive, six individuals reported that they were currently utilizing community mental health resources. Among the remaining patients who screened positive for depression, 62.9% (22 out of 35 patients) accepted a referral to the WCCC mental health clinic, while 13 declined referral. Among patients with positive depression screens, the demographics of patients who accepted a referral to psychiatry were similar to those who declined: age (41.0 vs. 40.7), distance traveled to WCCC (6.92 vs. 6.58), language discordance (27% vs. 38%), and the number of other medical comorbidities (6.68 vs. 5.38). Interestingly, patients who accepted referral scored significantly higher on PHQ9 than those who declined referral (10.43 vs. 7.08, p=0.013).

CONCLUSIONS: The WCCC was able to successfully implement the PHQ as a point-of-care depression screening tool for all patients. Our data reveal a 4-fold higher rate of depressive symptoms relative to city- wide estimates for uninsured patients. This underscores the need for consistent wide-spread depression screening at free clinics serving the uninsured. Referral acceptance to the WCCC mental health clinic was higher than the national average for primary care settings (62.9% vs. 50.0%), and may reflect patient's existing trust in the WCCC and the convenience of a real-time on-site referral. Further research is needed to understand the drivers of a patient's willingness to accept a referral to psychiatry.

IMPLEMENTATION OF MEDICATION TREATMENT FOR OPIOID USE DISORDER IN CORRECTIONAL SETTINGS

Sachini Bandara, Alene Kennedy-Hendricks, Sydney Merritt, Colleen Barry, Matthew Eisenberg, Brendan Rabideau, Brendan Saloner. Health Policy and Management, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD. (Control ID #3390578)

BACKGROUND: Individuals who are incarcerated have a substantially elevated risk of experiencing a fatal overdose when reentering the community. Opioid agonist treatments (i.e., methadone and buprenorphine) can significantly reduce risk of overdose. However, access to these medications remains limited in most correctional settings. Efforts are increasing to expand access to these medications as early adopters, such as Rhode Island, have demonstrated notable reductions in overdose mortality and as litigation and state legislation compel correctional facilities to provide these medications. Yet little is known regarding best practices for implementing medication in correctional settings. This study identifies perceived barriers and facilitators related to provision of medications for treating OUD in correctional settings among correctional security and correctional health officials.

METHODS: The authors have conducted 35 of 50 interviews with leaders and decision-makers in correctional settings with knowledge of substance use treatment protocols. Interviews are audio-recorded, transcribed, and analyzed using a hybrid inductive-deductive approach to coding for key themes. Participants include leaders in correctional systems that currently provide medication treatment as well as systems that do not offer medication treatment for OUD beyond limited subgroups (e.g., pregnant women). Participants include wardens, sheriffs, correctional medical directors, probation and parole agency directors, and other leadership roles.

RESULTS: Key barriers to implementation include: lack of knowledge of and stigma related to medication treatment; limited community experience with medication treatment; compliance with DEA and other regulations for providing medications within correctional facilities; medication dispensation and management of relationships with medical vendors that oppose medication treatment. Facilitators include: leadership commitment to medication treatment; aligned perspectives on these medications among correctional officials and the medical vendor; robust medication treatment infrastructure in the community; Medicaid expansion to support continuity of care following release; external grant funding; and a local convening body that brings together multiple sectors to address overdose mortality.

CONCLUSIONS: Broadening access to medication treatment for OUD in correctional settings is feasible across diverse geographic settings. Jurisdictions interested in expanding access to medication treatment can learn from one another's experiences managing compliance with the regulatory requirements related to providing these medications, the logistics of dispensing medication within correctional facilities, and building mechanisms to ensure continuity of treatment. However, stigma and misinformation remain major barriers to expansion of these medications among both correctional officials and medical providers serving persons under correctional supervision.

IMPLICIT BIAS: TRENDS IN EVALUATION

Elisabeth Cannell[2]; Tiffany E. Cook[3]; Jeffrey Wilhite[2]; Lisa Altshuler[2]; Richard E. Greene[1,2]. [1]Medicine, NYU Grossman School of Medicine, New York, NY; [2]Division of General Internal Medicine, New York University School of Medicine, New York, NY; [3]Office of Diversity Affairs, NYU Grossman School of Medicine, New York, NY. (Control ID #3391068)

BACKGROUND: Academic medical centers have identified a need to train faculty about implicit bias. Prior to interview season, NYU held implicit bias workshops with departments, in which participants were asked to evaluate applicants for positions in their departments. Participants rated applicants on a scale from 1-10 and listed 2 positive and 2 negative adjectives about them. The resumes were identical except for gender and race. Individual assessment forms were collected without data to identify the participants or the departments in which they worked.

METHODS: The adjectives were categorized into 10 types of positive adjectives and 7 types of negative adjectives in order to analyze any systematic differences in which types of adjectives were using based on demographics. For example, the most common positive categories of adjectives related to education/experience, work ethic, and intelligence, and the most popular negative categories were related to dishonesty, social difficulty, and assertiveness. Chi-square tests were performed on positive adjectives and negative adjectives testing differences between two genders (Woman, Man) and three racial groups (Black, Caucasian, Latinx).

RESULTS: N=153 applicant evaluations were reviewed. There was no significant difference in the final rating scores for the different applicants. The gender data showed a significant difference in how men and women were described with the second of the two positive adjectives ascribed (p = 0.012, chi=21.063). For negative adjectives, the category of the first adjective written was significantly different between men and women (p = 0.043*, chi = 13.018). The most noteworthy distributions of adjectives were that "bright" was used for only females in the intelligence category, "assertive" was more often used positively for men and negatively for women. Evasiveness was more often attributed to men than women, while distractibility by familial issues was more often applied to women. Regarding race and ethnicity, there were no significant differences among race in the positive adjectives given. However, the second positive adjective given by race/ethnicity showed some statistically significant difference by category (p =0.007*, chi=35.96). With regard to the negative adjectives given, the first was statistically significant, describing Caucasians as difficult to get along with. The most noteworthy distributions of adjectives were that "hardworking" was used mostly for Latinx and intelligence categories were less likely to be used for Black applicants.

CONCLUSIONS: Even during activities that are part of implicit bias workshops, differences in perceptions of race/ethnicity and gender persist with identical descriptions of hypothetical candidates. These data also suggest that workshop participants were more likely to ascribe similar adjectives

by gender or race/ethnicity as their first instinct but when assigning a second adjective, they may have leaned more on bias or stereotype.

IMPROVING CHOLESTEROL GUIDELINE ADHERENCE IN OUTPATIENT CLINICS BY EMBEDDING ASCVD RISK CALCULATION INTO THE ELECTRONIC HEALTH RECORD

Kevin Smith[1]; Stephen A. Petty[1]; George Waits[3]; Richa Bundy[1]; Alain Bertoni[2]; Claudia L. Campos[1]. [1]Internal Medicine, Wake Forest Baptist Medical Center, Winston Salem, NC; [2]Epidemiology and Prevention, Wake Forest Baptist Medical Center, Winston-Salem, NC; [3]Cardiology, Houston Methodist, Houston, TX. (Control ID #3391483)

BACKGROUND: The 2013 American College of Cardiology (ACC) and American Heart Association (AHA) guidelines for cholesterol treatment recommend the use of the Pooled Cohort Equation to estimate 10-year risk of cardiovascular events using an atherosclerotic cardiovascular disease (ASCVD) calculator to guide therapy. Online calculators are time consuming during busy clinic workflows and may contribute to low adoption of guidelines. Our objective was to examine ACC/AHA guideline adherence after automating the ASCVD calculator into the electronic health record (EHR) at 2 internal medicine clinics at Wake Forest University.

METHODS: This retrospective study examined statin prescription before and after the release of the ASCVD risk score calculator in the EHR. The analyzed population included patients with encounters from March 2018 through September 2019 who met criteria for statin therapy based on 10 year ASCVD risk (≥7.5%). The first utilization of the tool in the patient's chart was considered the index encounter to determine if the patient was prescribed a statin. We excluded those with a statin allergy, abnormal CK or ALT values. Demographic variables, ASCVD score, and statin prescription at or prior to the index encounter were collected. Statistical analysis of statin prescribing pre- and post- ASCVD score intervention was performed using McNemar's test. All other descriptive analyses utilized t-tests and chi-squared tests where appropriate.

RESULTS: A total of 1185 patients had the tool used during the study period and 778 were included for analysis. Patients were predominantly female (59%), African American (61%) and had a mean age of 58 years old. 69% of patients with an indication for statin therapy were not on a statin. After the intervention, this dropped to 26% ($p<0.0001$). Age, gender, ASCVD score, and lipid levels were not associated with statin non-prescription, though non-white patients were somewhat less likely to be prescribed a statin ($p=0.06$).

CONCLUSIONS: Automating the ASCVD calculation in the EHR increased adherence to guideline- recommended statin prescription and should be considered for implentation as a standard clinical decision support tool. In further analysis, there were no clear demographic variables that increased the likelihood of statin prescription.

IMPROVING DIABETES MEDICATION ADHERENCE THROUGH AUTOMATING PHARMACY REFILLS: A RANDOMIZED QUALITY IMPROVEMENT INTERVENTION

John Geyer[1]; Chatty O'Keeffe[2]; Kaylen Nelson[2]; Cassandra Song[3]; Christopher Vanderwarker[2,4]; Jacqueline Britton[2]; Ashok Reddy[2,5]; Linnaea C. Schuttner[2]. [1]General Internal Medicine, University of Washington, Seattle, WA; [2]VA Puget Sound Health Care System, Department of Veterans Affairs, Seattle, WA; [3]Pharmacy, VA Puget Sound Health Care System, Seattle, WA; [4]University of Washington, Seattle, WA; [5]Medicine, University of Washington School of Medicine, Seattle, WA. (Control ID #3389883)

BACKGROUND: Nonadherence to medications is common and leads to adverse health outcomes. The medication refill process is cumbersome and may impact medication adherence. Choice architecture in behavioral economics suggests that subtle design changes to systems can have an outsized effect on behavior. Applying this theory to medication refills, we examined the effects of an operational change from patient- initiated refills to a 'default' automated process. We implemented this change as a quality improvement project within the Veterans Health Administration Puget Sound Health Care System (VAPSHCS).

METHODS: Patients were eligible for inclusion if they had received any oral diabetic medication refills from VAPSHCS and had an A1c within the prior 6 months with a poor medication possession ratio (MPR < 80%, defined as a measure of medication dispensation over time). A random sample of 200 eligible patients was randomized 1:1 to an intervention of automated pharmacy refills versus usual care. In the intervention, oral diabetic medication refills were mailed to intervention patients two weeks prior to scheduled due date. Control patients received care as usual, requiring patients to self-initiate refills of medications. Enrollment occurred from April - June 2019. Outcomes were collected December 15th, 2019.

RESULTS: A total of 199 patients were randomized to intervention (n = 100) or control (n = 99) with baseline similarity in demographics between groups. On average, patients were 69.6 years old (SD 10.8), male 95.5%, white race 62.8%, with an average A1c of 7.7% and MPR for all diabetic drugs of 57.5% (SD = 22.0%). Of patients randomized to the intervention, 40 patients agreed to participate. We used logistic and linear multivariate regression models for analysis with cluster robust standard errors to account for repeat measures. In intent to treat analysis at 6 months, compared to control patients, intervention patients had no difference in A1cs (difference 0.02, P = 0.91) nor in MPR for diabetic medications (difference 5.4%, P = 0.15). Among patients who enrolled (per-protocol analysis), there was no difference in A1cs (difference 0.45, P = 0.08), but as expected, the MPR for diabetic medications was 21.8% greater than usual care patients (P < 0.001). However, for other medications not refilled automatically (statins, ACE/ARBs), the MPR was greater in the intervention group (difference 9.8%, P = 0.045). Feedback about the program was positive (75% of comments) among enrollees.

CONCLUSIONS: An automated refill process for oral diabetic medications among medication nonadherent patients did not impact glycemic outcomes after 6 months but may have improved patient refill behavior for other medications which were not part of the automated process. Future efforts to automate refills for chronic disease medications could feasibly be integrated into health care systems and may improve refill behavior for patients with poor medication adherence.

IMPROVING GUIDELINE-CONCORDANT CHRONIC OPIOID PRESCRIBING IN AN ACADEMIC PHYSICIAN PRACTICE: AN 18-MONTH FOLLOW-UP SURVEY

Mim Ari, Rebecca Chohlas-Wood, Mengqi Zhu, Lisa M. Vinci, George Weyer, Neda Laiteerapong. Medicine, University of Chicago, CHICAGO, IL. (Control ID #3392058)

BACKGROUND: Chronic opioid therapy (COT) may improve patient quality of life and pain, but is associated with risks of opioid misuse, overdose and death. In 2016, the CDC published the Guideline for Prescribing Opioids for Chronic Pain to provide recommendations for safe and effective COT in primary care settings. In order to increase guideline application to clinical practice, it is essential to evaluate the process of evolving physician practice. This study evaluated changes in physician knowledge, attitudes, beliefs, and practice patterns about chronic opioid prescribing after 18 months of continuous quality improvement efforts.

METHODS: In 2017, 37 internal medicine physicians at a single academic medical center anonymously completed a baseline survey (95% response rate). After the survey, quality improvement efforts included EHR implementation of policy changes (e.g. state law to check prescription monitoring program (PMP)), system- level changes (e.g. comprehensive urine drug screen (UDS), EHR tools), and physician-level interventions (e.g. didactics, local practice guideline creation, clinical decision support tools). An 18-month follow-up survey was administered (N=30, 77% response rate) which included questions about awareness, perceived usefulness, and practice patterns of key aspects of the CDC guideline. Items related to "regard" (biases, emotions, and expectations) for patients on COT were also assessed. Results were summarized by basic descriptive statistics. Fisher's Exact Test for binary outcomes was used to assess for significant changes (two- sided p-value <0.05) between surveys.

RESULTS: At 18-month follow-up, physicians had increased awareness of patient provider agreements (PPAs) (51% to 97%), naloxone prescribing (41% to 83%), UDS interpretation (35% to 72%) and PMP use (70% to 97%) (all p<0.001). Physicians' perceived usefulness of naloxone in managing patients on COT also increased (57% to 90%, p<0.001). Physicians' perceived usefulness of PPAs (76%) and the PMP (76%) were high at baseline and increased (83% and 90% respectively) but not significantly. In addition, physicians were less likely to report "never" adhering to guideline recommendations to use PPAs (46% to 10%), prescribe naloxone (73% to 4%), order UDS (65% to 20%), or check the PMP (27% to 3%) (all p<0.001), and were more likely to report increases in prescribing naloxone "frequently/always" (3% to 57%) and checking the PMP with every refill (27% to 80%) (p<0.001). Changes in physician regard for patients on COT were not significant.

CONCLUSIONS: After an 18-month multilevel quality improvement intervention to implement the CDC guideline for COT at an academic medical center, we increased physician levels of awareness, perceived usefulness, and self-reported guideline-concordant practice of many key CDC recommendations. Our approach to quality improvement could be adapted into other healthcare systems attempting to improve adherence to COT guidelines

IMPROVING PATIENT SAFETY CULTURE IN A COMMUNITY HOSPITAL SETTING

Eva Olariu[1]; Nathan T. Douthit[1]; Allison P. Rogers[2]. [1]Internal Medicine, Brookwood Baptist Health, Vestavia Hills, AL; [2]Medical Education - Internal Medicine, Brookwood Baptist Health, Birrmingham, AL. (Control ID #3390690)

BACKGROUND: Resident physicians do not regularly report patient safety events. According to recent literature, less than 2% of reported errors are from residents. Patient safety events increase cost, morbidity and mortality. Various methods at our institution have attempted to improve reporting events, however have only resulted in a temporary spike in reporting that decreases after the intervention. These interventions routinely fail because residents are not taught what a reportable patient safety event is, how to report events, nor have time to report events and fail to see the purpose. If residents are trained in patient safety, given protected time to report events and take part in the management of these reports this may address the failed sustainability, and finally create a successful patient safety culture.

METHODS: The subject population included residents in the PGY 1, 2, and 3 years at our institution during the 2017-2019 academic years. Events reported by residents were analyzed and compared before and after the intervention. House staff was asked to complete a survey before and after the intervention.

The intervention was a "patient safety" rotation. This involved rounding with the inpatient medicine team and assisting in identifying and reporting any patient safety errors as well as attending the institution's "patient safety huddle". This resident was required to complete online modules to receive a Basic Certificate in Quality and Safety.

Data was viewed in the password protected MIDAS system and survey results were de-identified for confidentiality. Patient safety was not negatively impacted in any way. Data was analyzed with Microsoft Excel.

RESULTS: Since the intervention, patient safety reporting dramatically increased. Within the 2 academic calendar years, 2 patient safety events were reported by residents before the intervention and 35 were reported afterwards. Before the intervention, on average 0.1 events were reported per month. This increased to approximately 4 events per month for the following 8 months after the intervention. Before the intervention, 83% of residents confirmed never having reported an error. 6 months after the intervention, this decreased to 43% of residents. Overall, our results show that the patient safety rotation intervention increased error reporting among residents and awareness to patient safety culture at our institution.

CONCLUSIONS: Improving patient safety culture is integral to the improvement of morbidity and mortality of an institution. A key component to this are residents that are forefront in many patient safety events. Our institution targeted increasing awareness and reporting of safety events via a patient safety rotation. We have found this to be a successful and welcomed addition to our program. We present the findings of our intervention with hopes that this may help other institutions to institute similar programs and eventually see dramatic improvements in patient safety culture in residency programs nationwide.

IMPROVING PRIMARY CARE EXPERIENCES FOR HOMELESS VETERANS WITH SERIOUS MENTAL ILLNESS

Audrey Jones[1,2]; Sonya Gabrielian[3,4]; Young-il Kim[7]; Aerin DeRussy[5]; Ann E. Montgomery[5]; Kevin R. Riggs[7,5]; Sally K. Holmes[5]; Erika Austin[6]; David Pollio[10]; Lillian Gelberg[4,3]; John Blosnich[8,9]; April E. Hoge[5]; Allyson Varley[7]; Adam Gordon[1,2]; Stefan Kertesz[7,5]. [1]IDEAS Center, VA Salt Lake City Health Care System, Salt Lake City, UT; [2]Internal Medicine, University of Utah School of Medicine, Salt Lake City, UT; [3]VA Greater Los Angeles Health Care System, Los Angeles, CA; [4]David Geffen School of Medicine at UCLA, Los Angeles, CA; [5]Research, Birmingham VA Medical Center, Birmingham, AL; [6]Biostatistics, UAB, Birmingham, AL; [7]University of Alabama at Birmingham School of Medicine, Birmingham, AL; [8]Center for Health Equity Research and Promotion, VA Pittsburgh Healthcare System, Pittsburgh, PA; [9]Suzanne Dworak-Peck School of Social Work, University of Southern California, Los Angeles, CA; [10]University of Alabama at Birmingham, Birmingham, AL. (Control ID #3389679)

BACKGROUND: Persons with serious mental illness (SMI, including schizophrenia spectrum, psychotic and bipolar disorders) are overrepresented among persons who are homeless. Compared to other patients, those with SMI and homeless experiences have increased morbidity and mortality, poor physical functioning, and high rates of dissatisfaction with their health status. In 2012, the Department of Veterans Affairs (VA) implemented a paradigm of primary care services (homeless-patient aligned care teams (HPACTs)) tailored to the needs of homeless-experienced Veterans (HEV). Compared to mainstream VA primary care, HPACTs have smaller panel sizes, more access accommodations and linkages to mental health services. To inform efforts to enhance primary care engagement and reduce morbidity and mortality among HEV with SMI, we sought to examine if HPACTs provide this vulnerable population with superior a primary care experience, compared to mainstream VA primary care.

METHODS: The Primary Care Homeless Service Tailoring (PCQ-HoST) study surveyed a random sample of HEV about their primary care experience in 26 VA facilities. For respondents with SMI documented in VA medical records (N=1,095), we determined favorable, neutral, and unfavorable experiences on 4 scales from a validated primary care instrument: Accessibility/Coordination, Patient-Clinician Relationship, Perceived Cooperation among Caregivers, and Homeless-Specific Needs. We used survey-weighted multinomial logistic regression models, controlling for demographic and clinical covariates, to assess differences in the valence of patient reported experiences for respondents in HPACTs vs. mainstream primary care.

RESULTS: Among 1,095 HEV respondents with SMI, 969 (91%) had complete data on study variables; 626 (65%) of these respondents were in HPACT. Compared to those in mainstream primary care, HPACT respondents were younger; they were more likely to be male, nonmarried, to self-report a drug problem, and to have a history of chronic homelessness. After covariate adjustment, HPACT respondents were more likely to report favorable experiences than the mainstream primary care respondents on each scale: access (adj. % = 44.9 vs. 26.9), relationship (44.9 vs. 29.9), cooperation (39.1 vs. 27.6), and homeless-specific needs (39.4 vs. 23.7); all p-values $\leq$ 0.001. Respondents in HPACT also reported fewer unfavorable experiences on all scales, with marked differences in attention to homeless-specific needs (adj. % = 43.0 vs. 60.2), cooperation (27.4 vs. 41.0), relationship (28.5 vs. 44.8), and access (28.2 vs. 40.4); p-values $\leq$ 0.001.

CONCLUSIONS: While some recently homeless Veterans with SMI hold unfavorable impressions of primary care, these unfavorable experiences are mitigated in VA clinics specifically designed for homeless Veterans. To address the profound health disparities experienced by this population, additional research is needed to identify specific primary care features that contribute to optimum experiences and outcomes for HEV with SMI.

IMPROVING SOCIAL SUPPORT DISCUSSIONS IN PRIMARY CARE CLINIC

Katherine Chebly[1]; Michael S. Shen[2]. [1]Medicine, New York University School of Medicine, Jamaica, NY; [2]Internal Medicine, New York University, New York City, NY. (Control ID #3377582)

BACKGROUND: The physiology by which chronic social isolation stress advances cardiovascular, endocrine, neoplastic, and cognitive disease is well understood. (Cacioppo, 2015) Social isolation stress is a known risk factor for mortality with effects similar to smoking and obesity. (Holt-Lunstad, 2015) Yet little is known about if and how physicians investigate a patient's social support system in the clinic setting. (Behforouz, 2014) This study aims to highlight the frequency and nature of physicians' social support discussions with patients, in order to improve discussion and documentation of social determinants of health, specifically social isolation stress.

METHODS: This study analyzes a previously collected data-set (Schoenthaler, 2017), namely 92 audiotaped then transcribed conversations between patients and physicians during routine primary care visits. The study includes 27 primary care providers at a public hospital in NYC and 92 adult patients who are English- speaking, carry a hypertension diagnosis, and have received primary care from the same provider for at least 3 months. A grounded theory approach is used to categorize conversation themes, including how often social isolation stress is discussed as a risk factor for mortality versus other known risk factors for disease.

RESULTS: In study results to date, social isolation stress is discussed as a risk factor for mortality in 6% of physician encounters, whereas other morbidity/mortality risk factors are discussed with greater frequency (medication adherence: 99%; diet: 41%; exercise: 32%; smoking: 29%). Social support in general is brought up in 32% of transcripts, most often while asking a patient about the well-being of family members, or less commonly while asking about one's living situation or home health needs. In 53% of transcripts, patients bring up social support (or lack thereof) as a discussion topic; 40% of those efforts are met by physicians who change the subject or do not acknowledge the patient's comment.

CONCLUSIONS: The study findings suggest that, despite evidence that social isolation stress is a risk factor for worsening morbidity and mortality, physicians rarely inquire with patients about their social support systems. Improving physician social history-taking to include social isolation could be an important health system transformation leading to improved risk stratification of patients for a variety of disease processes, increased ability to connect patients to much-needed social services, and richer physician-patient relationships.

IMPROVING THE ACCURACY OF MEDICAL STUDENT PHYSICAL ACTIVITY MEASUREMENT

Richard K. Leuchter[1]; Margi Stuber[2]; Daniel M. Croymans[1]. [1]Internal Medicine, UCLA Health, Los Angeles, CA; [2]Psychiatry and Biobehavioral Sciences, David Geffen School of Medicine at UCLA, Los Angeles, CA. (Control ID #3388316)

BACKGROUND: Past research suggests that medical student physical activity (PA) levels are comparable to the national average. These findings support the conclusion that PA is a less suitable target to enhance trainee well-being than other metrics (e.g. fatigue, burnout, duty hours). Prior studies have relied upon CDC guidelines for aerobic activity to distinguish "active" from "inactive" medical students, but these guidelines have grouped moderately active and highly active individuals into a single "active" category. This categorization is at odds with the American Heart Association's guidelines promoting intense PA over moderate PA for its greater health benefits. In the current study, we addressed this shortcoming by applying the WHO PA suggestions to the medical student population in order to distinguish moderate PA from high PA, also termed health-enhancing physical activity (HEPA). We then compared these proportions to the CDC guidelines for aerobic exercise and an age-adjusted national average. Finally, we described the relationship between HEPA and stress levels among U.S. medical students.

METHODS: Two-point cross-sectional survey was administered in the winters of 2013 and 2014 at the David Geffen School of Medicine at UCLA. All medical students were eligible (response rate 1046/1392 [75%]). PA and perceived stress were measured by the International Physical Activity Questionnaire- Short Form (IPAQ-SF) and Perceived Stress Scale (PSS), respectively.

RESULTS: Compared to an age-matched national average, medical students had comparable rates of compliance with the CDC aerobic exercise guidelines (65% vs 58%; p=0.38). However, medical students engaged in significantly less HEPA than their peers (27% vs 72%; OR 0.14; 95% confidence interval [CI] 0.078-0.21; p<0.001). PA among medical students was instead skewed towards moderate activity compared to their age-matched peers (53% vs 16%; OR 5.92; 95% CI 2.99-8.85; p<0.001). HEPA active students were significantly more likely to be in the lowest quartile of stress (32% vs 25%; OR 1.44; 95%; CI 1.07-1.81; p=0.02) and much less likely to fall into the highest stress quartile (22% vs 29%; OR 0.71; CI 0.51-0.90; p=0.03). There were no such statistically significant relationships between stress and moderate levels of PA.

CONCLUSIONS: While they are currently the gold standard for classifying PA, the CDC aerobic exercise guidelines overestimate the PA levels of medical students, who actually engage in significantly less HEPA than the national average. HEPA active medical students manifest significantly lower stress than those engaging in moderate PA only. This demonstrates

both physical and mental health justifications for quantifying and analyzing moderate PA and HEPA separately. We therefore recommend a paradigm shift in how medical trainee PA is measured and incorporated into current and future interventions to enhance medical student well-being.

IMPROVING THE QUALITY OF INPATIENT DISCHARGE INSTRUCTIONS: AN EVALUATION AND IMPLEMENTATION OF BEST PRACTICES

Benjamin Rodwin[1,2]; Victor P. Bilan[2]; Craig G. Gunderson[3,2]; Naseema Merchant[1,2]. [1]Internal Medicine, Yale School of Medicine, New Haven, CT; [2]Internal Medicine, VA Connecticut Healthcare System, West Haven, CT; [3]Internal Medicine, Yale Medical School, West Haven, CT. (Control ID #3343983)

BACKGROUND: The hospital discharge process is a time that is ripe for errors and miscommunications. Studies show that many patients admitted to the hospital do not understand their reason for hospitalization or their plan of care after discharge and that when patients are not aware of their discharge plans, it is more likely that they will be readmitted or suffer a preventable adverse event. Furthermore, it has been shown that improving the quality of discharge instruction in addition to addition to other interventions, can result in an increase in completion of recommended care following discharge.

METHODS: We instituted two sequential interventions to improve the quality of discharge instructions at our institution. Our interventions included targeted educational outreach and a redesign of the discharge instructions template. A random sample of discharge instructions were reviewed monthly over a 15-month period from October 2017 through December 2018 and were evaluated using of 11 quality metrics. We evaluated the number of discharge instructions quality metrics that were completed, the readmission rate before and after each intervention, as well as patient and provider characteristics associated with number of quality metrics completed over the course of the study.

RESULTS: Discharge instructions from 225 patients were reviewed. Prior to our intervention, an average of 5.36 out of 11 possible quality metrics were completed. This increased to 5.6 after an educational intervention, and increased further to 7.16 following implementation of the redesigned template. The 30-day risk standardized readmission rate readmission rate fluctuated over this time from a baseline of 10.48% to 12.71% and 10.97% following each intervention, respectively. Among provider characteristics, medical students completed significantly more quality metrics than interns, residents, or attendings ($p<0.05$ for all). There was a non-significant difference in the number of quality criteria met for male vs female patients (6.00 vs 7.23) ($p = 0.071$). There was not a significant correlation in number of quality criteria met by patient age (correlation coefficient 0.04, $p=0.51$) or length of stay (correlation coefficient 0.05, $p=0.43$).

CONCLUSIONS: We found that while an education intervention was not effective in changing the quality of discharge instructions, a redesigned electronic template was able to improve the average number of quality metrics which were completed. Neither intervention led to a meaningful change in readmission rates.

Additionally, we found significant differences in the quality of discharge instructions based on the level of training of the author. Further research is needed to determine best practices for patient education that can result in decreased preventable readmissions and to ensure that providers at all levels of training are completing discharge instructions appropriately.

INCARCERATION AS A MEDIATOR OF BLACK-WHITE DISPARITIES IN PREMATURE MORTALITY: AN ANALYSIS OF THE NATIONAL LONGITUDINAL SURVEY OF YOUTH 1979 COHORT

Benjamin Bovell-Ammon[1]; Ziming Xuan[3]; Michael Paasche-Orlow[2]; Marc Larochelle[2]. [1]Internal Medicine, Boston Medical Center, Boston, MA; [2]General Internal Medicine, Boston University School of Medicine and Boston Medical Center, Boston, MA; [3]Community Health Sciences, Boston University School of Public Health, Boston, MA. (Control ID #3390562)

BACKGROUND: Racial disparities in incarceration and mortality are well known. However, it is not well understood if racial disparities in incarceration explain disparities in mortality.

METHODS: We conducted a retrospective cohort study using data from the National Longitudinal Survey of Youth 1979 cohort (NLSY79), an ongoing, nationally representative longitudinal study of individuals born from 1957 to 1964. The study period was from 1979 to 2016. The exposure, prior incarceration, was identified if: (a) individuals reported prior incarceration on the 1980 survey; (b) their current residence was ever identified as jail/prison; or (c) they were not surveyed in a given wave due to incarceration. The primary outcome of premature mortality (before age 60) was defined as being recorded deceased at or prior to the 2016 survey year. We used NLSY79 mutually exclusive race/ethnicity categories assigned in the initial survey: black, Hispanic, or non-black non-Hispanic. We followed a 4-step mediation analysis using multivariable logistic regression models (adjusting for age and sex) to assess the relationships between (1) race and incarceration, (2) incarceration and premature mortality, and (3) race and premature mortality, and then (4) evaluated incarceration as a mediator of the association between race and premature mortality, with the Sobel test for mediation.

RESULTS: Among 9964 individuals included in the analysis, 30.1% were black, 19.7% were Hispanic, and 50.4% were male. During the study period, 747 respondents (7.5%) were incarcerated, and 915 (9.2%) died. Compared to non-black non-Hispanic individuals, both black and Hispanic individuals were significantly more likely to experience incarceration, OR 3.76 (95% CI [3.13, 4.51]) and OR 2.86 [2.25, 3.65]), respectively. Individuals with any experience of incarceration were more likely to die prematurely, OR 1.95 (95% CI [1.59, 2.41]). Black individuals were significantly more likely to die prematurely than non-black non-Hispanic individuals, OR 1.57 (95%CI [1.35, 1.83]), but Hispanic individuals had similar odds of premature death to non-black non-Hispanic individuals OR 1.14 (95% CI [0.94, 1.37]). The inclusion of incarceration partially attenuated the association between black individuals and mortality to OR 1.48 (95%CI [1.26, 1.71]); Sobel test statistic was 3.70 ($p<.001$). Because Hispanic race/ethnicity was not significantly associated with premature death, we did not assess mediation for that group.

CONCLUSIONS: These data suggest that premature mortality among blacks may be partially explained by racial differences of incarceration. Criminal justice policy should be a key consideration in efforts to address racial disparities in public health.

INCLUSION AND EXCLUSION CRITERIA IN INDUSTRY-SPONSORED CLINICAL TRIALS OF DRUGS FOR TYPE 2 DIABETES, 2006-2015

Audrey D. Zhang[1]; Joshua D. Wallach[2]; Joseph S. Ross[3]. [1]Medicine, New York University School of Medicine, New York, NY; [2]Environmental Health Sciences, Yale School of Public Health, New Haven, CT; [3]Internal Medicine, Yale University School of Medicine, Woodbridge, CT. (Control ID #3391238)

BACKGROUND: Clinical trials are the gold standard for evaluating the efficacy and safety of new drugs, but they are often conducted in specialized environments with narrowly-defined patient populations based on strict inclusion and exclusion criteria. This approach fosters internal validity, but at the expense of generalizability, increasing uncertainty among prescribers of the real-world benefits and harms of a drug. Our objective was to characterize the inclusion and exclusion criteria used for clinical trials of pharmaceutical products treating type 2 diabetes over one decade.

METHODS: We performed a review of all industry-sponsored clinical trials evaluating new drugs approved for type 2 diabetes by the US Food and Drug Administration (FDA) between 2006-2015. Using the ClinicalTrials.gov registry, we identified all registered industry-sponsored trials of these drugs evaluating outcomes of patients with type 2 diabetes. We excluded clinical trials not primarily evaluating efficacy or safety (e.g. those primarily enrolling healthy patients, evaluating pharmacokinetics/pharmacodynamics) and non-adult trials. Using trial registrations and corresponding publications, we identified and characterized inclusion and exclusion criteria, both by specific thresholds described (e.g. exclusion of patients with GFR<60) and by general disease categories (e.g. exclusion on the basis of renal disease). Selection of categories was informed by FDA guidance for industry on developing drugs for diabetes mellitus.

RESULTS: We identified 10 drugs initially approved by the FDA for type 2 diabetes from 2006-2015, with 338 corresponding industry-sponsored clinical trials evaluating type 2 diabetes-related indications for adults. Common inclusion criteria were age (n=338, 100%), HbA1c (n=302, 89.3%), and BMI (n=223, 66.0%). 169 (50.0%) trials contained upper bounds on inclusion age, with a median upper bound of 77 (IQR 75-80).

The most common exclusion criteria were cardiovascular and cerebrovascular events (n=239, 70.7%), renal dysfunction (n=222, 65.7%), and hepatic dysfunction (n=202, 59.8%). Among the 127 (37.6%) trials defining a GFR threshold for exclusion on the basis of renal dysfunction, the median was 60 mL/min (IQR 30-60). Among the 122 (36.1%) trials defining a liver enzyme threshold for exclusion on the basis of hepatic dysfunction, the median was 3x the upper limit of normal (IQR 2.5-3). Other patients with markers of uncontrolled or end-stage diabetes were also commonly excluded, including those with recurrent hypoglycemia or hyperglycemia (n=141, 41.7%), neuropathy including gastroparesis (n=52, 14.5%), or proliferative maculopathy or retinopathy (n=49, 15.4%).

CONCLUSIONS: Industry-sponsored clinical trials of drugs for type 2 diabetes commonly feature restrictive inclusion and exclusion criteria, including characteristics and comorbidities common to patients with diabetes. These criteria may limit the generalizability of results from clinical trials to populations of real-world patients.

INCORPORATING A PHARMACIST-DRIVEN MODIFIED MEDICATION THERAPY MANAGEMENT PROGRAM FOR IMPROVED BLOOD PRESSURE CONTROL IN A COMMUNITY-BASED RESIDENT CLINIC

Stephannie Aronovic, Kelli Fox, Craig Sewell, Chelsey Petz. Internal Medicine, Riverside Methodist Hospital, Columbus, OH. (Control ID #3346281)

BACKGROUND: Nearly one third of the adult US population has hypertension, only half of which have optimal control of their blood pressure (BP). Patient-centered barriers to improved control, which may be especially salient in resident-driven community clinics, include low health literacy and medication nonadherence. Previous studies have demonstrated that a "team change" approach to hypertension, in which some or all of the responsibilities of management were transferred to another provider, were the most effective interventions. Our goal was to introduce a pharmacist-driven modified medication therapy management (MMTM) program within a resident clinic to target patient understanding and adherence barriers to better achieve target BPs.

METHODS: Resident physicians were asked to electronically refer patients ≥18 years of age on antihypertensive therapy with BP above 140/90 to our pharmacist-driven MMTM program. The pharmacy technician reviewed the consult and attempted contact within 24 hours to schedule an appointment. Appointments were led by a licensed pharmacist, who completed medication reconciliation and evaluated for medication errors and barriers to adherence. Personalized strategies to address barriers were reviewed and medication refills were synchronized. A BP kit and pill box were provided, and diet was reviewed. The visit was documented in the electronic medical record and a copy was sent to the patient's primary care physician. Each patient was scheduled for a 3 month follow up with BP recheck. Patients completed an anonymous feedback survey to allow for changes to program structure. Blood pressure at referral and follow up were recorded.

RESULTS: Eighty-seven referrals were made to the program. Implementation of electronic referrals significantly increased the number of referrals received. Amongst participants who completed the program in its entirety, there was a statistically significant drop in mean systolic blood pressure from 153 to 145 (p=0.006) using a paired two-tail t-test. Mean diastolic pressures dropped from 87 to 84 (p=0.087). Patient perceptions of the program were overwhelmingly positive, with 100% of surveys rated as 4 or 5 out of 5 (most helpful) on a Likert scale survey.

CONCLUSIONS: The success of our initiative highlights a novel approach for improving BP control in a resident clinic by using a multidisciplinary team. Improvements with our initiative are similar to BP reductions seen with other commonly recommended non-pharmacologic interventions, such as the DASH diet, and weight loss. Our program promoted lifestyle changes, but most importantly employed individualized tools to help attain treatment goals. Our results echo previously successful studies that utilized team-based interventions for improved control of a chronic disease, but with added benefit of enhancing systems-based practice in a resident clinic. Extensive opportunities remain to expand MMTM to other chronic disease processes in order to add clinical value and improve patient care.

INCORPORATING CVD RISK PREDICTION INTO CLINICAL PRACTICE

Jeremy Sussman[1,2]; Linda Takamine[3]; Jane Forman[4]; Kunal Mathur[1]; Bradley Youles[5]; Laura Damschroder[6]. [1]Internal Medicine, University of MIchigan, Ann Arbor, MI; [2]VA Ann Arbor Healthcare System, Ann Arbor, MI; [3]Health Services Research & Development, VA, Ann Arbor, MI; [4]HSR&D, VA Center for Clinical Management Research, Ann Arbor, MI; [5]Health Services Research & Development, Department of Veterans Affairs, Ann Arbor, MI; [6]Ann Arbor VA Center for Clinical Management Research, Ann Arbor, MI. (Control ID #3392602)

BACKGROUND: With the introduction of Big Data, risk prediction is playing a growing role in clinical medicine, particularly in cardiovascular disease (CVD) prevention, where a patient's risk of developing a heart attack or stroke is now a core determinant of treatment for every class of drugs. However, the influence of these risk prediction tools on clinical decisions has been limited. We sought to understand providers' facilitators and barriers to incorporating risk prediction into their regular clinical practice.

METHODS: Between June and November 2018, we conducted 37 semi-structured interviews with primary care providers at 9 VA sites. In

interviews (30 to 60 min), we asked providers to evaluate the hypothetical introduction of a risk prediction model for CVD prevention and treatment at VA facilities that would replace the use of individual targets, such as LDL or blood pressure. We used inductive content and matrix analysis to generate findings.

RESULTS: Providers offered detailed assessments of how adopting the risk prediction model might impact their clinical practice. While most providers welcomed the model, they all mentioned both positive and negative aspects. Their assessments may be grouped into four categories.

1) The relationship between quantified medicine and holistic practice: Some providers felt a quantified approach cannot capture an individual patients' context, among other relevant factors.

2) Reliability: Many providers wanted to know the model's inputs as well as the population and studies upon which it is based, and whether an institution such as the AHA has endorsed it. Some said that other outcomes, such as rehospitalization rates, were more valid. Others said that patient compliance affects their ability to reduce a patient's risk.

3) Impact on workflow: Positive impacts mentioned included the ability to prioritize patients, looking at one measure instead of many individual ones, and that a pre-calculated and easy to access risk number could streamline workflow. Providers reacted negatively to the possibility that the model would add to tasks and pop-up reminders.

4) Whether introducing the risk prediction model would add value: Added value included reducing unnecessary fallouts, making benefits of treatment clearer, depicting meaningful outcomes, enhancing patient understanding by giving them a "visual," which motivates patients to adhere to treatment. Doubts included: basing performance measures on how much a provider can reduce a patient's risk does not solve the problems that current measures have; the model may be too technical for patients to understand; and given the sheer number of quality initiatives that are continually rolled out, adopting a risk prediction approach seems like just another "flavor of the month."

CONCLUSIONS: Providers generally welcomed risk prediction in CVD prevention. However, resistance by some must be addressed, as Big Data increasingly drives more quantified medicine.

INCREASED ACCESS AND DECREASED MORTALITY THROUGH A TRANSITIONS OF CARE PROGRAM FOR RURAL VETERANS

Heather M. Gilmartin[1,2]; Christine D. Jones[3,1]; Theodore Warsavage[1]; Chelsea A. Leonard[4]; Lynette Kelley[1]; Ashlea L. Mayberry[1]; Margaret E. Plomondon[1,2]; Christine Engstrom[1]; Peter J. Kaboli[5]; Robert E. Burke[6]. [1]Denver/Seattle Center of Innovation, Rocky Mountain Regional VA Medical Center, Aurora, CO; [2]Health Systems, Management and Policy, University of Colorado, School of Public Health, Aurora, CT; [3]Medicine, University of Colorado, Denver, Aurora, CO; [4]Seattle Denver Center of Innovation, Department of Veterans Affairs, Denver, CO; [5]Internal Medicine, Iowa City VAMC, Iowa City, IA; [6]Research and Hospital Medicine Sections, Denver VA Medical Center, Denver, CO. (Control ID #3367750)

BACKGROUND: The transition from hospital to home is a high-risk period for patients. Rural Veterans who receive care in urban Veterans Affairs (VA) hospitals represent a particularly high-risk group prone to experiencing gaps in care around transitions, potentially resulting in higher rates of hospital utilization and adverse health outcomes. To address these issues, the rural Transitions Nurse Program (TNP), a nurse-led pre-and post-discharge care coordination intervention, was implemented at 11 VA hospitals nationally. A transitions nurse assesses discharge readiness, provides structured post-discharge communication with inpatient and outpatient medical teams, and calls the patient within 72 hours of discharge to discuss post- discharge care and confirm attendance at follow-up appointments. We evaluated whether the program increased primary care provider (PCP) visits within 14 days of discharge, reduced readmissions, emergency department (ED) visits, and mortality rates at 30 days of discharge.

METHODS: In this cohort study, Veterans who received the TNP intervention from 5/1/2017 to 3/31/2019 were propensity matched to concurrent controls (1:2) based on likelihood of being enrolled in TNP, including demographics and comorbidities. Matching was conducted at the site level; effectiveness was assessed with standardized differences. Hazard ratios (HR) were calculated for time to event outcomes (30-day rehospitalization, ED visit and death) and odds and risk ratios (OR and RR) were calculated for binary outcomes (PCP visit). Confidence intervals (CI) were obtained using bootstrapping. Tests were conducted to assess for a mediation effect of PCP visit on the time to event outcomes.

RESULTS: Our sample included 2,608 Veterans who received the TNP intervention and 5,216 matched controls. All standardized differences in propensity matched variables were <0.1. Veterans enrolled in TNP were more likely to see their PCP within 14 days of discharge (RR 1.63 [95% CI 1.54, 1.71]) and have a reduced risk of death within 30 days (HR 0.34 [95% CI 0.21, 0.57]) than matched controls. ED visits (HR 1.01 [95% CI 0.89, 1.14]) and readmission (HR 1.11 [95% CI 0.97,1.27) at 30 days were not different between Veterans enrolled in TNP and controls. PCP visits had a significant mediating effect on ED visits, but not readmissions or death.

CONCLUSIONS: Veterans that received the TNP intervention had increased access to primary care and were less likely to die within 30 days of hospitalization compared to propensity matched controls. These benefits may be attributable to the pre-discharge interactions with Veterans to assess discharge readiness with the inpatient team. This may have ensured only those ready to go home were discharged. The post-discharge follow-up call may have also influenced the risk of death due to early identification of issues, prompting referral to a PCP, ED or hospital. These findings suggest an emphasis on pre-and post-discharge care coordination interventions could enhance Veteran outcomes.

INCREASED PREVALENCE OF METABOLIC SYNDROME AMONG PATIENTS WITH GASTRIC ANTRAL VASCULAR ECTASIA IN A CIRRHOTIC COHORT

Ravi Jariwala[1]; Basem Alkurdi[3]; Peng Li[2]; Theresa Hydes[4]; Shajan Peter[4]; Mohamed Shoreibah[4]. [1]Internal Medicine, University of Alabama at Birmingham (UAB), Birmingham, AL; [2]School of Nursing, University of Alabama at Birmingham, Birmingham, AL; [3]Hepatology, Largo Medical Center, Largo, FL; [4]Hepatology and Gastroenterology, University of Alabama at Birmingham, Birmingham, AL. (Control ID #3361440)

BACKGROUND: Gastric antral vascular ectasia (GAVE) accounts for 4% of non-variceal upper gastrointestinal bleeds (UGIB), manifesting with iron deficiency anemia and a need for blood transfusions. Approximately 30% of individuals with GAVE have cirrhosis of the liver and nearly two-thirds have an autoimmune condition, however, case series are small. Non-alcoholic fatty liver disease (NAFLD) is the most common

cause of chronic liver disease in the US. One previous case-series suggests GAVE as a manifestation of metabolic syndrome, however, it is unclear how this relates to the presence of cirrhosis. We aimed to investigate whether there is an association between GAVE and metabolic syndrome in cirrhotics by using patients with esophageal variceal hemorrhage (EVH) as a control group.

METHODS: We conducted a retrospective review on 941 patients who had an esophagogastroduodenoscopy (EGD) for an UGIB. GAVE was diagnosed based on endoscopic or biopsy findings. EVH patients were included if they had active bleeding or stigmata of recent hemorrhage. Patients diagnosed with both GAVE and EVH were excluded. Primary outcome data included the prevalence of obesity, hypertension, hyperlipidemia, and type 2 diabetes among study groups. The prevalence of autoimmune disease was also analyzed.

RESULTS: We identified 96 cirrhotic patients who met inclusion criteria in the GAVE group and 104 in the EVH group. Mean BMI was significantly higher in the GAVE cohort (33 kg/m^2 vs 28 kg/m^2, p<0.0001), as was the prevalence of type 2 diabetes mellitus, hypertension and hyperlipidemia (53.1% vs 37.5%, p<0.05; 76% vs 47.1%, p<0.0001; 38.5% vs 14.4%, p=0.0001 respectively). Non-alcoholic steatohepatitis (NASH) cirrhosis was also more prevalent in cirrhotics diagnosed with GAVE compared to those with an EVH (50% vs 24%, p=0.0001). The severity of liver disease was similar between groups according to the MELD-Na score (18.3 vs 20.2, p=0.2014), the presence of ascites (77.9% vs 71.2%, p=0.2766), and hepatic encephalopathy (64.2% vs 57.7%, p=0.3468). No significant difference in the prevalence of autoimmune disease was detected between the two cohorts (26% vs 19.2%, p=0.2492), despite the GAVE group being predominantly female (54.2% vs 27.9%, p=0.0002).

CONCLUSIONS: Cirrhotic patients with GAVE have an increased prevalence of metabolic syndrome compared to a control group of individuals with cirrhosis and EVH. To our knowledge, this is the first study to identify an association between GAVE and features of metabolic syndrome in a cirrhotic population. Translational studies are needed to determine if this relationship is causative. In other words, does metabolic syndrome induce vascular endothelial changes? Increased awareness of this relationship among physicians is likely to improve the detection of GAVE within this group.

INCREASING ACCESS TO MEDICATION-ASSISTED TREATMENT AND COMPLEMENTARY AND INTEGRATIVE HEALTH THERAPIES FOR OPIOID USE DISORDER IN PRIMARY CARE

Evelyn T. Chang[1,7]; Rebecca Oberman[2,7]; Amy N. Cohen[3,7]; Stephanie L. Taylor[7]; Elisa Gumm[4]; Aram Mardian[5]; Shawn Toy[6]; Araceli Revote[6]; Britney Lewkowitz[7]; Elizabeth M. Yano[7]. [1]General Internal Medicine, VA- Greater Los Angeles, Los Angeles, CA; [2]MIRECC, VA Greater Los Angeles, Los Angeles, CA; [3]MIRECC, Greater Los Angeles VA Healthcare Center, Los Angeles, CA; [4]Southern Arizona VA Medical Center, Tucson, AZ; [5]Chronic Pain Management Program, Phoenix VA Health Care System, Phoenix, AZ; [6]VISN 22, Gilbert, AZ; [7]Center for the Study of Healthcare Innovation, Implementation & Policy, VA Greater Los Angeles Healthcare System, Sepulveda, CA. (Control ID #3389831)

BACKGROUND: Evidence-based therapies for opioid use disorder (OUD) and chronic pain such as medication-assisted treatment (MAT) and complementary and integrative health (CIH; e.g., acupuncture and meditation) therapies exist. However, their adoption has been slow, particularly in primary care, due to numerous implementation challenges. We sought to expand the use of MAT and CIH by using an evidence- based quality improvement (EBQI) implementation strategy. We aimed to pilot how effectively EBQI could engage primary care in facilitating MAT and CIH delivery to patients with OUD.

METHODS: We used EBQI to engage two sites from June 2018-September 2019. EBQI included top-down and bottom-up multi-level stakeholder engagement, with external facilitators providing technical support, practice facilitation, and routine data feedback. We conducted pre-implementation key stakeholder interviews (14 providers, 5 Veterans) to understand OUD, MAT and CIH experiences at baseline. We established a local QI team at each site with diverse stakeholders (e.g., primary care, pain, nursing, addiction, pharmacy), meeting virtually twice monthly. We met monthly with regional stakeholders to review formative data on our progress and discuss methods to address implementation barriers. We twice convened a national-level advisory board to ensure alignment with national priorities. We conducted exit interviews with 8 key providers to assess their experiences with the implementation pilot.

RESULTS: Pre-implementation interviews indicated facility-level and provider-level barriers to prescribing buprenorphine, including strong provider resistance. Stakeholders indicated acceptance and utilization of CIH therapies. Both sites conducted educational meetings (e.g., Grand Rounds) and educational outreach visits (i.e., X-waiver trainings). Site A also offered clinical preceptorships for newly X-waivered primary care prescribers. Site B also used mass media and mailings to educate patients about MAT and CIH options and dashboards to identify potential candidates for MAT. After fifteen months, both sites increased their OUD treatment rates to >90th percentile of VHA medical centers nationally. Exit interviews indicated an attitudinal shift in MAT delivery in primary care. Stakeholders valued the EBQI process, particularly cross-site collaboration.

CONCLUSIONS: Despite initial implementation barriers, we effectively engaged stakeholders using EBQI strategies to overcome these challenges. QI teams used an assortment of implementation strategies, ultimately transforming their facilities to among the highest performers in VHA OUD treatment. EBQI may be an effective strategy to engage stakeholders to implement MAT and CIH therapies to treat OUD.

INCREASING KNOWLEDGE AND COMFORT IN INTIMATE PARTNER VIOLENCE SCREENING AMONG INTERNAL MEDICINE INTERNS

Jillian Kyle[2,1]; Raquel A. Buranosky[2]; Melissa McNeil[2]. [1]Medicine, Veterans Affairs, Pittsburgh, PA; [2]Medicine, University of Pittsburgh Medical Center, Pittsburgh, PA. (Control ID #3376377)

BACKGROUND: Intimate Partner Violence (IPV) is common and underrecognized in primary care. Routine IPV screening increases victim identification, resource utilization, and relationship departures. Despite screening guidelines, physicians do not routinely ask about IPV. This discrepancy is often due to surmountable barriers including personal discomfort, knowledge deficits, or resource unawareness. Many residency programs do not include formal IPV training or focus principally on knowledge acquisition. The objective of our study was to increase intern knowledge, comfort, and screening rates through a combined didactic and communication skills curriculum.

METHODS: The curriculum was presented to internal medicine interns during their ambulatory block. Participants completed a pre-survey of comfort, opinion, knowledge, and demographic questions. The curriculum didactic explored definitions, power-control dynamics, screening guidelines, health impacts, and documentation. During skill development, interns brainstormed word choice for framing, screening, and response with facilitator feedback. Two simulated patient cases were completed, during which interns received supportive coaching and performance feedback. Four weeks post-curriculum, residents were invited to complete a post-survey. Comfort and opinion questions were measured on a seven-

point Likert scale and analyzed using Wilcoxon signed-rank test. Knowledge-based questions were true-false and multiple choice and analyzed using McNemar's test.

RESULTS: Forty interns completed the curriculum January-October 2019. Twenty-nine interns completed both pre- and post-surveys (72% response). Interns demonstrated statistically significant increases on all measures of self-perceived knowledge and comfort. Particularly important areas of improvement included increases in self-reported compliance with guideline-based screening recommendations (mean 2.8 to 4.24), ability to identify patients eligible for screening (mean 3.52 to 5.69), comfort discussing IPV with patients (mean 3.52 to 5.3), and ability to make referrals within the community (mean 3.05 to 4.86) ($p<0.01$). Interns demonstrated high IPV knowledge prior to the curriculum but showed statistically significant improvement in recognizing IPV perpetrator characteristics and understanding high danger situations ($p<0.05$).

CONCLUSIONS: A combined didactic-communication skills curriculum significantly improved intern IPV- specific comfort and self-reported screening practices. Improvement in knowledge was also demonstrated, but likely limited by high intern knowledge pre-curriculum and question wording that suggested a most appropriate answer. Further analysis will reveal if screening and documentation increased through chart review of eligible patients. This curriculum is feasible and easily transferrable to other programs interested in increasing resident comfort with IPV screening through skill development.

INFLAMMATORY BIOMARKER SRAGE IS ASSOCIATED WITH LIVER INJURY AND FIBROSIS IN ATHEROSCLEROSIS RISK IN COMMUNITIES (ARIC) STUDY PARTICIPANTS

Marci Laudenslager[2]; Mariana Lazo[1]; Dan Wang[1]; Natalie Daya[1]; Elizabeth Selvin[1]; Victor Chen[2]; Jeanne M. Clark[2]. [1]Epidemiology, The Johns Hopkins Bloomberg School of Public Health, Welch Center for Prevention, Epidemiology and Clinical Research, Baltimore, MD; [2]Medicine, The Johns Hopkins University, Baltimore, MD. (Control ID #3390826)

BACKGROUND: Nonalcoholic fatty liver disease (NAFLD) is the most common chronic liver disease in the United States. Inflammatory pathways are key in the development of NAFLD though the precise mechanisms that drive disease progression remain poorly understood. sRAGE is a biomarker that attenuates inflammatory pathway activation. Hence, low levels of sRAGE are correlated with increased inflammation. We sought to describe associations between sRAGE and NAFLD in a large community-based cohort.

METHODS: We conducted a cross-sectional analysis of a subset of 2553 ARIC participants at study visit 2 (1990-2). The exposure was sRAGE (analyzed by quartiles comparing the lowest vs. other quartiles); the outcome was NAFLD as determined by elevated ALT, AST or fibrosis score (FIB-4 index). We defined ALT and AST elevation as levels above the 95th percentile based on gender-specific distributions in normal weight nondiabetic subjects (ALT ≥31 U/L F, ≥32 U/L M; AST ≥33 U/L F and M). FIB-4 elevation was defined as an index ≥1.30. We used multivariable logistic regression (MLR) models to assess cross-sectional associations between sRAGE and NAFLD. We then investigated the association between sRAGE and development of NAFLD between baseline (visit 2) and 6-year follow up (visit 4) using MLR.

RESULTS: In cross-sectional analyses (n=2317, mean age 58 years, 58% female, 78% white), persons in the lowest quartile of sRAGE had significantly higher odds of elevated ALT vs. other quartiles (OR 1.66; 95% CI 1.09-2.55) but not elevated AST (OR 0.86; 95% CI 0.54-1.36). Odds of elevated FIB-4 were reduced in the lowest vs. other quartiles of sRAGE (OR 0.70; 95% CI 0.58-0.87). In the prospective analyses, there were no associations between low sRAGE and any outcome measure. However, we did find a dose response relationship between increasing quartiles of sRAGE and incident elevated FIB-4 index (p-for-trend <0.01).

CONCLUSIONS: We found an inverse relationship between sRAGE and liver inflammation (high ALT) in a cross-sectional study of ARIC participants. This is consistent with prior studies linking low sRAGE to inflammatory disease states. Surprisingly, we found a direct association between sRAGE and high FIB-4 possibly due to changes in the balance of inflammatory and prosclerotic pathways in liver fibrosis. Our findings suggest that sRAGE is dynamic in NAFLD and patterns may vary with severity of disease. Since this pathway is highly targetable, sRAGE may be relevant in the development of novel agents for NAFLD – a disease for which there are no FDA-approved therapies.

INFLUENCE OF GENDER ON LEARNER ASSESSMENT (INGLASS) IN GRADUATE MEDICAL EDUCATION: MULTI-SITE STUDY OF ROLE OF FACULTY GENDER IN RESIDENT ASSESSMENT

Robin Klein[1]; Nneka Ufere[2]; Jennifer Koch[3]; Erin D. Snyder[4]; Sarah Schaeffer[5]; Anna Volerman[6]; Vanessa Thompson[7]; Katherine Julian[8]; Kerri Palamara[9]. [1]Internal Medicine, Emory, Atlanta, GA; [2]Medicine, Massachusetts General Hospital, Boston, MA; [3]Medicine, University of Louisville, Louisville, KY; [4]Medicine, University of Alabama at Birmingham, Birmingham, AL; [5]Medicine, University of California, San Francisco, San Francisco, CA; [6]Medicine & Pediatrics, University of Chicago, Chicago, IL; [7]SFGH DGIM, UCSF, San Francisco, CA; [8]Medicine, UCSF, San Francisco, CA; [9]Department of Medicine, Massachusetts General Hospital, Boston, MA. (Control ID #3341313)

BACKGROUND: The role of faculty gender in gender-based differences in assessment remains unclear. This study aims to assess the influence of faculty gender on gender-based differences in resident assessment in Internal Medicine (IM) residency training.

METHODS: We conducted a retrospective, cross-sectional study at six US IM residency programs of faculty assessments of residents during medicine inpatient rotations from July 2016 to June 2017 using a competency-based assessment framework. Data included 3,600 evaluations by 605 faculty (48% female) for 703 IM residents (45% female). We calculated standardized scores based on rating distribution for the core competencies and milestones per site. We examined interaction of faculty gender, resident gender, and PGY on standardized scores, adjusting for site, time of year, IM ITE percentile rank and faculty rank and specialty.

RESULTS: There were no significant differences in male and female PG1 scores with male and female faculty. With male faculty, there was no significant difference in scores of male and female residents in PGY2 but in PGY3, male faculty rated male residents higher than female residents in all competencies, reaching statistical significance medical knowledge and practice-based learning and improvement. Female faculty rated female PGY2 residents significantly higher than male residents in all competencies except medical knowledge. Female faculty rated male PGY3 residents higher than female residents in all competencies, reaching statistical significance in patient care. While female residents' scores significantly increased in all competencies from PGY1 to PGY2 with both male and female faculty ($p=0.04$ to $p<0.001$), there was no significant change in female residents' scores from PGY2 to PGY3 with either male or female faculty. Male residents' scores significantly increased in all competencies from PGY1 to PGY2 with male faculty ($p=0.04$ to $p<0.001$). Male residents' scores from female faculty significantly increased from PGY2 to PGY3 in all competencies ($p<0.001$) and in four of six competencies with male faculty ($p\leq0.04$). The interaction of resident gender, PGY, and faculty gender was significant in the Patient Care competency ($p=0.04$).

CONCLUSIONS: This is the first study to report faculty gender as a notable factor in gender-based differences in resident assessment. We found that both male and female faculty contribute to the gender-based differences in female residents' scores, specifically the "peak and plateau"

pattern whereby female residents' scores peaked in PGY2 and failed to improve in PGY3. We also noted a trend whereby female faculty rated PGY2 male residents lower than female residents but this reversed in PGY3. Reasons for this are unclear. Evidence suggests male learners may overestimate confidence compared to female peers and traditional male gender role reinforces stoicism, independence, and reluctance to seek help. Future work in implicit gender bias should look into the role of faculty gender.

INFLUENCE OF GENDER ON LEARNER ASSESSMENT (INGLASS) IN GRADUATE MEDICAL EDUCATION: MULTI-SITE STUDY OF ROLE OF RESIDENT GENDER IN ASSESSMENT

Robin Klein[1]; Nneka Ufere[8]; Erin D. Snyder[2]; Jennifer Koch[4]; Sarah Schaeffer[7]; Anna Volerman[5]; Vanessa Thompson[6]; Katherine Julian[3]; Kerri Palamara[9]. [1]Internal Medicine, Emory, Atlanta, GA; [2]Medicine, University of Alabama at Birmingham, Birmingham, AL; [3]Medicine, UCSF, San Francisco, CA; [4]Medicine, University of Louisville, Louisville, KY; [5]Medicine, University of Chicago, Chicago, IL; [6]SFGH DGIM, UCSF, San Francisco, CA; [7]Medicine, University of California, San Francisco, San Francisco, CA; [8]Medicine, Massachusetts General Hospital, Boston, MA; [9]Department of Medicine, Massachusetts General Hospital, Boston, MA. (Control ID #3341306)

BACKGROUND: Competency-based education relies on valid assessment and bias is a potential threat to the integrity of resident assessment. This study aims to assess the influence of resident gender on resident assessment in Internal Medicine (IM) residency training.

METHODS: We conducted a retrospective, cross-sectional study at six US IM residency programs of faculty assessments of residents during general ward rotations from July 2016 to June 2017 using a competency-based assessment framework. Data included 3,600 evaluations by 605 faculty (48% female) for 703 IM residents (45% female). We calculated standardized scores based on rating distribution for the ACGME's core competencies and IM Milestones at each site and used standardized scores in aggregate for analysis. We examined interaction of gender and post-graduate year (PGY) on standardized scores, adjusting for site, time of year, IM In-Training Exam percentile rank and faculty rank and specialty.

RESULTS: Resident gender significantly influenced assessment scores as residents progressed through training. There was no significant difference in standardized scores for male and female PGY1 residents in across the core competencies. PGY2 female residents outscored male peers in all competencies, reaching statistical significance in Patient Care, Systems-Based Practice, Professionalism and Interpersonal and Communication Skills. Male PGY3 residents significantly outscored female residents in all six competencies, reaching statistical significance in all competences except Interpersonal and Communication Skills. Scores of male and female residents increased from PGY1 to PGY2 in all competencies. While male residents' scores significantly increased in all competencies from PGY2 to PGY3 ($p<0.01$), there was no significant change in female residents' scores from PGY2 to PGY3. The interaction between resident gender and PGY was significant in the six competencies ($p=0.02$ to $p<0.001$) and 12 of 20 reporting Milestones assessed in our study ($p<0.05$).

CONCLUSIONS: This is the first multisite study of implicit gender bias in IM resident assessment using a competency-based framework. We found that resident gender was a significant factor influencing resident assessment and gender-based differences in assessment linked to time in training. A "peak and plateau" pattern was noted whereby female residents' scores peaked in PGY2 and failed to improve in PGY3. Seen in all competencies for female residents, it contrasted to the positive trajectory of male residents' scores. This may represent a "glass ceiling" phenomena or invisible obstacle affecting female residents later in training that limits advancement in the assessment trajectory.

IN HOSPITAL OUTCOMES FOR FAMILY MEDICINE VS. INTERNAL MEDICINE: A COMPARATIVE PROSPECTIVE COHORT STUDY

Kanana Aburayyan[1]; Ahmad Ramahi[1]; Marwa Sabha[2]; Mohammed Awad[1]; Sarah K. Mustafa[3]; Momen Banifadel[1]; Sami Ghazaleh[1]; Ahmed Elzanaty[1]; Zeid Nesheiwat[1]; Moaath Mustafa Ali[2]. [1]Internal medicine, university of Toledo, Sylvania, OH; [2]Internal Medicine, University of Maryland, Ellicott City, MD; [3]Internal Medicine, University of Toledo, Sylvania, OH. (Control ID #3392088)

BACKGROUND: There is lack of studies comparing hospitalization and post-hospitalization outcomes between internal medicine hospitalists and family medicine hospitalist. In this prospective cohort study, we compare length of stay, cost of hospitalization, 30-day all cause readmission and 30-day mortality in hospitalized patients treated by family medicine versus internal medicine hospitalists services at a single institution.

METHODS: We conducted a classical prospective cohort study. Consecutive patients were recruited dynamically between 2/25/2019 -4/30/2019. Patients included were ≥18 years admitted to IM services for any reason. Excluded patients who did not consent and patients admitted to academic services. We collected following data: age, sex, ethnicity, assistance at home, food security most the year, residence prior to admission, type of insurance, admission diagnosis (16 categories) and co-morbidities (17 categories).

Length of stay, hospital cost, 30-day all cause readmission and 30-day mortality were outcomes of interest. Treatment arms were compared by 2 methods. We compared patients who were seen by family medicine exclusively with patients treated exclusively by internal medicine services during admission. Propensity score was used to balance baseline characteristics between comparative arms. Baseline characteristics were compared using parametric and non-parametric analysis. Difference in length of stay and hospital cost was estimated by multivariable linear regression adjusted to co-variates. Differences in 30-day readmission and 30-day mortality were estimated by multivariable cox proportional hazard regression. In another method, exposure to family medicine and internal medicine was converted to a continuous independent variable (i.e. family medicine percentage). Outcomes were estimated using regression models using family medicine percentage and other covariates.

RESULTS: A total of 747 patients were included in the study with a mean age of 60.5 ± 19 years. Forty, 333 and 374 patients were seen by family medicine, internal medicine and a combination of both services, respectively. Using average treatment on the treated as an estimand, family medicine care provided a shorter adjusted hospital stay by 0.5 days (CI: -0.92- -0.04, p-value=0.026) compared to internal medicine. Adjusted 30-day readmission hazard ratio was 2.2 higher in family medicine (CI: 1.05-4.72, p-value=0.037). No difference was seen in adjusted cost of hospitalization or adjusted cost of hospitalization. Multiple regression models of complete cohort (n=747) did not show any difference in outcomes with increased exposure to family medicine care.

CONCLUSIONS: Compared to internal medicine hospitalist, family medicine hospitalists provide shorter stay with no cost saving, this translated into increased .hospital bed availability. However, 30-day all cause readmission was 2 times higher, this has important economic implications

INITIATION OF LONG-ACTING OPIOIDS FOLLOWING HOSPITAL DISCHARGE AMONG OPIOID-NAïVE PATIENTS

Bhushan Deshpande[1]; Ellen McCarthy[1,2]; Yoojin Jung[3]; Timothy Anderson[1,3]; Shoshana J. Herzig[1,3]. [1]Harvard Medical School, Boston, MA; [2]Hinda and Arthur Marcus Institute for Aging Research, Hebrew SeniorLife, Boston, MA; [3]Division of General Medicine, Beth Israel Deaconess Medical Center, Boston, MA. (Control ID #3391633)

BACKGROUND: Opioids with a longer duration of effect ("long-acting opioids") are associated with risk of overdose and morbidity compared to short-acting opioids even at equivalent dosing. Guidelines recommend against initiating long-acting opioids during hospitalization. We evaluated prescription of long- acting opioids following hospitalization among opioid-naïve older adults.

METHODS: We used a random sample of fee-for-service Medicare beneficiaries in 2016 who were ≥65 years old, did not have cancer or hospice claims, and had not filled an opioid prescription in the 30d prior to hospitalization. We used multivariable logistic regression to identify characteristics associated with prescription of ≥1 long-acting opioid within 7d of hospital discharge compared to those prescribed only short-acting opioids. Predictors included sociodemographics, chronic conditions and medication claims, markers of medical complexity and functional status, indication for hospitalization, and prior opioid use.

RESULTS: There were 282,369 hospitalizations in our cohort; 200,647 (71.1%) were medical and 81,722 (28.9%) were surgical. 57,156 (20.2%) had a claim for short-acting opioids only and 1,555 (0.6%) for ≥1 long-acting opioid. Compared to patients with a claim for short-acting opioids only, patients with a claim for a long-acting opioid were younger (aOR varied by age) and more likely have certain painful diagnoses/procedures (musculoskeletal injury aOR 1.6, 95% CI 1.4-1.8; spine surgery aOR 3.0, 95% CI 2.3-4.0; arthroplasty aOR 7.1, 95% CI 5.8-8.7), to have had ≥2 prior hospitalizations (aOR 1.4, 1.1-1.7), and been hospitalized for >7d (aOR 1.5, 1.2-1.8). Although patients with a medical DRG were more likely than those with a surgical DRG to have a long-acting opioid claim (aOR 3.8, 3.1-4.7), the majority of patients with a claim for a long-acting opioid had a surgical (989; 63.6%) rather than medical DRG (566; 36.4%). Patients prescribed long-acting opioids were more likely to have opioid use disorder (aOR 2.6, 2.1-3.3) and a concurrent post-discharge claim for benzodiazepines (aOR 1.4, 1.2-1.8). Prior long-term high-dose opioid use had the strongest association with a long-acting opioid claim (aOR 26.7, 20.8-34.1); after excluding such patients (880), the incidence of long-acting opioid prescription (1,376; 0.5%) and associated characteristics were similar.

CONCLUSIONS: The majority of opioid-naïve individuals discharged with long-acting opioids after acute hospitalization are surgical patients, which is particularly concerning as post-operative pain is typically acute and self-limited. Moreover, patients started on long-acting opioids at discharge had higher incidence of known risk factors for opioid-related adverse events, including co-prescription of benzodiazepines, history of prior long-term high-dose opioid use, and opioid use disorder, highlighting the necessity to develop systems- based solutions to improve guideline-concordant prescribing of long-acting opioids.

INPATIENT MANAGEMENT OF CANCER PATIENTS WITH FEBRILE NEUTROPENIA: GUIDELINE CONCORDANT OR INADEQUATE?

Maitreyee Rai[1]; Meghana Parsi[1]; Neha Puri[1]; Jugeet Kanwal[1]; Pushti Khandwala[1]; Sruthi Samala[1]; mylene s. go[2]. [1]Internal Medicine, Crozer Chester Medical Center, Brookhaven, PA; [2]Hematology oncology, crozer Chester medical center, Upland, PA. (Control ID #3391276)

BACKGROUND: The American Society of Clinical Oncology (ASCO) and Infectious Disease Society of America (IDSA) recommend risk stratification of cancer patients on chemotherapy presenting with febrile neutropenia (FN) and timely administration of appropriate empiric antibiotics. We studied the primary outcome of guideline-concordant risk stratification and antibiotic administration, and patient outcomes in FN patients. The secondary outcome was to assess the predictive capacity of the MASCC (Multinational Association of Supportive Care in Cancer) scoring system in identifying patients with high risk.

METHODS: We conducted a retrospective chart review of 154 hospitalized FN patients from the year 2013 to 2019 in 4 community hospitals. Inclusion criteria were adult patients (>/= 18 years), Internal Medicine service, cancer diagnosis, neutropenia (Absolute neutrophil count(ANC) <1000 cells/uL) & fever (temperature >100.4F sustained over 1 hour period or one-time temperature of >/=101 F). We assessed the adherence of our clinicians to the ASCO/ IDSA guidelines. Statistical analysis was performed to determine the predictive capacity of the MASCC scoring system in identifying high-risk patients.

RESULTS: Out of 154, 1 patient (0.64%) had risk stratification with the MASCC score. We calculated the MASCC score for all patients. 95 were classified as low risk (score >/=21) and 59 were high risk (score <21). The first dose of empiric antibiotics was given within 30 minutes of triage in 3 patients (1.95%), between 30minutes to 3 hours in 125 (81.16%), and more than 3hours in 26 (16.88%). 136 (88.31%) patients did receive antipseudomonal coverage. 132 patients had one or more indications for vancomycin use, out of which 117 received vancomycin. 120 (77.92%) patients recovered (77 in low risk and 43 in high-risk group). 26 (16.88%) patients had one or more of the following complications - a level of care upgrade, bacteremia, fungemia, resistant microbial strains in cultures, clostridioides difficile infection, death. A two-sample t-test demonstrated that the mean MASCC score among patients with high-risk parameters on admission was significantly lower than those without (Mean=19.74 vs. 24.80, p<0.0001). For every one-unit increase in the MASCC score, the odds of having high-risk parameters is decreased by 47.5% (odd's ratio OR=0.535, 95% CI=0.373-0.769).

CONCLUSIONS: Our study revealed a good predictive capacity of the MASCC scoring system in identifying the high-risk patients. The use of MASCC, however, remained underused among the clinicians in our community hospitals. The majority of patients did receive IDSA guideline-concordant anti-pseudomonal and vancomycin coverage. However, the timing of antibiotic administration was delayed more than 3 hours in a significant number of patients. Future steps to ensure patient risk stratification, triage and prompt administration of empiric antibiotics can potentially improve patient outcomes and bridge the gap between treatment recommendations and actual practice.

INPATIENT PATIENT SAFETY EVENTS IN VULNERABLE POPULATIONS: A RETROSPECTIVE COHORT STUDY

Lucy Schulson[1]; Victor Novak[2,3]; Jennifer Stevens[3]; Bruce E. Landon[4]. [1]Internal Medicine, Boston University/ Boston Medical Center, Boston, MA; [2]Soroka University Medical Center, Be'er Sheva, Israel; [3]Beth Israel Deaconess Medical Center, Boston, MA; [4]Health Care Policy, Harvard Medical School, Boston, MA. (Control ID #3391970)

BACKGROUND: Patient safety events are an important cause of morbidity and mortality, and vulnerable populations may be at increased risk. Limited prior research has examined the extent to which patient race/ethnicity, English proficiency, or socioeconomic status puts them at higher risk for inpatient patient safety events.

METHODS: We conducted a single center retrospective cohort study of inpatient non-ICU admissions of those ≥ 18 years from January 1, 2014 to

December 31, 2018. We excluded those with a length of stay (LOS) > 15 days or a prior admission within 30 days. The primary exposures of interest were self-identified race/ethnicity (white, African-American, Latino, Asian, and other/unknown), Medicaid insurance /self-pay, and limited English proficiency (LEP), which we identified when patients chose a preferred language other than English at registration. Our primary outcome of interest was any patient safety event, which we defined as any event identified by a modified version of the IHI global trigger tool that uses laboratory and pharmacy data to automatically identify patient safety events ("automated") or by the hospital-wide voluntary provider reporting system ("non-automated"). We also examined each category of events in stratified analyses. We performed bivariate analyses using chi-square and Mann-Whitney tests. To estimate adjusted results, we used negative binomial regression adjusting for demographic factors, primary diagnosis, inpatient service, comorbidities, LOS, and year.

RESULTS: We studied 123,887 hospital stays, of which 8.2% (10,200) had any patient safety event. There were 3063 automated patient safety events (2.5% of admissions) and 7992 non-automated patient safety events (6.5%). In adjusted analyses, there was no increased incidence of any patient safety event among those with Medicaid/self-pay, among those of different race/ethnicities, nor among those with LEP. By contrast, in stratified analyses, African-Americans and Latinos were at increased risk for an automated patient safety event compared to whites (IRR 1.11, 95% CI 1.00, 1.23; IRR 1.22 95% CI 1.00, 1.43) but not non-automated events. Medicaid was associated with increased risk for only non-automated events (IRR 1.08, 95% CI 1.00, 1.16). There was no significant difference in risk by LEP for automated or non-automated patient safety events (IRR 0.96, 95% CI 0.84, 1.13; IRR 0.93, 95% CI 0.86, 1.02).

CONCLUSIONS: In this single institution study, we found no difference in overall risk for patient safety events by insurance, race/ethnicity, or LEP. Medicaid insurance was associated with increased risk for non-automated events suggesting the importance of socioeconomic status in patient safety. Race was a risk factor for automated events but not reported events, possibly due to underreporting. Those with LEP do not appear to be at increased risk for events, but it is unclear if this represents a true null risk or lower rates of reporting for this population.

INTEGRATING STEADI FALLS PREVENTION PROGRAM INTO A BUSY ACADEMIC PRACTICE

Ryan J. Moran[1,2]. [1]General Internal Medicine, University of California, San Diego, La Jolla, CA; [2]Department of Family Medicine and Public Health, University of California, San Diego, La Jolla, CA. (Control ID #3386619)

BACKGROUND: In 2016, US residents over age 65 totaled almost 50 million, an increase of over 40% since 2000. Approximately one-third of community-residing adults age 65+, and one-half over 80 fall annually. Falls are dangerous, and fall-related mortality has increased over 30% just between 2007 to 2016. Many falls are preventable, and the Centers for Disease Control and Prevention (CDC) has outlined an evidenced based screening tool, Stopping Elderly Accidents, Deaths & Injuries (STEADI) but penetration into routine clinical practice has been slow.

METHODS: A modified evidenced based screening tool was integrated into a busy academic primary care practice between June and October 2019. Waiting-room materials were created highlighting fall-risk, allowing individual self-selection to screen via a modified STEADI questionnaire, shown to identify 95% of high risk individuals, and uniquely numbered. If positive, further discussion with a provider was implored. Booklets with evidenced-based CDC and community resources, including free and low cost fall prevention exercise programs were generated incase a provider had no time to discuss fall-prevention strategies or the patient was interested in more information, and made available in exam-rooms. Disseminated materials were tallied, and Epic Slicer-Dicer reports were used to compare difference-in-differences of the impact from the same period the year before, and against other clinics within the same academic integration system for ICD-10 codes determined a priori for falls-based screening. These codes were used in a study integrating STEADI; however providers were not told to change their practice or code in any particular way. Generalized linear modeling (SAS 9.4 GENMOD) was utilized to determine significance. No clinical staff were asked to do anything except collect the completed waiting room screens.

RESULTS: In three months, 255 questionnaires were taken; 5 (2%) were returned by for later review. 110 booklets for falls prevention information were removed from exam rooms. Including the same three months from the year before (6 months total), there were 43,284 clinical encounters at all sites for individuals 65+, with an average falls-related ICD-10 coding of 11%. Comparing the clinic with the falls screening program to other clinics within the integrated system, and against the year before, the absolute differential in coding was 0.7% (clinic of interest difference of 0.6%, vs. other clinics -0.14%). Modeling difference-in-differences showed a 4.7% increase in screening-related ICD-10 codes, which was statistically significant (P=<.0001). There was no reported disruption to clinic workflows.

CONCLUSIONS: Selective screening in an academic practice resulted in an increase in falls-related ICD-10 coding. Few screening questionnaires were returned limiting chart review opportunity. Information with evidenced-based falls-prevention strategies, and community-based resources were disseminated. Clinical integration of this program was well received.

INTENSIFICATION OF OLDER ADULTS' DIABETES MEDICATIONS AT HOSPITAL DISCHARGE LEADS TO INCREASED HYPOGLYCEMIA VISITS WITHOUT LONG TERM BENEFIT

Timothy S. Anderson[1]; Bocheng Jing[2]; Sei Lee[2]; Sarah Ngo[2]; Kathy Fung[2]; Michael A. Steinman[2]. [1]Medicine, Beth Israel Deaconess Medical CEnter, Jamaica Plain, MA; [2]Div of Geriatrics, UCSF/SFVA, San Francisco, CA. (Control ID #3387775)

BACKGROUND: Transient elevations of blood glucose are common in hospitalized older adults and may lead clinicians to discharge patients on intensified diabetes medication regimens even when diabetes is not the primary reason for hospitalization. This practice may expose patients to risks of overtreatment and hypoglycemia, particularly those whose diabetes was previously at goal, however the clinical outcomes are unknown.

METHODS: We used national VA and Medicare data to examine veterans age >65 years with diabetes not previously taking insulin who were hospitalized in a VA in 2011-2013 for common medical conditions. Using propensity score matching based on >120 demographic and clinical variables, patients discharged on intensified diabetes medications were compared to those who were not. Competing risk regressions were used to assess co-primary outcomes of severe hyperglycemia and hypoglycemia events (ED visit or hospitalization) at one year. Secondary outcomes included hypoglycemia visits (clinic visit, ED visit, or hospitalization), all-cause readmissions and change in hemoglobin A1c within 1 year of discharge which was assessed using difference-in-differences analyses.

RESULTS: The matched cohort included 3194 patients (mean [SD] age 73 [7] years; 98% male) evenly divided among those who did vs did not receive diabetes medication intensifications with excellent covariate balance (standardized mean differences for all covariates <0.1). Mean (SD) pre-admission hemoglobin A1c was 7.9% (1.6%). At 1 year, patients receiving intensifications had no significant difference in severe hyperglycemia events (hazard ratio (HR) 0.54; 95% CI, 0.28 to 1.03), severe hypoglycemia events (HR 1.23; 95% CI, 0.87 to 1.74), or all-cause readmissions (HR 1.00; 95% CI, 0.91 to 1.10), but did have an increased

risk of overall hypoglycemia visits (HR 1.30; 95% CI, 1.01 to 1.69). There was no difference in change in hemoglobin A1c among those who did vs did not receive intensifications [mean A1c 7.7% vs 7.8%, difference-in-differences -0.1% (-0.3% to 0.1%)].

CONCLUSIONS: Among hospitalized older veterans, those discharged on intensified diabetes medications had no difference in severe hyperglycemia events, severe hypoglycemia events, or hemoglobin A1c control at one year but had an increased risk of hypoglycemia encounters. Our findings indicate that intensifying diabetes regimens at hospital discharge may pose greater risks than benefits and should be reserved for only patients at high short-term risk of severe hyperglycemia.

INTENSIFYING OFFICE-BASED BUPRENORPHINE TREATMENT THROUGH GROUP MEDICAL VISITS

Aaron D. Fox[1]; Chinazo Cunningham[2]. [1]Medicine, Montefiore Medical Center, Bronx, NY; [2]Medicine, Albert Einstein College of Medicine & Montefiore Medical Center, Bronx, NY. (Control ID #3391588)

BACKGROUND: Little evidence exists to guide primary care physicians (PCPs) when their patients continue to use illicit opioids during office-based buprenorphine treatment. Group medical visits allow health care teams to provide group counseling and medical management to multiple patients simultaneously, which may increase psychosocial support and improve treatment outcomes. Observational data regarding group medical visits are promising, but more rigorous evaluation is necessary. Our objective was to pilot test feasibility, acceptability and preliminary effectiveness of group medical visits in primary care for patients with ongoing illicit opioid use.

METHODS: We conducted a pragmatic randomized controlled trial of a novel 8-session buprenorphine group medical visit (GMV) intervention. Patients at an urban community health center were eligible if non- prescribed opioids were present in ≥50% of their urine drug tests after 12 weeks of buprenorphine treatment. We developed a novel intervention manual based on focus groups with buprenorphine patients and an evidence-based cognitive behavioral therapy manual. Participants in the GMV condition received 8 weekly 90-minute group sessions facilitated by a physician and psychologist along with prescriptions for buprenorphine-naloxone (bup-nx). Participants in the treatment as usual (TAU) condition received bup-nx prescriptions from their PCPs. Outcomes were assessed at 2, 4, 6, 8, 12, 16, and 24 weeks following study initiation. *Feasibility* was determined by GMV attendance. *Acceptability* was determined by patient satisfaction (17 items addressed perceived quality of care and helpfulness of different treatment components; 5-point Likert scale: 1 = very unsatisfied; 5 = very satisfied). The primary *effectiveness* outcome was abstinence from illicit opioids at the 8 and 12 week visits based on self-report and urine drug testing. A secondary outcome was *retention in treatment* at 24 weeks, defined as having an active bup-nx prescription 20-28 weeks after study enrollment.

RESULTS: Of 19 participants, most were male, Latinx, and median age was 52. Patient satisfaction was high in both arms (mean = 4.72 out of 5, 95% CI = 4.55 – 4.87) with no significant difference. The 10 GMV participants attended an average of 4.5 of 8 visits with 3 participants attending 1 or no visits. Abstinence was low (0% in GMV vs. 11% in TAU) with no significant difference. Retention in treatment at 24 weeks was high (70% in GMV vs. 77% in TAU) with no significant difference.

CONCLUSIONS: An office-based 8-session buprenorphine group medical visit intervention was feasible and acceptable to participants. Though few participants achieved abstinence from illicit opioid use during the intervention, the higher intensity group medical visits did allow for delivery of group counseling and psychosocial support without harming treatment retention. Next, we will study GMVs over a longer intervention period with broader treatment outcomes (e.g., quality of life) in a fully powered RCT.

INTENSITY OF BLOOD PRESSURE DRUG DOSING FOR HYPERTENSION TREATMENT IN VETERANS

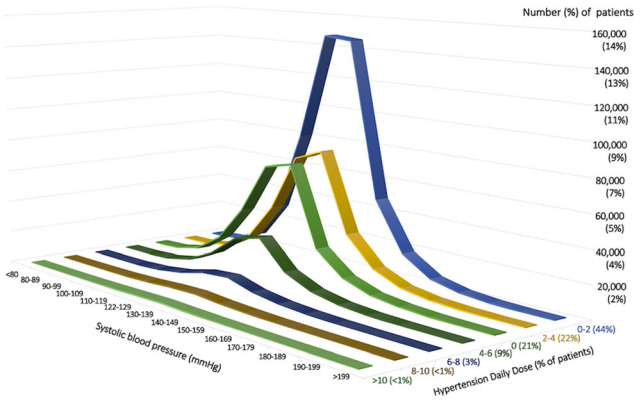
Carole E. Aubert[1,4]; Jinkyung Ha[2]; Jeremy Sussman[3,8]; Kenneth M. Langa[7,8]; William Cushman[5,6]; Mary Tinetti[9]; Hyungjin M. Kim[10,11]; Matthew Maciejewski[12,13]; Leah Gillion[4]; Angela Larkin[4]; Chiao-Li Chan[2]; Eve A. Kerr[3,4]; TImothy Hofer[3,4]; Lillian Min[7,2]. [1]Department of General Internal Medicine and Institute of Primary Health Care (BIHAM), Bern University, Bern, Bern, Switzerland; [2]Division of Geriatric and Palliative Medicine, Department of Medicine, University of Michigan, Ann Arbor, MI; [3]Department of General Internal Medicine and Institute of Primary Health Care (BIHAM), University of MIchigan, Ann Arbor, MI; [4]Veterans Affairs Center for Clinical Management Research, University of Michigan, Ann Arbor, MI; [5]Preventive Medicine Section, Memphis VA Medical Center, Memphis, TN; [6]Division of Preventive Medicine, University of Tennessee Health Sciences, Memphis, TN; [7]VA Ann Arbor Healthcare System and Medical Center VA Geriatric Research Education and Cilnical Center (GRECC), University of Michigan, Ann Arbor, MI; [8]Institute for Social Research, University of Michigan, Ann Arbor, MI; [9]Medicine, Section of Geriatrics, Yale School of Medicine, New Haven, CT; [10]Biostatistics, University of Michigan, Ann Arbor, MI; [11]Center for Statistical Consultation and Research, University of Michigan, Ann Arbor, MI; [12]ADAPT Center of Innovation Durham, VA Health Care System, Durham, NC; [13]Department of Population Health Sciences, Duke University, Durham, NC. (Control ID #3389459)

BACKGROUND: Hypertension affects >80% of older Americans. To date, healthcare systems have focused mostly on blood pressure (BP). However, we lack understanding of the intensity of BP drugs prescribed to achieve varying levels of BP control. For older patients, multiple drugs and high doses may have adverse consequences. Therefore, we developed a method to capture the intensity of BP drugs dispensed by healthcare systems to older outpatients. This measure captures multiple BP drug classes and is standardized meaningfully to doses tested in clinical trials. In this study, we applied the method to the national VA healthcare system and described the resulting BP control achieved in older Veterans.

METHODS: We included patients aged ≥65 years with hypertension (ICD-9 401.x) and VA primary care (07/2011- 06/2013), excluding managed care enrollees. We linked VA pharmacy with Medicare Part D fills. A patient was on a BP drug based on fills within 180 days of primary care visits. We adjusted the dose downward for delayed refills. Doses were converted to Hypertension Daily Dose (HDD) units. For each BP drug, one HDD unit is the closest available dose to half the maximum beneficial dose demonstrated in trials. We aggregated the HDDs for each patient's BP regimen. For example, a patient on lisinopril 20mg (1 HDD, or half maximal dose of 40mg) and hydrochlorothiazide 25mg (1 HDD, or half maximal dose of 50mg) was assigned a total of 2 HDDs. For each patient, the BP and drugs were measured on the last primary care visit of the first available quarter of 2011-2013. The BP was the average of that visit plus the prior 2 primary care BPs within 6 months.

RESULTS: In 1,113,549 patients, most (82%) had systolic BP (SBP) <140mmHg (Figure). More than half of patients (59%) had SBP 120-139mmHg, while 22% had SBP <120mmHg and 6.7% ≥150mmHg. The majority (44%) received up to 2 HDDs (corresponding to the maximal dose of a single BP drug), followed by 2-4 HDDs (22%). One-fifth (21%) didn't fill any drug, despite SBP ≥150mmHg in 1.4% of all patients. One percent filled BP drugs despite SBP <100 mmHg.

CONCLUSIONS: Most outpatient older Veterans met BP targets by filling modest intensity BP drug regimens. A small proportion of patients were receiving BP drugs despite very low SBP.



INTENSIVE MEDITATION FOR MIGRAINES: EFFECTS OF VIPASSANA MEDITATION AT ONE YEAR

Madhav Goyal[1,2]; Jennifer Haythornthwaite[3]; Sharat Jain[4]; B L. Peterlin[5]; Megha Mehrotra[6]; David M. Levine[7]; Jason Rosenberg[8]; Mary Minges[10]; Sudha Jain[4]; David Seminowicz[11]; Daniel E. Ford[9]. [1]Medicine, Johns Hopkins, Baltimore, MD; [2]NorthBay Healthcare, Vacaville, CA; [3]Psychiatry & Behavioral Sciences, Johns Hopkins School of Medicine, Baltimore, MD; [4]Vipassana, Igatpuri, India; [5]Lancaster General Neuroscience Institute, Lancaster, PA; [6]UC Berkeley, Berkeley, CA; [7]Medicine, Johns Hopkins U., Balt, Md., MD; [8]Kaiser, Halethorpe, MD; [9]Medicine, Johns Hopkins University, Baltimore, MD; [10]Mount Sinai Beth Israel, New York, NY; [11]University of Maryland, Baltimore, MD. (Control ID #3390004)

BACKGROUND: Many who suffer from migraines do not respond to prophylactic medication or do not tolerate side effects. Systematic reviews of preventive agents document reductions of 0.4 to 1.5 headaches per month in episodic migraine, above the reduction of about 1 per month seen with placebo. Since only 20-40% of patients are classified as treatment responders (reduction > 50%), there remains a significant unmet need. Behavioral approaches are recommended for the treatment of migraine, as stress and pain catastrophizing can contribute to both frequency and severity of headaches. Vipassana meditation is taught at a silent 10 day retreat and remains one of the most intensive forms of standardized meditation training in the world. A focus of the training is how to reduce one's tendency to react to stimuli. Due to the nature of the training, we hypothesized that Vipassana meditation would reduce migraine frequency and severity and improve quality of life.

METHODS: Prospective interventional study including patients with both Chronic Daily Headache (CDH; > 15 headaches days/ month of which > 8 were migraines) and Episodic Migraine (EM; > 4 migraines/ month). Patients completed at least 1 month of electronic daily headache diaries prior to the meditation retreat and then for 12 months following the retreat. They also completed surveys at baseline, 3, 6, 12 months assessing catastrophizing, stress, and quality of life.

Patients naive to Vipassana meditation were recruited from local headache/neurology clinics and community/web advertisements. Exclusion criteria included anything that may interfere with ability to participate in a 10 day course. Participants continued to use their prophylactic or acute medications throughout the study.

Generalized estimating equations evaluated the impact of the retreat on headache and migraine frequency, headache intensity and duration, medication use, and days of work missed due to headaches.

RESULTS: 300 were screened and 58 attended the retreat. 36 CDH and 9 EM completed the retreat (78%). Among completers, at 12 months, migraine frequency was reduced by 2.7 per 28 days (95%CI -4.3, -1.3) and headaches by 3.4 per 28 days (-4.9, -1.9) relative to baseline. 29% reported a 50% reduction in headache frequency. Acute medication use dropped by 2.2 days (-3.9, -0.5) per 28 days. Migraine specific quality of life, pain catastrophizing and perceived stress all improved significantly from baseline. One adverse event occurred.

CONCLUSIONS: While it is not possible to conclude if the reductions in reported headaches are due to expectation effects, for patients and clinicians the important results may be that the absolute reductions and 50% responder rates are still similar to what patients would achieve using popular medications. Training in a 10 day Vipassana meditation retreat may supplement pharmacotherapy to reduce the burden of chronic or episodic migraines for those who find this intervention an acceptable approach.

INTERNAL MEDICINE PROVIDERS' COLORECTAL CANCER SCREENING RECOMMENDATIONS AND PRACTICES

Maryam Sattari, Stacy Beal, Thomas J. George. Medicine, University of Florida College of Medicine, Gainesville, FL. (Control ID #3392431)

BACKGROUND: Despite well-established effectiveness of colorectal cancer (CRC) screening in its prevention and early detection, only two thirds of eligible adults undergo screening in the United States. Unfortunately, CRC continues to cause significant morbidity and mortality as the third-leading cause of cancer-related deaths despite the ability to detect it early. A physician's recommendation is the greatest predictor of successful completion of preventive care. This study assessed the beliefs of providers in an internal medicine clinic at the University of Florida (UF) about the effectiveness of CRC screening, their recommendations for screening, and how they conduct CRC screening in their clinical practices.

METHODS: An anonymous, 34 item, questionnaire was administered to forty-five practicing providers at the clinic.

RESULTS: Twenty-nine (64.4%) responded, representing 10 (100%) faculty, 4 (100%) nurse practitioners, and 15 (46.9%) internal medicine residents. All respondents strongly agreed that CRC screening is very important, 18 (62.1%) strongly agreed that colonoscopy is the best screening test, and 10 (24.4%) strongly agreed that colonoscopy is readily available to their patients.

Colonoscopy and fecal immunochemical testing (FIT) were the two most common modalities recommended for screening, with every participant reporting use at least some of the time. While 22 participants (75.7%) reported never ordering flexible sigmoidoscopy and 19 (65.5%) did not use fecal occult blood testing (FOBT) or stool DNA testing for screening, four participants (13.8%) reported screening by a single FOBT/FIT from a rectal exam in the office.

Fifteen providers (51.7%) reported recommending only one specific test for screening, with 100% typically recommending a colonoscopy first and a FIT, only if the patient is unwilling or unable to undergo colonoscopy. All 14 participants (48.3%) who reported discussing more than one screening test, included both FIT and colonoscopy in the discussion. Four (13.8%) also reported discussing stool DNA testing and 2 (6.9%) CT colonography.

The most frequently cited barriers to CRC screening were lack of enough time to discuss screening with patients and difficulty of the bowel preparation required for colonoscopy.

CONCLUSIONS: Awareness of CRC screening among primary care providers in this study was high.

However, knowledge gaps about CRC recommendations, including modalities for screening, were evident. Targeted educational programs and consistency in practice patterns are being developed.

INTERNAL MEDICINE RESIDENT KNOWLEDGE, ATTITUDES, AND PRESCRIBING PRACTICES RELATED TO HIV PRE-EXPOSURE PROPHYLAXIS (PREP)

Gregory M. McWilliams, Grant B. Ellsworth, Roy M. Gulick. Department of Medicine, New York- Presbyterian/Weill Cornell Medical Center, New York, NY. (Control ID #3389649)

BACKGROUND: Clinical trials show that HIV Pre-exposure Prophylaxis (PrEP) is an effective tool in reducing HIV transmission among high-risk populations. In June 2019, the US Preventive Services Task Force gave PrEP an "A" grade (high certainty that the net benefit is substantial) in individuals at high risk of HIV acquisition. Nevertheless, providers often are not comfortable prescribing PrEP in part due to a lack of knowledge about current prescribing guidelines.

METHODS: We gave an anonymous survey to 67 PGY-1 and PGY-3 internal medicine residents at a large, urban academic medical center before and immediately after a 30-minute lecture about PrEP. The endpoints assessed were 1) knowledge about PrEP, 2) attitudes toward PrEP, and 3) PrEP prescribing practices. We administered an identical survey six months after the initial lecture to assess retention of knowledge and changes in residents' PrEP prescribing habits.

RESULTS: 67 of 67 (100%) residents at the lecture took the pre-lecture survey while 66 of 67 (99%) residents completed the survey immediately after the lecture. The quiz scores measuring PrEP knowledge before and immediately after the lecture were 46% and 81%, respectively ($p < 0.001$). Before the lecture, 22 of 67 (33%) of residents were extremely likely to prescribe PrEP to high risk patients compared to 38 of 66 (58%) of residents immediately following the lecture ($p=0.001$). Prior to the lecture, 54 of 67 (81%) of residents felt that knowledge about PrEP was a barrier to prescribing the drug in at-risk patients; however, immediately after the lecture, 38 of 66 (58%) of residents felt that knowledge was a barrier ($p=0.007$).

34 of 67 (51%) of the original respondents participated in the follow-up survey at six months. Quiz scores reflecting PrEP knowledge before and six months after the lecture were 46% and 58%, respectively ($p=0.002$). Before the quiz, 25 of 67 (38%) residents reported managing patients already on PrEP, but in the follow up period, 23 of 34 (68%) residents reported managing patients already on PrEP ($p=0.009$). There was no difference in the number of residents who reported initiating patients on PrEP nor having a discussion with them about using PrEP as an HIV prevention tool.

CONCLUSIONS: An educational intervention about PrEP to internal medicine residents improves knowledge of guideline-based prescribing practices; this knowledge appears to be retained six months after the initial lecture. Residents were more likely to report managing patients already on PrEP six months after the educational intervention. Collectively, these data suggest a greater fluency and comfort with PrEP following the educational intervention. However, follow up surveys at six months did not demonstrate that residents were initiating therapy in PrEP-naive patients nor counseling them on the benefits of PrEP as an HIV prevention tool. These events may not have been captured due to the short interval follow up or the low frequency of clinical opportunity to prescribe PrEP in our practice.

INTERNET CLAIMS ON THE HEALTH BENEFITS OF CANNABIS USE

Nicholas Lau[1]; Madeleine Gerson[1]; Deborah R. Korenstein[3]; Salomeh Keyhani[2,1]. [1]Population Health and Policy Research Group, Northern California Institute for Research and Education, San Francisco, CA; [2]Department of Medicine, University of California, San Francisco, San Francisco, CA; [3]Department of Education, Memorial Sloan Kettering Cancer Center, Pelham, NY. (Control ID #3390713)

BACKGROUND: As cannabis is legalized in the United States, people are likely turning to the internet for information about its potential health benefits. In this study, we characterize internet claims about the health benefits of cannabis use in the lay press and evaluate the evidence base supporting claims.

METHODS: We performed a cross-sectional study of a sample of internet claims regarding the health benefits of cannabis use. We extracted information on claims from two different sources on June 15, 2019: (1) We searched Google for "marijuana benefits," "weed benefits," and "marijuana health." Our sample includes the top ten lay webpages from each Google search. Internet links to the scientific literature were not included as the focus of this analysis was to characterize information available in the lay press. (2) We searched Buzzsumo, a social media analyzer tool that calculates online engagement with news articles, which measures an article's engagement by its number of likes, shares, and comments on social media sites. We used the terms: "marijuana benefits OR cannabis benefits OR weed benefits," and "marijuana health," restricting our search to articles published in the previous two years. We excluded articles irrelevant to cannabis use, and only included high-impact articles (over 10,000 engagements) because they had the most reach with an online audience. Two reviewers independently reviewed webpages and articles to extract and categorize claims about the health benefits of cannabis use. Two experts (SK, DK) reviewed the literature to determine the validity of each claim based on available trial evidence. Disagreements were resolved by discussion. The evidence was categorized as not true, partly true, true, and unable to assess.

RESULTS: We found 467 individual claims regarding the health benefits of cannabis use and defined 81 categories. Of the 81 claim categories in our sample, we identified 80.2% as not true, 8.6% as partly true, and 4.9% as true based on trial evidence; 6.2% were unable to be assessed. Among the 10 most common claims, not true claims related to the efficacy of cannabis for general pain, cancer, anxiety, post-traumatic stress disorder, neuroprotection, and Alzheimer's disease. The remainder of claims among the 10 most common were true (related to chemotherapy-induced nausea/vomiting and to spasticity from multiple sclerosis) and partly true (related to seizures and sleep).

CONCLUSIONS: Most internet claims about the health benefits of cannabis use are not true based on available evidence. More clinical trials on cannabis use health outcomes are necessary for patients and clinicians to make informed decisions.

IS BURNOUT BEST UNDERSTOOD AT THE LEVEL OF THE INDIVIDUAL, PRACTICE, OR SYSTEM?

Samuel T. Edwards[1]; Miguel Marino[2]; Leif Solberg[5]; Laura Damschroder[3]; Kurt C. Stange[4]; Thomas Kottke[5]; Bijal A. Balasubramanian[6]; Rachel Springer[2]; cynthia perry[7]; Deborah Cohen[2]. [1]General Internal Medicine, Boston VA Healthcare System, Boston, MA; [2]Family Medicine, Oregon Health & Science University, Portland, OR; [3]Ann Arbor VA Center for Clinical Management Research, Ann Arbor, MI; [4]Family Medicine & Community Health, Case Western Reserve University, Cleveland, OH; [5]HealthPartners, Minneapolis, MN; [6]Epidemiology, University of Texas School of Public Health, Dallas, TX; [7]School of Nursing, Oregon Health and Science University, Portland, OR. (Control ID #3387557)

BACKGROUND: Burnout is prevalent among clinicians and staff in primary care and is associated with negative consequences. However, burnout is often treated as a problem of individuals, not of the practices or systems in which they work. In this study, we analyzed the multilevel

factors associated with burnout by comparing practices with unusually high and low levels of burnout.

METHODS: We conducted a survey of clinicians and staff in a sample of small to medium-sized primary care practices participating in a national initiative focused on improving the delivery of cardiovascular preventive services. We limited our sample to practices with at least three responses across multiple roles and with response rate>50%. Our primary outcome was a single item, five-level self-report measure of burnout. We also collected information on practice structural characteristics, Adaptive Reserve (a measure of practice capacity for organizational learning and development), use of quality improvement strategies, and practice- level satisfaction with their electronic health record (EHR) system.

RESULTS: 7,740 clinicians and staff from 715 primary care practices responded, an 86% response rate. The intraclass correlation (ICC)-1, the proportion of total variation that can be explained by practice membership, was 0.104 (95% CI = 0.085-0.123), suggesting a moderate practice level effect. In 30% of practices (n=214), no practice members reported burnout ("no-burnout"), while in 13% of practices (n=94) over 40% of their practice members reported burnout ("high-burnout"). Compared to high-burnout practices, no-burnout practices were more commonly solo practices (e.g. 6-10 clinicians vs. solo, adjusted odds ratio [aOR] of high practice burnout 5.55, p<0.01), clinician owned (hospital or health system owned vs. clinician owned, aOR of high practice burnout 3.37, p<0.01) and less commonly participated in accountable care organizations (ACOs; aOR of high practice burnout 2.06, p=0.04). Mean Adaptive Reserve was higher for no-burnout (0.76) compared to high-burnout practices (0.58, p <0.01); select subscales, including facilitative leadership, communication, sense-making and psychological safety, were each significantly higher. No-burnout practices reported using more quality improvement (QI) strategies (Change Process Capability Questionnaire Strategy Score mean=10.8) than high-burnout (mean=7.0) practices (p=0.02) and reported less dissatisfaction with electronic health records (p=0.01).

CONCLUSIONS: Understanding burnout at the level of individuals, practices and systems has potential to lead to multilevel solutions. Specific factors associated with practice-level burnout suggest that the current approach to system consolidation may increase burnout, reduce practice capacity for organizational learning, and reduce engagement in quality improvement. Future improvement efforts should focus on supporting smaller practice arrangements and increasing practice capacity.

ISOLATION IN THE ENCLAVE: A QUALITATIVE STUDY OF SOCIAL ISOLATION AMONG CHINESE AND HISPANIC/ LATINO IMMIGRANTS IN CHICAGO

James Zhang[1]; Itzel Lopez-Hinojosa[1]; Yueling Ji[4]; Aresha Martinez-Cardoso[3]; Elizabeth L. Tung[2]. [1]Pritzker School of Medicine, University of Chicago, Chicago, IL; [2]Section of General Internal Medicine, University of Chicago, Chicago, IL; [3]Department of Public Health Sciences, University of Chicago, Chicago, IL; [4]Department of East Asian Languages and Civilizations, University of Chicago, Chicago, IL. (Control ID #3387942)

BACKGROUND: Social isolation is shown to have adverse consequences for psychosocial health, physical outcomes and mortality. While previous studies have documented that immigration may be associated with higher risk for social isolation, few studies have examined potential mechanisms of this relationship. This qualitative study explores narratives of social isolation among Chinese and Hispanic/Latino immigrants who live in ethnic enclaves, identifying mechanisms of social isolation in participants' lives and downstream effects on their health and healthcare.

METHODS: In 2019 we conducted 14 in-depth, semi-structured focus groups with 80 immigrant adults living in the United States. Participants were recruited from four community sites in Chinese- and Spanish-speaking enclaves. Interviews were conducted in participants' native languages. Focus groups were audio- recorded and transcribed verbatim. Codes were generated from transcripts using grounded theory and the constant comparison method. For internal consistency, a codebook was iteratively developed by 4 reviewers, including 1 reviewer who coded all Chinese transcripts, and 1 reviewer who coded all Spanish transcripts. Discrepancies were resolved using a standard of intercoder agreement.

RESULTS: The mean age of participants was 61.4±13.1 years; 61% were Chinese-speaking and 39% were Spanish-speaking. Participants were largely female (62%), unemployed (68%), and attained less than a high school graduation (53%); approximately one-third were uninsured (34%). The most commonly reported reasons for immigration were to move closer to family (36%) and improve quality of life (26%). The mean duration of residence in the U.S. was 17.7±14.0 years. Participants identified several key mechanisms of isolation. Among them, many described language barriers as isolating: "Since I didn't know how to speak English…I still mainly go to places in Chinatown. I seldom go to other places." Participants also described challenges related to forming social networks: "I don't have as many friends and relatives here…I stay in the senior apartment and can't talk to anyone." Many Spanish-speaking participants described fear of police and immigration enforcement as isolating: "Well, you can't go out because the police are also there going after you." Both personal- and community-level experiences of social isolation had downstream impacts on healthcare: "We can only find Chinese speaking doctors. That is why the line is long." Participants also noted negative health consequences: "Health has been jeopardized for immigrants, because of being far away from their country…and because of the little guidance there is for people who get sick."

CONCLUSIONS: Despite many benefits of ethnic enclaves for the U.S. immigrant population, participants described narratives of social isolation on both a personal and community level. Various mechanisms of social isolation often led to downstream impacts on health and healthcare, which can potentially exacerbate health disparities.

IS SERVING AS A PEER COACH HELPFUL OR HARMFUL? FINDINGS FROM A TRIAL FOR PATIENTS WITH CHRONIC PAIN

Marianne S. Matthias[1]; Alan B. McGuire[2]; Joanne Daggy[5]; Susan Ofner[5]; Marina Kukla[3]; Matthew J. Bair[4]. [1]HSR&D, Roudebush VAMC, Indianapolis, IN; [2]Richard L Roudebush VAMC, Indianapolis, IN; [3]Richard L. Roudebush VA Medical Center, Indianapolis, IN; [4]Medicine, Center for Health Information and Communication, Indianapolis, IN; [5]Indiana University, Indianapolis, IN. (Control ID #3387400)

BACKGROUND: Peer support has been shown to be effective in helping patients to self-manage chronic conditions. While a few qualitative studies suggest that peer coaching benefits coaches, such effects have not been systematically evaluated. This is a notable gap, because it is imperative to understand whether coaching helps peer coaches or places additional burdens on them that negatively affect their own health. Our objective was to better understand potential effects of peer coaching on coaches by exploring outcomes of coaches in a peer-led self-management intervention for chronic pain.

METHODS: Evaluation of a Peer Coach-Led Intervention to Improve Pain Symptoms (ECLIPSE) was a clinical trial testing peer-led pain self-management. Coaches either had prior pain self-management training or were referred by their providers. After coach training, coaches were paired with a patient with chronic pain for 6 months. Outcomes were administered to both patients and coaches and included total pain (Brief Pain Inventory), pain catastrophizing, depression, and anxiety. For each outcome, a linear mixed model with fixed effect of time as categorical, was fit

to all time points (baseline, 6 and 9 months). The Šidák method was used to adjust for multiple comparisons.

RESULTS: At baseline, coaches (N=55) had significantly lower total pain, depression, and catastrophizing than patients; no significant differences were observed for anxiety. Relative to baseline, coaches' anxiety (GAD-7) increased from 4.7 to 5.4 at 6 months (p=.036, ES=.16) and 5.5 at 9 months (p=.019, ES=.18). Catastrophizing increased significantly from 12.6 at baseline to 16.5 at 6 months (p=.005, ES=.34), then dropped to 15.7 at 9 months. After adjusting for multiple comparisons, no changes remained significant.

CONCLUSIONS: This study does not support the notion that peer coaching benefits coaches. Before adjustment, anxiety and pain catastrophizing increased. Anxiety increases could be a result of shifting from a patient to a "provider" role as a coach. Talking with patients about their pain might have led to higher catastrophizing by increasing coaches' awareness of their own pain. However, no increases were clinically significant, and even at higher levels, coaches' anxiety and catastrophizing were lower than those of the patients whom they coached. Although this study was exploratory and limited by lack of a control group for the coaches, results suggest that peer coaching may not be inherently beneficial, that coaches should be monitored, and procedures should be in place if they experience worsening of symptoms. Peer coaching remains a promising model, with high potential for implementation, for a number of chronic conditions requiring self-management. However, to maximize benefits of coaching, it is essential to ensure that coaches do not experience adverse effects.

IS WEIGHT LOSS ASSOCIATED WITH REMISSION OF TYPE 2 DIABETES IN MEDICALLY UNDERSERVED AREAS IN THE AMERICAN SOUTH?

Ming Chen[2,4]; Satya Surbhi[2,3]; James E. Bailey[1,2]. [1]Medicine and Preventive Medicine, University of Tennessee Health Science Center, Memphis, TN; [2]Center for Health System Improvement, Medicine, University of Tennessee Health Science Center, Memphis, TN; [3]Medicine, University of Tennessee Health Science Center, Memphis, TN; [4]Institute of Health Outcome and Policy, University of Tennessee Health Science Center, Memphis, TN. (Control ID #3393159)

BACKGROUND: Type 2 diabetes (T2DM) is a chronic disease, resulting in high morbidity, mortality and healthcare expenditure, especially among individuals residing in medically underserved areas. Obesity affects 39.6% of the United States adults and is highly associated with T2DM. Prior studies have demonstrated that approximately 5% of T2DM patients in community settings achieve complete remission according to HbA1c levels, but the reasons are unclear. Recent clinical trials suggest intensive weight loss may lead to diabetes remission. Therefore, this study aims to examine if weight loss and/or primary care exposure are associated with diabetes remission in community settings.

METHODS: A retrospective cohort study using 2015-2018 Diabetes Wellness and Prevention Coalition Registry data was conducted. We included adult patients (age > 18) with T2DM who had an index visit with HbA1c test ≥ 6.5 between 2016 and 2017, without prior diagnosis of type 1 diabetes [ICD-9-CM: 250.x1, 250.x3; ICD-10-CM E10.x]) in the 12 months before index visit, and with one or more follow-up HbA1c tests after index visit. The primary outcome was diabetes remission (any, partial, and complete remission) identified by a modified algorithm based on the American Diabetes Association. The primary independent variable was change in body mass index (BMI), defined as the difference between BMI at baseline and follow-up. Eligible patients were followed for one year from the index visit to diabetes remission. Chi- squared tests for categorical variables and Mann-Whitney U tests for continuous variables were used to examine differences in characteristics between patients who achieved remission(any, partial, or complete) versus patients without remission.

RESULTS: Of 9518 patients with T2DM, 17.9% (N=1708) achieved any diabetes remission, 15.9% (N=1512) achieved partial remission and 2.1% (N=196) achieved complete remission. Change in BMI was -1.47 ± 3.21 in those with any remission vs. -0.48 ± 2.68 in those without ($p < 0.0001$), -1.24 ± 2.40 in those with partial remission vs. -0.54 ± 2.83 ($p < 0.0001$), and -2.60 ± 6.32 in those with complete remission vs. -0.59 ± 2.69 ($p < 0.0001$). Patients who achieved diabetes remission (any, partial, or complete) had more primary care visits (all $p < 0.05$) and lower Charlson Comorbidity Index (all $p < 0.05$). More males achieved complete remission ($p < 0.0001$), while the effect of gender on remission was not significant in the cohort with partial remission only (p=0.418).

CONCLUSIONS: Patients in medically underserved areas of the American South frequently achieve partial remission and occasionally achieve complete remission of diabetes. Weight loss is strongly associated with an increased likelihood of remission, and primary care utilization increases the incidence of diabetes remission. Further investigations are warranted to understand how primary care is effective (primarily through increased use of diabetic pharmacotherapy or through care support for healthy eating and weight loss).

JOB SATISFACTION AND CAREER PRIORITIES OF EARLY-CAREER ACADEMIC HOSPITALISTS

Shradha Kulkarni[1]; Margaret Fang[1]; Jeffrey Glasheen[2]; Vikas Parekh[3]; Julie Machulsky[4]; Jade Myers[5]; Brad Sharpe[1]. [1]Department of Medicine, University of California, San Francisco, San Francisco, CA; [2]University of Colorado, Aurora, CO; [3]University of Michigan, Ann Arbor, MI; [4]Community, SGIM, Alexandria, VA; [5]Society of Hospital Medicine, Philadelphia, PA. (Control ID #3389473)

BACKGROUND: Academic hospitalists engage in multiple and varied career directions, including medical education, quality improvement, leadership, and research. In 2009, the Society of Hospital Medicine (SHM), the Society of General Internal Medicine (SGIM), and the Association of Chiefs and Leaders of General Internal Medicine (ACLGIM) launched the Academic Hospitalist Academy (AHA), an annual conference that aims to provide hospitalists with educational, scholarly, and professional development skills. Our study describes the demographics and career priorities of academic hospitalists who participated in the AHA.

METHODS: As part of AHA enrollment, all attendees are asked to complete an anonymized, voluntary survey prior to the start of the conference. The survey includes questions about participant demographics, academic rank, job satisfaction, and career priorities. We collected the survey responses from all 11 years of the AHA (2009 to 2019) and described trends in participant demographics and responses.

RESULTS: A total of 812 of 817 AHA participants who viewed the survey completed it (99% completion rate). The number of survey respondents in a given year ranged from 48 to 89. The mean age of participants was 34 years (95% confidence interval [CI] 25 – 44 years), and the mean years of hospitalist clinical experience was 3.2 [0 – 9.4 years]. The proportion of participants that were female increased from 42.2% in 2009 to 60% in 2018 and 2019 (p-value for linear test for trend is 0.001). Most hospitalists were somewhat or very satisfied with their job. Hospitalists consistently identified teaching and clinical care as the best parts of their job (56.0% and 31.1%, respectively). Improving teaching skills was the most common primary conference goal listed by attendees (48.9%), followed by networking, promotion, scholarship, and quality improvement.

CONCLUSIONS: Over the 11 years of the Academic Hospitalist Academy, increasing proportions of women enrolled. Teaching was the leading contributor to job satisfaction, followed by clinical care. Attendees considered improving teaching skills as their primary conference goal. With these data, AHA and other groups engaged in hospitalist career development can better tailor their training to the needs and priorities of academic hospitalists.

LANGUAGE DISCORDANCE IS ASSOCIATED WITH SUBOPTIMAL PATIENT-PROVIDER COMMUNICATION IN THE EMERGENCY DEPARTMENT

David S. Edelman[1,2]; Dana Palmer[2,3]; Emily Romero[2,4]; Bernard Chang[5]; Ian Kronish[4]. [1]Vagelos College of Physicians and Surgeons, Columbia University, New York, NY; [2]Mailman School of Public Health, Columbia University, New York, NY; [3]Department of Epidemiology, Columbia University Irving Medical Center, New York, NY; [4]Center for Behavioral Cardiovascular Health, Columbia University Irving Medical Center, New York, NY; [5]Department of Emergency Medicine, Columbia University Irving Medical Center, New York, NY. (Control ID #3387504)

BACKGROUND: Over 64 million U.S. residents speak a non-English language (NEL) at home. NEL, limited English proficiency (LEP), and patient-provider language discordance may adversely influence communication, care outcomes, and health disparities. This effect can be heightened in the emergency department (ED) where there is a need to collect an accurate and efficient history with acutely ill patients from diverse backgrounds. In this study, we sought to determine the associations of primary NEL, LEP, and language discordance with communication among patients presenting to the ED with suspected acute coronary syndrome (sACS). We hypothesized that language discordance would be most strongly associated with patient perceptions of poor patient-provider communication.

METHODS: This was a secondary analysis of an ongoing observational cohort of English or Spanish- speaking patients with sACS presenting to an urban ED. Primary language, degree of English fluency, and patient-provider primary language discordance were assessed by patient self-report in the ED. Patient- reported communication was concurrently assessed using the Interpersonal Processes of Care survey (IPC), a validated 18-item tool for assessing the psychosocial aspects of communication among diverse populations in the domains of patient-physician communication, shared-decision making, and interpersonal style. Patient-reported communication was categorized as suboptimal if mean IPC score ≤4. The associations between primary NEL, LEP, and language discordance with patient-reported communication were concurrently assessed using logistic regression, with and without adjusting for sociodemographic characteristics (age, gender, ethnicity, education, and health insurance status), presence of a companion in the ED, and depression (PHQ-8 score ≥10).

RESULTS: Between 2014-2017, 933 sACS ED patients (46% female; 56% Hispanic; mean age 60.7 years) completed the IPC. Overall, 48.0% reported primary NEL, 29.6% LEP, and 42.6% language discordance. In bivariate analyses, primary NEL (OR 1.38, 95% CI 1.04-1.82), LEP (OR 1.45, 95% CI 1.06-1.98), and language discordance (OR 1.64, 95% CI 1.23-2.18) were associated with suboptimal communication. In the fully adjusted model, language discordance remained significantly associated with suboptimal communication (aOR 1.57, 95% CI 1.05-2.33), while primary NEL (aOR 1.06, 95% CI 0.55-2.04) and LEP (aOR 0.90, 95% CI 0.48-1.68) did not.

CONCLUSIONS: Patients presenting to the ED with sACS who reported language discordance had greater odds of suboptimal patient-provider communication. Language discordance may be the most important factor linking NEL with poor communication. Future studies should evaluate the impact of language discordance on other health outcomes in sACS patients undergoing evaluation in the ED, and should consider interventions that improve communication when language discordance exists.

LARGEST NATIONAL ONCOLOGY PAY-FOR-PERFORMANCE PROGRAM INCREASES EVIDENCE-BASED CANCER DRUG PRESCRIBING, BUT DOES NOT LOWER SPENDING

Justin Bekelman[1,2]; Atul Gupta[3]; Ezra Fishman[5]; David Debono[6]; Michael J. Fisch[7]; Ying Liu[5]; Gosia Sylwestrzak[5]; John Barron[5]; Amol S. Navathe[4,2]. [1]Department of Medicine, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]Leondard Davis Institute of Health Econmics, Philadelphia, PA; [3]Department of Health Care Management, The Wharton School, Philadelphia, PA; [4]Department of Medical Ethics and Health Policy, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [5]HealthCore, Inc., Wilmington, DE; [6]Anthem, Inc., Woodland Hills, CA; [7]Medical Oncology, AIM Specialty Health, Chicago, IL. (Control ID #3391417)

BACKGROUND: Cancer drug prescribing by medical oncologists accounts for the greatest variation in practice and largest portion of spending on cancer care. Consequently, efforts to standardize quality and control cost growth of the estimated $173 billion spent on cancer care in the US in 2020 have focused heavily on promoting evidence-based cancer drug prescribing. Our objective was to evaluate the association between a national commercial insurer's ongoing pay-for-performance (P4P) program for oncology and changes in prescribing of evidence-based cancer drugs and spending.

METHODS:

Retrospective difference-in-differences study utilizing administrative claims data for 6.7% of US adults covered by the insurer. Our sample included patients 18 years of age or older with breast, colon, or lung cancer who were prescribed cancer drug regimens by 1,867 participating oncology physicians between 2013 and 2017. We leveraged the geographically staggered, time-varying rollout of the P4P program to simulate a stepped-wedge study design. Specifically, we estimated a patient-level model clustered by physician and used physician fixed-effects to examine pre/post changes in evidence-based prescribing and spending for patients of participating physicians eligible earlier versus later in the period of P4P program rollout. The exposure was a time-varying dichotomous variable equal to 1 for patients prescribed a cancer drug regimen by a participating oncologist after the P4P program was offered. Only participating physicians and their patients were included in this study to mitigate selection effects. The primary outcome was whether a patient's drug regimen was an evidence-based regimen. We evaluated four categories of spending over a 183 day (6 month) episode period: cancer drug spending; other (non-cancer drug) health care spending; total episode spending; and patient out-of-pocket spending.

RESULTS: The P4P program was associated with an increase in evidence-based regimen prescribing from 57.1% of patients in the pre-intervention period to 62.2% in the intervention period for a difference of +5.1 percentage points (95% CI 3.0 percentage points to 7.2 percentage points, $P<0.001$). The P4P program was also associated with a differential $3,235 (95% CI $1,004 to $5,466, $P=0.005$) increase in cancer drug spending, a differential $253 (95% CI $101 to $406, $P=0.001$) increase in patient out-of-pocket spending, but no significant changes in other health care spending ($-564, 95% CI -$2,545 to $1,416, $P=0.58$) or total health care spending ($2,651, 95% CI -$319 to $5,621, $P=0.08$) over the 6-month episode period.

CONCLUSIONS: Our findings suggest that P4P programs may be effective in increasing evidence-based cancer drug prescribing at national scale – enhancing cancer care quality. However, they may increase out-

of-pocket expenses and may not lead to savings in total health care spending at 6 months.

LEADERSHIP EXPERIENCES OF SECOND-YEAR INTERNAL MEDICINE RESIDENTS: A NEEDS ASSESSMENT FOR LEADERSHIP CURRICULA

Maureen Lyons[1]; Julie Oyler[3]; Katherine A. Iossi[4]; Sarah B. Merriam[2]. [1]Internal Medicine, Washington University School of Medicine, Saint Louis, MO; [2]Internal Medicine, University of Pittsburgh Medical Center, Pittsburgh, PA; [3]General Internal Medicine, University of Chicago Medical Center, Chicago, IL; [4]Department of General Internal Medicine and Geriatrics, OHSU/PVAMC, Portland, OR. (Control ID #3390494)

BACKGROUND: Physicians routinely assume leadership roles and the need for leadership education and training is increasingly recognized. Despite this growing emphasis, formal leadership curricula within residency training programs are few. Given the urgent need to develop evidence-based leadership curricula, we conducted a multi-institution qualitative study exploring residents' leadership experiences and beliefs to serve as a needs assessment for future curricular development.

METHODS: Voluntary, anonymous, structured telephone interviews were conducted with second-year categorical internal medicine residents at 4 institutions. An experienced interviewer conducted 20-minute interviews which were audio-recorded, de-identified, and transcribed verbatim. A codebook was developed and refined iteratively. Two coders independently applied the codes to transcripts. Discrepancies in coding were adjudicated with the full research team until agreement was achieved.

RESULTS: 14 residents were interviewed (7 males, 7 females, most 28-32 years old). Few endorsed formal leadership training or experience prior to residency. Residents generally defined leadership as the capacity to 1) supervise or manage others, 2) act in a decision-making role, and 3) facilitate a conducive work environment. All residents viewed themselves as leaders within the context of clinical rotations. Residents identified several characteristics of effective leadership including clinical expertise (necessary but not sufficient), effective delegation, strong interpersonal skills, coaching and developing others, and effective communication. Residents identified several characteristics of ineffective leadership, in addition to absence of aforementioned skills of effective leaders: disengagement, unwillingness to pitch in, and lack of clear expectations or feedback. With respect to existing formal leadership training within their programs, some identified training in communication skills, providing feedback, and setting expectations. Many had difficulty identifying or labeling existing leadership training. The majority desired further leadership training, with variety in the modes of delivery and areas of focus deemed to be important and/or necessary.

CONCLUSIONS: This qualitative study provides insight into residents' leadership experiences. Resident physicians view themselves as leaders within a clinical context yet desire additional leadership development. Informal, experiential leadership experiences during residency may not obviate the need for additional formal training. Areas of potential focus (identified by residents as important) might include nonclinical skills necessary to effectively lead clinical teams, including principles of delegation, fostering effective team dynamics and environment, and resident-as-coach. Given that residents struggled to identify existing development opportunities, programs might also consider more clearly labeling existing leadership development efforts (e.g., feedback, communication) as such.

LEARNING FROM SUCCESS: HOW MEDICAL CENTERS KEEP VETERANS WITH SERIOUS MENTAL ILLNESS ENGAGED IN PRIMARY CARE

Julian Brunner[1]; Alicia Gable[1]; Pushpa V. Raja[2]; Jessica Moreau[1]; Kristina M. Cordasco[3,1]. [1]Center for the Study of Healthcare Innovation, Implementation & Policy, VA Greater Los Angeles Healthcare System, Sepulveda, CA; [2]Department of Mental Health, VA Greater Los Angeles Healthcare System, Los Angeles, CA; [3]Medicine, VA Greater Los Angles Healthcare System/ UCLA, Los Angeles, CA. (Control ID #3391323)

BACKGROUND: People with serious mental illness (SMI) are at substantial risk for premature mortality, dying on average 10-20 years earlier than the general population, primarily due to high rates of medical comorbidities. Engagement in primary care (PC) can be life-saving for this population, but many with SMI become disengaged from PC. Therefore, the Veterans Health Administration (VA) measures PC engagement among Veterans with SMI, and has identified it as a priority target for quality improvement. To inform improvement efforts at our local VA medical center, we sought to identify promising practices for supporting engagement in PC among Veterans with SMI.

METHODS: We conducted semi-structured telephone interviews with 15 key informants across a national sample of 11 VA medical centers with above-median performance on engagement of patients with SMI in PC, and with substantial homeless populations (>1,000 Veterans). Interviewees were selected based on their involvement in engaging SMI patients in care, and included leaders of behavioral/mental health (MH) services or PC services tailored for Veterans with SMI. Interviews were conducted in May-July 2019 and audio-recorded. Using detailed notes from interview recordings, we prepared structured summaries of each interview to highlight key points in a template based on the interview guide. We organized summaries into matrices for analysis, grouping summarized points by topic to facilitate comparison across interviews. Our interdisciplinary team reviewed and discussed these tables, and iteratively developed and refined themes.

RESULTS: Interviewees reported substantial and diverse efforts aimed at engaging Veterans with SMI in PC. While details differ across sites, strategies can be classified as using 1) targeted outreach, 2) routine practices, or 3) both. Targeted outreach strategies entail deliberate, systematic approaches for identifying and contacting patients with SMI at risk of disengaging from care, and facilitating their return to PC or other needed services. In contrast, routine practices embedded in normal clinical activities were also frequently described as important strategies for maintaining engagement in PC among Veterans with SMI. These routine practices include cultural norms and/or structured care pathways through which MH professionals attend to and facilitate engagement in PC, and PC staff actively monitor and manage patients' primary care provider (PCP) assignments and visit intervals.

CONCLUSIONS: VA facilities with high levels of PC engagement among Veterans with SMI use extensive engagement strategies, including a diverse array of targeted outreach and routine practices. Further characterization and evaluation of the effectiveness and implementation of these strategies is needed to identify and promote practices that improve engagement and outcomes for people with SMI.

LENGTH OF STAY AND HOSPITAL COST OUTCOMES IN LOCUM HOSPITALISTS VERSUS NON-LOCUM HOSPITALISTS: A PROSPECTIVE COHORT STUDY

Sarah K. Mustafa[1]; Marwa Sabha[1,2]; Momen Banifadel[1]; Mohammed Awad[1]; Kanana Aburayyan[1]; Marcel Ghanim[1]; Damynus Gekonde[1]; Ahmad Ramahi[1]; Amala Ambati[1]; Sami Ghazaleh[1]; Pinang Shastri[1];

Ahmed Elzanaty[1]; Mohammed Alsarie[1]. [1]Internal Medicine, University of Toledo, Sylvania, OH; [2]Internal Medicine, University of Maryland, Ellicott City, MD. (Control ID #3374784)

BACKGROUND: Locums are used for short term coverage or when hospitals face difficulties in recruitment. Due to increasing and unmet medical needs worldwide, the utilization of locum physicians continues to increase. One quarter of healthcare managers used locum hospitalists in the last 12 months, making hospitalists as the second most common service in demand for locum physicians.

METHODS: We conducted a classical prospective cohort study. Consecutive patients were recruited dynamically between 2/25/2019 -4/30/2019. Patients included were ≥18 years admitted to IM services for any reason. Excluded patients who did not consent and patients admitted to academic services. We collected following data: age, sex, ethnicity, assistance at home, food security most the year, residence prior to admission, type of insurance, admission diagnosis (16 categories) and comorbidities (17 categories).

Length of stay and hospital cost were outcomes of interest. Propensity score was calculated and matching was performed using inverse probability of treatment weighting. Subsequently, we fitted weighted multiple linear regression models for length of stay and hospital cost to compare locum and non-locum services. Baseline characteristics were compared using parametric and non-parametric analysis. Diagnostics were used to assess propensity score model and multiple regression models. We matched patients seen solely by locum (n=49) to patients seen solely by non-locum (n=296) and subsequently obtained average treatment on the treated. To account for cross over, complete cohort (n=747) was standardized to obtain "locum-percentage" exposure. Locum-percentage was calculated by diving locum physician-days by the sum or locum-days and non-locum-days for each patient. Locum-percentage ranged from 0% when patient was entirely cared by non- locum physicians up to 100% when patient was entirely treated by locum hospitalist. Locum percentage was used as independent variable to fit regression models to estimate the average treatment effect.

RESULTS: A total of 747 patients were admitted in study period. The mean age was 60.5 ± 19 years and females were 52%. Baseline characteristics were well balanced with standardized biases less <0.1 post propensity matching (figure 1). Adjusted length of stay was 1.3 days shorter in locum compared to non-locum (CI: -1.96- -0.68, p-value <0.001). Adjusted hospital cost was 1822 dollars less in locums compared to non-locums (CI: -2608- -1036, p-value <0.001). Using locum percentage as independent predictor for length of stay, an increment from 0% to 100% in locum involvement in patient care is associated with an average 0.9 decrease in hospital stay (CI: -0.14- -1.7, p-value= 0.017). Similarly, hospital cost was lower by 800 dollars using locum-percentage as a predictor but this was not statistically significant (p-value =0.07)

CONCLUSIONS: In contrary to the "expected", locum physicians provided hospital cost saving and shorter hospital stay in comparison to non-locums.

LEVEL, TRAJECTORY, OR RATE: PREDICTING MORTALITY WITH THE LACTATE TREND IN SEVERE SEPSIS

Alexander J. Beagle[1]; Priya A. Prasad[2]; Jeffrey Gotts[3]; Carolyn Calfee[3]; Michael Matthay[3]; Kathleen D. Liu[3]; Kirsten Kangelaris[3]. [1]School of Medicine, University of California, San Francisco, San Francisco, CA; [2]Division of General Internal Medicine, Department of Epidemiology and Biostatistics, UCSF, San Francisco, CA; [3]University of California, San Francisco, San Francisco, CA. (Control ID #3391432)

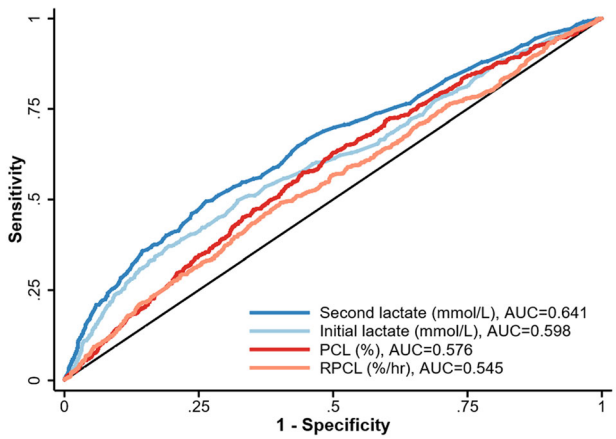
BACKGROUND: Change in lactate, often expressed as Proportional Change in the initial Lactate (PCL, or "lactate clearance"), has prognostic value in severe sepsis and septic shock. Prior studies have calculated PCL after fixed delays (e.g., second lactate always drawn six hours after the first), but in clinical practice, lactate is not re-measured at fixed delays. Whether second lactate timing affects the prognostic value of PCL is unclear. We evaluated whether expressing PCL as per-hour Rate of PCL (RPCL) improves predictive utility for in- hospital mortality in critically ill septic patients, and evaluated PCL and RPCL in comparison to absolute lactate levels.

METHODS: Electronic health record (EHR) data were extracted for all adult emergency department presentations at an academic medical center from 2012–2018 that met validated Sepsis-III EHR criteria, had at least two lactates, and had initial lactate of at least 4 mmol/L or required vasopressors. PCL was calculated as $(lactate^{T2}–lactate^{T1})/lactate^{T1}\times100\%$, and RPCL as $PCL/hours^{T2\text{-}T1}$. Receiver-operator-characteristic (ROC) curves for in-hospital mortality were used to compare first lactate, second lactate, PCL, and RPCL.

RESULTS: In 2,594 patients, median time to second lactate was 3.6 hours (IQR 2.3–5.8). Lactates decreased from a median of 4.4 (IQR 2.6–6.3) to 2.6 mmol/L (IQR 1.6–4.3) for median RPCL of -7.7 %/hour (IQR -15.2 – -1.4). All lactate parameters were associated with mortality (P<0.001). PCL had larger area under the curve (AUC) than RPCL (AUC=0.576 vs. 0.545, P<0.001). The second lactate level (AUC=0.641) had larger AUC than first lactate, PCL, and RPCL (Figure, three comparisons, all P<0.001).

CONCLUSIONS: PCL marginally outperforms RPCL to predict in-hospital mortality in patients with severe sepsis or shock, despite variable delay length. The prognostic values of RPCL and PCL are limited compared to absolute lactate levels. When two lactates are measured, the second may carry the most prognostic value.

Figure. ROC curves depicting ability of various lactate-derived measures to predict in-hospital mortality in 2,594 patients with sepsis



Nonparametric ROC curves from 2,594 patients with initial lactates of at least 4 mmol/L or shock defined as requiring vasopressors. PCL is the percent change from the initial to second lactate levels. RPCL is PCL adjusted for time to the second lactate level (i.e., percent change from the initial to second lactate levels per hour). The black reference line represents a measure with no predictive value.

LEVERAGING HIV CARE TO CONTROL HYPERTENSION IN EASTERN UGANDA: A FIDELITY EVALUATION BY DIRECT OBSERVATION

David J. Heller[1,2]; Anne Nakitende[4]; Dhruv S. Kazi[3]; Edwin Charlebois[5,4]; Dalsone Kwarisiima[4]; Florence Mwangwa[4]; Diane Havlir[5,4]; James G. Kahn[6,5]. [1]General Internal Medicine, Icahn School

of Medicine at Mount Sinai, New York, NY; [2]Arnhold Institute for Global Health, Icahn School of Medicine at Mount Sinai, New York, NY; [3]Smith Center for Outcomes Research, Beth Israel Deaconess Medical Center, Boston, MA; [4]Infectious Diseases Research Collaboration (IDRC), Kampala, Uganda; [5]Medicine, University of California, San Francisco, San Francisco, CA; [6]Institute for Health Policy Studies, University of California, San Francisco, San Francisco, CA. (Control ID #3391867)

BACKGROUND: Hypertension (HTN) is the leading risk factor for human mortality worldwide. In Uganda, adult HTN prevalence is more than 27%, with under 10% aware of their diagnosis - of which under half achieve blood pressure control.

The SEARCH study (NCT01864603), a cluster-randomized trial of the impact of universal HIV screening and treatment on HIV incidence in Uganda and Kenya, also offers screening and treatment for hypertension. Our previous work indicates that SEARCH achieved over 90% sensitivity and specificity in identifying persons with potential HTN, but only 42% of these persons linked to follow-up care. It remains unclear whether SEARCH's patient screening counseling protocols for persons with HTN are consistently followed – or whether their educational messages are reaching this population.

METHODS: We used structured interviews and observation checklists to evaluate fidelity and consistency of HTN screening and treatment protocols within 10 communities in Eastern Uganda associated with the SEARCH study. We observed providers' assessment of patients' blood pressure – relative to the results they recorded – as well as the teaching they provided persons with suspected HTN regarding lifestyle change. We then interviewed those counseled, to gauge their knowledge retention.

RESULTS: Between September 2015 and February 2016, we observed 161 provider interactions (36 at community health campaigns (CHCs) and 125 at health clinics (HCs), and interviewed 142 patients with HTN (43 at campaigns and 99 at clinics). Providers at CHCs recorded patients' HTN status in 100% of cases, but only recorded it correctly in 78%; they counseled 96% of patients regarding lifestyle change for HTN, but only 42% regarding HTN as an underlying concept. At HCs, 97% of providers counseled on medication adherence, but only 68% on alcohol moderation; 62% and 40% of participants, respectively, recalled these messages. At CHCs, patients most commonly cited salt use (91%) alcohol use (65%), and other factors (77%) as causes of HTN; they cited obesity (10%) and old age (12%) least commonly. 88% of participants felt they understood HTN counseling well; 84% felt change in their behavior was likely. At HCs, 87% felt they understood counseling well, and 88% felt behavior change was likely.

CONCLUSIONS: SEARCH HTN providers largely adhered to blood pressure screening and medication treatment protocols, but were less consistent in providing behavior change counseling. Participants, in turn, showed incomplete knowledge of HTN prevention and treatment strategies, but were motivated to act on the knowledge they received. This result aligns with qualitative data from interviews among persons with HTN in Uganda. SEARCH has revised its HTN counseling protocols (through education booklets and provider checklists) based on these data – evaluation of this intervention is pending. Similar tools to promote behavior change could improve HTN control in other contexts in East Africa.

LIFE DESIGN IN MEDICINE: PERCEPTIONS OF SENIOR RESIDENTS

Lynae Conyers[1]; Scott Wright[2]. [1]General Internal Medicine, Johns Hopkins, Baltimore, MD; [2]medicine, jhusom, Baltimore, MD. (Control ID #3392408)

BACKGROUND: Deciding what is to come after training is an essential task during residency. Myriad factors such as family considerations, debt level, and mentoring impact career choices. However, less is known about the individual and program-level strategies utilized by trainees to help clarify these decisions. The application of design thinking principles to life/ career planning has been termed "life design" and may have relevance for trainees as they anticipate life after residency. Internal Medicine-Pediatrics (MP) residents have perhaps the most career options available to them upon completing residency. The aims of this study were to: i) characterize the career exploration strategies employed by MP residents, and ii) assess if any strategies were associated with higher confidence with their career plans.

METHODS: We reviewed websites for all 78 ACGME-accredited MP program to identify 4th year resident names and emails. When emails were not available, we contacted program directors for this information. Surveys were sent to the residents electronically in May 2019 and included items on intended career, helpfulness of strategies used to inform career decision (22 items, 1-4 Likert-type scale), and confidence in intended career plan (1-4 Likert-type scale). We examined the relationship between career exploration strategies and confidence in intended career.

RESULTS: Surveys were sent to 145 residents at 45 programs. Eighty-six residents (59%) across 31 programs (69%) responded. Twenty respondents (23%) would be pursuing a career in a subspecialty area, 31 (36%) were going into primary care, and 21 (24%) were to work as hospitalists; a majority of respondents indicated they would see both adult and pediatric patients. Concern about pursuit of the wrong career was endorsed by 19.8% of respondents. The most helpful career exploration strategies included - exposure to desired career during residency [M 3.5 (SD 0.7)], reflection on how career fits with views of life and work [3.4 (0.7)], identification of times or experiences when one felt most engaged/ energized in work [3.3 (0.9)], and seeking mentorship [3.2 (0.8)]. Exposure to one's anticipated career during residency ($p=0.003$) and seeking mentorship ($p=0.001$) were significantly associated with higher confidence in career plans.

CONCLUSIONS: MP residents utilize a variety of strategies to determine their career plans including a combination of experiential and reflective practices. Intentional utilization of specific life design strategies during residency training may help boost trainees' confidence in their career choices.

LIMITED ENGLISH PROFICIENT PATIENTS AND EMERGENCY ROOM ADMISSION RATES FOR AMBULATORY CARE SENSITIVE CONDITIONS IN CALIFORNIA

Lucy Schulson[1]; Meng-Yun Lin[4]; Michael K. Paasche-Orlow[3]; Amresh D. Hanchate[2]. [1]Internal Medicine, Boston University/ Boston Medical Center, Boston, MA; [2]Social Sciences and Health Policy, Wake Forest School of Medicine, Winston-Salem, NC; [3]Medicine, Boston University, Boston, MA; [4]Section of General Internal Medicine, Boston Medical Center, Boston, MA. (Control ID #3391601)

BACKGROUND: Prior research has demonstrated that racial and ethnic minorities and those with public insurance may be at increased risk for admission for Ambulatory Care Sensitive Conditions (ACSCs), a measure of potentially avoidable hospitalizations. Less is known about the risk for admission for those with Limited English Proficiency (LEP) and how hospital factors impact this risk. The purpose of this study was to examine differences in hospital admission rates following ED visits generally and for ACSCs comparing those with and without LEP.

METHODS: Using California's inpatient and ED administrative data, we identified all ED visits in 2017. We included ED visits for community dwelling individuals ≥18 years for whom the primary diagnosis was not pregnancy or childbirth. LEP patients were identified as those with a language other than English as the principal language for communication with providers. We compared admission rates for LEP vs. English

proficient (EP) patients overall and by ACSC using a series of linear probability models with incremental sets of covariates, including age, sex, self-identified race/ethnicity, insurance type, median income of patient's zip code, primary diagnosis, and Elixhauser co-morbidities. To examine if the LEP vs. EP difference in admission rate varied by the hospital volume of LEP patients served we created and included a dichotomous indicator of high (70th percentile and above) vs. low LEP serving hospital as a (interaction) covariate. We estimated models with and without hospital-level random effects. In all models, we estimated standard errors clustered at the hospital level. Sub-analyses were performed by specific ACSCs and languages.

RESULTS: There were 9,641,689 ED visits included in our sample of which 14.7% were for patients with LEP. In fully adjusted analyses, LEP visits were at higher risk for any admission and admissions for chronic ACSCS compared to EP visits, but the difference did not reach statistical significance (17.8%, 95% CI 14.5%, 19.2% vs. 16.9%, 95% CI 15.4%, 20.2%; 35.4%, 95% CI 31.6%, 35.5% vs. 33.6%, 95% CI 33.4%, 37.5%). However, for chronic pulmonary obstructive disease (COPD) ED visits the corresponding difference was significant (36.8%, 95% CI 35.0%, 38.6% vs. 33.3%, 95% CI 31.7%, 34.9%). There was no significant difference in admissions for other ACSCs between LEP and EP. The difference in admission rate for LEP vs. EP visits in a low-LEP serving hospital was 1.3% (95% CI 1.0%, 1.7%) compared to 0.74% for those seen in a high-LEP serving hospitals (95% CI 0.33%, 1.2%).

CONCLUSIONS: LEP is a risk factor for admission to the hospital overall and for some ACSCs but much of this effects seems due to hospital factors. The proportion of LEP patients served at a hospital does not seem to impact admission rate difference between LEP and EP patients. Further research is needed to understand why these disparities exist and if they are represent inefficiencies in care.

LINGUISTIC BIAS IN LANGUAGE USED BY PHYSICIANS IN MEDICAL RECORDS OF AFRICAN AMERICAN AND WHITE PATIENTS

Mary Catherine Beach[1]; Somnath Saha[2]; Jenny Park[1]; Brant Chee[1]. [1]Medicine, Johns Hopkins University, Baltimore, MD; [2]Section of General Internal Medicine, Portland VA Medical Center, Portland, OR. (Control ID #3391992)

BACKGROUND: Studies have found that African Americans and women report having their medical issues ignored or downplayed by health professionals. Because language used by clinicians in patient medical records may reveal their unconscious biases, our study sought to find examples of language specifically suggesting disbelief of patients, and then to explore racial/ethnic and gender differences in use of such language within medical records.

METHODS: In a previous content analysis of 600 randomly selected internal medicine ambulatory encounter notes from 2017, we identified 3 linguistic features that may cast doubt on the truthfulness of the patient: (1) quotes (e.g. *pt reports she had a "reaction" to the medication*); (2) specific negatively charged words (e.g. 'claims,', 'insists,' 'adamant'); and (3) clausal complements, a sentence construction in which the source of information is conveyed by providing the facts as a clause preceded by a word such as 'that' (e.g. *pt reports that the headache started yesterday* vs. *the headache started yesterday*). Although clausal complements are common in medical records and do not cast explicit doubt on the truth of the information, the field of linguistics has shown that the choice of that construction reflects an effort not to endorse the information as first-hand knowledge. We therefore hypothesized that the overall number of sentences constructed with that format may reflect greater doubt. We used natural language processing methods to evaluate the prevalence of these features in all notes written in 2017 at an ambulatory internal medicine clinic and then tested for differences by race and gender, using mixed-effects Poisson regression models accounting for clustering of notes within patients and providers.

RESULTS: Our study sample included 7,986 notes written by 164 clinicians about 1890 patients (801 Black women, 630 Black men, 254 white women, and 205 white men). There were significant differences by race in the prevalence of all three linguistic features: notes written about Black patients had a greater number of quotes (p=0.039), negative language (p=0.006) and clausal complements (p<0.001). Analyses by gender were mixed: notes about female vs. male patients did not differ in terms of negative language but had a greater number of quotes (p=0.002) and fewer clausal complements (p<0.001). There were no significant interactions between race and gender.

CONCLUSIONS: Our data suggest that African American patients may be subject to systematic bias in physicians' perceptions of their credibility, a form of testimonial injustice. Further studies are needed to understand these phenomena.

LIVING AT THE MARGIN: ACA INCOME-CUTOFFS AND STABILITY OF COVERAGE

Anna Goldman[1]; Sarah Gordon[2]. [1]Internal Medicine, Boston Medical Center, Boston, MA; [2]Department of Health Law, Policy, and Management, Boston University School of Public Health, Boston, MA. (Control ID #3391333)

BACKGROUND: Disruptions in health insurance coverage are associated with adverse health outcomes. The Affordable Care Act's (ACA) major insurance provisions, Medicaid expansion and the Marketplaces, carry built-in coverage disruptions through income cutoffs for eligibility. In Medicaid expansion states, 138% of the federal poverty level (FPL) is the cutoff for Medicaid eligibility and is a lower-bound cutoff for subsidized Marketplace insurance. Pre-ACA studies predicted that these cutoffs would result in frequent switching between Medicaid and Marketplace coverage. The objective of this study was to assess whether the ACA increased coverage disruptions among those with incomes near 138% cutoff.

METHODS: We employed a difference-in-differences framework comparing insurance disruptions and loss among those with incomes within 30 percentage points (pp) of the Medicaid cutoff (108-168% FPL), to those with incomes above or below the threshold (0-107% and 169-300% of FPL), before and after the ACA was implemented in 2014 (n=45,094; 10,583 in "near-cutoff" group). We used the two-year, longitudinal datasets available in the Medical Expenditure Panel Survey for the years 2009-2017. We defined our study groups (near-cuff vs. control) based on income data from year 1 of the survey. We then assessed whether the near-cutoff group was more likely to experience coverage disruptions or loss in year 2 of the survey. We also examined the direction of the health insurance transition. Subgroup analyses included restricting to Medicaid expansion states and restricting our exposure group to those with incomes just below (108-138%) versus just above (138-168%) the cutoff.

RESULTS: Coverage disruptions increased by 2.7 percentage points (pp) (p=0.01) and insurance loss increased by 2.8 pp (p<0.01) in the near-cutoff group compared to the control group in the post-ACA period. Among those living in Medicaid expansion states, coverage disruptions increased 5.2 pp (p=0.04) and coverage loss increased 4.8 pp (p=0.03). Individuals with incomes just below the cutoff (108-138% FPL) experienced rates of insurance disruptions and loss 4.6 pp (p=0.01) and 4 pp higher (p<0.01) respectively relative to controls. The subgroup with incomes just above the cutoff (138-168% FPL) experienced no change in either outcome. Less than one percent of the near-cutoff group moved from Medicaid to Marketplace or from Marketplace to Medicaid in the post-ACA period.

CONCLUSIONS: Adults with household incomes near the cutoff for Medicaid were at higher risk of insurance disruptions and loss after the ACA compared to low and middle income adults. The effect was driven by individuals moving from Medicaid coverage to being uninsured, particularly among those with incomes just below the cutoff. Our findings demonstrate that upper-bound income cutoffs create instability for Medicaid enrollees close to the threshold. Policy solutions include bridging insurance programs such as a Basic Health Plan or transitioning to a single-payer health system.

LONGITUDINAL COHORT STUDY OF THE ASSOCIATION BETWEEN GRIT AND BURNOUT AMONG FIRST YEAR INTERNAL MEDICINE RESIDENTS

Andrew J. Klein[1]; Thomas Grau[3]; Kwonho Jeong[2]; Scott D. Rothenberger[2,1]; Kathryn Berlacher[4]. [1]Division of General Internal Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA; [2]Center for Research on Health Care Data Center, University of Pittsburgh School of Medicine, Pittsburgh, PA; [3]VA Pittsburgh Health System, Pittsburgh, PA; [4]Heart and Vascular Institute, University of Pittsburgh Medical Center, Pittsburgh, PA. (Control ID #3391342)

BACKGROUND: Grit is a personal characteristic defined as passion and perseverance for long-term goals. It has been associated with success and avoidance of burnout in a number of fields, including surgery and emergency medicine trainees. We aimed to evaluate the association between grit and burnout among our first- year internal medicine (IM) residents.

METHODS: We conducted a prospective cohort study of the 2018-2019 PGY1 IM residents at a major academic institution. All PGY1 residents were eligible to participate and were sent the validated Short Grit Scale and Maslach Burnout Inventory (MBI) at the start of training and at 6 and 12 months. An additional background survey was administered to collect information on potential confounders. Our primary outcome was the association between initial grit score and MBI score within the domains of emotional exhaustion (EE) and/or cynicism (CYN) at 6 and 12 months while controlling for initial burnout score. The primary analysis was conducted using a linear mixed effects model with an alpha level of 0.05. Our secondary outcomes included the association between grit and dichotomous high/low burnout in each domain at 6 or 12 months, grit and persistent burnout defined as high EE or CYN at 6 and 12 months, and the association of initial high MBI domain scores with high MBI scores in the same domain at 6 and 12 months using logistic regression. Additionally, we assessed whether Grit remained stable across time points using repeated- measures ANOVA.

RESULTS: A total of 81 participants completed at least one of our surveys from June 2018 to June 2019, 53 of whom were eligible for inclusion in the primary analysis, having completed the burnout and grit surveys at time 0, at least one other time point and having demographic data. There was no association between Grit and EE (p=0.501) or CYN (p=0.714) burnout domain scores adjusting for age, gender, race, program, and home country. Grit was not associated with high EE (OR 0.59, 95% CI 0.31-1.14; p=0.118) or high CYN (OR 0.87, 95% CI 0.45-1.68; p=0.683) at 6 or 12 months or with persistent high EE (OR 0.62, 95% CI 0.29-1.62; p=0.215) or persistent high CYN (OR 1.00, 95% CI 0.47-2.11; p=0.998) at 6 and 12 months. High initial EE or CYN (OR 8.86, 95% CI 1.05-74.93; p=0.045) was found to significantly predict later high burnout scores in EE or CYN. Grit scores and self-efficacy (SE) scores remained stable throughout intern year (p=0.145 and 0.464, respectively), while EE and CYN significantly increased (both p<0.001).

CONCLUSIONS: In our single-center study of PGY1 Internal Medicine residents, Grit was not associated with burnout. However, our analysis shows that higher burnout scores early in the year are associated with higher burnout scores at 6 and 12 months. While further research is needed, our results should empower program leadership to feel confident using early burnout scores to help identify residents at high risk for progressive and persistent burnout.

LONGITUDINAL TRENDS IN ENROLLEES' EMPLOYMENT AND STUDENT STATUS AFTER MEDICAID EXPANSION

Renuka Tipirneni[1,2]; Minal Patel[3,2]; John Z. Ayanian[2,1]; Jeffrey T. Kullgren[4,1]; Edith C. Kieffer[5,2]; Matthias Kirch[2]; Adrianne N. Haggins[6,2]; Sarah J. Clark[7,2]; Sunghee Lee[8,2]; Erica Solway[2]; Tammy Chang[9,2]; Jamie Luster[1]; Erin Beathard[2]; Zachary Rowe[10,2]; Susan D. Goold[1,2]. [1]Internal Medicine, University of Michigan, Ann Arbor, MI; [2]Institute for Healthcare Policy and Innovation, University of Michigan, Ann Arbor, MI; [3]Health Behavior & Health Education, University of Michigan, Ann Arbor, MI; [4]VA Center for Clinical Management Research and Department of Internal Medicine, Ann Arbor VA Healthcare System and University of Michigan, Ann Arbor, MI; [5]School of Social Work, University of Michigan, Ann Arbor, MI; [6]Emergency Medicine, University of Michigan, Ann Arbor, MI; [7]Pediatrics, University of Michigan, Ann Arbor, MI; [8]Institute for Social Research, University of Michigan, Ann Arbor, MI; [9]Family Medicine, University of Michigan, Ann Arbor, MI; [10]Friends of Parkside, Detroit, MI. (Control ID #3382436)

BACKGROUND: Medicaid "community engagement" requirement (work, school, job training, job searching, or volunteering) waivers have received CMS approval in nine states, but there is little data on current trends in Medicaid enrollees' engagement in these activities. Our objective was to assess longitudinal changes in enrollees' employment and student status after implementation of Michigan's Medicaid expansion, which expanded coverage in 2014 and now covers ~664,000 individuals.

METHODS: We conducted a longitudinal telephone survey with a cohort of Medicaid expansion enrollees age 19-64, with incomes up to 133% of the federal poverty level (FPL), at 3 time points in 2016 (N=4,090, RR=53.7%), 2017 (N=3,104; RR=83.4%), and 2018 (N=2,608, RR=89.4%). Survey items measured employment status and student status; demographic characteristics were obtained from Medicaid program files. We used mixed models with year as a fixed effect to assess changes in the proportion of enrollees who were employed or students, incorporating weights adjusting for sample design and nonresponse.

RESULTS: Most respondents had incomes under 100% FPL (61.7% with 0-35% FPL, 22.9% with 36-99% FPL, and 15.4% with 100-133% FPL), 89.3% had at least a high school diploma/GED, and respondents ranged in age (39.6% age 19-34, 34.5% age 35-50, 25.9% age 51-64). From 2016 to 2018, the proportion of enrollees who were employed or students increased from 54.5% to 61.4% ($p<0.001$). Increases were observed in subgroups with lower baseline rates of employment or student status, including those with a chronic condition (47.8% to 53.8%, $p<0.001$) and those with a mental health or substance use disorder (48.5% to 56.0% $p<0.001$). Employed enrollees worked 34.7 mean hours per week on all paid jobs in 2018. Among enrollees who were in school, 57.7% were full-time and 42.3% were part-time students. Enrollees who were not employed or students in 2018 (38.6%) reported being unable to work (47.3%), out of work (40.4%) or retired (12.3%). Among enrollees who reported being unable to work, primary reasons included poor health/disability (91.4%) and caregiving responsibilities (7.1%). Among all enrollees who were not employed in 2018, 36.8% were searching for a job and 9.1% had completed or were enrolled in job training.

CONCLUSIONS: From 2016 to 2018, employment or student status increased among Michigan Medicaid expansion enrollees, including among subgroups with comorbidities. Federal courts are currently weighing whether community engagement requirements will promote the Medicaid program's goals of improved coverage and health, as well as associated improvements in employment and related activities. Our

findings suggest that Medicaid expansion itself was associated with the desired outcome of employment and related activities. The value of Medicaid community engagement requirements should be considered along with the additional administrative burden on individuals and states.

LONGITUDINAL WELLNESS THROUGHOUT AN ACADEMIC YEAR: DESCRIBING DEMOGRAPHIC CHARACTERISTICS IN A LARGE INTERNAL MEDICINE (IM) RESIDENCY

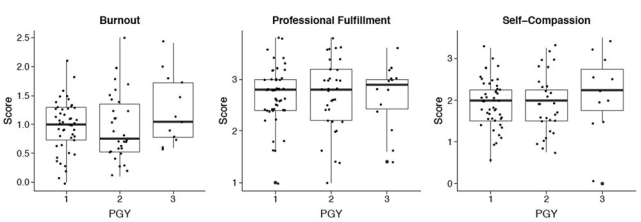
Dana Larsen[1]; Nathaniel Mercaldo[5]; Arabella Simpkin[3]; Tanya Keenan[4]; Molly Paras[2]. [1]Department of Medicine, Massachusetts General Hospital, Boston, MA; [2]Department of Medicine, Division of Infectious Disease, Massachusetts General Hospital, Boston, MA; [3]Department of Medicine, Division of General Internal Medicine, Massachusetts General Hospital, Boston, MA; [4]Department of Medicine, Division of Hematology and Oncology, Massachusetts General Hospital, Boston, MA; [5]Massachusetts General Hospital, Boston, MA. (Control ID #3384450)

BACKGROUND: Burnout is prevalent in residency programs throughout the country and has been shown to have a negative impact on healthcare. We sought to quantify changes in resident wellness over the course of an academic year.

METHODS: As part of a longitudinal educational study from 2018-2019, 192 IM residents at an academic center completed an online survey early in the academic year and again 10 months later. The survey included the Professional Fulfillment Index (PFI), a 16-item validated assessment scored on a 5-point Likert scale (0-4) across 2 scales: professional fulfillment (PF; higher scores indicate greater well-being) and burnout (BO; higher scores indicate greater burnout), and a 4-item self-compassion (SC) measure (higher scores indicate less self-compassion). Mixed effect models were used for data analysis.

RESULTS: Of the 192 residents, 98 (51%) completed baseline PFI surveys. Of these, 55% were male and 52% were PGY-1. There existed no difference in baseline BO or PF scores by gender though SC was significantly higher amongst females (1.82 vs 2.15; p=0.03). Post-graduate year one (PGY-1) residents also had greater SC (m=1.92) than PGY-3 residents (m=2.40; p=0.03), and while PF was not statistically different between those groups (p=0.78), PGY-3 had a near significant increase in BO (m=1.32) compared with PGY-1 (m=0.97; p=0.05). Twenty-two residents completed PFI surveys at the end of the academic year, with notable absence of PGY-3's. Across PGY-1's, there was an increase in BO (0.97 to 1.31; p=0.01) which was not observed in PGY-2's (0.98 to 1.00; p=0.93). This was similar in PF; however, the opposite was true for SC, with no change across PGY-1's (1.92 to 1.87; p=0.75) and an increase in PGY-2's (1.91 to 1.08; p<0.01).

CONCLUSIONS: In this IM residency, initial average PFI and SC scores identify a higher SC in female compared with male residents, though PFI scores statistically lacked a significant difference. Interestingly, PGY-3 residents had less SC at baseline than PGY-1 residents and trended toward a higher degree of burnout which may speak to a cumulative effect of 3 years of training without a "reset" at the beginning of each year. The lack of improvement across any of the PFI scales in an era of intense focus on resident wellness indicates ongoing efforts are needed to change the status quo.



LONG-TERM MORTALITY AND FUNCTIONAL STATUS IN OLDER ADULTS WITH ATRIAL FIBRILLATION AFTER STROKE

Anna L. Parks[1]; Margaret Fang[2]; Michael A. Steinman[3]; Alexander Smith[4]; Sachin J. Shah[5]. [1]Hematology / Medicine, University of California, San Francisco, San Francisco, CA; [2]Medicine, University of California, San Francisco, San Francisco, CA; [3]Geriatrics / Medicine, SF VA Medical Center, San Francisco, CA; [4]Medicine, UCSF, San Francisco, CA; [5]Division of Hospital Medicine, Department of Medicine, University of California, San Francisco, San Francisco, CA. (Control ID #3391613)

BACKGROUND: Atrial fibrillation (AF) disproportionately affects older, multimorbid adults and increases risk of stroke. Short-term consequences of stroke are well-described, but less is known about how stroke affects long-term outcomes in AF patients who have other risk factors for death and functional decline. Understanding long-term effects of stroke is important to guide shared decision-making on anticoagulation. Our goal was to determine if, and to what degree, stroke affects mortality and functional disability over time in older AF patients.

METHODS: We used data from 1992-2014 from the Health and Retirement Study, a longitudinal, nationally representative survey of Americans ≥ 50 years old that is linked to Medicare claims. We identified subjects ≥ 65 years diagnosed with AF who did not need help from another person completing any of 6 activities of daily living (ADLs) (walking across a room, dressing, bathing, eating, toileting, getting out of bed). Using incidence density sampling, we identified patients who had an incident stroke and matched them using time from AF diagnosis with 5 comparator nonstroke patients. Outcomes were time to death and to dependence in any of 6 ADLs assessed at 2-year intervals. We used a survival analysis framework accounting for competing risks.

RESULTS: We identified 184 subjects with AF and incident stroke and 935 controls. Two years after stroke, 52% (95% CI 45-60%) of stroke patients had died versus 24% (95% CI 21-26%) of controls. By 4 years, 72% (95% CI 64-79%) of stroke patients had died versus 40% (95% CI 37-44%) of controls, and by 8 years, 91% (95% CI 85-96%) versus 64% (95% CI 60-67%) had died. The cumulative incidence of ADL dependence at 2 years was 52% (95% CI 45-59%) for stroke patients versus 23% (95% CI 21-27%) for controls, at 4 years was 66% (95% CI 59-73%) versus 40% (95% CI 36-43%), and at 8 years was 78% (95% CI 71-83%) versus 59% (95% CI 56-63%).

CONCLUSIONS: In a nationally representative sample of older AF patients, by 2 years after stroke, half of patients with stroke had died, more than double the risk of those without stroke. Stroke was associated with significantly greater loss of functional independence over time. These results inform decision-making and patient counseling on anticoagulation and preventive interventions, as well as advance care planning.

LOUISIANA DISREGARDS THE CHA2DS2VASC FOR PATIENTS WITH LOW SCORES

Ashley Russell[1]; Nassir Marrouche[2]; Lilas Dagher[2]; Yan Zhao[2]. [1]Internal Medicine Residency, Tulane University, New Orleans, LA; [2]Cardiology, Tulane University, New Orleans, LA. (Control ID #3391799)

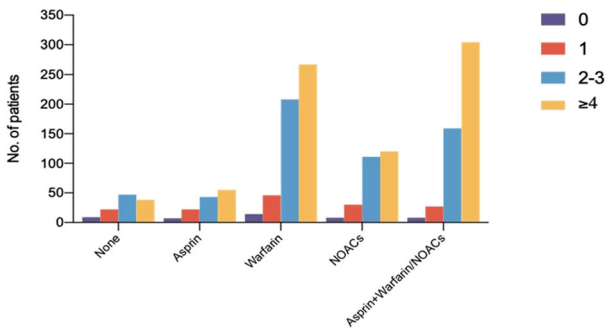
BACKGROUND: Anticoagulation is not indicated for atrial fibrillation (AF) patients with low risk CHA2DS2VASC scores, yet discrepancies from guidelines are seen in Louisiana prescribing patterns. The objective is to investigate adherence to guideline-directed antithrombotic management in patients with AF stratified based on CHA2DS2VASC scores.

METHODS: Analysis included Tulane Medical Center outpatient clinic data over the past ten years to identify characteristics of 1,129 AF patients and their management. AF patients prescribed Aspirin (ASA), Warfarin, non-vitamin K oral anticoagulants (NOACs), or no therapy and their corresponding CHA2DS2VASC scores were identified.

RESULTS: In patients with a CHA2DS2VASC score of zero, 27% received no ASA or anticoagulation, 21% ASA, 3% Warfarin, and 24% NOACs ($p < 0.001$). In AF patients with a CHA2DS2VASC score of one, 20% received no therapy, 20% ASA, 9% Warfarin, and 27% NOACs ($p < 0.001$). Among those with a score of two to three, 22% were not prescribed NOAC or Warfarin and 16% of patients with a score of greater than or equal to four were not prescribed NOAC or Warfarin ($p<0.001$). Most patients with a CHA2DS2VASC of greater than or equal to two were prescribed anticoagulation, in line with guidelines. Conversely, the management of patients with a CHA2DS2VASC score of zero and one is highly variable.

CONCLUSIONS: Evidence that only 27% of AF patients with a score of zero received no ASA or anticoagulation prescriptions indicates guidelines are mostly not being followed for low risk AF patients. Patients are receiving NOACs across the board, regardless of their score. More guidance is needed on how to manage AF patients with a low CHA2DS2VASC score. Further investigation of more ways to risk stratify AF patients ultimately for the prevention of stroke is warranted.

Figure 1: AF Patients on Type of Medical Therapy Organized by CHA_2DS_2VASC Score



LOWER LEVELS OF SOCIAL SUPPORT ARE NOT ASSOCIATED WITH POORER OUTCOMES FOR PATIENTS RECEIVING HOSPITAL-AT-HOME CARE

Matthew R. Augustine[1,2]; Albert L. Siu[3]; Kenneth Boockvar[4,3]; Linda DeCherrie[5]; Bruce leff[6]; Alex Federman[1]. [1]Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; [2]GRECC, James J Peters (Bronx) VA Medical Center, Bronx, NY; [3]Geriatrics and Palliative Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; [4]GRECC, James J Peters VA Medical Center, Bronx, NY; [5]Geriatrics, Icahn School of Medicine at Mount Sinai, New York, NY; [6]Geriatrics, Johns Hopkins University School of Medicine, Baltimore, MD. (Control ID #3374419)

BACKGROUND: Higher levels of social support have been associated with improved clinical outcomes during and after acute illness and may play an important role in patients receiving hospital-level care at home. We examine the association of social support on outcomes for patients receiving acute hospital-level care at home versus traditional inpatient hospitalization for acute illnesses.

METHODS: We performed a secondary analysis of a prospective cohort evaluation of a hospital at home (HaH) program of the Mount Sinai Hospital System, involving 295 participants receiving HaH care and 212 patients undergoing traditional hospitalization from November of 2014 to August of 2017. Informational and Instrumental social support were assessed at baseline using two 4-item measures from the Patient-Reported Outcomes Measurement Information System and dichotomized to high and lower social support (SS). To account for data missing at random, we used multiple imputation. We used linear or logistic regression with inverse probability of treatment weighting to examine the confounding and moderating effects of social support upon 4 clinical outcomes. Outcomes included length of stay (LOS) for acute care and any hospitalization, emergency department (ED) visit, or referral to a skilled nursing facility (SNF) in the 30-day post-acute period.

RESULTS: The study population (N=295) was predominantly ≥75 years of age (57%) and female (79%), had high school or higher education (79%), had fee-for-service Medicare insurance (61%), and were admitted for pneumonia (18.9%), urinary tract infection (18.7%), or heart failure (14.9%). Fewer patients receiving HaH compared to traditional hospitalization reported high informational SS (HaH 41% vs. Control 51%, $p=0.012$) and high instrumental SS (HaH 31% vs. Control 37%; $p=0.062$). The effects of HaH upon most outcomes remained significant and unchanged: LOS (base model: -1.89 days; 95% CI -2.48, -1.29; $p<0.001$; controlling for SS: -1.95 days; 95% CI -2.55, -1.34; $p<0.001$), hospitalization (base model: OR 0.63; 95% CI 0.42, 0.96; $p=0.031$; controlling for SS: OR 0.62; 95% CI 0.40, 0.95; $p=0.030$), and referral to SNF (base model: OR 0.14; 95% CI 0.07, 0.28; $p<0.001$; controlling for SS: OR 0.16; 95% CI 0.07, 0.33; $p<0.001$). The association of HaH with any ED visit was attenuated by instrumental SS (base model: OR 0.61, 95% CI 0.39-0.97, $p=0.037$; controlling for SS: OR 0.71, 95% CI 0.44-1.14, $p=0.15$). There were no significant interactions between HaH and high informational or instrumental SS for any of the 4 outcomes.

CONCLUSIONS: Lack of high-levels of SS had little effect on the association of HaH with positive outcomes of care, suggesting similar benefits of HaH services for patients with lower levels of SS. The specific acute and post-acute services of this HaH program may uniquely fill gaps of inadequate SS. Ongoing evaluation of SS in the context of other HaH programs is warranted.

MACHINE LEARNING-BASED AND RULE-BASED SEPSIS RISK PREDICTION TOOLS: A QUALITATIVE STUDY OF IMPLEMENTATION CHALLENGES AND APPROACHES

Mugdha Joshi[1]; Keizra S. Mecklai[1]; Lipika Samal[2]. [1]Medicine, Harvard Medical School, Boston, MA; [2]Brigham and Women's Division of General Internal Medicine, Harvard Medical School, Boston, MA. (Control ID #3390799)

BACKGROUND: Mandated reporting of sepsis outcomes have led many institutions to implement surveillance software to improve sepsis outcomes. Commercial EMRs, external vendors, and home grown risk prediction tools offer a variety of approaches. Traditional rule-based models draw on the Systemic Inflammatory Response Syndrome (SIRS) criteria while newer predictive models utilize machine-learning (ML) based algorithms to predict sepsis risk. The purpose of this study is to identify challenges and approaches for successful implementation of sepsis surveillance tools.

METHODS: Semi-structured interviews were conducted with hospital leaders overseeing sepsis clinical decision support implementation at U.S. medical centers (n=14). Participants were recruited via purposive sampling. Interviews probed implementation process, challenges faced, and recommended approaches. Responses were independently coded by two coders with consensus approach and inductively analyzed for themes.

RESULTS: Challenges shared by institutions with both SIRS and ML models categorize to technical build, optimization of alerts, workflow integration, tool validation, implementation time, and working with external vendors. Institutions using ML models reported greater difficulty with clinician acceptance of these tools due to user expectation

management, limited tool intuitiveness, distrust in the technology, and confusion. Successful institutions report multiple approaches to improving acceptance including user education, expert support, and practitioner-led efforts.

CONCLUSIONS: In this small but diverse set of hospitals, we found that in addition to the known socio- technical challenges of implementing clinical decision support, less clinically intuitive ML models may require additional attention to user education, support, and expectation management.

MAINTAINING MOBILITY: PREDICTING MOBILITY LOSS DURING HOSPITALIZATION ON HOSPITAL DAY ONE

Logan Pierce, Sachin J. Shah. Division of Hospital Medicine, Department of Medicine, University of California, San Francisco, San Francisco, CA. (Control ID #3392176)

BACKGROUND: Older adults commonly lose mobility during hospitalization. Loss of mobility may be preventable if it is identified and addressed early in a patient's hospital course. However, currently, there is no systematic method to identify at-risk patients early. To address this gap, we created a model to predict, on the first hospital day, patients' likelihood of losing mobility during their hospitalization.

METHODS: We conducted a retrospective cohort study of patients discharged from the inpatient medicine service of an urban academic medical center. We included patients discharge from 1/1 to 12/31/2019, who were ≥65 years old and charted as ambulatory on admission by the bedside RN. We extracted demographic, clinical, and functional data from the medical record. We only included predictors available on the first hospital day. We determined mobility status using the mobility sub-scale of the Braden Score, which is recorded twice daily by bedside nurses.

Using an 80/20 split, we created derivation and validation cohorts. We employed ensemble machine learning methods to develop the prediction model. We used a weighted combination of model fit methods, including gradient boosted trees, linear regression, and random forest. The final model was applied to the validation set to assess discrimination and estimates of variable importance were calculated for each predictor.

RESULTS: 2215 patients met inclusion criteria; at discharge 172 patients (7.8%) had lost mobility. We observed no difference in baseline characteristics between the derivation and validation groups. The mean age was 77 years, most patients were female (51%), and most were admitted through the Emergency Department (85%) to a floor bed (71%).

The final model predictors included patient sex, age, admit source, level of care, payer class, foley status, gastric tube status, NPO status, number of medications administered, number of peripheral IVs inserted, Glasgow Coma Scale, and admission diagnosis. The final model discriminated relatively well, with a c-statistic of 0.73 in the validation set. Medication count and age explained the greatest variance in outcomes, 28% and 27%, respectively.

CONCLUSIONS: It is possible to predict those at risk of losing mobility using data only from hospital day one. Such a tool allows physicians, nurses, and therapists to intervene early in the care of patients at the greatest risk of mobility loss.

MANAGING ANXIETY IN PRIMARY CARE WITH THE NEW ANXIETY MANAGEMENT ALGORITHM STANDARDIZING TREATMENT EXPERIENCE (NAMASTE): A LONGITUDINAL COHORT ANALYSIS

Bryan Dobbs[1]; Diane Dolan-Soto[3]; Seth A. Berkowitz[2]; Amy Weil[3]. [1]School of Medicine, University of North Carolina, Chapel Hill, NC; [2]Division of General Medicine & Clinical Epidemiology, UNC School of Medicine, Chapel Hill, NC; [3]Internal Medicine, UNC Chapel Hill School of Medicine, Chapel Hill NC, NC. (Control ID #3390667)

BACKGROUND: Generalized Anxiety Disorder (GAD) is persistent and excessive worry, fear, and/or stress that exists outside of developmentally normative fear and anxiety. GAD is common and contributes to disability and adverse health outcomes, including increased suicide risk. GAD care particularly concerns primary providers given the relative shortage of psychiatric care.

The UNC Internal Medicine Clinic (IMC) staff developed the New Anxiety Management Algorithm Standardizing Treatment Experience (NAMASTE) to help providers identify and manage anxiety disorders.

NAMASTE standardizes anxiety disorder treatment including identification, medication management and counseling, and uses the GAD-7, a validated 7-item measure of GAD symptoms, to monitor treatment response.

We sought to determine whether the NAMASTE program was associated with greater reductions in GAD-7 scores than seen in usual care.

METHODS: We conducted a retrospective cohort study of IMC primary care patients older than 18 years from 1/1/2016 to 7/5/2019. Patients were included if they had at least 4 GAD-7 assessments in the medical record and their first GAD-7 was at least 10, indicating at least moderate anxiety. All GAD-7s in the record were abstracted.

We also collected data on the following covariates: age, gender, counseling use, use of augmenter medications like buspirone, and other mental health diagnoses.

We categorized whether participants were managed as part of the NAMASTE program or outside of the program.

The primary outcome was GAD-7 score. For analysis, we used longitudinal linear models with the GAD-7 measurement occasion as the unit of analysis and generalized estimating equations (GEE) to account for repeated measurements within individuals.

RESULTS: Two hundred fourteen individuals met inclusion criteria (NAMASTE n = 96, Non-NAMASTE n = 118). Overall, there were no significant differences between the groups' covariates at baseline, except mean baseline GAD-7 (NAMASTE mean = 16, SD 3.5; Non-NAMASTE mean = 14, SD 3.2). In unadjusted analyses, mean follow-up GAD-7 score was 10 (SD 5.1) in NAMASTE and 11 (SD 4.8) in non-NAMASTE. In GEE models adjusted for baseline GAD-7 and the above covariates, NAMASTE participants had larger decreases in GAD-7 scores than non-NAMASTE participants (-0.15, 95%CI -0.26 to -0.04, p = 0.004).

CONCLUSIONS: NAMASTE participation was associated with larger decreases in GAD-7 scores than usual care. Limitations of this study include non-random assignment to the intervention. Though we adjusted for potential confounders, we may not have had data on all factors that influenced receipt of treatment and treatment response. An important direction for future research would be testing the NAMASTE program in a randomized trial. Until then, noting the burden of anxiety and other mental health disorders in our population, NAMASTE can still provide structured care within the bounds of our primary care clinic that is associated with symptomatic improvement.

MEANINGFUL IMPROVEMENT 24 WEEKS AFTER INITIATING SUBCUTANEOUS TANEZUMAB FOR OSTEOARTHRITIS OF THE HIP OR KNEE IN PATIENTS FROM EUROPE AND JAPAN

Francis Berenbaum[1]; Francisco Blanco[2]; Ali Guermazi[3]; Kenji Miki[4]; Greg Tutino[5]; Takaharu Yamabe[6]; Lars Viktrup[7]; Rod Junor[8]; William Carey[9]; Mark T. Brown[6]; Christine R. West[6]; Kenneth M. Verburg[6]. [1]Sorbonne Université, INSERM, AP-HP Hospital Saint Antoine, Paris,

France; [2]INIBIC-Complexo Hospitalario Universitario de A Coruña, A Coruña, Spain; [3]Boston University School of Medicine, Boston, MA; [4]Osaka Yukioka College of Health Science, Hayaishi Hospital, Osaka, Japan; [5]Pfizer Inc., New York, NY; [6]Pfizer Inc., Groton, CT; [7]Eli Lilly and Company, Indianapolis, IN; [8]Pfizer Ltd., Tadworth, United Kingdom; [9]Pfizer Ltd., Tadworth, United Kingdom. (Control ID #3385544)

BACKGROUND: Tanezumab is a monoclonal antibody that inhibits nerve growth factor, and has early and sustained efficacy following subcutaneous administration in patients with osteoarthritis (OA). This analysis from a randomized study (NCT02709486) conducted in Europe and Japan assessed the proportion of patients with moderate (≥30%) or substantial (≥50%) clinically important improvements in Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) Pain score, and corresponding changes in WOMAC Physical Function score, at Week 24.

METHODS: The patients had radiographically confirmed OA (hip or knee); WOMAC Pain (Screening and Baseline) and Physical Function (Baseline) scores ≥5 on 11-point scales; Baseline Patient's Global Assessment of OA 'fair', 'poor', or 'very poor '; and a history of insufficient pain relief from acetaminophen, and inadequate pain relief from, intolerance to, or contraindication to nonsteroidal anti-inflammatory drugs and either tramadol or opioids (or unwillingness to take opioids). Patients received three subcutaneous doses of placebo, tanezumab 2.5 mg, or tanezumab 5 mg (Baseline, Week 8, Week 16). The proportions of patients with ≥30%, ≥50%, ≥70%, or ≥90% reduction from Baseline at Week 24 in WOMAC Pain and WOMAC Physical Function were assessed. Since tanezumab 2.5 mg did not meet all three co-primary endpoints, these secondary responder endpoints were unadjusted for multiplicity.

RESULTS: A total of 849 patients were analyzed. At Week 24, a significantly greater proportion of patients treated with tanezumab than placebo had ≥30% (56.6%, 65.6%, and 68.7% in the placebo, tanezumab 2.5 mg, and tanezumab 5 mg groups, respectively) or ≥50% (33.8%, 45.4%, and 47.9%, respectively) improvement from Baseline in WOMAC Pain (both groups, unadjusted, $P<0.05$ versus placebo); the proportion of tanezumab-treated patients achieving ≥70% (17.8%, 21.3%, and 23.2%, respectively) or ≥90% (3.2%, 5.3%, and 6.0%, respectively) improvement was not significantly different from placebo. At Week 24, a significantly greater proportion of patients treated with tanezumab than placebo had ≥30% (51.2%, 64.9%, and 68.7%, respectively) or ≥50% (32.4%, 41.5%, and 44.7%, respectively) improvement from Baseline in WOMAC Physical Function (both groups, unadjusted, $P<0.05$ versus placebo); the proportion of tanezumab- treated patients achieving ≥70% improvement was not significantly different from placebo (14.6%, 19.1%, and 17.3%, respectively), but significantly more tanezumab-treated patients than placebo had a ≥90% improvement in Physical Function (1.8%, 5.3%, and 5.3%, respectively, both groups, unadjusted, $P<0.05$ versus placebo).

CONCLUSIONS: Significantly more patients in each tanezumab treatment group (2.5 mg and 5 mg) had a moderate or substantial clinically important improvement in pain at Week 24, compared with placebo. Similar improvements in function were observed. There were few differences between the tanezumab treatment groups.

MEANINGFUL IMPROVEMENT IN WOMAC PAIN SUBSCALE SCORE AT 16 WEEKS AFTER INITIATING SUBCUTANEOUS TANEZUMAB VERSUS PLACEBO IN PATIENTS WITH OSTEOARTHRITIS IN NORTH AMERICA

Thomas J. Schnitzer[1]; Richard Easton[2]; Shirley Pang[3]; Dennis Levinson[4]; Greg Tutino[5]; Glenn Pixton[6]; Lars Viktrup[7]; Isabelle Davignon[8]; Mark T. Brown[8]; Christine R. West[8]; Kenneth M. Verburg[8]. [1]Northwestern University, Chicago, IL; [2]Michigan Orthopaedic and Spine Surgeons, Rochester Hills, MI; [3]St. Joseph Heritage Healthcare, Fullerton, CA; [4]Chicago Clinical Research Institute, Chicago, IL; [5]Pfizer Inc., New York, NY; [6]Pfizer Inc., Morrisville, NC; [7]Eli Lilly and Company, Indianapolis, IN; [8]Pfizer Inc., Groton, CT. (Control ID #3386318)

BACKGROUND: Tanezumab is a monoclonal antibody that inhibits nerve growth factor and is under investigation for the treatment of osteoarthritis (OA), showing early and sustained efficacy with subcutaneous administration. This analysis assessed the proportion of treated patients attaining moderate (≥30%) or substantial (≥50%) clinically important improvements in Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) Pain score, and corresponding changes in WOMAC Physical Function score, at Week 16.

METHODS: This randomized, multi-center, dose titration study (NCT02697773) was conducted in North America. Patients had radiographically confirmed OA (hip or knee); WOMAC Pain score ≥5 at screening and baseline and Physical Function score ≥5 at baseline (both 11-point scales); Patient's Global Assessment of OA 'fair', 'poor', or 'very poor' at baseline; and a documented history that acetaminophen was insufficient, and nonsteroidal anti-inflammatory drugs, and either tramadol or opioids, were inadequate or unsuitable. Patients received placebo at baseline and Week 8, tanezumab 2.5 mg at baseline and Week 8 (tanezumab 2.5 mg group) or tanezumab 2.5 mg at baseline and tanezumab 5 mg at Week 8 (tanezumab 2.5/5 mg group). The proportions of patients with ≥30%, ≥50%, ≥70%, or ≥90% reduction from baseline at Week 16 in WOMAC Pain or Physical Function were assessed.

RESULTS: The analysis included 696 patients. Significantly more tanezumab-treated patients than placebo- treated patients had ≥30% (54.7%, 68.0%, and 70.4% in the placebo, tanezumab 2.5 mg, and tanezumab 2.5/5 mg groups, respectively) or ≥50% (37.9%, 54.5%, and 57.1%, respectively) improvement from baseline in WOMAC Pain at Week 16 (both groups $P<0.05$ versus placebo); ≥70% improvement in WOMAC Pain was also achieved by significantly more patients in each tanezumab group than placebo (25.0%, 34.6%, and 36.5%, respectively, both groups $P<0.05$), but the proportion with ≥90% improvement was not significantly different from placebo in the tanezumab groups (9.5%, 14.7%, and 14.2%, respectively). Significantly more tanezumab-treated patients than placebo-treated patients had ≥30% (54.3%, 65.8%, and 71.7%, respectively), ≥50% (36.6%, 54.1%, and 57.1%, respectively), or ≥70% (22.8%, 34.2%, and 36.1%, respectively) improvement from baseline in WOMAC Physical Function at Week 16 (both groups $P<0.05$); but the proportion with ≥90% improvement was not significantly different from placebo in the tanezumab groups (10.3%, 14.3%, and 14.6%, respectively).

CONCLUSIONS: Significantly more patients treated with tanezumab (both treatment groups) than placebo had a moderate or substantial clinically important improvement in pain at Week 16. A similar pattern was seen for function. There were few differences between the two tanezumab treatment groups.

MEASLES IMMUNITY SCREENING IN A NYC MEDICAL STUDENT-RUN FREE CLINIC

Brittany T. Abel[1]; Amanda H. Ceravolo[1]; Anna Cornelius-Schecter[1]; Ashita S. Batavia[2]; Pamela Charney[3]. [1]Medical College, Weill Cornell Medicine, New York, NY; [2]Medicine, Weill Cornell Medical College, New York, NY; [3]Internal Medicine, Weill Cornell Medical College, New York City, NY. (Control ID #3369763)

BACKGROUND: The New York City Department of Health reported 390 cases of measles between October 2018 and April 24, 2019. In light of this outbreak, local healthcare providers were urged to ensure adult patients' immunity to measles. The Weill Cornell Community Clinic, a

student-run free clinic providing primary care to uninsured, low-income New Yorkers ages 18 and up, implemented measles immunity screening beginning April 25, 2019. This study aims to report the outcomes of this measles immunity screening protocol and the prevalence of measles non-immunity and associated demographic characteristics among uninsured, low-income adult patients of a New York City medical student-run free clinic.

METHODS: Patients underwent serological measles immunity testing during their regularly scheduled clinic visit if 1) they did not have an accessible measles vaccination record or serological-proven immunity 2) they were having blood drawn for other tests during the visit and 3) they consented to the test. Serological testing was performed via anti-measles IgG antibody assay which yields results of immune, non-immune or equivocal immune status. All patients found to be non-immune were offered two doses of MMR vaccine at least 28 days apart. Results of measles screening protocol, including serum anti-measles antibody results when performed, as well as demographic information were collected from the medical record for patients seen between April 25, 2019 and November 11, 2019. Data were analyzed using descriptive statistics, T tests and Fisher's Exact tests.

RESULTS: There were 83 unique patients seen during the screening period, at least 73.5% of whom were born outside of the United States. Only three patients (3.6%) had accessible measles vaccination records. Nine patients (10.8%) had serological immunity checked prior to the screening period. Of the remaining 71 patients, 18 (21.7%) did not have serological measles immunity testing performed for the following reasons: no bloodwork drawn at the appointment (n=11), missed (n=1), refused (n=2). Of the 56 patients who underwent serological measles immunity testing during the screening period, eight were found to be non- immune (14.3%). Seven of eight patients found to be non-immune went on to receive at least one MMR vaccine (87.5%). Compared to immune patients, measles non-immune patients were younger (mean 36.8 ± SD 8.5 years vs. 51.0 ± 12.6 years, p=0.003) and less likely to be black (OR 0.0 95% CI 0.0-0.77, p=0.033). There were no differences between measles non-immune and immune patients in sex, primary language or borough of residence.

CONCLUSIONS: Uninsured, low-income adult patients of a New York City student-run free clinic between April 25, 2019 and November 11, 2019 rarely had accessible, documented measles vaccination records. We found 14.3% of patients who underwent serological measles immunity testing to be non-immune, with most non-immune patients going on to receive the MMR vaccine. The non-immune patients tended to be younger and non-black.

MEASUREMENTS OF RESILIENCE AND GRIT AMONG INTERNAL MEDICINE RESIDENTS: VALIDITY AND ASSOCIATIONS WITH MEDICAL KNOWLEDGE, PROFESSIONALISM, AND CLINICAL PERFORMANCE

Fares Alahdab[2]; Andrew J. Halvorsen[3]; Jayawant N. Mandrekar[4]; Brianna E. Vaa[5]; Victor M. Montori[6]; Colin P. West[1]; M. Hassan Murad[7]; Thomas J. Beckman[1]. [1]Internal Medicine, Mayo Clinic, Rochester, MN; [2]Knowledge Synthesis Unit, Mayo Clinic, Rochester, MN; [3]Department of Medicine, Mayo Clinic, Rochester, MN; [4]Health Sciences Research, Mayo Clinic, Rochester, MN; [5]General Internal Medicine, Mayo Clinic, Rochester, MN; [6]Medicine, Mayo Clinic, Rochester, MN; [7]preventive medicine, mayo clinic, Rochester, MN. (Control ID #3391530)

BACKGROUND: Resident physician burnout, which has been widely studied, is a complex phenomenon with systems and individual components. Resilience and grit may represent modifiable, individual factors that counter burnout. However, there is lack of validity evidence regarding measures of resilience and grit among physicians-in-training.

METHODS: We evaluated CD-RISC 10 and GRIT-S instrument scores among IM residents at the Mayo Clinic Rochester, Minnesota between July 2017 and June 2019. For both instruments, we analyzed dimensionality, internal consistency reliability, and criterion validity in terms of relationships between resilience and grit, with standardized measures of residents' medical knowledge (in-training examination [ITE]), clinical performance (faculty and peer evaluations and mini-clinical evaluation exercises [mini- CEX]), and professionalism/dutifulness (conference attendance and evaluation completion).

RESULTS: A total of 213 out of 253 (84.2%) survey-eligible IM residents provided both CD-RISC 10 and GRIT-S survey responses. Internal consistency reliability (Cronbach alpha) was excellent for CD-RISC 10 (0.93) and GRIT-S (0.82) overall, and for the GRIT subscales of consistency of interest (0.84) and perseverance of effort (0.71). Regarding criterion validity, CD-RISC 10 scores were negatively associated with ITE percentile (β = -3.4, 95% CI: -6.2 to -0.5, P=0.02) and mini-CEX (β = -0.2, 95% CI: -0.5 to -0.02, P=0.03). GRIT-S scores were positively associated with evaluation completion percentage (β = 3.1, 95% CI: 0.4 to 5.8, P=0.02) and conference attendance (β = 3.4, 95% CI: 0.1 to 6.6, P=0.04).

CONCLUSIONS: This study revealed favorable validity evidence for CD-RISC 10 and GRIT-S among internal medicine residents. The negative relationship between CD-RISC 10 and both ITE and mini-CEX scores may suggest residents' abilities to demonstrate resilience within a competitive training environment, despite performing less favorably on standardized assessments of medical knowledge and clinical performance. As hypothesized, we identified positive associations between grit and behaviors related to the dutifulness aspect of professionalism, namely evaluation completion and conference attendance. This initial validity study provides a foundation for further research on resiliency and grit among physicians-in-training.

MEASURING FLOURISHING AMONG INTERNAL MEDICINE AND PSYCHIATRY RESIDENTS

Madeline Rodriguez[1]; Margot Kelly-Hedrick[2]; Anne E. Ruble[2]; Scott Wright[3]; Margaret S. Chisolm[4]. [1]Internal Medicine, Johns Hopkins Bayview, Baltimore, MD; [2]Department of Psychiatry and Behavioral Sciences, Johns Hopkins University School of Medicine, Baltimore, MD; [3]medicine, jhusom, Baltimore, MD; [4]Psychiatry and Behavioral Sciences, Johns Hopkins University, Baltimore, MD. (Control ID #3390058)

BACKGROUND: Many residents experience burnout, which has prompted national attention on trainee well-being. Well-being goes beyond the absence of burnout, and exploration of well-being in graduate medical education is relatively lacking. A recently developed measure of flourishing – defined by VanderWeele in 2017 as a broad conception of well-being including six domains: (1) happiness and life satisfaction, (2) mental and physical health, (3) meaning and purpose, (4) character and virtue, (5) close social relationships, and (6) financial and material stability - may provide insight into this important topic. To date, the flourishing measure has not been studied in medical trainees. The purpose of this study was to investigate flourishing and its correlates in a sample of medical residents. We hypothesized that higher flourishing scores in trainees would correlate with higher quality of life, satisfaction with work-life balance, and empathic concern, as well as lower burnout.

METHODS: Internal medicine residents and psychiatry residents at two residency programs responded to a cross-sectional, online survey (December 2017-February 2018) which focused on the flourishing measure, producing two scores: the Flourish Index (FI) and Secure Flourish Index (SFI); these were our primary and secondary outcomes respectively. The SFI includes the items contained in the FI, plus additional assessment of

material and financial stability. Participants were queried about other data, using mostly validated measures, including: quality of life, burnout, work-life balance, empathic concern, and sociodemographic characteristics. Simple and multiple linear regressions were performed to examine the relationship between FI/SFI and other variables.

RESULTS: The response rate was 92% (n=92/101). Participants reported a mean FI score of 6.8 (SD=1.6) and mean SFI score of 6.9 (SD=1.6). In the best multivariate model for FI, low quality of life, low work-life balance satisfaction, high emotional exhaustion, lower empathic concern, and having a pet were all significantly associated with lower FI scores (R^2=0.59, F[14,69]=7.10, p<.0001) indicating lesser flourishing, controlling for other variables. Similarly, low quality of life, high emotional exhaustion, lower empathic concern, and having a pet were all significantly associated with lower SFI scores (R^2=.55, F[14,69]=6.06, p<.0001), controlling for other variables.

CONCLUSIONS: The associations between flourishing indices and well-being metrics, as well as burnout, suggest the flourishing measure may be useful for assessing trainee well-being and growth.

MEDICAID SECTION 1115 WAIVER DEMONSTRATION PROGRAMS: TRANSPARENCY AND ACCOUNTABILITY UNDER THE AFFORDABLE CARE ACT

Leo Lopez[3,1]; Joseph S. Ross[1]; David Silvestri[2]. [1]Internal Medicine, Yale University School of Medicine, New Haven, CT; [2]New York City Health + Hospitals, New York City, NY; [3]National Clinician Scholars Program, Yale University School of Medicine, New Haven, CT. (Control ID #3391869)

BACKGROUND: Under Section 1115 of the Social Security Act, the Secretary of Health and Human Services may waive Medicaid requirements and permit states to pilot experimental models of healthcare delivery, provided these still advance Medicaid objectives. To promote transparency and accountability, the ACA introduced two additional reporting requirements for states with waivers. Starting in 2012, states with Section 1115 waivers must publish annual progress reports describing demonstration program implementation and also conduct and report on periodic demonstration program evaluations. Both the annual progress reports and period evaluations must be reported publicly. We sought to examine states' compliance with ACA demonstration program annual reporting and program evaluation requirements.

METHODS: We conducted a a two-part cross-sectional study of of the Medicaid 1115 waiver demonstration programs' annual reports and periodic program evaluations. Using the publicly available Centers for Medicare and Medicare Services' (CMS) administrative record, we identified all active demonstration programs and determined the percentage making annual reports publicly available, comparing 2011-2013 (pre-ACA) and 2016-2018 (post-ACA). Next, we determined adherence to CMS reporting guidelines for all publicly available demonstration program evaluations from 2016-2018, using a binary scoring system characterizing the following eight evaluation components: Executive Summary; Background; Hypothesis; Methods; Results; Conclusions; Interpretations and Policy Implications; and Lessons Learned.

RESULTS: From 2011-2013 (pre-ACA), there were 126 anticipated annual reports from CMS administrative records, 6 (4.8%) of which were publicly available. In contrast, from 2016-2018 (post-ACA), there were 93 anticipated annual reports, 54 (58%) of which were publicly available (p<0.001). From 2016-2018 (post- ACA), there were 20 publicly available demonstration program evaluations. The median number of program evaluation components reported was 5 (IQR, 2-6). The most commonly reported program evaluation component was Results (n=18; 90%) and General Background Information (n=15; 75%), whereas Interpretations and Policy Implications, and Lessons Learned and Recommendations were least commonly reported (n=4 for both; 20%). Notably, eleven evaluations that were submitted to CMS for consideration for demonstration program renewal failed to document Interpretations and Policy Implications.

CONCLUSIONS: Despite an increase in public annual reporting on Section 1115 demonstration programs after passage of the ACA, over 40% of annual reports required under the ACA have not been published publicly, and they consistently fail to adhere to CMS reporting guidelines reporting guidelines of key evaluation components. Given the importance of Medicaid Section 1115 waivers to pilot innovative, health- delivery systems, enforcement of existing CMS rules to ensure transparency and accountability is needed, particularly for program renewals.

MEDICAL CONDITIONS MANAGED BY SPECIALISTS USING TELEMEDICINE AMONG RURAL MEDICARE BENEFICIARIES

Krisda H. Chaiyachati[1]; Michael L. Barnett[2]; Jeffrey Souza[3]; Haiden A. Huskamp[3]; Ateev Mehrotra[3]. [1]General Internal Medicine, The University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]Health Policy and Management, Harvard T.H. Chan School of Public Health, Boston, MA; [3]Health Care Policy, Harvard Medical School, Boston, MA. (Control ID #3391958)

BACKGROUND: Rural Americans, relative to suburban and urban counterparts, are older, have a greater burden of chronic medical conditions (e.g., dementia, diabetes), and have less access to specialty care. Given telemedicine's ability to improve access to specialty care, policies at the state and federal level are changing to support telemedicine's expansion. The traditional Medicare program has historically reimbursed telemedicine visits, primarily focusing on older, rural Americans. While telemedicine for the treatment of mental health disorders has been described among Medicare beneficiaries, how telemedicine is being used by specialists to manage medical conditions is understudied, and so is its potential to help rural populations with chronic medical conditions and limited access. To fill this gap, we describe how telemedicine has been used by specialists to manage or co-manage medical conditions among rural Medicare beneficiaries.

METHODS: Using a 100% sample of traditional rural Medicare beneficiaries in 2017, we identified telemedicine visits using relevant modifiers, place of service, or CPT codes. Visits were categorized using the primary diagnosis code and provider specialty. After excluding visits for mental health conditions, we described common conditions treated, provider type, location of the encounter (e.g., inpatient, outpatient, or skilled nursing facility), and utilization by the beneficiary's state of residence, reported as telemedicine visits per 1000 rural beneficiaries by state.

RESULTS: In 2017, there were 87,738 telemedicine visits for medical conditions (30% of all telemedicine visits) provided to 50,437 (0.9%) rural beneficiaries. The majority (56%) of these visits were for five conditions: cognitive disorders (e.g., dementia and delirium) (23.3%), cardiovascular diseases (9.9%), sleep disorders (8.1%), neurologic diseases (e.g., post-stroke care and epilepsy) (7.6%), and hematologic disorders (e.g., anemias and anticoagulation monitoring) (7.3%). The majority of visits occurred with a physician (73%) vs. non-physician providers (27%) such as nurse practitioners. Over 95% of visits originated from an outpatient setting. The per-rural-beneficiary volume of telemedicine visits ranged from 0 per 1000 visits in New Jersey to 45 per 1000 in South Dakota. The Western region of the U.S. had the highest per-rural- beneficiary volume of telemedicine visits.

CONCLUSIONS: Telemedicine in the Medicare program has been modestly used for conditions important to aging adults, and with a wide geographic variation. While policies at the state and federal level are changing to create legislation favorable for telemedicine's expansion

(e.g., payment parity laws and expanding broadband access), how best to focus public resources requires understanding how telemedicine is used before assessing whether its use has improved the health of under-resourced populations. Our study provides a critical first step and may guide policymakers and practitioners as they shape telemedicine's future.

MEDICALLY UNDERSERVED PATIENT PERSPECTIVES REGARDING BEST PRIMARY CARE APPROACHES TO SUPPORT HEALTHY EATING AND WEIGHT LOSS FOR PATIENTS WITH OBESITY

Sierra M. Gaffney[1]; J. Carolyn Graff[2]; Satya Surbhi[3]; Kirstie Finch[1]; Michelle Duncan[1]; Patti Smith[3]; James E. Bailey[4]. [1]College of Medicine, University of Tennessee Health Science Center, Memphis, TN; [2]College of Nursing, University of Tennessee Health Science Center, Memphis, TN; [3]Center for Health System Improvement, Medicine, University of Tennessee Health Science Center, Memphis, TN; [4]Medicine and Preventive Medicine, University of Tennessee Health Science Center, Memphis, TN. (Control ID #3392081)

BACKGROUND: Obesity and obesity-related chronic conditions place major health and financial burdens on people in the United States. Multicomponent intensive behavioral weight loss programs focused on plant-based whole foods have been successful in achieving remission of diabetes and other obesity-related chronic conditions. However, it is unclear which intervention components are likely to be most effective for low-income and minority patients struggling with obesity. This study seeks to determine whether primary care multi-component plant-based healthy eating and weight loss programs would be of interest and what component interventions would be most appreciated from the perspective of patients in medically underserved areas.

METHODS: We identified patients with obesity and at least one obesity-related chronic condition being seen in a Federally Qualified Health Center (FQHC) using a regional Diabetes, Prevention, and Wellness Coalition practice-based research network. Patients were recruited by phone. We conducted concurrent surveys and focus groups to understand patients' experiences with healthy eating and weight loss, as well as their perceptions about specific primary care and community-based resources that aid healthy eating and weight loss. Focus groups were recorded and transcribed using Dragon Professional software. NVivo qualitative data analysis software was used to identify common discussion themes.

RESULTS: Participants (N=17) were mostly African American (94%), with an average age of 49.3 years. 47.1% of participants listed cost as a major barrier to plant-based healthy eating. Cost of healthy food was referenced 18 times in the group discussion, knowledge gaps were referenced 15 times, and insufficient motivation was also frequently referenced as a barrier to healthy eating and weight loss. Patient interest in primary care clinic-based healthy eating and weight loss interventions was high, with 100% reporting that health coaches would be a strong support for healthy eating and weight loss, 100% reporting interest in recipe ideas, 82% in support groups, 94% in healthy food boxes for diet replacement, and 77% in cooking classes. Only 6% had ever met with a dietician or nutritionist, but 47% reported interest in doing so. Of the 94% of patients taking medication (N=16), 100% reported interest in trying a plant-based diet in order to reduce their number of medications.

CONCLUSIONS: These findings suggest that medically underserved patients are highly interested in multi-component plant-based healthy eating and weight loss programs based in primary care. Furthermore, this study provides important information on the components that are of most interest to these patients. The most popular supports and resources (i.e. health coaches, healthy food boxes, support groups, and meal plans) addressed commonly identified barriers to plant-based healthy eating including high food costs, knowledge gaps, and insufficient motivation.

MEDICAL STUDENT KNOWLEDGE OF AND ATTITUDES TOWARD US DRUG PRICING

Susan Chimonas[1]; Anna Kaltenboeck[2]; Maha Mamoor[2]; Deborah R. Korenstein[3,2]. [1]Center for Health Policy and Outcomes, MSKCC, New York, NY; [2]Center for Health Policy and outcomes, Memorial Sloan Kettering Cancer Center, Hauppauge, NY; [3]Medicine, Memorial Sloan Kettering Cancer Center, New York, NY. (Control ID #3372812)

BACKGROUND: High US drug costs have garnered increasing national attention from policymakers and the public, with multiple proposed approaches to reform. While doctors/prescribers are key stakeholders regarding drug prices, poor knowledge of the complex forces that shape drug pricing may be a barrier to effectively addressing and advocating for patients' needs. Medical schools offer opportunity for early professional education about drug pricing, but student knowledge of drug pricing and its determinants and attitudes toward learning about drug pricing are not well understood. We assessed student knowledge of drug pricing and experiences of and attitudes toward education about drug pricing.

METHODS: We surveyed a national sample of students from US medical schools. The survey was accessed online through a link from an article posted on the Student Doctor Network (SDN), an on-line student forum; survey completers could enter a lottery to win $100 gift cards. Survey items included questions about demographics, attitudes toward drug pricing and its teaching (e.g. quantity/quality of instruction, importance, interest in learning more), and knowledge of drug pricing and its determinants. We used descriptive statistics and chi-square tests to assess associations of knowledge with class year and self-reported quality/quantity of drug pricing instruction. The study was reviewed by our institutional IRB and deemed exempt.

RESULTS: Among 815 viewers of the SDN article, 361 visited the survey and 240 (66%) students completed it. 53% were female; most were white (62%) or Asian (28%) and in MD (82%) or DO (13%) programs: 33% in year 1 and 22%, 24%, and 21% in years 2, 3, and 4. Clinical/non-primary care was the most common anticipated field (61%). Nearly all participants (>99%) said it was somewhat or very important to understand factors that influence drug pricing. Among year 3-4 students (n=108), 64(59%) reported receiving medical school instruction on drug pricing, among whom few rated the quantity as adequate (7%) or the quality as excellent (3%) or good (8%). Among 10 knowledge questions related to drug costs, reimbursement and pricing, the median correct score was 6; many responded "don't know" to questions about rates of brand name prescribing (54%) and physician reimbursement for intravenous drugs (51%). Fewer than half (44%) knew that drug prices are uncorrelated with research/development costs. Knowledge was associated with year in school (p=0.011) but not with reported instructional quality or quantity. Over 90% of participants were interested in learning more about drug pricing.

CONCLUSIONS: Medical students report interest in factors influencing drug prices but inadequate instruction, and knowledge is incomplete. To equip future doctors to effectively participate in the debate around drug prices, educators should discuss drug prescribing and reimbursement and teach about determinants of drug pricing.

MEDICARE PATIENTS ARE LESS LIKELY THAN YOUNGER PATIENTS TO BE REFERRED FOR WEIGHT MANAGEMENT AND ARE LESS LIKELY TO ATTEND

Elizabeth Pfoh[1]; Leslie Heinberg[3]; Michael B. Rothberg[2]. [1]Medicine, Cleveland Clinic, Cleveland, OH; [2]Internal Medicine, Cleveland Clinic, Cleveland, OH; [3]Cleveland Clinic, Cleveland, OH. (Control ID #3375038)

BACKGROUND: Medicare only covers limited weight management services within the health system (e.g. behavioral therapy in primary care). Knowing whether Medicare patients have a reduced likelihood of attending a weight management program can inform whether insurance access is a barrier to care after receiving a referral. The objective of this study is to identify the likelihood of Medicare patients to receive a referral to a weight management program and attend after that referral.

METHODS: This retrospective cohort study included adults between 18 and 90 years who had a primary care visit between 2015 and 2018 in a large integrated health system. We excluded patients diagnosed with cancer or pregnancy due to expected weight change and patients with a body mass index (BMI) <30. We identified whether a patient had a consult to a weight management program and whether there was a visit to any weight management program within 365 days of the consult. Demographics and health characteristics were collected from the electronic health record. Patients ≥65 years were identified as Medicare patients. Logistic regression models adjusted for age (as a continuous variable), sex, race, marriage status, BMI and age-adjusted Charlson comorbidity score were used to identify the odds of receiving a consult and attending a weight management program for patients in the Medicare group vs non-Medicare group.

RESULTS: Our study included 167,792 adults of which 17% of patients received a consult. In the adjusted regression model Medicare patients had 26% reduced odds (AOR:0.74) of receiving a consult vs non- Medicare patients ($p<0.01$). The adjusted odds of receiving a consult increased 34% (AOR 1.34) for each additional point on the Charlson comorbidity score and 43% for every 5 points on the BMI (AOR 1.43). The adjusted odds decreased 2% for every additional year of age (AOR:0.98)($p<0.01$).

Of patients who received a consult, 26% had a subsequent weight management visit. Patients who attended a weight management program averaged one less consult than patients who did not (2.5 vs 3.5 consults, $p<0.01$). On average there was 40 days between the last consult and first weight management visit. The adjusted odds of attending a visit was 34% lower (AOR: 0.66) for patients in the Medicare group compared to patients in the non-Medicare group ($p<0.01$). Neither BMI nor Charlson comorbidity score was associated with attending a weight management program among patients who received a referral ($p>0.05$). Increased age continued to be associated with decreased odds of attending a visit (AOR:0.99 for every additional year, $p<0.01$).

CONCLUSIONS: Medicare age, weight and number of comorbidities impacted the likelihood of a clinician referring a patient to a weight management program, but only age affected the likelihood of attending. In addition to age, Medicare insurance may be a barrier to attending weight management services in a health system after referral.

MEDICATION ERRORS IN TRANSITIONS OF CARE FROM HOSPITAL TO SKILLED NURSING FACILITIES: A GERIATRIC TEAM'S NEEDS ASSESSMENT TO INCREASE AWARENESS AND SPUR INSTITUTIONAL CHANGE

Katherine L. Coffey-Vega[1]; Bethany Delk[2]; Christa Brooker[2]; Amber Inofuentes[3]; Paul Helgerson[1]; Jessica Dreicer[1]. [1]Department of Medicine, University of Virginia, Charlottesville, VA; [2]Department of Pharmacy, University of Virginia Medical Center, Charlottesville, VA; [3]Medicine, University of Virginia, Charlottesville, VA. (Control ID #3392178)

BACKGROUND: Providers who care for elderly and disabled patients in post-acute care venues are all too familiar with medication administration errors that occur with patient transitions from the hospital to Skilled Nursing Facilities (SNFs). These errors, if ever discovered, are often not identified and corrected for several days, which places the patient at risk for serious complications, hospital bounce backs and even death. In order to increase institutional awareness about these issues, a needs assessment was performed to characterize the prevalence of two types of errors at hospital discharge: errors contained within the discharge summary (internal discordance), and errors in the medications ordered at the SNF (transcription errors). The primary objective of this work was to characterize and share the prevalence of such errors in order to increase awareness and motivate practice and culture change within both the discharging health system and the receiving SNFs.

METHODS: A needs assessment was conducted to characterize the prevalence of medication errors occurring with transitions from the inpatient medicine service at the University of Virginia to fifteen SNFs in Virginia over a four week period (52 discharges total). Discharge audits were performed by a small team with members who specialize in inpatient and post-acute geriatric medicine. Discharge summaries were reviewed for internal consistency and whether the final medication list reflected the correct and intended therapies. MARs (Medication Administration Records) were obtained from each SNF within 24 hours of each patients' discharge and were compared with the medication list in the final discharge summary.

RESULTS: Over a four week audit of 52 discharges, 57% of discharge summaries contained a clinically significant mismatch between the discharge summary text and the final medication list in the discharge summary. In 69% of discharges, there were discrepancies between the final discharge summary medication list and the medications that were ordered at the SNF. Serious errors included excessive insulin dosing, omission of anticoagulant therapy for acute DVT, omitted IV antibiotics, and errors in doses of critical anti- arrhythmic medications.

CONCLUSIONS: A four week, intensive review of UVA discharge summaries and receiving SNF MARs revealed significant rates of discharge summary internal discordance and SNF transcription errors. These findings were shared with Directors of Nursing (DONs) at a number of SNFs leading to increased awareness and broader internal audit processes aimed at reducing transcription errors. Findings were also presented to hospital leadership leading to both immediate corrective actions and additional QI projects aimed at identifying and correcting contributing systemic factors. We anticipate performing additional targeted needs assessments for other hospital service lines to further increase understanding and awareness, and to encourage corrective actions throughout the health system.

METABOLIC ACIDOSIS: A NEW REASON FOR INTERNISTS TO COUNSEL OBESE PATIENTS ABOUT CHRONIC KIDNEY DISEASE

Douglas Lambert[1]; Jamie Kane[1]; Matthew Abramowitz[2]. [1]Internal Medicine, Northwell Health System, Great Neck, NY; [2]Nephrology, Montefiore Medical Center, Bronx, NY. (Control ID #3385730)

BACKGROUND: Obesity is highly prevalent in the United States; and is projected to increase by 2030. In counseling obese patients, internists commonly emphasize the consequences of obesity including diabetes, hypertension, and cardiovascular disease. However, the increased risk for chronic kidney disease (CKD) is infrequently discussed. This deserves greater emphasis given the impact of end stage kidney disease and dialysis on quality of life and mortality. Prior research has shown that obese patients have more acidic urine, suggesting a state of metabolic acidosis – a known risk factor for CKD and mortality. Using a retrospective cohort study design, we explored this association further by 1) examining the association between body mass index (BMI) and serum bicarbonate, and 2) assessing incidence of clinical metabolic acidosis based on BMI.

METHODS: We assembled a large, racially and ethnically diverse cohort (n = 96,147) using data from the electronic health record of a large, urban healthcare system between January 2010 and December 2015. Inclusion

criteria were age > 18 years, and valid demographic, BMI, and outpatient laboratory data. Exclusion criteria were the presence of medical conditions and/or use of medications affecting serum bicarbonate. We ran multivariable linear regression and multilevel mixed effects modelling to examine the association between BMI and serum bicarbonate. Next, we used cox proportional hazards modelling to evaluate the risk of incident metabolic acidosis by BMI groups.

RESULTS: There was a progressive and highly significant association between higher BMI and lower bicarbonate. The association was J-shaped, attenuating but remaining highly significant at the highest BMI values. This association was greatest among white patients without baseline diabetes at a BMI of 40 – 42.9. Cox proportional hazards analysis revealed a progressively increased risk of incident metabolic acidosis at higher BMIs. The maximum hazard ratio was 1.20 (95% CI 1.14 – 1.26, $p < 0.001$) at a BMI of 35 – 39.9, declining to 1.15 (95% CI 1.09 – 1.22, $p < 0.001$) at a BMI > 40, reinforcing a J-shaped relationship between a higher BMI and metabolic acidosis.

CONCLUSIONS: A higher BMI contributes a significant risk for lower serum bicarbonate, and for incident clinical metabolic acidosis, a known risk factor for kidney functional decline and mortality. Our results imply that metabolic acidosis may be a new pathophysiological mechanism linking obesity to CKD; and future research is warranted to investigate such a relationship. Internists should also incorporate in their counseling of obese patients a discussion of the increased risk for kidney disease attributable to excess weight.

MISSED DRUG USE AMONG INFECTIVE ENDOCARDITIS CASES IS ASSOCIATED WITH FRAGMENTED CARE: EVIDENCE FROM SIX STATES

Paul Christine[1]; Michael Usher[3]; Cuong Q. Pham[2]; Ryan Kelly[2]; Tyler Winkelman[4]. [1]Internal Medicine, University of Michigan, Ann Arbor, MI; [2]General Medicine, University of Minnesota, Saint Paul, MN; [3]Department of Medicine/Division of General Internal Medicine, University of Minnesota Medical School, Minneapolis, MN; [4]Internal Medicine, Hennepin County Medical Center, Minneapolis, MN. (Control ID #3392204)

BACKGROUND: Infective endocarditis (IE) is a highly morbid complication related to injection drug use. Studies using national administrative data suggest that hospitalizations for drug use-associated infective endocarditis (DUA-IE) have increased over the last ten years, now accounting for 10-12% of IE cases. However, drug use as a contributing factor to IE hospitalizations is often missed or not included in coding documentation, resulting in undercount of DUA-IE. When substance use is missed during an IE-related hospitalization, care may become fragmented because of early discharge, untreated substance use, or resulting complications that necessitate care at a different hospital. We assessed whether missed drug use during IE hospitalizations was associated with higher levels of fragmented care and underestimation of DUA- IE burden.

METHODS: We analyzed data from State Inpatient Databases and State Emergency Department Databases from six states (FL, GA, IA, NY, UT, VT) from 2011-2015 where patients could be tracked across hospitals. Patients older than 16 with ICD-9/10 codes for admissions with IE were included. IE was categorized as DUA using ICD-9/10 codes for drugs/conditions associated with injection drug use (heroin, methamphetamine, cocaine, and hepatitis C). We labeled IE cases as a "missed" DUA-IE case if they had no diagnosis of drug use during their index hospitalization but received a drug use diagnosis during an ED visit or inpatient stay in the calendar year of their index IE hospitalization. We compared "missed" DUA-IE cases to DUA-IE cases where drug use was identified in the index hospitalization and non-DUE-IE cases with respect to demographics, length of stay (LOS) and total charges. To assess care fragmentation, we stratified IE groups by whether the patient was admitted to 1 or >1 hospital within 90-days of the index IE admission.

RESULTS: There were 52147 non-DUA-IE cases, 6872 DUA-IE cases, and 2676 "missed" DUA-IE cases identified by linking drug use across multiple encounters. Missed cases represented a 39% increase in total DUA-IE cases. Compared to DUA-IE cases identified at index hospitalizations, missed cases were more likely to be older, Black, insured by Medicare, and from rural areas. They also had higher 30-day readmission rate (23.2% vs 14.5%$p<0.001$) and higher charges ($p<0.001$), with similar LOS. Fragmented care was most common among patients with missed DUA-IE (33.3%), followed by DUA-IE cases identified during index hospitalization (20.5%) and non-DUA-IE cases (13.7%). When accounting for fragmentation, we found DUA-IE accounted for 18.2% of IE hospital days in 2011 which rose to 25.5% in 2015.

CONCLUSIONS: Missed diagnoses and fragmented care are common features of patients with DUA-IE. This results in underestimation of both DUA-IE prevalence and hospital utilization due to DUA-IE.

MODIFIABLE FACTORS ASSOCIATED WITH DIABETES ADHERENCE IN RURAL PRIMARY CARE CLINICS

Scott Hur[1]; Laura M. Curtis[2]; Terry Davis[3]; Connie Arnold[3]; Jean Mcsweeney[5]; Gan Jennifer[4]; Mary J. Kwasny[6]; Michael S. Wolf[7]; Kristie Hadden[8]. [1]General Internal Medicine & Geriatrics, Northwestern University, Des Plaines, IL; [2]General Internal Medicine, Northwestern University, Chicago, IL; [3]LSU Health Sciences Center - Shreveport, Shreveport, LA; [4]Center for Health Literacy, Medical Humanities & Bioethics, University of Arkansas for Medical Sciences, Little Rock, AR; [5]College of Nursing, University of Arkansas for Medical Sciences, Little Rock, AR; [6]Preventive Medicine, Northwestern University, Chicago, IL; [7]Medicine, Northwestern University, Chicago, IL; [8]University of Arkansas for Medical Sciences, Little Rock, AR. (Control ID #3391590)

BACKGROUND: Proper diabetes medication adherence requires patients to maintain consistent and accurate medication taking behaviors. Using data from an ongoing, pragmatic multi-site trial evaluating a diabetes self-management intervention in patients with type 2 diabetes in Arkansas, we aim to identify potentially modifiable barriers and risks to poor diabetes medication adherence.

METHODS: The study consists of a 2-arm, patient-randomized, pragmatic trial among 756 patients with type 2 diabetes in 6 rural PCMH clinics in Arkansas. Baseline data is collected through structured in-person interviews tied to a clinic visit. Diabetes adherence is measured by the Adherence to Refills and Medication Scale – Diabetes (ARMS-D), consisting of 11 Likert-scale items with scores ranging from 11-44 where higher scores denote decreased diabetes medication adherence. The ARMS-D consists of a 7-item medication taking subscale and a 4-item medication refill subscale. Potential factors associated with poorer diabetes medication adherence include patient activation, health literacy, and diabetes distress measured by the Consumer Health Activation Index (CHAI), the Newest Vital Sign (NVS), and the Diabetes Distress Scale (DDS), respectively. Multivariate linear regression models tested the independent effects of patient activation, healthy literacy, and diabetes distress on 1) ARMS-D total score, 2) ARMS-D medication taking subscale, and 3) ARMS-D medication refill subscale.

RESULTS: Patients in our sample on average were 55.8 (SD=11.7) years old, 67% female, 54 %African American, 63% with a household income of less than $20,000, and 56% with less than a college education. Mean scores for the overall ARMS-D, medication taking subscale, and medication filling subscale were 15.3 (SD=3.6), 9.1 (SD=2.7), and 6.1 (SD=1.8) respectively. Patient activation (β=-0.04; p=0.03) and diabetes distress (β=0.06; $p<0.0001$) were significantly associated with lower diabetes medication adherence, measured by the full scale. In the medication

taking subscale, health literacy (β=-0.11; p=0.03), patient activation (β=-0.04; p=0.002) and diabetes distress (β=0.05; p<0.0001) were significantly associated with lower adherence. Health literacy, activation, and diabetes distress were not associated with the medication refill subscale. All models were controlled for age, income, education, and sex.

CONCLUSIONS: Preliminary analyses show that higher patient activation and health literacy, and lower diabetes distress may improve diabetes medication adherence. Interventions should focus on engaging, educating, and providing support for patients in managing their medications in order to improve adherence and diabetes-related outcomes.

MORAL DISTRESS AMONG PHYSICIAN TRAINEES: CONTEXTS, CONFLICTS, AND COPING MECHANISMS IN THE TRAINING ENVIRONMENT

Stephanie E. McLaughlin[1]; Harriet Fisher[3]; Katharine Lawrence[2]; Kathleen Hanley[1]. [1]Internal Medicine, New York University, New York, NY; [2]Department of Population Health, New York University Grossman School of Medicine, New York, NY; [3]Medicine, NYU School of Medicine, New York, NY. (Control ID #3390697)

BACKGROUND: Moral distress is defined as a situation in which an individual believes they know the ethically appropriate action to take but are unable to take that action. The concept of moral distress is increasingly recognized as an important mediator of occupational stress and burnout in healthcare, particularly in the nursing literature. However, there is a dearth of literature focusing on moral distress among physician trainees, particularly as regards the clinical training environment. This study explores the phenomenon of moral distress among internal medicine trainees, with an emphasis on the contexts of clinical training and professional role development.

METHODS: We report qualitative data from a mixed methods prospective observational cohort study of internal medicine (IM) residents and associated faculty at a large, urban, academic medical institution. Five focus groups were conducted with 15 internal medicine residents (PGY1-3), between January and October 2019. In each focus group trained facilitators conducted semi-structured interviews using prompts which focused on definitions of, experiences with, and consequences of moral distress. Transcripts were independently coded by investigators, and analyzed by major themes and sub-themes. Discrepant themes and codes were reviewed by the full research team to establish clarity and consensus. Data were analyzed using Dedoose® software.

RESULTS: Focus group participants were equally distributed by gender (7 women, 8 men) and across training year (30% PGY1, 20% PGY2 40% PGY3). Experience with moral distress was universal among participants. Trainees identified several drivers of moral distress that were unique to their professional development as clinicians and their role as trainees/learners within clinical teams, including: feelings of inadequacy in clinical or procedural skills, being asked to perform duties outside of their scope of practice, discomfort with the idea of 'practicing' skills on patients, poor team communication, disagreements with senior team members, experiences of disempowerment as junior team members, and overwhelming or inappropriate administrative or non-clinical burdens. Participants also identified unique, place-based moral distress across different clinical environments, including intensive care units, wards, and outpatient environments, as well as between private, public, and government-run hospital facilities.

CONCLUSIONS: Physician trainees experience considerable moral distress in the context of their professional development, with unique drivers of moral distress identified in the training and clinical team context. This improved understanding of factors unique to the trainees' experience has implications for tailoring educational experiences as professional development activities, as well as potential wellness- and resilience-building among physician trainees. It may also inform the training of physician leaders and seniors clinicians who engage with trainees in learning and clinical environments.

MORAL DISTRESS AMONG PHYSICIAN TRAINEES: DRIVERS, CONTEXTS, AND ADAPTIVE STRATEGIES

Stephanie E. McLaughlin[1]; Harriet Fisher[3]; Katharine Lawrence[2]; Kathleen Hanley[1]. [1]Internal Medicine, New York University, New York, NY; [2]Department of Population Health, New York University Grossman School of Medicine, New York, NY; [3]Medicine, NYU School of Medicine, New York, NY. (Control ID #3390670)

BACKGROUND: Moral distress is defined as a situation in which an individual believes they know the ethically appropriate action to take but are unable to take that action. The concept of moral distress is increasingly recognized as an important mediator of occupational stress and burnout in medicine, particularly in the nursing profession. However, there is a dearth of literature on moral distress among physician trainees, with the majority focused on dilemmas in end-of-life care. This study explores the phenomenon of moral distress among internal medicine trainees, with particular focus on drivers, situational contexts, and adaptive strategies such as coping mechanisms.

METHODS: We report qualitative data from a mixed methods prospective observational cohort study of internal medicine (IM) residents and associated faculty at a large, urban, academic medical institution. Five focus groups were conducted with 15 internal medicine residents (PGY1-3), between January and October 2019. In each focus group trained facilitators conducted semi-structured interviews using prompts which focused on definitions of, experiences with, and consequences of moral distress. Transcripts were independently coded by investigators, and analyzed by major themes and sub-themes. Discrepant themes and codes were reviewed by the full research team to establish clarity and consensus. Data were analyzed using Dedoose® software.

RESULTS: Focus group participants were equally distributed by gender (7 women, 8 men) and across training year (30% PGY1, 20% PGY2 40% PGY3). Experience with moral distress was universal among participants, and was identified across four major domains: personal values and morals, professional competency and training challenges, interpersonal relationships and conflicts, and systems/structural issues. Participants identified unique, place-based moral distress across different clinical environments, including intensive care units, wards, and outpatient environments, as well as between private, public, and government- run hospital facilities. Participants described a number of adaptive mechanisms for managing moral distress, including social support and connectivity, humor, and disassociation.

CONCLUSIONS: Physician trainees experience considerable moral distress across multiple domains during the course of their training. They also develop unique adaptive strategies and coping mechanisms to manage and learn from distressing experiences. This improved understanding of moral distress among physician trainees, particularly drivers and protective factors, has important implications for the training of physicians, and may have a role in promoting wellness and resilience among physicians across the training and professional pipeline.

MORE FECAL IMMUNOCHEMICAL TESTS ARE NEEDED TO MATCH THE CLINICAL BENEFIT OF EQUIVALENT NUMBERS OF MULTITARGET STOOL DNA TESTS: CRC-AIM MICROSIMULATION MODEL RESULTS

Leila Saoud[1]; A. Mark Fendrick[2]; Andrew Piscitello[3]; Bijan J. Borah[4]; A. Burak Ozbay[1]; Michael Matney[1]; Marcus Parton[1]; Kristen Hassmiller

Lich[5]; Paul Limburg[6]. [1]Exact Science Corporation, Madison, WI; [2]Division of Gastroenterology, University of Michigan, Ann Arbor, MI; [3]EmpiriQA, LLC, Long Grove, IL; [4]Health Services Research, Mayo Clinic, Rochester, MN; [5]Health Policy & Management, Gillings School of Global Public Health, University of North Carolina at Chapel Hil, Chapel Hill, NC; [6]Gastroenterology, Mayo Clinic, Rochester, MN. (Control ID #3390678)

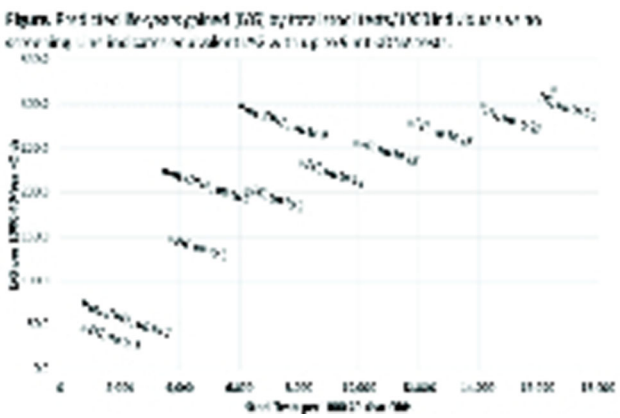
BACKGROUND: In clinical settings, adherence to colorectal cancer (CRC) screening guideline recommendations is variable. If fully adherent, individuals screened between ages 50–75 would undergo 9 triennial multitarget stool DNA (mt-sDNA) tests or 26 annual fecal immunochemical tests (FIT), which may be unrealistic. The microsimulation model CRC-AIM was used to compare the impact of varying numbers of completed tests on predicted CRC outcomes of triennial mt-sDNA or annual FIT screening.

METHODS: Sensitivity and specificity from DeeP-C trial data were used for screening inputs. Outcomes of mt-sDNA and FIT screening strategies were simulated for individuals free of diagnosed CRC at age 40 and screened from ages 50–75. Simulated individuals were randomly assigned to up to 1, 5, or 9 (9=100% adherence) mt-sDNA tests and up to 1, 5, or 9 to 26 (26=100% adherence) FIT tests during the screening window. Simulated individuals may complete fewer than their assigned tests if they die or have a positive stool test. Predicted outcomes are per 1000 individuals vs no screening.

RESULTS: Life-years gained (LYG)/1000 individuals was greater with up to 1, 5, or 9 mt-sDNA tests (74, 224, and 298, respectively) vs equivalent numbers of FIT tests (44, 147, and 202). The LYG/1000 individuals was 303 for triennial mt-sDNA and 316 for annual FIT when adherence was 100%. An individual would have to take up to 22 FIT tests to reach approximately the same LYG as an individual who took up to 9 mt- sDNA tests (Figure). For each scenario, the incremental ratios of COL/LYG (≤7.9) were favorable for mt- sDNA vs FIT and are below the CISNET-accepted ratios of 39–65.

Reductions in CRC-related incidence and mortality were greater with up to 1, 5, or 9 mt-sDNA tests vs equivalent numbers of FIT tests. The number of total stool tests/1000 individuals was similar between mt-sDNA and FIT when individuals were randomly assigned up to 1, 5, or 9 tests and was lower for triennial mt- sDNA vs annual FIT when adherence was 100%.

CONCLUSIONS: At least twice as many FIT tests are needed to match the same clinical benefit as mt- sDNA (22 vs 9) with the guideline recommended screening window. Real world adherence to stool-based testing is imperfect and should be simulated using realistic inputs in comparative effectiveness modelling.



MORPHINE-HYDROMORPHONE METABOLISM IN CHRONIC PAIN MANAGEMENT

Tyler George[1]; Jennifer Sato[2]; Ameer Ghodke[1]; Nicole Trupiano[3]; Paul Chelminski[1]; Timothy Ives[1]. [1]Medicine, University of North Carolina at Chapel HIll, Chapel HIll, NC; [2]UNC Eshelman School of Pharmacy, Chapel Hill, NC; [3]University of Michigan Medical School, Ann Arbor, MI. (Control ID #3389318)

BACKGROUND: The nation-wide opioid epidemic has emphasized the importance of provider tools to ensure safe opioid prescribing and improved patient monitoring. Interpreting urine toxicology screens (UTS) and urine opioid confirmations (UOCs) have become critical components to monitor medication adherence with opioids in chronic pain management. Hydromorphone is an oftentimes overlooked metabolite resulting from long-term morphine therapy, introducing a quandary for providers monitoring opioid regimens. Studies have explored this trend in the past, but research describing this pathway has been limited in regards to how kidney and liver function impacts metabolism. This study explores a relationship between UOC hydromorphone levels with kidney and liver function values. The results will ultimately help clinicians assess patient adherence to morphine therapy and reduce the risk of opioid misuse in the general population.

METHODS: The study is a retrospective analysis. 46 patients seen by the UNC Internal Medicine Pain Service (IMPS) from April 4th, 2014 through July 30th, 2018 who were prescribed morphine at any dose and had a UOC screen at any subsequent appointment were included in this study. 225 opiate confirmations were analyzed. Patients were excluded if they had known opioid therapy agreement violations, particularly for inconsistent opioid use, if no subsequent UOC was performed after morphine was prescribed, if a patient was concomitantly prescribed hydrocodone, hydromorphone, or codeine, or if a patient's UOC discovered metabolites of hydrocodone or codeine even without a corresponding prescription. Patient age, gender, ethnicity, BMI, MME of last morphine prescription, and time of last morphine administration were collected for each patient. Lab values collected for each patient were within 6 months of UOC. Kidney and liver function lab values included serum creatinine (SCr), blood urea nitrogen (BUN), aspartate aminotransferase (AST), alanine aminotransferase (ALT), and alkaline phosphatase (ALP). A univariate and multivariate analysis using linear regression and censored regression models were completed.

RESULTS: In the univariate analysis, morphine concentration ($p<0.0001$), race ($p=0.076$), BMI ($p=0.002$), MME of last dose ($p=0.010$), and BUN ($p=0.047$) were found to be associated with UOC hydromorphone levels. In the multivariable analysis, morphine concentration and BUN were able to predict hydromorphone concentration with statistical significance. When censored values were excluded, UOC morphine concentration still predicted UOC hydromorphone with significance ($p<0.0001$) and MME of last dose trended towards significance ($p=0.080$).

CONCLUSIONS: Clinicians treating patients with opioids, specifically morphine, for chronic pain can utilize UOC morphine concentration and BUN levels to predict the expected UOC hydromorphone concentration in an effort to reduce the potential for opioid misuse and confidently assess patient adherence to the prescribed regimen.

MULTIDISCIPLINARY ROLES AND RESPONSIBILITIES AROUND DISCHARGE COMMUNICATION: A MULTI-INSTITUTIONAL SURVEY OF INTERNAL MEDICINE RESIDENTS

Shreya P. Trivedi[1]; Zoe Kopp[5]; Paul Williams[2]; derek hupp[7]; Nick Gowen[6]; Leora I. Horwitz[3]; Mark D. Schwartz[4]. [1]Internal Medicine,

NYU, New York, NY; [2]General Internal Medicine, Temple University Hospital, Philadelphia, PA; [3]Population Health, NYU School of Medicine, New York, NY; [4]Population Health, NYU School of Medicine, New York, NY; [5]Internal Medicine, UCSF, San Francisco, CA; [6]Internal Medicine, University of Arkansas Medical Sciences, Little Rock, AR; [7]Internal Medicine, University of Iowa, Iowa City, IA. (Control ID #3392386)

BACKGROUND: Safely and effectively discharging a patient from the hospital requires working within a multidisciplinary team. However, with multiple stakeholders responsible for the discharge and competing clinical duties, diffusion of responsibility may result in relinquished ownership, particularly as mandated administrative discharge tasks are often prioritized over taking the time to communicate discharge plans with patients. Residents are uniquely positioned to offer insight on the workings of multidisciplinary teams at discharge, since residents play a central role in the transitions of care process within academic hospital systems. Learning from residents' perspectives on discharge roles and responsibilities can shed light on gaps in order to improve accountability to the patient and increase communication efficacy among team members.

METHODS: Internal Medicine residents at 7 academic institutions completed a cross-sectional survey that asked them who they felt was primarily responsible to perform discharge education with patients, and at what frequency they themselves completed six key discharge communication practices with patients. Using multiple linear regression, we examined the relationship between who residents report is primarily responsible for discharge education and their own reported proportion of communication practice domains done frequently (>60% of time). We used content analysis to assess free response comments on ways in which discharge multidisciplinary team communication could be improved.

RESULTS: Among the 613/966 resident responses (62% response rate), 35% reported they were not sure which member of the multidisciplinary team is primarily responsible for discharge education with patients If residents believed educating patients at discharge was the primary responsibility of the intern, that resident had a 19.5% (95% CI 13.2%, 25.9%) higher proportion of reported discharge communication domains addressed frequently versus those that were not sure who was responsible. To improve multidisciplinary discharge communication, residents called for explicit expectations among team members: 1) What should be communicated to the patient and by whom? 2) How do we communicate discharge plans effectively to each other? 3) What kind of discharge culture allows the patient and care team to thrive?

CONCLUSIONS: Residents report lack of clarity on who is responsible for key patient communication practices at discharge. This diffusion of ownership impacts how much residents invest in patient education, with more perceived responsibility associated with more key discharge communication practices reportedly done on a regular basis. Our results suggest we need to create and explicitly operate under a shared mental model of each team player's responsibility for communication to the patient, to each other and examine the hospital system's priorities and incentives and its impact of the discharge culture.

MULTIDISCIPLINARY TEAM INTERVENTION FOR ELDERLY ORTHOPEDIC INPATIENTS AND ITS IMPACT ON POLYPHARMACY AND POTENTIALLY INAPPROPRIATE MEDICATIONS

Hiroyuki Seto[1]; Toshio Shimokawa[2]; Jun Ohnishi[1]; Yohei Kanzawa[1]; Kei Kawano[1]; Takahiro Nakajima[1]; Naoto Ishimaru[1]; Saori Kinami[1]; Yuichi Imanaka[3]. [1]General Internal Medicine, Akashi Medical Center, Akashi, Hyogo, Japan; [2]Clinical Study Support Center, Wakayama Medical University Hospital, Wakayama, Japan; [3]Department of Healthcare Economics and Quality Management, Graduate School of Medicine Kyoto University, Kyoto, Japan. (Control ID #3352436)

BACKGROUND: Polypharmacy and potentially inappropriate medications (PIMs) are commonly observed in elderly orthopedic inpatients. Polypharmacy is associated with an increased risk of falls, delirium and other adverse events, but may continue during and after hospitalization. Deprescribing has been proposed as a means of reducing polypharmacy in frail, older people. Meanwhile, its effectiveness against polypharmacy in elderly orthopedic inpatients has not been widely studied. We evaluate the effectiveness of intervention to reduce polypharmacy and PIMs in elderly patients admitted to our orthopedic department.

METHODS: We compare the outcomes of patients receiving intervention vs. patients not receiving intervention in this single-center retrospective observational study. Included were all orthopedic patients aged ≥ 75 years who had been prescribed ≥ 6 different medications at hospital admission between May 2017 and April 2019. Intervention comprised polypharmacy screening and deprescription of any unnecessary medications during hospital stays. Our multidisciplinary team included general internal medicine physicians, nurses and pharmacists. Primary outcome was change in the mean number of regular medicines and reduction in PIMs. Secondary outcomes included falls, delirium, and any adverse events during hospitalization, and emergency department (ED) visits and unplanned hospital admissions for any reason within six months after discharge. Comparisons between the intervention and usual care groups were analyzed using propensity score matching.

RESULTS: This study included 164 patients (intervention group, n = 82; control group, n = 82). Mean patient age was 83.6 years in the intervention group and 83.8 years in the control group. Mean numbers of prescribed medications and at admission were 9.77 in the intervention group, 9.46 in the control group. Mean PIMs were 1.57 in the intervention group, 1.67 in the control group. Mean change in number of regular medicines at discharge was -1.34 ± 2.49 in the intervention group and $+0.18 \pm 1.70$ in the control group ($p < 0.001$). In the intervention, discontinuation of PIMs occurred in 30 patients (36.6%), in the control group it was 14patients (17.1%) (Odds ratio (OR) 2.78, 95% CI 1.28 to 6.30; p = 0.008). Adverse events were significantly reduced in the intervention group compared with the control group (OR 0.34, 95% CI 0.12 to 0.87; p = 0.021). No significant differences were found between the intervention and usual care groups in falls (OR 1.00, 95% CI 0.18 to 5.57; p = 1.00), delirium (OR 1.12, 95% CI 0.54 to 2.33; p = 0.864), ED visit (OR 0.72, 95% CI 0.25 to 2.00; p = 0.641) or unplanned hospital admission (OR 1.42, 95% CI 0.49 to 4.35; p = 0.627).

CONCLUSIONS: Multidisciplinary team polypharmacy screening and deprescribing intervention effectively reduced the number of prescribed medicines and PIMS in elderly orthopedic inpatients. Adverse events were significantly reduced.

MULTIMORBIDITY AND PRIMARY CARE OFFICE VISIT FREQUENCY

Melissa Y. Wei, John Poe. Internal Medicine, University of Michigan, Ann Arbor, MI. (Control ID #3391321)

BACKGROUND: Primary care office visits provide the foundation for disease prevention and management, and are crucial for coordinated, holistic care for patients with multimorbidity (multiple chronic conditions). However, they are a limited resource. Despite this, there is limited evidence to guide decision making for how frequently patients should be seen. The strongest predictor of office visit frequency is provider discretion, not patient medical complexity. We aimed to identify predictors of office visits and quantify the variance explained by multimorbidity, functional status, and other patient characteristics.

METHODS: We queried the electronic health record database for living adults >18 years-old with general medicine and geriatric medicine outpatient encounters at a large academic institution between January 1, 2015 and October 15, 2019. Multimorbidity was measured using a validated ICD-coded multimorbidity- weighted index (MWI-ICD) that weights chronic conditions by their impact on physical functioning. We examined the kernel density and correlation between predictors and office visits. The exposure MWI-ICD included ICD-9 coded conditions through October 2015 examined continuously (linear and quadratic) and categorically. The outcome was outpatient visits through October 2019. To determine the association between MWI-ICD with office visits, we used multiple linear regression (yielded consistent results with a generalized linear model with gamma link for count data) adjusted for available demographics including age (linear and quadratic), sex, race/ethnicity, and marital status.

RESULTS: We included 20,547 patients who generated 91,318 outpatient visits between 2015-2019. Patients were 57% female, 73% Caucasian, with a mean age of 59.3±17.3 years, MWI-ICD of 7.59±9.3 (range 0-117), and 7.80±7.2 (range 1-126) office visits over 5 years. MWI-ICD was moderately correlated with office visits (Spearman's rho=0.38). Multimorbidity was positively associated with more office visits: each point increase in MWI-ICD was associated with 0.20 (95%CI: 0.17-0.22, $p<0.001$) more visits in adjusted models. Older age and being female, married, Asian or African American were also associated with significantly more office visits. The coefficient of determination was 0.18, suggesting MWI-ICD (multimorbidity with physical functioning embedded) explained only a modest proportion of variance in office visits.

CONCLUSIONS: Adults who were older, female, Asian or African American, with worse multimorbidity were more likely to be seen for general and geriatric medicine outpatient visits. Multimorbidity using a validated MWI-ICD that embeds physical functioning explained only 18% of the variation in office visit encounters. After adjusting for patient characteristics, office visit frequency varied widely, regardless of medical complexity. Given the ever-growing demand for primary care and shortage of PCPs, multimorbidity and functional status may be used to guide decision support for office visit frequency.

MY HIP FRACTURE (MY HF): A MIXED METHODS EVALUATION OF A NOVEL EDUCATIONAL TOOL TO COMMUNICATE INDIVIDUALIZED HIP FRACTURE PROGNOSTIC INFORMATION TO PATIENTS AND SURROGATES

Corita Vincent[1]; Vincent Chien[1]; Peter Wegier[2]; Allison Kurahashi[2]; Hedieh Molla Ghanbari[3]; Jesse Wolfstadt[4]; Peter Cram[1]. [1]Division of General Internal Medicine, University of Toronto, Toronto, ON, Canada; [2]Temmy Latner Centre for Palliative Care, Sinai Health System, Toronto, ON, Canada; [3]Department of Family and Community Medicine, University of Toronto, Toronto, ON, Canada; [4]Division of Orthopaedic Surger, University of Toronto, Toronto, ON, Canada. (Control ID #3390656)

BACKGROUND: Despite improvements in hip fracture (HF) care over the past 20-years, mortality after HF for older adults is extremely high and survivors commonly have long term functional impairment. While healthcare professionals generally understand that HF constitutes an inflection point in the health of older adults, data suggest that patients and surrogate decision makers (SDMs) are typically unaware of the seriousness. Our multi-disciplinary team developed, iteratively refined, and pilot tested a novel educational tool (My-HF) to provide patients and SDMs with personalized estimates of HF prognosis. Our long-term goal is to examine whether My-HF can improve HF patient and SDM knowledge and understanding and reduce regret and surprise. We report results from our mixed-methods pilot testing of My-HF.

METHODS: We developed a paper-based HF educational tool designed to communicate individualized treatment and prognosis information to patients and SDMs. Design was informed by input from orthopaedic surgeons, internists, geriatricians, and methodologists with expertise in risk communication. The My-HF tool provides information about: 1) type of surgery performed; 2) predicted risk of death and major complications within 30-days, derived from a validated risk model; 3) anticipated post-HF discharge trajectory. We conducted a mixed-methods study to assess usability of My-HF using a convenience sample of patients hospitalized with acute HF at a major Toronto teaching hospital between May and December 2019. SDMs were interviewed for patients who were incapable. Patients (or SDMs) were approached post-operatively, prior to hospital discharge. We used semi-structured interviews to solicit input and preferences regarding the My-HF tool. Thematic analysis was used to identify themes and concepts.

RESULTS: We conducted 16 interviews: 8 patient interviews, 8 SDM interviews (mean age of patients 79.31, 75% female). My-HR was generally well received and provision of personalized risk estimates was not felt to create undue concern, though some were surprised by the range of possible adverse outcomes including mortality and need for long term care. While many interviewees liked the information about type of surgical repair that was performed, others found this to be of little value. My-HF was updated based upon feedback and suggestions and will now be converted into a web-based app to allow for further evaluation.

CONCLUSIONS: Patients with HF and SDMs are accepting of My-HF and find that personalized HF information is useful. Further study is needed to assess the impact of My-HF on patient and surrogate understanding of HF knowledge and other patient reported outcomes.

NAMES AND SPACES: IMPROVING RESIDENT COMMUNICATION PATHWAYS AND INTERPROFESSIONAL RELATIONSHIPS THROUGH GEOGRAPHIC COHORTING

Katarzyna Mastalerz[1,2]; Sarah Jordan[3]. [1]Internal Medicine, Rocky Mountain VA Medical Center, Aurora, CO, Denver, CO; [2]Hospital Medicine, University of Colorado, Aurora, CO; [3]Geriatric Medicine, University of Colorado, Aurora, CO. (Control ID #3359975)

BACKGROUND: Geographic cohorting (GCh) of physicians to a single hospital unit is increasingly common. GCh is associated with improved teamwork and efficiency, but leads to increased face-to-face workflow interruptions for physicians. Interruptions are associated with errors and physician frustration, leading to concerns that GCh may contribute to physician burnout. Our study aimed to explore the impact of GCh on resident physician perceptions of communication.

METHODS: We conducted a qualitative study of medical and transitional-year residents in a community teaching hospital who rotated on GCh units between July 2017 and March 2018. Residents teams had >80% patients on the same unit. GCh units also had daily bedside interdisciplinary rounds (IDR) and interprofessional (IP) co-leadership. We conducted five semi-structured interviews and 12 focus groups. These were audio-recorded and professionally transcribed. Interview topics included experiences with GCh, bedside IDR, and teamwork on GCh units. We used thematic analysis to inductively analyze data and identify key themes.

RESULTS: We interviewed 25 interns and 16 senior residents (n=41). Resident participants were predominantly male (63%) and Caucasian (64%). Key discovered themes were that GCh: 1) positively affects relationship dynamics on teams and increases familiarity with IP colleagues, 2) creates pathways for communication, 3) helps efficiency and fluidity in communication across teams, and 4) encourages face-to- face talk. Residents identified that on GCh wards, "*We get to know the nurses and case managers and pharmacists that are taking care of the patients. That makes it a lot easier to get work done when you can just walk over and talk to them."* Residents described how familiarity with IP teammates

helps facilitate opportunities for communication; one said: *"I'm more likely to reach out to the nurses in person, since I know from [bedside IDR] who is taking care of the patient. I have a face- I can recognize them. It feels better to know them by name."* Residents also identified how geographic proximity invited more timely and interconnected communication by creating opportunities to communicate with teammates throughout the day. Part of the ability to communicate efficiently was bypassing technology-led communication in favor of highly valued, face-to-face communication. One resident said: *"The geographic thing is really undervalued. Using pagers and telephone communication is accepted, but not an ideal way to communicate within the healthcare setting."*

CONCLUSIONS: From the resident point of view, GCh fosters IP relationships and communication. Residents describe that GCh creates communication pathways, and increases face-to-face communication, which residents perceive as superior to technology-based communication. These resident perspectives suggest that the increased face-to-face interruptions previously observed in GCh studies may ultimately represent interactions that lead to improved IP communication and relationships.

NARRATIVE WRITING IN PRE-CLERKSHIP MEDICAL EDUCATION AS A TOOL FOR DEVELOPING EMPATHY AND PROFESSIONAL IDENTITY FORMATION

Christina Seto[1]; Ethan Hartman[1]; Caridad Hernandez[3]; Analia Castiglioni[2,5]; Jeffrey La Rochelle[4,5]. [1]College of Medicine, University of Central Florida, Orlando, FL; [2]Internal Medicine, University of Central Florida College of Medicine, Orlando, FL; [3]Clinical Sciences, University of Central Florida, Orlando, FL; [4]Medical Education, University of Central Florida College of Medicine, Orlando, FL; [5]Orlando VA Medical Center, Orlando, FL. (Control ID #3391517)

BACKGROUND: Narrative medicine is integral to medical schools for developing students' empathy and professional identity. University of Central Florida College of Medicine (UCFCOM) provides longitudinal clinical experience during the first two (pre-clerkship) years of medical school, at the end of which students write a narrative reflection. Our study sought to understand narrative writing as a tool for pre-clerkship medical students to process these early clinical experiences. We hypothesized that narrative writing allows medical students to develop empathy skills and build narrative foundations, prior to and independent of ultimate career choice.

METHODS: We performed a retrospective thematic analysis (NVivo®) of 40 de-identified narratives written by medical students at the UCFCOM during pre-clerkship clinical experiences from 2015-2017. Central narrative themes were identified and converted into quantitative data using the amount of narrative coded at each theme for each author (percent coverage). We then correlated these themes to categorical measures of career choice using residency match data. Categories included primary care (i.e. IM, pediatrics, and EM) and non-primary care (i.e. all other fields). Narrative themes (i.e. percent coverage) were compared to career choice (i.e. match data) using one-way ANOVA.

RESULTS: Thematic analysis of student narratives highlighted three central themes: (1) Anticipating future career as a physician *["It takes a special doctor to step outside of the science and into the psychosocial aspect to treat the patient as a whole…I hope that I never lose sight of the human behind the diagnosis…"],* (2) Emotion toward the patient *["She is my role model of caring and kindness, and I will try to be thoughtful and caring during interactions with others, and attempt to live up to her"*], and (3) Expectations vs. reality [*"Patients are not clinical vignettes on exams. They are not problems to solve. They are real and living and their stories matter"].* Quantitative analysis comparing narrative themes and career choice found no significant differences in themes between groups.

CONCLUSIONS: Narrative reflection allows students to foster a sense of empathy for their patients, as well as a sense of purpose in their chosen profession. Furthermore, these themes appear in narratives written by UCFCOM pre-clerkship medical students with almost equal frequency regardless of match specialty, suggesting that narrative reflection is a powerful tool for all medical students to learn empathy skills and develop their narrative foundation. As medical students become residents and ultimately practicing physicians, a strong foundation of humanity is essential.

NATIONAL PROFILE OF THE GROWING POPULATION OF OLDER ADULTS WHO ACCESS COMMUNITY HEALTH CENTERS

Stephanie Nothelle, Jessica Colburn, Cynthia M. Boyd. Geriatric Medicine and Gerontology, Johns Hopkins University School of Medicine, Baltimore, MD. (Control ID #3391880)

BACKGROUND: Community health centers (CHCs) are federally funded safety-net clinics that provide care to low income and medically underserved persons. The proportion of CHC patients age ≥65 doubled in the last ten years, yet little is known about older adults who access CHCs. We aim to describe the demographic and clinical characteristics of the older adult CHC population, including healthcare utilization, receipt of supportive services, and differences in these factors by age.

METHODS: In this cross sectional analysis, we used data from the 2014 Health Center Patient Survey, a national survey of CHC patients. We limited our analyses to those age ≥55. We used ≥55 instead of ≥65 years because of the higher prevalence of chronic disease and lower life expectancy in the population that typically uses CHCs and to assess differences in those under versus over 65. We used descriptive statistics to characterize older adults across demographic and clinical variables. To determine differences by age, we stratified older adults into three age groups (55-64, 65-74, 75+). We used t-tests and chi-squared to calculate p values and survey weights to make national estimates.

RESULTS: We included 1875 older adults, representing a population of over 4.2 million. Sixty percent were age 55-64, 51% were female, and 60% were white. The majority (73%) had Medicare or Medicaid and 47% reported fair or poor health. Older adults in all groups had an average of 3 chronic conditions and 0.6 impairments in activities of daily living (ADL). Most (69%) had ≥3 chronic conditions and/or ADL impairment, meeting a common definition of "serious illness." Psychiatric disease was significantly more common in younger age groups (38% v 32% v 19%, p=0.007) and cancer was significantly more common in older age groups (8% v 15% v 25%, p=0.006). Regardless of age, most older adults reported taking ≥5 prescription medications (54%) and one in five reported ≥2 emergency department visits or ≥1 hospitalization in the last year. Approximately one-quarter of older adults received CHC help with affording medications (28%), while 73% received counseling on lifestyle changes for blood pressure control. Despite this, 10% were unable to get needed medical care and 16% were unable to get a needed prescription. Those in the older age groups (65-74, 75+) were significantly less likely to receive help affording medication or counseling on lifestyle changes for blood pressure.

CONCLUSIONS: Older adults who access CHCs have significant disease burden. Adults age 55-64 who access CHCs face a similar number of chronic diseases and ADL impairments as adults over 65 and thus may have a similar life expectancy; however, adults aged 55-64 were significantly more likely to be counseled on lifestyle changes. These findings highlight that additional focus on complex health needs for older adults who access CHCs may need to include adults who are <65, and that CHCs are serving a population that is seriously ill.

NATIONAL SURVEY OF WELLNESS PROGRAMS IN U.S. AND CANADIAN MEDICAL SCHOOLS

Alison Schutt[2]; Katherine Chretien[3]; James N. Woodruff[4]; Valerie G. Press[4]; Monica Vela[5]; Wei Wei Lee[1]. [1]General Internal Medicine, University of Chicago, Chicago, IL; [2]Pritzker School of Medicine, Chicago, IL; [3]George Washington University, Washington DC, DC; [4]Medicine, University of Chicago, Chicago, IL; [5]Medicine, University of Chicago Pritzker School of Medicine, Chicago, IL. (Control ID #3388672)

BACKGROUND: Over the past decade, studies have found a high prevalence of mental illness and suicidal ideation among medical students. While many medical schools have developed student wellness programs to address these troubling trends, little is known about the scope and content of these programs and more research is needed on the impact of wellness programming to guide interventions and resource allocation. To address this gap, we conducted a national survey on the prevalence, content, evaluation strategies, and barriers of existing wellness programs at LCME accredited medical schools.

METHODS: In July 2019, 159 US and Canadian medical schools were surveyed about the structure, resources and evaluation strategies of their wellness programs. Based on the literature review, the authors developed a framework to describe the components of wellness programs and structured the survey around four focus areas: 1) preventative programming, 2) reactive programming, 3) structural and curricular initiatives and 4) culture of wellness. Additional questions focused on general characteristics of each school's wellness program, mental health resources, screening offered to students, barriers, and evaluation practices.

RESULTS: Response rate was 65% (104 schools). Ninety (93%,90/97) had a formal wellness program and the mean FTE support for leadership was 0.77. Wellness budget did not correlate with school type or size ($p>0.05$). Most schools reported adequate programming on preventative (62%, 53/85), reactive (86%, 73/85) and cultural initiatives (52%, 44/85), but too little focus on structural initiatives (56%, 48/85). Barriers included lack of financial (52%, 45/86), administrative (35%, 30/86), and faculty support (20%, 17/86). Most (65%, 55/84) schools reported in-house mental health professionals, with dedicated time to see medical students with mean FTE of 1.62 (SD 1.41). Most (62%, 52/84) responding schools evaluated wellness programming, most commonly using the AAMC Graduation Questionnaire (83%, 43/52), annual student surveys (62%, 32/52), and surveys of individual wellness events (50%, 26/52). Barriers to evaluation included lack of time (54%, 45/84), administrative (43%, 36/84), financial support (24%, 20/84), and expertise (23%, 19/84).

CONCLUSIONS: This is the first large national study to describe the state of wellness programs at LCME accredited medical schools in the U.S. and Canada. Wellness programs are widely established at US and Canadian medical schools and most focus on preventative and reactive initiatives as opposed to structural. Rigorous evaluation of the impact of programs on student well-being is needed to inform resource allocation and program development. Schools should ensure adequate financial and administrative investments to support the success of their wellness programs.

NATIONAL TRENDS IN EPIDEMIOLOGY AND COSTS OF HOSPITALIZATIONS FOR PATIENTS WITH DEMENTIA

Timothy S. Anderson, Edward R. Marcantonio, Shoshana J. Herzig. Medicine, Beth Israel Deaconess Medical Center, Brookline, MA. (Control ID #3387777)

BACKGROUND: Dementia is associated with higher Medicare expenditures in large part due to increased hospitalization rates relative to patients without dementia. Data on contemporary trends in reasons for hospitalization, potentially preventable hospitalizations, and costs of care for patients with dementia are lacking.

METHODS: We used the Healthcare Cost and Utilization Project (HCUP) National Inpatient Sample from 2010 to 2016 to identify all acute unplanned hospitalizations of adults >=65 with dementia (defined by established discharge diagnosis codes). We grouped discharge diagnoses into clinically meaningful categories using HCUP Clinical Classification Software. We identified hospitalizations for ambulatory care sensitive conditions (ACSCs) using AHRQ prevention quality indicators. ACSCs include both acute and chronic conditions for which high quality outpatient care may prevent the need for hospitalization. We examined trends in hospitalization rates, discharge disposition, and costs (estimated using HCUP cost-to-charge ratios) across years. Discharge weights were applied to generate nationally representative estimates.

RESULTS: Among all unplanned hospitalizations of older adults, 17.1% were for patients with dementia. The annual incidence of hospitalizations of older adults with dementia rose from 1.64 million in 2010 to 1.70 million in 2016. The most common discharge diagnoses were infections (26.4%), circulatory conditions (19.8%), and injuries (12.2%). During the study period, hospitalization rates for infections rose 20.6%, genitourinary conditions rose 33.9%, injuries rose 16.2%, and nervous system conditions rose 15.5%. Hospitalizations for hematologic conditions decreased 19.2%. ACSCs accounted for 24.0% of hospitalizations of older adults with dementia in 2010 declining to 21.8% in 2016. Though only 10.1% of patients were admitted from skilled nursing facilities, 55.8% were discharged to skilled nursing facilities. The proportion of patients discharged home increased from 36.5% in 2010 to 38.0% in 2016, accompanied by an increased use in home health services from 16.0% to 18.8%. Mean inflation-adjusted costs of hospitalization increased from $9,554 in 2010 to $10,446 in 2016. Total inflation-adjusted hospitalization costs for patients with dementia increased from $14.7 billion in 2010 to $17.5 billion in 2016 ($19.3 billion unadjusted). In 2016, $6.3 billion was spent on potentially preventable hospitalizations including $3.2 billion for ACSCs and $3.1 billion for injuries.

CONCLUSIONS: Patients with dementia accounted for one in six hospitalizations of older adults in the United States with rising incidence and costs. Despite modest reductions in hospitalizations for care sensitive conditions, one-third of hospitalizations of patients with dementia remain potentially preventable, including 22% for ambulatory care sensitive conditions and 12% potentially modifiable with injury prevention efforts.

NATIONAL TRENDS IN MEDICARE OPIATE PRESCRIPTIONS: THE ROLE OF PHYSICIANS AND NON-PHYSICIAN PROVIDERS

Ofer Z. Fass, Nicholas J. Beccarino, Seyed Ali Akbar Khalessi Hosseini. Internal Medicine, NYU Langone Health, New York, NY. (Control ID #3349246)

BACKGROUND: The opiate epidemic remains a major public health crisis with approximately 50,000 overdose deaths annually. This epidemic stems in part from over prescription of opiates and is therefore linked to physician prescribing habits. In recent years, non-physician providers such as physician assistants and nurse practitioners have become increasingly vital in the provision of care, supplying up to 25% of primary care in certain areas. In this study, we used the Medicare Provider Utilization and Payment Data: Part D Prescriber Public Use File (PDPPUF) to evaluate changes in opioid prescribing habits of physician specialties and non-physician providers.

METHODS: We searched the Medicare PDPPUF for opiate prescriptions reimbursed from 2013 to 2017. Opiates queried included codeine, fentanyl, methadone, morphine, oxycodone, and tramadol. Prescribing

trends evaluated included Medicare claims by specialty and total number of Medicare claims. Chi-squared goodness-of-fit tests were used to calculate differences in prescribing trends between years.

RESULTS: The majority of reimbursement requests for opiates were filed by internal medicine/primary care providers, accounting for 61.6% of all prescriptions in 2013. From 2013 to 2017, the number of opiates prescribed by internal medicine/primary care physicians decreased by 14.5% ($P < .001$). Non-internal medicine physicians similarly decreased prescriptions by 12.2% ($P < .001$). However, non-physician providers increased prescriptions by 30.8% ($P < .001$). By 2017, non-physician providers grew to account for 25.1% of all Medicare opiate prescriptions. Overall number of opiate prescriptions decreased 6% ($P < .001$), with significant increases noted between 2013 and 2015 for codeine, fentanyl, morphine, oxycodone, and tramadol ($P < .001$).

CONCLUSIONS: The number of opiate reimbursement requests by internal medicine/primary care and non- internal medicine physicians significantly decreased between 2013 and 2017 while the overall number of opiate prescriptions decreased only slightly. This disconnect appears to be driven by increasing opiate prescription by non-physician providers. Recent data has shown that targeting specific providers with education-based interventions can decrease opiate prescription by greater than 50%. Non-physician providers are vital for expanding the provision of primary care; however, the observed trends suggest that interventions targeting the prescribing habits of these providers may be effective in decreasing total opiate prescriptions and overdose deaths.

NEIGHBORHOOD RACIAL DIVERSITY IS ASSOCIATED WITH WHITE MEDICAL STUDENTS' LEVELS OF ANTI-BLACK IMPLICIT BIAS

Brooke A. Cunningham[1]; Jeph Herrin[2]; John Dovidio[3]; Sara E. Burke[4]; Sylvia Perry[6]; Liselotte Dyrbye[8]; Natalie M. Wittlin[3]; Ron Lam[2]; Sean Phelan[5]; Rachel Hardeman[7]; Ivuoma N. Onyeador[3]; Mark Yeazel[10]; Michelle van Ryn[9]. [1]Family Medicine and Community Health, University of Minnesota, Minneapolis, MN; [2]Flying Buttress Associates, Charlottesville, VA; [3]Psychology, Yale University, New Haven, CT; [4]Psychology, Syracuse University, Syracuse, NY; [5]Health Sciences Research, Mayo Clinic, Rochester, MN; [6]Psychology, Northwestern University, Evanston, IL; [7]Health Policy and Management, University of Minnesota, Minneapolis, MN; [8]Medicine, Mayo Clinic, Rochester, MN; [9]School of Nursing, Oregon Health & Science University, Portland, OR; [10]Family Medicine and Community Health, University of Minnesota, Minneapolis, MN. (Control ID #3392541)

BACKGROUND: One of the most effective ways to reduce antiblack implicit racial bias over the long-term is through intergroup contact. Research shows that living in environments in which interracial contact is generally more frequent can reduce bias, independent of and beyond personal contact, in part because that experience establishes positive intergroup orientations as normative and valued. This study examines the relationship between neighborhood racial diversity and change in antiblack implicit racial bias over time among a nationally representative cohort of medical students.

METHODS: We used data from the Cognitive Habits and Growth Evaluation (CHANGE) Study (changestudy.org), a longitudinal examination of medical students at 49 US medical schools. Participants completed questionnaires and tests of implicit racial biases during their first semester of medical school (Y1, baseline, fall 2010) and final semester of medical school (Y4, follow-up, spring 2014). Our primary dependent variable was the change in the black-white implicit association test (IAT) score from Y1 to Y4. Our primary independent variable was whether or not the respondent reported growing up in a minority neighborhood, defined as ≥ 50% minority. To assess the relationship between neighborhood racial diversity and change in IAT score we used structural equation models (SEMs) in order to perform multivariate mixed- effects modeling while accounting for the correlated nature of the key variables and to examine the simultaneous influence of neighborhood on baseline (Y1) and final (Y4) outcomes. Analyses adjusted for age, gender, parent income, school factors (having taken an implicit association test, favorability of interaction with Black faculty, and exposure to negative comments by physicians about Black patients) and individual difference characteristics hypothesized to be related to levels of implicit bias including external and internal motivation to respond without prejudice, interracial anxiety, and explicit attitudes towards Blacks, as measured by the feeling thermometer.

RESULTS: At baseline, the mean IAT for White medical students who grew up in racially diverse neighborhoods (WRDN) was 0.45. The mean IAT for White medical students who grew up in predominantly White neighborhoods (WPWN) was 0.49. Over the course of medical school, implicit racial bias decreased for both groups. WRDN had a greater decrease in implicit racial bias than WPWN ($\beta = -0.06$, $p=0.035$), after adjusting for school factors and a variety of relevant individual difference characteristics.

CONCLUSIONS: This study of medical students is consistent with other research that shows that neighborhood racial diversity is associated with future implicit racial bias. If implicit bias is as stubborn as the literature suggests, to reduce bias in the physician workforce, it may be important to assess prospective medical students' substantive experiences with racial minorities prior to matriculation, rather than attempting to modify beliefs after admission.

NEIGHBORHOOD SOCIOECONOMIC STATUS AND RISK OF HOSPITALIZATION IN PATIENTS WITH CHRONIC KIDNEY DISEASE

Milda R. Saunders[1]; Ana C. Ricardo[2]; Jinsong Chen[3]; Amanda H. Anderson[4]; Esteban A. Cedillo-Couvert[3]; Michael J. Fischer[2]; Jesus Hernandez-Rivera[4]; Margaret T. Hicken[5]; Jesse Y. Hsu[6]; Xiaoming Zhang[6]; Denise Hynes[3,7]; Bernard Jaar[8]; ohn W. Kusek[9]; Panduranga Rao[5]; Harold I. Feldman[6]; Alan S. Go[10]; James Lash[3]. [1]Medicine, University of Chicago Medicine, Chicago, IL; [2]Medicine/Nephrology, University of Illinois at Chicago, Chicago, IL; [3]Medicine, University of Illinois at Chicago, Chicago, IL; [4]Medicine, Tulane University, New Orleans, LA; [5]Medicine, University of Michigan, Ann Arbor, MI; [6]Center for Clinical Epidemiology and Biostatistics, University of Pennsylvania, Philadelphia, PA; [7]Oregon State University, Portland, OR; [8]Medicine, Johns Hopkins, Baltimore, MD; [9]NIDDK, National Institutes of Health, Bethesda, MD; [10]Division of Research, Kaiser Permanente Northern California, Oakland, CA. (Control ID #3391752)

BACKGROUND: In the U.S., 30% of health care expenditures are due to hospitalizations. Patients with chronic kidney disease (CKD) experience significantly greater morbidity than the general population, and have a significantly higher hospitalization rate. The extent to which neighborhood-level socioeconomic status (SES) is associated with hospitalization has been less explored, both in the general population and among those with CKD. We sought to examine whether the risk for hospitalization for those with CKD increases with lower neighborhood SES after accounting for individual-level characteristics.

METHODS: We evaluated the relationship between neighborhood SES and hospitalizations for adults with CKD participating in the Chronic Renal Insufficiency Cohort Study. Neighborhood SES quartiles were created utilizing a validated neighborhood-level SES summary measure expressed as z-scores for six census- derived variables. The relationship between neighborhood SES and hospitalizations was examined using Poisson regression models after adjusting for demographic characteristics,

individual SES, lifestyle and clinical factors while taking into account clustering within clinical centers and census block groups.

RESULTS: Among 3,291 participants with neighborhood SES data, mean age was 58 years, 55% were male, 41% non-Hispanic white, 49% had diabetes, and mean eGFR was 44 ml/min/1.73 m^2. In the fully-adjusted model (Table 1), compared to individuals in the highest SES neighborhood quartile, individuals in the lowest SES neighborhood quartile had higher risk for all-cause hospitalization (Rate Ratio [RR], 1.28, 95% CI, 1.09 to 1.51) and non-cardiovascular hospitalization (RR 1.30, 95% CI, 1.10 to 1.55). The association with cardiovascular hospitalization was in the same direction but not statistically significant (RR 1.21, 95% CI, 0.97 to 1.52).

CONCLUSIONS: Neighborhood SES is associated with risk for hospitalization in individuals with CKD even after adjusting for individual SES, lifestyle and clinical factors. These findings suggest consideration of novel policy and system-level public health and primary prevention approaches within disadvantaged communities to improve outcomes for individuals with CKD.

Table 1. Association of Neighborhood SES with Hospitalizations (Rate Ratio, 95% CI)

SES Quartile	Model 1	Model 2	Model 3
All-Cause Hospitalizations			
1 (Lowest SES)	1.59 (1.36, 1.85)	1.32 (1.12, 1.57)	1.28 (1.09, 1.51)
2	1.55 (1.36, 1.77)	1.37 (1.18, 1.59)	1.31 (1.13, 1.51)
3	1.33 (1.18, 1.51)	1.21 (1.07, 1.38)	1.15 (1.01, 1.31)
4 (Highest SES)	Ref	Ref	Ref
Non-CV related Hospitalizations			
1 (Lowest SES)	1.62 (1.38, 1.90)	1.36 (1.14, 1.62)	1.30 (1.10, 1.55)
2	1.57 (1.37, 1.81)	1.39 (1.20, 1.62)	1.32 (1.13, 1.54)
3	1.33 (1.17, 1.51)	1.21 (1.05, 1.38)	1.14 (1.00, 1.30)
4 (Highest SES)	Ref	Ref	Ref
CV-Related Hospitalizations			
1 (Lowest SES)	1.48 (1.21, 1.81)	1.22 (0.98, 1.53)	1.21 (0.97, 1.52)
2	1.49 (1.23, 1.79)	1.29 (1.05, 1.58)	1.25 (1.02, 1.53)
3	1.35 (1.12, 1.62)	1.24 (1.02, 1.50)	1.19 (0.98, 1.43)
4 (Highest SES)	Ref	Ref	Ref

Model 1: Clustered by clinical center and census block group and adjusted for age, sex, race/ ethnicity;
Model 2: Model 1 + SES (education, income, occupation, health insurance)
Model 3: Model 2 + BMI, cigarette smoking, systolic blood pressure, diabetes, eGFR, CV medications (ACEI/ARB, aspirin, statin), urine albumin/24 h.

NEIGHBORHOOD SOCIOECONOMIC STATUS IS ASSOCIATED WITH ADVANCE CARE PLANNING: GEOCODING OF ELECTRONIC HEALTH DATA

Sarah Nouri[1]; Courtney R. Lyles[2]; Anna D. Rubinsky[1]; Kanan Patel[3]; Riya Desai[2]; Mindy deRouen[1]; Aiesha Volow[4]; Kirsten Bibbins-Domingo[1]; Rebecca L. Sudore[5]. [1]Medicine, University of California, San Francisco, San Francisco, CA; [2]Center for Vulnerable Populations at SFGH, University of California San Francisco, San Francisco, CA; [3]Medicine-Geriatrics, UCSF, San Francisco, CA; [4]Geriatrics, University of California, San Francisco, San Francisco, CA; [5]Medicine/Geriatrics, University of California, San Francisco, San Francisco, CA. (Control ID #3391977)

BACKGROUND: Engagement in advance care planning (ACP) is low among diverse older adults. Given sociocultural influences on end-of-life preferences, barriers to ACP engagement may extend to neighborhood-level factors, but this is unknown. We aim to determine whether neighborhood socioeconomic status (nSES) is associated with ACP engagement using geocoded data linked to the electronic health record (EHR).

METHODS: Home addresses of patients who receive primary care at the University of California San Francisco, live in the SF Bay Area, and are ≥65 years old were geocoded to latitude/longitude coordinates then assigned to census tracts. ACP engagement (outcome variable; yes/no) was defined as having a scanned document (advance directive or POLST), ACP CPT code, or ACP note type. Our primary neighborhood-level variable was nSES—a composite variable from publicly available US Census data combining income, education, poverty, employment, occupation, and housing/rent values at the census tract level, divided into quintiles scaled to the SF region. Individual-level variables abstracted from the EHR included age (continuous), sex (male/female), race/ethnicity (white, Black, Latinx, Asian, Other), language preference (English, Spanish, Chinese, other), insurance type (private, Medicare, Medicaid), number of past-year primary care (PC) visits or hospitalizations, advanced illness (yes/no), and cognitive impairment (yes/no). We estimated the relative risk (RR) of ACP across nSES quintiles using mixed-effects modified Poisson regression with a random effect for census tract (1st (lowest) quintile as the referent).

RESULTS: Of 13,676 patients, 3957 (29%) had engaged in ACP. Mean age was 75 (SD 8); 7624 (58%) were female, 6811 (49%) identified as minority race/ethnicity and 2424 (18%) had non-English language preference. Of this cohort, 10% of patients lived in the 1st quintile of nSES, 15% in the 2nd, 18% in the 3rd, 26% in the 4th, and 31% in the 5th. In unadjusted analysis, higher nSES was associated with greater ACP engagement (RR 1.12 (95% CI 1.01-1.24) in 5th vs 1st quintile). After adjusting for all individual-level variables, nSES remained independently associated with ACP engagement (1.12 (1.02-1.23) in 5th vs 1st quintile). Patients with older age, female sex, more PC visits, more hospitalizations, advanced illness, and cognitive impairment were more likely to have engaged in ACP. Conversely, all minority race/ethnicity and non-English language preference groups and those with Medicaid insurance were less likely to have engaged in ACP.

CONCLUSIONS: This study sheds new light on the association between neighborhood-level factors and ACP engagement. Low nSES is associated with lower ACP engagement, even after adjusting for known individual-level predictors of ACP engagement captured in the EHR. These findings and use of geocoded EHR data will allow for future targeted, culturally appropriate interventions to increase ACP engagement in areas with the highest need.

NETWORK SIZE OR PROXIMITY? ASSOCIATION OF NETWORK CHARACTERISTICS WITH VIOLENCE-RELATED STRESS AND PTSD AMONG RACIAL/ETHNIC MINORITIES IN CHICAGO

Ololade Akingbade, Monica E. Peek, Elizabeth L. Tung. Section of General Internal Medicine, University of Chicago, Chicago, IL. (Control ID #3388539)

BACKGROUND: The epidemic of violence in the U.S has been linked to stress and PTSD. Social networks may be protective against the psychosocial consequences of violence, but research on network characteristics has been limited. To date, few studies, if any, have examined network proximity—the physical closeness of network confidantes. As studies on network size have been mixed, network proximity may help to explain relationships between social networks and psychosocial health in racial/ethnic minority adults.

METHODS: A sample of 504 adults were recruited from two clinics on the South and West sides of Chicago in 2018. Participants were recruited to complete a one-time in-person survey using Computer-Assisted Personal Interviewing software on tablets. Network size was measured using survey items from the National Social Life Health and Aging Project (NSHAP). Participants were asked to list each network confidante one by one ("Who are the people that you've most often discussed important things with over the past year?"). Network proximity was adapted from prior studies ("How far, in minutes or hours, does [listed individual] live from you?"). Stress due to violence and PTSD were measured using validated items. To examine the subgroup of participants at risk for stress due to violence and PTSD, we limited this analysis to participants who reported a prior exposure to community violence, either as a direct victim or indirect witness, close friend, or family member of someone who died violently. Violence exposure was measured using the Brief Trauma Questionnaire. We used logistic regression models to assess stress due

to violence and PTSD as independent functions of network characteristics (network size and proximity), controlling for age, gender, race/ethnicity, education level, insurance status, and clinic location.

RESULTS: Among the subgroup of participants reporting a prior exposure to community violence (n=297), the majority were female (69%) and non-Hispanic black (75%). Many were direct victims of a robbery or assault (66%), or indirect witnesses, close friends or family members of someone who died violently (80%). Approximately one-third (31%) screened positive for PTSD. The mean number of network confidantes was 2.4. Larger network size alone was not associated with stress due to violence or PTSD. However, having a larger network size (3 or more confidantes) within 30 minutes from home was significantly associated with 71% lower adjusted odds of PTSD (95% CI, 0.09-0.94). Associations with stress due to violence were not statistically significant.

CONCLUSIONS: In this sample of high-risk, racial/ethnic minority adults in Chicago, we found that network proximity, not network size alone, was consistently associated with lower PTSD. In a paradoxical era of growing digital connection and greater loneliness, further research is needed on the role of local networks and communities in mitigating the harmful effects of community violence.

NEW SOURCES OF SOCIAL RISK DATA AND THEIR ASSOCIATION WITH TOTAL PER CAPITA COST AMONG MEDICARE BENEFICIARIES

Wafa Tarazi[1]; Rachael Zuckerman[2]; Karen E. Joynt Maddox[3]; Lok Wong Samson[1]; Steve Sheingold[1]. [1]Office of the Assistant Secretary for Planning and Evaluation (ASPE), Department of Health and Human Services, Washington, DC; [2]Office of the Assistant Secretary for Planning and Evaluation, Department of Health and Human Services, Washington, DC; [3]Medicine/Cardiology, Washington University School of Medicine, Saint Louis, MO. (Control ID #3389754)

BACKGROUND: Previous research using Medicare claims data found that dual enrollment status was the most powerful predictor of poor outcomes among Medicare beneficiaries. However, there is a limited number of social risk factors in claims, and therefore using survey data may better capture additional social risk factors. The purpose of this study is to examine the association between new measures of survey-based social risk factors and total per capita cost (TPCC), a quality measure in Medicare's physician Value Modifier (VM) Program. This study links social risk factors from survey data to Medicare claims to understand the effect of various measures of social risk on spending.

METHODS: Data from the 2009–2013 nationally representative Medicare Current Beneficiary Survey (MCBS) Cost and Use, MCBS Income and Assets, and Medicare claims data were used to estimate the association between social risk factors and TPCC. OLS regressions were estimated for each individual social risk factor and then for all risk factors in the same model. The models included social risk factors derived from Medicare claims (dual enrollment, race/ethnicity and rurality), social risk factors reported in the MCBS (living alone, marital status, education, English proficiency, private insurance coverage, home ownership, income, and total assets), the area-level Social Deprivation Index and the current TPCC risk adjustment. The analysis includes Medicare beneficiaries aged 65 or older with claims and MCBS data during the study period.

RESULTS: Each social risk factor was statistically significantly associated with total per capita cost in the raw models (that did not include the TPCC risk adjustment), but only a few factors (including dual enrollment) were statistically significant when the models included the measure risk adjustment. In the raw models, dual enrollment, living alone, and marital status were statistically significantly ($p<.0001$) associated with $6,700, $1,700, and $2,500 additional per capita cost, respectively. Controlling for all social risk factors and the TPCC risk adjustment, dually-enrolled beneficiaries had a statistically significant ($p<.05$) additional $3,700 in spending compared to non-duals. In addition, beneficiaries who lived alone had a statistically significant ($p<.05$) additional $1,900 in spending compared to beneficiaries who did not live alone. Unmarried beneficiaries had a statistically significant ($p<.05$) less $2,000 than married beneficiaries. When the Social Deprivation Index was added, only dual enrollment remained statistically significant (additional $3,100 for dually-enrolled beneficiaries compared to others).

CONCLUSIONS: Dual enrollment and social support are powerful predictors of poor outcomes in the Medicare quality measures. Providers and health systems may need to consider social risk factors in order to connect patients with available community resources and implementing interventions that address social risk factors.

NORMAL VITALS AT EMERGENCY DEPARTMENT VISITS FOR ACUTE RESPIRATORY TRACT INFECTIONS: AN OPPORTUNITY FOR VIRTUAL CARE

Timothy Judson[1]; Judy Masselli[2]; Ralph Gonzales[2]. [1]Medicine, UCSF, San Francisco, CA; [2]Department of Medicine, UCSF, San Francisco, CA. (Control ID #3388368)

BACKGROUND: Over 8 million Americans visit the emergency department (ED) annually with acute respiratory tract infections (ARIs), among whom only a small fraction require hospitalization. Vital signs can help differentiate between ARIs that are self-limited and those that are more serious. Until recently, obtaining vital signs required an in-person visit. However, advances in device technology and same-day delivery have made remote vitals a feasible component of virtual care programs. To quantify the opportunity for such programs, we examined 1) the proportion of patients presenting to US EDs for ARIs with normal vital signs, and 2) the correlation between vital sign abnormalities and discharge disposition.

METHODS: We analyzed the most recent 2 years of data from the National Hospital Ambulatory Medical Care Survey (NHAMCS). We included all visits by adults with ARI defined by ICD-10 codes and reasons for visit structured data fields that resulted in dispositions of admission or discharge. We excluded visits related to pregnancy and those with missing vitals.

Normal vital signs were defined as temperature 96.5-100.3 degrees Fahrenheit, heart rate 55-99 beats per minute, systolic blood pressure 100-160mmHg, respiratory rate 12-20 breaths per minute, and oxygen saturation greater than 94.0%.

All analyses used survey weights. P values less than 0.01 were considered statistically significant.

RESULTS: Over the 2-year period of 2016-17, the NHAMCS survey estimates 16.9 (95% CI 16.2-17.5) million visits by adult patients with ARIs. Of these, 13.6 (95% CI 12.9-14.2) million met our inclusion criteria. An additional 1.6 million had at least one missing vital sign, and were excluded. Among patients with the complete set of five vital signs, 60.6% (95% CI 57.2-64.1) were all within the normal ranges.(Table 1) Patients with at least one abnormal vital sign were significantly more likely to be admitted than patients with all five vital signs within normal limits (2.99% [95%CI 1.77%-4.21%] vs. 1.04% [95% CI 0.3401.68%], $p<0.0001$).

CONCLUSIONS: The majority of patients presenting to the ED with ARI had normal vital signs. These patients were less likely to have serious disease necessitating hospitalization. This suggests an opportunity to improve care by expanding virtual options for ARI, such as by combining remote vital sign monitors with video visit platforms.

	Discharge disposition (weighted estimates in thousands)

OBTAINING INPUT FROM VETERANS AND VETERAN FAMILY MEMBERS INTO A LUNG CANCER SCREENING RESEARCH AGENDA

Jeff Whittle[1,2]; Katinka Hooyer[3]; Mark E. Flower[4]; Alice Yan[5]; onur asan[6]. [1]Primary Care, Zablocki VA Medical Center, Milwaukee, WI; [2]Medicine, Medical College of Wisconsin, Milwaukee, WI; [3]Family and Community Medicine, Medical College of Wisconsin, Milwaukee, WI; [4]n/a, n/a, Milwaukee, WI; [5]Public Health, University of Wisonsin Milwaukee, Milwaukee, WI; [6]school of systems and enterprises, stevens institute of technology, Hoboken, NJ. (Control ID #3392393)

BACKGROUND: Experts suggest that patient involvement throughout the research process improves research relevance; approaches to obtaining input vary. We sought input from patients regarding a research agenda for lung cancer screening (LCS) among Veterans, who have high lung cancer risk. We describe lessons learned.

METHODS: Using peer-to-peer recruitment within Veteran social networks, we recruited 12 Veterans or family members of Veterans familiar with lung cancer or smoking as a Patient Advisory Council (PAC). We met with them 8 times over 2 years; two of the meetings also included an 8-member stakeholder group (SG) including researchers, clinicians, and advocacy group members. Prior to the first joint meeting, PAC members practiced providing feedback on research ideas and methods and discussed how to make feedback most useful for researchers. We emphasized their expertise as consumers of research or medical services, noting they did not need to be expert in LCS to help identify research priorities. SG members were asked to consider insights they might gain from PAC input. After the first joint meeting, each group identified process changes that could facilitate exchange of ideas.

RESULTS: PAC and SG members both pushed for ensuring PAC members understood the LCS process. After the first joint meeting, PAC members asked for more intensive moderation to ensure that SG members did not dominate discussions. SG members suggested that some PAC members focused on personal issues without noting how this experience should inform the research agenda. PAC members reported that SG members seemed to be more receptive to their input in the second meeting, at least in part due to personal familiarity. PAC members prioritized several research topics not identified by SG as high priority, including: Influence of unique Veteran exposures (Agent Orange, burn pits) on lung cancer risk; impact of changes in Veterans Health Administration rules on LCS use; impact of CMS mandated smoking cessation counseling on smokers' participation in LCS; and use of Veteran peer support to encourage LCS. After detailed presentation of the LCS counseling process, PAC members expressed concern that emphasis on false positive results discouraged use of potentially life saving LCS. PAC and SG members agreed that variation in LCS use, dissemination of LCS, and real - world effectiveness of LCS were important research topics. PAC members felt they personally benefitted from learning about LCS and were interested in providing input into other areas of research. Both PAC and SG members were more cognizant of the benefits of PAC insights after the second joint meeting.

CONCLUSIONS: Veteran input highlighted topics that had not been recognized as important by experts and researchers. Both PAC and SG members recognized that information sharing was improved by repeated personal contacts and practice understanding the others' priorities. Optimal use of patient insights requires practice by both patients and researchers.

OHIO CARDIOVASCULAR HEALTH COLLABORATIVE (CARDI-OH) NEEDS ASSESSMENT RESULTS

Shireen Khoury[1]; Jackson T. Wright[2]; Adam T. Perzynski[1]; Aleece Caron[1]; Goutham Rao[2]; Siran Koroukian[3]; Glen D. Solomon[4]; Michael B. Holliday[5]; Stacey L. Gardner-Buckshaw[6]; Lance Dworken[7]; Elizabeth Beverly[8]; Randell Wexler[9]; Ann Nevar[3]; Melissa Nance[10]; Stephen Albanese[10]; Donald P. Wharton[10]; Mary S. Applegate[10]; Michael Konstan[2]; Shari Bolen[1]. [1]Center for Health Care Research and Policy, Case Western Reserve University at the MetroHealth System, Cleveland, OH; [2]Case Western Reserve University, University Hospitals Cleveland Medical Center, Cleveland, OH; [3]Case Western Reserve University, Cleveland, OH; [4]Wright State University School of Medicine, Dayton, OH; [5]University of Cincinnati School of Medicine, Cincinnati, OH; [6]Northeast Ohio Medical University, Rootstown, OH; [7]University of Toledo School of Medicine, Toledo, OH; [8]Ohio University Heritage College of Osteopathic Medicine, Athens, OH; [9]Ohio State University Wexner Medical Center, Columbus, OH; [10]The Ohio Department of Medicaid, Columbus, OH. (Control ID #3391464)

BACKGROUND: The Ohio Cardiovascular Health Collaborative (Cardi-OH), partially funded by the Ohio Department of Medicaid, engages teams from Ohio's 7 medical schools to partner with the Medicaid Managed Care Plans (MCPs), primary care clinics, and others to improve cardiovascular health and reduce cardiovascular healthcare disparities. Cardi-OH's collaborative model leverages shared learning of best practices and regional expertise, with initial foci on hypertension (HTN) management and social determinants of health (SDOH). To guide the development of learning activities for Medicaid clinicians across the state, a needs assessment survey was developed and deployed by Cardi-OH topic experts.

METHODS: Questions were distributed via web survey to all 98 active Cardi-OH members, spanning Ohio's 5 geographic regions. Questions asked about participants' use of HTN treatment algorithms, familiarity with and clinical application of hypertension (HTN) guidelines, perceptions of how MCPs could better assist their enrollees, perceived importance of identifying and addressing SDOH, and interest in case-based learning on HTN and SDOH, among other items. Results were summarized using descriptive analysis.

RESULTS: Of 98 individuals invited to complete the survey, 84 responded. Thirty-six of 84 respondents reported direct clinical roles, and were therefore eligible to complete the survey. Of those, 75% practiced in a primary care setting. Nearly 70% reported that they were 'extremely' or 'very' familiar with the 2017 ACC/AHA HTN guidelines. About half (56%) reported achieving guideline-based blood pressure (BP) targets in their patients 50-75% of the time. Few (11.1%) reported using a clinical HTN treatment algorithm. Regarding home BP monitoring, 44% reported being unsure whether home BP monitors were covered, over 60% were uncertain how to order a home BP monitor, and 33% reported insufficient time/resources to teach patients how to take accurate home BP readings. While 89% indicated that it was 'extremely' or 'very' important to screen for SDOH in routine clinical practice, less than 15% felt 'extremely' or 'very' confident that their practice could address SDOH. A majority of respondents were "extremely" or "very" interested in

additional learning around HTN management in special populations (e.g., racial minorities), practical strategies for medication adherence and lifestyle change in low-resource settings, team-based approaches to HTN care and SDOH. When asked about ways Medicaid MCPs could better assist their patients, respondents indicated transportation (81%), prescription coverage (64%), patient navigation of the health care system (75%), child care (36%), and health education resources (50%).

CONCLUSIONS: Our findings indicate a need and interest in ongoing education and practical strategies to improve HTN management, with an eye toward addressing SDOH, in low-resource settings across Ohio. Partnering with payers will be key in addressing policy changes which could improve patient outcomes.

OLDER ADULTS IN PUBLIC HOUSING: PERSPECTIVES ON HEALTHCARE, HEALTH, AND HOW SOCIAL ISOLATION NEGATIVELY IMPACTS HEALTH

Ruth Sanchez[1]; Brooke R. Wagen[2]; Whitney Williams[1]; Elizabeth Jacobs[3]. [1]Internal Medicine Department, Dell Medical School at the University of Texas at Austin, Austin, TX; [2]Internal Medicine/Population Health, Dell Medical School, Austin, TX; [3]Dell Medical School, University of Texas at Austin, Austin, TX. (Control ID #3386666)

BACKGROUND: Adults ≥ 65 are projected to outnumber children in the US by 2035. The growing lack of affordable housing combined with fixed incomes will lead to more older adults residing in public housing. Public housing authorities, in turn, will face growing health and social needs among their residents. In partnership with a local housing authority, we conducted a qualitative study to better understand the health and social needs of older adult public housing residents.

METHODS: We conducted semi-structured qualitative interviews with 27 older adults at two public housing sites in Austin, Texas; we asked about their experience of aging in public housing, their health, healthcare, and community life. We audio-recorded and transcribed each interview; interviews were systematically coded and coding was verified by a second coder. Spanish transcripts were coded in Spanish. We used constant comparative analysis to identify themes.

RESULTS: We interviewed 10 Spanish and 17 English-speakers; 16 were female and 11 male (mean age = 71.7 years). We identified four themes. First, older adults residing in public housing characterize good healthcare as that which is provided by physicians who are consistent, provide education, and listen to the problem that the patient perceives as the primary concern at each visit. Second, residents perceive good health to be fundamentally determined by healthy personal choices such as eating, moving, and obeying their doctor's orders. Third, they defined health as feeling good, being mobile, and lacking pain. Finally, they want many more opportunities to learn about health and to connect interpersonally within their public housing community. They reflected that current opportunities were not consistent and failed to provide the physical and mental stimulation that residents desire. They perceive limited meaningful community relationships as a significant contributor to poor health in other public housing residents' lives in their community, but not their own.

CONCLUSIONS: The older adult public housing residents in our study outlined what good health care and health looks like to them. They also identified how public housing authorities could do more to address one of the fundamental social determinants of health among older residents: social isolation. Future efforts to improve resident health should focus on programming that will promote physical and mental acuity while building upon resident ideas of good health. It may also be beneficial to build bridges between housing communities and physicians. This research highlights the importance of the social determinants of health in promoting better health among older adult public housing residents.

ONCOLOGIC SERVICES THROUGH PROJECT ACCESS AND OTHER SAFETY NET COORDINATION CENTERS

James B. Hammock[1]; Courtney P. Williams[2]; Monica S. Aswani[3]; John W. Thomas[1]; Gabrielle B. Rocque[2]. [1]Tinsley Harrison Internal Medicine Residency Program, UAB, Birmingham, AL; [2]Division of Hematology and Oncology, UAB, Birmingham, AL; [3]School of Health Professions, UAB, Birmingham, AL. (Control ID #3388286)

BACKGROUND: Since the 1996 formation of Project Access, a nationwide program linking uninsured, low-income, or underserved patients to specialty care, the United States (US) has experienced a growth of third-party safety net care coordination programs that provide subspecialty care at no or reduced cost. These programs pre-negotiate with local physicians and hospitals to offer pro-bono services to patients. Little is known about the provision of oncologic services within these programs, and even less is known about how the Affordable Care Act and Medicaid expansion have subsequently changed the need for these programs. This study evaluated the current landscape of oncologic services within US safety net care coordination programs in both Medicaid-expansion and non-expansion states.

METHODS: An internet search was conducted to obtain information on US safety net care coordination program location, health services offered, and patient eligibility criteria. The current status of Medicaid expansion across the US was also reviewed. Individual programs were called for verification of existence and clarification of services provided. For care coordination programs not offering oncologic care, program directors were interviewed to identify specific barriers that limit their program's ability to offer oncologic care.

RESULTS: Websites of 29 safety net care coordination programs in 22 states were identified, serving approximately 40 counties and 180,000 patients. Three programs (10%) were unreachable by phone, and data was extracted using only available information on each of their websites. Of identified programs, 62% (n=18) offered oncologic services. Of those offering oncologic services, 83% (n=15) offered free chemotherapy, and one program offered chemotherapy at a reduced cost. Nearly all programs offering chemotherapy did so through an affiliated large hospital system. Computed tomography (CT), magnetic resonance imaging (MRI), and/or positron-emission tomography (PET) scans were offered by 93% (n=27) of the programs. Three themes naturally emerged as the program directors were interviewed on specific barriers that limit their program's ability to offer oncologic care: (1) costs, (2) longitudinal care, and (3) multiphysician buy-in. Care coordination centers were most predominant in states that did not expand Medicaid.

CONCLUSIONS: Third-party care coordination centers provide a novel, and potentially unrecognized, approach to increasing oncology service access. Programs are more concentrated in states that have not expanded Medicaid, suggesting these states have a greater need for *pro-bono* subspecialty services. Further research should identify barriers contributing to the relative lack of oncologic services in these programs compared to other specialties, as well as strategies to overcome them.

ONLINE NURSING HOME QUALITY INFORMATION AND HOSPITAL READMISSIONS: INSIGHT FROM NURSING HOME COMPARE AND YELP REVIEWS 2014-2018

Kira Ryskina[1]; Anietie U. Andy[2]; Kirstin Manges[1]; Kierra A. Foley[3]; Rachel M. Werner[4]; Raina Merchant[2,5]. [1]Medicine, University of Pennsylvania, Philadelphia, PA; [2]Center for Digital Health, Philadelphia, PA; [3]University of Pennsylvania School of Nursing, Philadelphia, PA; [4]Medicine, University of Pennsylvania and Philadelphia VA, Philadelphia, PA; [5]Department of Emergency Medicine, University of Pennsylvania, Philadelphia, PA. (Control ID #3356894)

BACKGROUND: Over 40% of older adults who require post-acute care after hospitalization are discharged to skilled nursing facilities (SNFs), which provide short-term nursing and rehabilitation services after hospital discharge. To improve outcomes and reduce costs of SNF care, Medicare invested in public reporting of SNF quality information. However, SNF quality ratings published by Medicare's Nursing Home Compare (NHC) website have been only weakly correlated with hospital readmissions. Whether unsolicited consumer reviews of SNFs available on Yelp.com provide useful information about SNF rehospitalization rates is unknown.

Our objectives were to (1) measure the association between rehospitalization rates and Yelp ratings of SNFs; (2) compare how well Yelp vs. NHC ratings explain the variation in rehospitalizations from the SNFs; (3) identify characteristics of Yelp reviews of SNFs with high vs. low rehospitalization rates.

METHODS: This was a retrospective observational study of 1,536 SNFs with online reviews on Yelp posted in 2014 - 2018 (10.4% of all SNFs). Risk-standardized rehospitalization rates were obtained from NHC. Hierarchical linear regression was used to measure the association between a SNF's rehospitalization rate and the publicly reported quality ratings. Natural language processing was used to identify topics associated with reviews of SNFs in the top and bottom quintiles of rehospitalization rates.

RESULTS: SNFs with the best rating on *both* Yelp and NHC had 2.0% lower rehospitalization rates compared to the SNFs with the worst rating on both websites (21.3% vs. 23.3%, p=0.04) (Table). Compared to the NHC ratings alone, Yelp ratings explained an additional 0.6% of the variation in rehospitalization rates across SNFs (adjusted R^2 0.009 vs. 0.013, p=0.003). Analysis of qualitative comments on Yelp identified several areas of importance to the reviewers, such as the quality of physical infrastructure and equipment, staff attitudes, and communication with caregivers.

CONCLUSIONS: Areas of SNF experience that are important to the public are not included in current Medicare ratings of SNFs. Patients, hospitals, and payers may be able to leverage this information to reduce rehospitalizations from SNFs.

Table: Risk-Standardized 30-Day Hospital Readmission Rates from Skilled Nursing Facilities by Their Yelp and Medicare's Nursing Home Compare Ratings

	Readmission Rate, %	95% CI
Nursing Home Compare Star Rating		
1-star (Worst)	23.3	22.7-23.9
2-star	22.7	22.3-23.1
3-star	22.7	22.3-23.1
4-star	22.7	22.4-23.1
5-star (Best)	21.8*	21.6-22.1

ONLINE SEARCHES FOR QUITTING VAPING DURING THE 2019 OUTBREAK OF E-CIGARETTE OR VAPING PRODUCT USE-ASSOCIATED LUNG INJURY

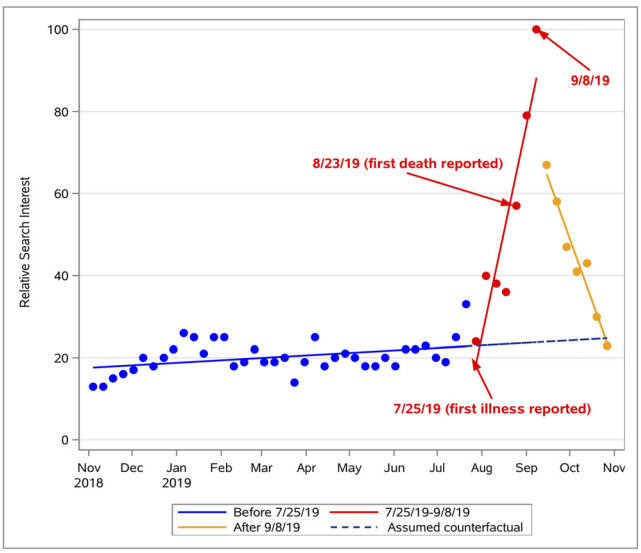
Sara Kalkhoran, Yuchiao Chang, Nancy A. Rigotti. Medicine, MGH, Boston, MA. (Control ID #3391258)

BACKGROUND: The prevalence of current e-cigarette use (vaping) is increasing in the US. The 2019 outbreak of e-cigarette or vaping product use-associated lung injury (EVALI) in the US raised concerns about the health effects of e-cigarettes, and may have increased users' interest in quitting. Our goal was to evaluate trends in internet searches for quitting e-cigarettes before and during the EVALI outbreak.

METHODS: We used Google Trends to search for terms related to quitting e-cigarettes and vaping from the week of 11/4/2018 to the week of 10/27/2019. We looked at relative search interests, where data are indexed from a scale of 0 to 100, with 100 being the week with the maximum search interest. We categorized the data into three periods: before 7/25/19 (date of the first media reports of illness), from 7/25/19 to 9/8/19 (the week of maximum search interest), and after 9/8/19. We used an interrupted time series approach to compare the relative search interest in the 3 periods using SAS version 9.4.

RESULTS: The relative search interest in quitting e-cigarettes started increasing shortly after 7/25/19 (Figure). Compared to the would-be observed volume from the original time trend (dotted line), there was a 3.7-fold increase on 9/8/19 (P<0.001). At the end of the evaluation period, the relative search interest returned to the level predicted by the original trend. The slopes from the increasing trend during 7/25/19 to 9/8/19 and the decreasing trend after 9/8/19 were both significantly different from the trend before 7/25/19 (both P<0.001).

CONCLUSIONS: Internet searches for quitting e-cigarettes increased during the EVALI outbreak in the US. The fact that individuals seek information about quitting e-cigarettes suggests that many users are dependent on these products and may need behavioral and/or pharmacologic assistance. Healthcare providers should routinely screen for and document e-cigarette use in addition to combustible tobacco use to identify e-cigarette users and assist those who are interested in quitting.



OPIOID PRESCRIPTIONS ON DISCHARGE FROM POST-ACUTE REHABILITATION AND RISK OF LONG-TERM OPIOID USE

James Rotenberg[1,2]; John T. Farrar[1]; Christopher B. Roberts[2]; Warren B. Bilker[3,4]. [1]Center for Clinical Epidemiology & Biostatistics, University of Pennsylvania, Philadelphia, PA; [2]Center for Health Equity Research & Development, Corporal Michael Crescenz VA Medical Center, Philadelphia, PA; [3]Department of Biostatistics, Epidemiology, and Informatics, University of Pennsylvania, Philadelphia, PA; [4]Department of Psychiatry, University of Pennsylvania, Philadelphia, PA. (Control ID #3390640)

BACKGROUND: The national opioid (OPR) epidemic remains a significant challenge. Providers are still unable to predict reliably who will

develop opioid use disorder (OUD). Eliminating opioid prescriptions (Rx) risks leaving patients' pain untreated. The early post-initiation period is crucial in predicting subsequent OPR-related complications. Many with OUD are first exposed during acute hospitalization. Limited prior studies suggest that hospital discharge Rx increases subsequent long-term opioid use (LTOU), a common OUD surrogate. Little is known about the long-term effects of Rx upon discharge from post-acute skilled nursing facility (SNF) rehabilitation, an increasingly prevalent discharge site.

METHODS: This was a retrospective cohort study using Veterans Health Administration (VHA) administrative data. Inclusion criteria were: U.S. Veterans and residents; a VHA encounter in 2011, baseline OPR-naïve and cancer-free; VHA Medical (Med) or Surgical (Surg) hospitalization 2012-2016; acutely OPR- exposed; discharged to a VHA SNF then home. Exclusion criteria were: residing in a long-term care facility, hospice enrollment, or a cancer diagnosis (other than non-melanoma skin cancer), unless >12 months post- discharge. Follow-up was through 2017. New LTOU, evaluated 12 months post-discharge, was defined as a composite of an OPR use episode lasting >90 days, and either a) ≥120 days' supply of OPR dispensed, or b) >10 Rx's in 1 year. Covariates included age at discharge, gender, race, ethnicity, socioeconomic status (SES, as quintile of home zip median income), Charlson Comorbidity Index (CCI), and admission type (Med/Surg).

RESULTS: Of a cohort of 1,977 (96% Male), 469 were dispensed an OPR within 48 hours of discharge. (See table). Gender, SES and ethnicity were similar between groups (χ^2 $p<0.3$). On follow-up, 11 (exposed) and 42 (unexposed) were diagnosed with OUD, and 55 vs 89 developed LTOU, respectively. In unadjusted analyses, the relative risk of OUD wasn't different (RR 0.84, 95% CI 0.44-1.62); however LTOU was more common for those receiving discharge Rx (RR 1.99, 95% CI 1.44-2.74).

CONCLUSIONS: Using observed VHA data, SNF discharge home with (vs without) an Rx increased the likelihood of subsequent LTOU, but not OUD diagnosis. These findings may suggest that SNF providers can reduce LTOU by stopping unnecessary OPR before discharge.

OPIOIDS WITHOUT PAIN? DOCUMENTATION OF THE CLINICAL RATIONALE FOR OPIOID ANALGESICS PRESCRIBED TO YOUNG ADULTS, 2006-2015

Tisamarie B. Sherry[1]; Bradley Stein[2]; Adrienne Sabety[3]; Rosanna Smart[5]; Nicole Maestas[4]. [1]Economics, Sociology and Statistics, RAND Corporation, Arlington, VA; [2]RAND Corporation, Pittsburgh, PA; [3]Harvard University, Cambridge, MA; [4]Harvard Medical School, Boston, MA; [5]RAND Corporation, Santa Monica, CA. (Control ID #3391540)

BACKGROUND: Young adults age 16-30 experience the highest rates of opioid misuse, and exposure to opioid analgesics – even for legitimate medical reasons – is an important risk factor. Accordingly, there is a need to improve opioid prescribing safety in this population. One important dimension of safe prescribing is the need for a clearly documented clinical rationale for opioid therapy: documenting the reason for a prescription can improve appropriate medication use and patient safety, particularly for medications with a high risk of adverse effects or misuse such as opioids. Yet providers often fall short of this: nearly 30% of office visits by older adults who receive opioids lack a documented pain diagnosis. Documentation of the reason for opioids is especially important among young adults given their increased vulnerability to opioid misuse, but has yet to be studied in this population. We therefore examined the share of opioid prescriptions with a documented pain diagnosis among young adults age 16-30, and variations by patient, provider and visit characteristics.

METHODS: Using data from the National Ambulatory Medical Care Survey we identified outpatient visits by young adults age 16-30 between 2006-2015 at which an opioid analgesic was prescribed and calculated the share of these visits with a "pain diagnosis" (i.e. provider-assigned ICD-9 codes for conditions that commonly cause pain severe enough to require prescription-strength analgesics). We identified the most common pain and non-pain diagnoses recorded at visits where an opioid was prescribed, and used multivariable logistic regression to identify patient, provider and visit characteristics associated with documentation of a pain diagnosis.

RESULTS: Opioids were prescribed in 2,447 visits (60,932,437 visits when weighted to be nationally representative), of which 29.8% had no documented pain diagnosis. At visits in which a pain diagnosis was documented, the most frequently assigned diagnoses included back pain, "other chronic pain" and post- surgical pain. The probability of a documented pain diagnosis was significantly higher at problem-oriented visits than preventive visits; among surgeons than among primary care physicians; and at visits paid by Workers' Compensation.

CONCLUSIONS: At nearly 1 in 3 ambulatory visits by young adults at which an opioid was prescribed between 2006-2015, there was no documented pain diagnosis and the medical indication for an opioid was uncertain. Clear documentation of the justification for opioid therapy is a critical aspect of safer, appropriate prescribing – yet our findings demonstrate significant gaps in achieving this goal, even among young adults at greatest risk of opioid misuse. Our finding that documentation of the reasons for opioids is higher at visits paid by Workers' Compensation – in which the treated condition must be recorded to allow claims payment – indicates a role for insurers in improving opioid prescribing safety by requiring documentation of their medical necessity.

OPPORTUNITIES, PITFALLS AND ALTERNATIVES IN ADAPTING ELECTRONIC HEALTH RECORDS FOR HEALTH SERVICES RESEARCH

Glen B. Taksler[1,2]; Jarrod Dalton[2]; Adam T. Perzynski[3]; Michael B. Rothberg[1]; Alex Milinovich[2]; Nikolas I. Krieger[2]; Neal V. Dawson[3]; Mary Jo Roach[3]; Michael D. Lewis[4]; Douglas Einstadter[3]. [1]Medicine Institute, Cleveland Clinic, Cleveland, OH; [2]Department of Quantitative Health Sciences, Cleveland Clinic, Cleveland, OH; [3]Center for Health Care Research and Policy, Case Western Reserve University at MetroHealth, Cleveland, OH; [4]Division of Hospital Medicine, Metrohealth Medical Center, Cleveland, OH. (Control ID #3389624)

BACKGROUND: Electronic health records (EHRs) offer potential to study large numbers of patients but are designed for clinical practice, not research. Despite increasing availability, utilizing EHR data for research presents challenges.

METHODS: We created two large-scale, EHR-derived data sets on >3 million unique patients, documenting up to 18 years of care. First, a primary care registry contains data for >800,000 patients seen by a primary care provider at a large health system from 2006-2015. It provides access to commonly-requested EHR variables for ambulatory encounters, in a single file and easy-to-use format. Second, a cross-institutional database studies variation in atherosclerotic disease risk by socioeconomic position over time, with data for >3 million patients from 1999-2017. It combines data from 2 health systems representing approx. 70% market share in the region, one with primarily commercially-insured patients and the other Medicaid or uninsured patients.

In both registries, we cleaned, validated and transformed data into longitudinal format. We geocoded patient addresses to the census block-group level and linked results with publicly-available neighborhood-level data sources, such as the US Census. The atherosclerotic disease risk registry also merged EHRs for patients with encounters at both institutions.

Through this process, we identified 9 pitfalls and potential solutions for other researchers to consider when obtaining large-scale, EHR-derived data. We describe these based on our experience.

RESULTS: Although EHRs are a focus of big data analysis and increasingly viewed as a source of research data, the reality of utilizing EHRs for research is complicated. The researcher must 1) define the relevant patient population, recognizing that some patients obtain most of their care within one health system whereas others obtain care across systems; 2) carefully identify a patient's primary care provider (PCP) based on historical encounters, not the PCP field in the EHR; 3) recognize the EHR as containing episodic data (a patient's current health as of each encounter), which must be transformed and validated to obtain longitudinal health status; 4) account for changes in health system composition and treatment options over time; 5) understand that the EHR is not always well-organized, documented or accurate; 6) design methods to identify the same patient across multiple health systems; 7) account for the enormous size of the EHR as compared with computing resources available to researchers; 8) recognize that associations found in the EHR may be non-representative of the general population, potentially requiring a comparison of the patient population with US Census data and 9) consider barriers to data access.

CONCLUSIONS: When carefully designed, it is feasible to build large-scale EHR-based data registries to facilitate health services research. Attention to the intricacies of EHR data allow for more informed analysis and interpretation of results.

ORAL ANTICOAGULANT USE IN A RACIAL/ETHNIC DIVERSE POPULATION WITH ATRIAL FIBRILLATION

Eric Sun[1]; Ankur Srivastava[2]; Aliaskar Hasani[1]; Jay Chudow[3]; Andrew Krumerman[3]; Kevin Ferrick[3]; John Fisher[3]. [1]Internal Medicine, Montefiore Medical Center, Bronx, NY; [2]Albert Einstein College of Medicine, Bronx, NY; [3]Montefiore Medical Center, Bronx, NY. (Control ID #3387960)

BACKGROUND: Racial and ethnic minorities are less likely than white patients to receive direct oral anticoagulant (DOAC) for atrial fibrillation (AF) related stroke prevention. However, such phenomenon might not hold true in a multi-racial/ethnic population. In light of recent ACC guideline update recommending DOAC over warfarin for AF, this study investigated oral anticoagulant (AC) use and its prescribing pattern in a tertiary medical center serving a diverse community.

METHODS: In a retrospective study of patients with newly diagnosed AF who were prescribed AC at Montefiore Medical Center between 2015 and 2018, self-reported racial/ethnic group (white, black, Hispanic and other), AC prescribed (DOACs or warfarin), CHA_2DS_2-VASc scores, AC prescribers (cardiologist or non-cardiologist) and insurance status were identified. Logistical Regression model was used to determine prescribing pattern with adjustment of various parameters.

RESULTS: Among the 1674 patients (47% white, 18% black, 28% Hispanic and 6% other, mean age 71.9 and mean CHA_2DS_2-VASc score 2.1), Hispanic patients were prescribed DOAC more often than white patients (79% vs. 70% P=0.001, unadjusted OR 1.582 and CI 95% 1.211-2.067). Cardiologists prescribed DOAC more often than non-cardiologist (79% vs. 21% P=0.007, unadjusted OR 1.412, CI 95% 1.100-1.812). After adjusting for CHA_2DS_2-VASc score and insurance status, the significant difference when comparing white patient to Hispanic patients (P=0.001, adjusted OR 1.729, CI 95% 1.312-2.278) and cardiologists to non-cardiologists (P=0.03, adjusted OR 1.471, CI 95% 1.139-1.900) still held true.

CONCLUSIONS: Racial/ethnic biases in AC prescription do not appear present in our multi-racial/ethnic population located in Bronx, NY. However, cardiologists are more likely to prescribe DOAC than warfarin for AF.

ORGANIZATIONAL AND WORK EXPERIENCE FACTORS AFFECTING COMMUNICATION FLOW AT VHA CALL CENTERS AND PRIMARY CARE: A QUALITATIVE STUDY.

Melissa Medich[1]; Michael McGowan[1]; Danielle Rose[2]; Susan E. Stockdale[1]. [1]HSR&D Center of Excellence, Greater Los Angeles VA Healthcare System, Sepulveda, CA; [2]VA HSR&D Center for the Study of Healthcare Provider Behavior, VA GLA Healthcare System, Sepulveda, CA. (Control ID #3391699)

BACKGROUND: For most Veterans, phoning an administrative call center is their first step in engaging VA Healthcare Systems. Recent studies indicate Veterans experience lingering dissatisfaction communicating with their primary care (PC) teams and that telephone access, specifically the average speed of answer, has important consequences for patient satisfaction. This study explores the organizational and work experience factors that may impact communication between Veterans, call centers, and their PC teams.

METHODS: This cross-sectional, observational study focuses on Medical Support Assistants (MSAs) working in call centers and PC clinics, Administrative Staff Chiefs and MSA Supervisors in one regional network. We conducted site observations at call centers (n = 9) and primary care clinics (n=11) and semi- structured interviews with call center (n=16) and PC clinic MSAs (n=13). Site visits included informal discussions (n=20) with Administrative Staff Chiefs and MSA Supervisors, and observing MSAs. Interviews with MSAs focused on communication flows, training, and work experiences.

RESULTS: Most communication breakdowns occur due to a combination of issues involving location, technology, software, and protocols that, when combined, generate barriers to regular, open communication between call centers, PC clinics, and other service lines. Administrative staff and MSAs describe the organizational factors impacting call center functioning that include: physical location of call centers (co- located at medical center v. offsite), infrastructure (information technology and facility management support), high MSA turnover, lack of standardized training, and communication flow challenges. Contributing factors from work experience include: being short staffed, high job turnover, low pay, no career growth, navigating multiple software programs simultaneously, balancing multiple tasks, and dealing with 'angry Vets'. Promising practices to improve communication flows that we observed include offering MSAs hands-on experience / simulations of real-time work, standardized training, mechanisms to destress after difficult calls. One call center created Preceptor positions for Advanced MSAs, for personalized mentoring, team building and task variation. Other notable practices include: an open-door policy with Supervisors, daily group Skypes, and floor walkers used to monitor difficulties or immediate queries. Two call centers have negotiated with human resources for streamlined hiring process.

CONCLUSIONS: We identified several communication choke points: technology, scheduling processes, administrative protocols, and MSA work experiences. Our findings demonstrate the task complexity of scheduling and customer service provided in primary care. It also illustrates the complexity of communication flows between Veterans, call centers and their primary care teams.

OUCH! ADDRESSING MICROAGGRESSIONS ON THE INTERDISCIPLINARY TEAM

Stefanie Reiff, Marwa Moussa, Jung-Eun Ha, Laura Mansfield, Lorna Lee-Riley, Deserie Duran, Frank Volpicelli, Shreya P. Trivedi. Internal Medicine, NYU Langone Hospital - Brooklyn, Brooklyn, NY. (Control ID #3368744)

BACKGROUND: Microaggressions (Sue et al. 2007) are "verbal, behavioral, or environmental indignities, whether intentional or

unintentional, that communicate hostile, derogatory, or negative slights and insults with regards to race, gender, religion, or sexual orientation". In healthcare, studies have examined microaggressions' effect on trainee experience, patient-physician relationships, and frameworks for responding to them. To our knowledge no studies have examined microaggressions within the hospital interdisciplinary team (IDT).

The purpose of this study was to identify whether IDT microaggressions lead to workplace challenges and implement a framework to address them.

METHODS: We surveyed members of the Internal Medicine IDT (resident physician (RP), nurse (N), nurse practitioner (NP), social worker (SW), case manager (CM)) asking how much gender, race, sexual orientation, and team role made it challenging to succeed at the workplace using a five point scale ranging from "not a challenge" to "it interferes with my ability to be effective in my role".

They were then invited to a one hour workshop teaching recognition of micro and macroaggressions and how to constructively address these using the "OUCH" framework from Yale University:

When a microaggression is heard say, "Ouch!":

Open ended question: "What did you mean when you said X?"

Use the chance to teach: "You might have meant it to be funny but X is no joke."

Clarify your stance: "You might have meant well but X makes me uncomfortable."

Here at NYU: "…we have a commitment to respect."

Participants role-played OUCH with adapted workplace scenarios and were given a retrospective pre-post survey (Likert 1-4 scale) measuring self-reported confidence/ability to identify and respond to micro and macroaggressions. Answers were evaluated with a Wilcoxin ranked test of after-before.

RESULTS: 134 IDT members (42 RP, 25 CM, 16 SW, and 51 N; 72% females) completed the needs assessment. 54.1% stated they were misidentified in their roles in the workplace and 63.8% felt their role on the team was slightly challenging or worse with regards to effectivity in the workplace.

Ninety-five members of the IDT (29 RP, 20 SW, 15 N, 15 CM, 6 attendings, 1NP) participated in the workshop; 90/95 (94%) completed the survey. Significant improvement was found in each domain on the survey: identifying microaggressions (3.16 before, 3.69 after, $p < .001$), identifying macroaggressions (3.48 before, 3.76 after, $p < 0.001$), responding to microaggressions (2.78 before, 3.47 after, $p < 0.001$), responding to macroaggressions (2.9 before, 3.49 after, $p < 0.001$).

CONCLUSIONS: This study is one of the first to our knowledge to not only identify microaggressions relating to one's role on the IDT but then demonstrates improvement in identifying and responding to them via a one hour workshop. The OUCH framework has become a regular part of IDT dialogue. Next steps include determining sustainability and studying its effect on IDT communication and morale.

OUTCOME MEASURES FOR INTERVENTIONS TO REDUCE INAPPROPRIATE PRESCRIBING OF CHRONIC DRUGS

Carole E. Aubert[1,3]; Eve A. Kerr[2]; Jennifer K. Maratt[6,7]; Mandi L. Klamerus[4]; TImothy Hofer[5,2]. [1]Department of General Internal Medicine and Institute of Primary Health Care (BIHAM), Bern University, Bern, Bern, Switzerland; [2]Internal Medicine, University of Michigan and VA Center for Clinical Management Research, Ann Arbor, MI; [3]Veterans Affairs Center for Clinical Management Research, University of Michigan, Ann Arbor, MI; [4]Department of Veterans Affairs, VA Center for Clinical Management Research, Ann Arbor, MI; [5]Medicine, University of Michigan, Ann Arbor, MI; [6]Medicine, Indiana University School of Medicine, Indianapolis, IN; [7]Richard L. Roudebush Veterans Affairs Medical Center, Indianapolis, IN. (Control ID #3385776)

BACKGROUND: Inappropriate prescribing is an important problem, given the growing elderly and multimorbid population and associated polypharmacy. Many studies have tested interventions to withdraw inappropriate drugs (i.e. to deprescribe). However, we lack data on measures used to assess the success of such interventions.

METHODS: We conducted a literature review of intervention studies to deprescribe chronic drugs in adults. We used a comprehensive and systematic framework to categorize and synthesize the measures employed in the studies.

RESULTS: Most of the 93 identified studies used appropriateness prescribing measures, such as drug cessation or dose reduction, to evaluate the impact of the intervention. The following measures were used infrequently: patient- and provider-reported experiences, preferences and outcomes; patient-provider interactions; and measures of unintended consequences. The number and types of measures assessed varied highly across the studies. The table shows the resulting categorized synthesis of measures used across the studies.

CONCLUSIONS: Few studies employed the broad spectrum of relevant measures. This categorized synthesis could facilitate implementation of the full spectrum of measures in future deprescribing intervention studies, and more particularly of patient- and provider-relevant measures. This is important to ensure initiation, success, and sustainability of deprescribing.

OUT OF TIME: DIMINISHING RETURNS OF INTERPROFESSIONAL EXPOSURE THROUGHOUT THE CORE CLINICAL YEAR

Mark N. Alshak[1]; Jason Harris[1]; Alexandra H. Miller[1]; Amanda Su[2]; Ashita S. Batavia[3]; Pamela Charney[3]. [1]Weill Cornell Medical College, New York, NY; [2]Medicine, Johns Hopkins Hospital, Baltimore, MD; [3]Internal Medicine, Weill Cornell Medicine, New York, NY. (Control ID #3391904)

BACKGROUND: Interprofessional exposure (IPE) is associated with evidence-based improvements in care, population health, and reduced cost. IPE is required by the Liaison Committee on Medical Education, though it is given limited time in medical school curricula. The Weill Cornell Community Clinic (WCCC) is a medical student-run interdisciplinary free clinic. IPE to pharmacy students and their supervisors has been offered since 2016; here we evaluate the effect of IPE on medical students.

METHODS: At the WCCC, pharmacy students work with medical students on medication reconciliation and counseling. The validated 10-item Student Perceptions of Physician-Pharmacist Interprofessional Clinical Education Instrument (SPICE-R2) survey was used to assess attitudes towards IPE among medical students across three categories on a 1-5 scale: teamwork, roles/responsibilities, and patient outcomes. SPICE-R2 was administered to 55/58 eligible medical students at the beginning and end of their 6-week WCCC rotation from September 2018 to December 2019. Data was analyzed using 1-way ANOVA within categories and two-tailed t-tests across categories.

RESULTS: Overall, IPE improved students' attitudes toward interprofessional education and collaboration by 5.3% (average score improved from 4.15 to 4.37; p-value=0.0013). Understanding of the roles/responsibilities of pharmacy students improved 15.7% (3.39 to 3.92,

p<0.0001) after the WCCC rotation. There was no significant change in attitudes toward teamwork or patient outcomes. All three categories saw improvements in medical student attitudes in the first half of the clerkship year. Only attitudes in the roles/responsibilities category continued to show improvement in the second half of the clerkship year. Over the study period, the effect of IPE diminished — this was most pronounced in the teamwork category. Relative to the first half of the academic year, students reported an alarming 69% decrease in their appreciation for teamwork. This longitudinal trend was less pronounced in the other SPICE-R2 categories: roles/responsibilities (-47.3%) and patient outcomes (-35.5%).

CONCLUSIONS: In our study, IPE led to diminishing and ultimately negative attitudes toward interdisciplinary teamwork. This has not been previously reported, and underlying drivers need further study. Overall, IPE yielded modest gains in attitudes toward interprofessional collaborative practice. Regardless of prior clerkship exposure, IPE improved medical students' understanding of the roles and responsibilities of pharmacy students on an interdisciplinary team. This suggests student-run free clinics provide a unique and valuable IPE opportunity to understand interdisciplinary roles and responsibilities.

OUTPATIENT CARE FRAGMENTATION PATTERNS AND ASSOCIATION WITH HOSPITALIZATION IN HIGH-RISK VA PATIENTS

Donna M. Zulman[1,2]; Alison L. Greene[1,2]; Todd H. Wagner[3]; Matthew Maciejewski[4]; Sara Singer[1]; Cindie Slightam[2]; Ranak Trivedi[5,9]; Megan Vanneman[7,8]; Steven Asch[1,2]; Jean Yoon[3]; Mary K. Goldstein[6,9]; Derek Boothroyd[9]. [1]Division of Primary Care and Population Health, Stanford University School of Medicine, Stanford, CA; [2]Center for Innovation to Implementation, VA Palo Alto Health Care System, Menlo Park, CA; [3]Health Economics Resource Center, Department of Veterans Affairs, Menlo Park, CA; [4]HSR&D and Department of Population Health Sciences, Durham VA and Duke University, Durham, NC; [5]Center for Innovation to Implementation/Psychiatry and Behavioral Sciences, VA Palo Alto Health Care System/Stanford University, Menlo Park, CA; [6]VA Palo Alto Health Care System, Palo Alto, CA; [7]University of Utah School of Medicine, Salt Lake City, UT; [8]VA Salt Lake City Health Care System, Salt Lake City, UT; [9]Stanford University School of Medicine, Stanford, CA. (Control ID #3391551)

BACKGROUND: Care fragmentation—dispersion of a patient's care across clinicians and healthcare settings—increases risk for information loss, duplicative tests, and unwieldy self-care regimens, and is especially common for patients with complex medical needs. This study examines outpatient care fragmentation patterns and the association with subsequent hospitalization among Veterans Affairs (VA) patients at high-risk for hospitalization.

METHODS: For FY2014, we evaluated fragmentation patterns for 130,704 VA patients at high-risk for hospitalization (Care Assessment Needs score $\geq 90^{th}$ percentile for 1-year hospitalization) who were ≥ 65 years, enrolled in Medicare fee-for-service parts A + B, and had at least 4 VA or Medicare outpatient visits in FY14. We constructed five fragmentation measures for outpatient care: provider count (number of unique providers), concentration of care with an empirically defined "usual provider" using Breslau's Usual Provider of Care (UPC), care dispersion across providers using Bice-Boxerman's Continuity of Care Index (COCI) and an adaption of this measure (MMCI), and health system reliance (proportion of visits in the VA). We examined the distribution of each measure and variation by patient age, gender, race, ethnicity, marital status, rural status, history of homelessness, number of chronic conditions, and mental health care utilization. We then used multivariable logistic regression to examine the association between each fragmentation measure in FY14 and subsequent hospitalizations in FY15.

RESULTS: The study population was predominantly male (98%); 37% lived in rural areas; 79% were white, 16% were black, and 4% were Hispanic. Patients had a mean of 9 (SD=4) chronic conditions. In FY14, these patients had numerous VA outpatient visits (median 11, interquartile range 7-16); approximately one-third (33%) had an outpatient Medicare encounter, and 10% had a community visit paid for by the VA. During FY15, 46% of the study population was hospitalized and 14% died. Medians (IQRs) of the fragmentation measures were: provider count 6 (4-9), UPC 0.33 (0.25-0.44), COCI 0.13 (0.07-0.21), MMCI (0.34-0.61), health system reliance 1 (0.87-1). Patients with mental health care utilization and those with more chronic conditions had more fragmented care across all measures. In multivariable models, a high number of unique providers and having a high portion of care outside VA was associated with FY15 hospitalization (p<0.001), but other fragmentation patterns were not associated with future admission.

CONCLUSIONS: For VA patients at high-risk for hospitalization, individuals with greater medical complexity and mental health care utilization experienced more care fragmentation, and fragmentation across multiple providers was associated with future hospitalization. Measures of care fragmentation and their nuanced relationships with clinical outcomes can inform care coordination policy and programs for patients with complex needs.

OUTPATIENT CLINIC TO EMERGENCY DEPARTMENT TRANSFERS: EVALUATION OF REASONS FOR PATIENT TRANSFER AND OUTCOMES

Megan K. Veglia, Patrick Strickland, Samuel O. Schumann. Internal Medicine, Medical University of South Carolina, Charleston, SC. (Control ID #3392376)

BACKGROUND: The emergency department (ED) serves as an important setting for patient triage, stabilization and afterhours care. However, its role and value in the management of patients who have been referred from outpatient clinics is unclear. Little has been published on the reasons for patients to be transferred from outpatient clinics to the ED and the outcomes of these patients. Our study provides a descriptive analysis of reasons for patient transfer from an outpatient clinic to the ED and associated patient outcomes.

METHODS: Retrospective descriptive study was performed on patients transferred from an academic health center's internal medicine clinic (UIM) to the ED from June 2018 through May 2019. All patients were 18 years old or older and were seen in UIM's faculty, resident, or acute care clinic and subsequently transferred directly to ED. Administrative review identified all encounters where patients were seen in the ED within 12 hours after a UIM appointment. Administrative data abstraction from the clinical data warehouse then collected demographic and clinic information on identified patient encounters. Follow up chart review of identified patient encounters was performed to confirm direct transfer from UIM to ED. Encounters where patients were not directly transferred from UIM to ED were excluded. Additionally, chart review was used to collect information on clinical reasons for transfer, inpatient admission after transfer, and outpatient follow up after transfer. Both the administrative data file and the chart review data file were merged to create a comprehensive data file. Descriptive analysis was performed.

RESULTS: 423 patient encounters were identified as having an ED visit within 12 hours of a UIM appointment. 200 encounters were randomly selected for chart review. 168 (84%) were determined to have been transferred directly from UIM to the ED. The most common reason for patient transfer was the need for treatment not available in clinic (25%), followed by subspecialty consultation (22%), further clinical monitoring (19%) and imaging (18%). 47% of transferred patients were ultimately admitted to the hospital. Of patients transferred but not admitted, 45% did not have a follow up appointment within four weeks of ED transfer.

CONCLUSIONS: Patients transferred from UIM to the ED most often needed medical care beyond what could be offered in clinic. Almost half of transferred patients were admitted to the hospital. Improving direct admissions from outpatient clinics, improving delivery of urgent subspecialty evaluation and extending hours for imaging services may reduce unnecessary ED transfers. As with hospital discharge, patients transferred from clinic to the ED need close follow up appointments.

OVERLAP BETWEEN ACCOUNTABLE CARE ORGANIZATIONS AND BUNDLED PAYMENTS AND THE IMPACT ON PATIENTS

Amol S. Navathe[1,5]; Joshua M. Liao[2]; Erkuan Wang[5]; Ulysses Isidro[3]; Jingsan Zhu[5]; Deborah Cousins[5]; Rachel M. Werner[4]. [1]Leonard David Institute of Health Economics, Philadelphia, PA; [2]Department of Medicine, University of Washington, Seattle, WA; [3]Medical School, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA; [4]Department of Medicine, University of Pennsylvania and Philadelphia VA, Philadelphia, PA; [5]Department of Medical Ethics and Health Policy, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA. (Control ID #3390635)

BACKGROUND: Growing participation in alternative payment models leads to overlap in which beneficiaries can receive uncoordinated care under different models. Medicare policy currently does not incentivize overlap and may inadvertently penalize participants in prominent models such as bundled payments and accountable care organizations (ACOs). For example, bundled payment participants are favored in distributions of savings when beneficiaries overlap in ACOs. However, it is unknown if ACO- bundle overlap improves patient outcomes versus participation in a single model.

METHODS: We used 2013-2016 Medicare claims data for all Medicare fee-for-service beneficiaries hospitalized at all US hospitals. We determined patients' ACO status (based on attribution in the Medicare Sharing Savings Program) and bundled payment status (based on admission to a hospital participating in one of the 48 medical and surgical episodes in Medicare's Bundled Payments for Care Improvement Initiative). Overlap was defined as being attributed to an ACO and receiving care at a bundled payment hospital. We used difference-in-differences and ordinary least squares regression with hospital and ACO fixed-effects to evaluate whether overlap patients had differentially better outcomes than non-ACO-attributed patients treated at bundled payment hospitals. Our primary outcome was institutional post-acute care spending. Secondary outcomes were unplanned readmissions, mortality, discharge to institutional post-acute care, skilled nursing facility [SNF] length of stay, and discharge with home health.

RESULTS: The sample included 9,850,080 Medicare fee-for-service beneficiaries. In adjusted analysis for the 24 medical episodes, there was lower institutional post-acute spending among Overlap patients vs. non-ACO patients hospitalized at bundled payment hospitals (-$507 vs. -$191, p=0.03). Overlap patients also had lower SNF length of stay (-0.8 days vs. -0.4 days, p=0.02) and 90-day unplanned readmissions (-1.1% vs. -0.1%, p=0.001). While patients hospitalized at bundled payment hospitals for a medical episode were more likely to be discharged with home health, there were no differential changes by Overlap status. Among the 24 surgical episodes, institutional post-acute care spending did not differ by overlap status (-$789 vs. -$676, p=0.25). However, compared to non-ACO patients, Overlap patients hospitalized at bundled payment hospitals for surgical episodes had lower 90-day unplanned readmissions (-1.5% vs. -0.7%, p=0.001). While hospitalization at bundled payment hospitals for a surgical episode was associated with lower institutional post-acute care use and higher home health use, these differences did not vary by Overlap status.

CONCLUSIONS: ACOs and bundled payments may prompt participating organizations to implement different, complementary processes that improve outcomes for patients receiving overlapping care for both medical and surgical episodes. Policymakers may consider revising current policies to encourage overlap.

PATIENT ACTIVATION AND MHEALTH INTERVENTIONS DECREASED CARDIOVASCULAR DISEASE RISK FOR DIABETIC PATIENTS: THE OFFICE-GUIDELINES APPLIED TO PRACTICE PROGRAM.

Ade B. Olomu[1]; Zane Alroshood[2]; Ling Wang[1]; Richa Tikaria[1]; Amari Ellsworth[1]; Karen Kelly-Blake[3]; William Hart-Davidson[4]; Margaret Holmes-Rovner[5]. [1]Medicine, Michigan State University, East Lansing, MI; [2]Department of Medecine, Michigan State University, East Lansing, MI; [3]Center for Ethics and Department of Medicine, Michigan State University, East Lansing, MI; [4]College of Arts & Letters, Michigan State University, East Lansing, MI; [5]Center for Ethics, Michigan State University, East Lansing, MI. (Control ID #3390549)

BACKGROUND: Cardiovascular disease (CVD) deaths in patients with type 2 diabetes mellitus (T2DM) are 2-4 times higher than among those without T2DM. A key contributor is medication non-adherence. Our objective was to determine the impact of a patient activation program (Office-Guidelines Applied to Practice [Office-GAP]) plus mHealth intervention compared to mHealth alone in improving medication use and decreasing atherosclerotic CVD (ASCVD) risk score in patients with T2DM.

METHODS: Office-GAP included: 1) Patient activation group visit 2) Physician training for patient activation, and 3) Decision support checklist used in *real time* in the office. mHealth included teaching patients to send and receive text messages; patients received daily messages appropriate to their diagnosis for 14 weeks, along with appointment and medication reminders. Participants were diabetic patients with A1c>8 or uncontrolled hypertension (BP >130/80) attending Internal Medicine Residency Clinics. Patients were consecutively assigned to combined Office-GAP + mHealth group (Combined Intervention Arm/Green group) or mHealth only group (mHealth only Arm/White group) based on resident clinic designation. After a group visit, patients followed up with two physician visits over a 4-month period. Fifty-one (25 Green Team/26 White Team) patients who completed the pilot study were evaluated for evidence-based medication (EBM [Aspirin, Statin and ACEI/ARBs]) use for secondary prevention of heart disease. Additionally, ASCVD risk score at baseline and 4 months post intervention was determined. We evaluated only patients eligible for each medication use. Generalized Estimating Equation (GEE) regression model was used for statistical analysis controlling for gender, race, Charlson Index and other demographics.

RESULTS: Of 51 patients that completed the pilot study, statin use [OR=1.26 for Green; p=0.42 and OR=2.32 for White; p<0.01], aspirin use [OR=3.16 for Green; p=0.04 and OR=4.02 for White; p=0.03], and ACEI/ARBs use [OR=1.81 for Green; p=0.57 and OR=3.86 for White; p=0.08] increased over four months for both groups. There were no significant differences between Green and White group for EBM use. At four months follow-up, ASCVD risk scores decreased for both groups: 3.23 points for Green; p=0.05 and 3.98 points for White; p=0.01. We found no significant difference between both groups regarding decreased ASCVD risk score. Black participants had 6.62 points higher ASCVD score compared with White counterparts; p=0.01. ASCVD risk score increases with age (on average 1.01 points higher per year; p<0.01).

CONCLUSIONS: Office-GAP + mHealth and mHealth only interventions improved EBM use. There was no significant difference in impact of Office-GAP + mHealth compared to mHealth only on EBM use at

4months. Office-GAP and mHealth both decreased ASCVD risk scores by >3 points on average, while there is no statistical difference between both groups regarding decreased ASCVD risk score.

PATIENT ATTITUDES TOWARD SUBSTANCE USE SCREENING AND DISCUSSION IN PRIMARY CARE ENCOUNTERS

Leah Hamilton[1]; Sarah E. Wakeman[2]; Timothy WIlens[5]; Joseph Kannry[6]; Richard N. Rosenthal[7]; Keith Goldfeld[1]; Angeline Adam[1]; Noa Appleton[1]; Sarah Farkas[3]; Carmen Rosa[8]; John Rotrosen[4]; Jennifer McNeely[1,9]. [1]Population Health, NYU School of Medicine, New York, NY; [2]Medicine, Massachusetts General Hospital, Charlestown, MA; [3]Psychiatry, NYU School of Medicine, New York, NY; [4]NYU School of Medicine, New York, NY; [5]Psychiatry, Massachusetts General Hospital, Boston, MA; [6]Division of General Internal Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; [7]Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY; [8]Center for the Clinical Trials Network, National Institute on Drug Abuse, Bethesda, MD; [9]Medicine, Division of General Internal Medicine and Clinical Innovation, NYU Grossman School of Medicine, New York, NY. (Control ID #3390672)

BACKGROUND: Alcohol and drug use are often under-identified in primary care settings. While prior research indicates that patients are generally supportive of alcohol screening, less is known about attitudes toward drug screening or the collection of this information in electronic health records (EHRs). As a part of an implementation study of EHR-integrated substance use screening in primary care, conducted in the NIDA Clinical Trials Network, patients were surveyed on their attitudes toward screening for substance use during medical visits.

METHODS: Surveys were administered to patients in four urban academic primary care clinics on a quarterly basis, for one year following the introduction of a screening program. English-speaking adult patients presenting for a primary care visit were eligible. Participants were recruited from the waiting room and self-administered an 18-item survey exploring attitudes toward screening and discussing substance use with healthcare providers.

RESULTS: A total of 479 patients completed the survey (mean age 54.1; 58% female; 58% white, 23% black; 19% Hispanic/Latino). Participants overwhelmingly felt that they should be asked about their substance use (91%), and deemed it appropriate for their doctor to recommend reducing use if it could adversely affect their health (92%). Most (87%) were equally comfortable discussing alcohol or drug use. A majority (63%) preferred discussing substance use with their doctor over other medical staff. Responses were mixed regarding screening modality: 55% preferred face-to-face, 22% had no preference, 14% preferred self- administration. Participants reported that they would be honest with their provider (94%), but 32% were concerned about medical record confidentiality.

CONCLUSIONS: Primary care patients strongly supported being screened for drug and alcohol use, and would be comfortable discussing it with their doctor. However, patients' concerns about having their substance use documented in their medical record could pose a barrier to achieving accurate responses. These findings suggest a need to educate patients on the confidentiality of medical records and the value of disclosing substance use for their medical care.

PATIENT-CENTERED MEDICAL HOME (PCMH) TEAMS' USE OF RESOURCES AND STRATEGIES FOR IDENTIFYING AND MANAGING HIGH-RISK PATIENTS IN PRIMARY CARE

Susan E. Stockdale[1]; Evelyn T. Chang[2]; Donna M. Zulman[3]; Michael McClean[1]; Danielle Rose[4]; Lucinda B. Leung[5]; Gregory Stewart[7]; Karin M. Nelson[6]. [1]HSR&D Center of Excellence, Greater Los Angeles VA Healthcare System, Sepulveda, CA; [2]General Internal Medicine, VA-Greater Los Angeles, Los Angeles, CA; [3]Internal Medicine, Stanford University and VA Palo Alto, Stanford, CA; [4]VA HSR&D Center for the Study of Healthcare Provider Behavior, VA GLA Healthcare System, Sepulveda, CA; [5]Division of General Internal Medicine, UCLA David Geffen School of Medicine & West LA VA Medical Center, Los Angeles, CA; [6]Department of Medicine, University of Washington, VA Puget Sound, Seattle, WA; [7]University of Iowa, Iowa City, IA. (Control ID #3389823)

BACKGROUND: Most high-risk patients are managed in primary care, but primary care teams may not be well equipped or have training specific to this population. Patient-Centered Medical Home (PCMH) teams may be better equipped and trained, but little is known about which resources PCMHs find important for identifying these patients, which care management strategies they use, and whether use varies by team member role.

METHODS: We analyzed a national primary care personnel survey, fielded within Veterans Health Administration (VHA) July-September 2018. Respondents included primary care providers (PCPs: medical doctors, nurse practitioners, physician assistants), registered nurses (RNs), clinical associates (licensed practical nurses, medical assistants), clerical associates, social workers, pharmacists, behavioral health providers, nutritionists, health educators (n=5,803, 17.7% response rate). Respondents rated importance (3- point Likert scale) of 11 factors/population health management tools to identify high-risk patients and how likely (5-point Likert scale) they were to use 6 care management approaches. We conducted univariate and bi-variate analyses by role to understand which tools and approaches respondents found most important and useful.

RESULTS: Recent ER visits/hospitalizations (70%), specific medical/mental health diagnoses (57%), and specific prescription medicines (47%) were rated most important for identifing high-risk patients. RNs were significantly more likely than PCPs to report that the VA risk prediction algorithm (48% vs 31%), case management software (28% vs 16%), and quality dashboard (56% vs 32%) were very important. For help with managing their high-risk patients, a majority reported being likely/very likely to consult with specialists (90%), to request help from PCMH social workers, pharmacists, behavioral health, etc. (88%), and to refer to VA programs/services outside of PCMH (84%). A lower percentage reported being likely/very likely to discuss management of these patients with the PCMH team (68%) or for a specific team member to review and make care plans (64%). A lower percentage of PCPs reported being likely/very likely to use any strategies, compared with other disciplines.

CONCLUSIONS: PMCH team members find markers of patient utilization (ER visits, hospitalizations) especially useful for identifying high-risk patients as compared with other resources. In the PCMH, non-physician team members such as RN care managers could play a larger role in identifying high-risk patients, potentially avoiding costly emergency room or inpatient admissions. PCMH team members' reliance on clinicians and resources outside of the core PCMH team to manage high-risk patients suggests they lack the time or expertise to provide complex care management. Future research should explore what design features of specific tools and resources would make them more valuable/useful to PCMH teams, and what supports outside PCMH are needed to better manage care for high-risk patients.

PATIENT COMFORT AND EXPERIENCES WITH SCREENING FOR SOCIAL ISOLATION IN PRIMARY CARE SETTINGS

Elizabeth L. Tung[1]; Emilia De Marchis[2]; Laura M. Gottlieb[2]; Stacy T. Lindau[3]; Matthew S. Pantell[4]. [1]Section of General Internal Medicine,

University of Chicago, Chicago, IL; [2]Family & Community Medicine, University of California, San Francisco, San Francisco, CA; [3]Obstetrics/Gynecology and Geriatrics, University of Chicago, Chicago, IL; [4]Pediatrics, University of California, San Francisco, San Francisco, CA. (Control ID #3372914)

BACKGROUND: Social isolation is a key predictor of mortality that disproportionately affects vulnerable populations in the United States. Recently, some public health officials have declared social isolation a health epidemic, prompting accelerated support for routine screening in clinical settings. However, no studies to our knowledge have examined patients' comfort levels and prior experiences with screening for social isolation in the real world, nor whether current screening practices are associated with the levels of social isolation experienced.

METHODS: Adults (N=251) were recruited from 3 primary care clinics in Boston, Chicago, and San Francisco to complete a one-time survey. Surveys included a modified version of the Berkman-Syme Social Network Index (SNI), a screening tool endorsed by the National Academy of Medicine, as well as additional items to assess for comfort level and prior experiences with screening for social isolation. SNI scores ranged from 1 to 4, with 1 representing the highest level of social isolation and 4 representing the lowest level. We used ordinal logistic regression models to examine SNI levels as a function of screening characteristics (prior screening, discomfort with screening, desire for assistance, prior assistance), adjusting for age, gender, education, race/ethnicity, self-reported health status, and clinic.

RESULTS: In the sample population, 12% reported the highest level of social isolation (SNI=1), compared to 37% (SNI=2), 35% (SNI=3), and 16% (SNI=4; lowest level) at each respective level. While 94% reported no discomfort with screening for social isolation, only 12% reported having been asked about social isolation in a healthcare setting in the past 12 months. Discomfort with screening and participation in prior screening for social isolation were not associated with the level of social isolation experienced. However, having other social risks was associated with higher reports of isolation. For instance, difficulty paying for material needs (AOR=2.0; 95% CI, 1.1-3.8) and safety concerns due to intimate partner violence (AOR=2.9; 95% CI, 1.2-7.4) were both associated with a higher level of social isolation. Having a desire for assistance with social isolation was associated with a higher level of social isolation (AOR=6.0, 95% CI, 1.3-28.8), and also associated with 9.1 times higher adjusted odds (95% CI, 1.3-64.1) of fair or poor health, relative to those reporting good or better health.

CONCLUSIONS: Social isolation is a growing public health concern that is relevant to clinical decision- making. In this study, few patients reported being screened for social isolation, despite low levels of discomfort with screening. Sicker and more isolated patients expressed higher levels of interest in assistance. Future work should explore strategies to support clinical screening and other interventions related to social isolation.

PATIENT EXPERIENCE-BASED PHYSICIAN COMPENSATION AND QUALITY OF CARE IN THE UNITED STATES, 2012-2016

David Burstein, David T. Liss, Jeffrey A. Linder. Division of General Internal Medicine and Geriatrics, Northwestern University Feinberg School of Medicine, Chicago, IL. (Control ID #3391868)

BACKGROUND: Patient experience measures have increasingly been used in determining physician compensation. Ideally, patient experience-based physician compensation incents care that is timely, coordinated, and patient-centered. However, physicians express concern that patient experience-based compensation is a cause of stress and burnout; draws attention away from high-value preventive or chronic care; and incents low value care, like inappropriate antibiotic and opioid prescribing. However, the relationship between patient experience-based physician compensation and clinical quality is poorly understood.

METHODS: We performed a retrospective, cross-sectional visit-level analysis of ambulatory visits by adults to primary care physicians from the National Ambulatory Medical Care Survey (NAMCS) from 2012-2016.

We examined 7 measures of low value care (e.g., antibiotics for upper respiratory infections) and 10 measures of high value care (e.g., statins for diabetes) based on national clinical guidelines. We used Pearson's Chi Square test to assess the association of patient experience-based physician compensation with measure performance. To evaluate the independent association between patient experience-based compensation and performance, we used multivariable logistic regression with adjustment for year, patient sex, age, race/ethnicity, number of chronic diseases, primary source of payment, physician specialty, region of practice, practice size, physician ownership/employment status, and electronic medical record capabilities.

RESULTS: Between 2012 and 2016, there were 1.45 billion visits were made nationally by adults to primary care physicians from 2012-2016 and 16.8% of these visits were to physicians with patient experience-based compensation. Physicians with patient experience-based compensation performed significantly better on 3 of 17 measures than physicians without patient experience-based compensation: unnecessary cardiac screening at preventive visits (6% versus 9%; $p = 0.05$); HgbA1c < 8% in diabetes (66% versus 54%; $p < 0.01$); and A1c within last 12 months in diabetes (47% versus 39%; $p = 0.02$). In multivariable models, patient experience-based compensation was associated with better performance on only 1 of 17 measures: unnecessary cardiac screening (adjusted odds ratio [aOR], 0.62; 95% confidence interval [CI], 0.40 to 0.96). Patient experience-based physician compensation was not significantly associated with quality of care for 16 of 17 measures, which included antibiotic prescribing for upper respiratory infections (52% versus 56%; aOR, 1.00; 95% CI, 0.58 to 1.71), opioid prescribing for low back pain (4% versus 8%; aOR, 0.66; 95% CI, 0.30 to 1.47), statin prescribing for patients with diabetes (45% versus 41%; aOR, 1.01; 95% CI, 0.73 to 1.40), and control of blood pressure in patients with hypertension (77% versus 76%; aOR, 0.88; 95% CI, 0.67 to 1.16).

CONCLUSIONS: Patient experience-based compensation was generally not associated with better or worse quality of care.

PATIENT EXPERIENCES WITH A PATIENT-CENTERED MEDICAL HOME TEAM TAILORED FOR VETERANS WITH SERIOUS MENTAL ILLNESS

Alicia Bergman[1]; Alexander S. Young[2]; Rebecca Oberman[4]; Evelyn T. Chang[3]; Merlyn Vinzon[2,4]; Amy N. Cohen[4]. [1]Center for the Study of Healthcare Innovation, Implementation & Policy, VA Greater Los Angeles, North Hills, CA; [2]Psychiatry, VA & UCLA, Los Angeles, CA; [3]General Internal Medicine, VA- Greater Los Angeles, Los Angeles, CA; [4]MIRECC, Greater Los Angeles VA Healthcare Center, Los Angeles, CA. (Control ID #3392249)

BACKGROUND: Patients with serious mental illness (SMI) such as schizophrenia receive a disproportionately low amount of preventative

medical services and have higher rates of mortality compared to the general population. Due to associated cognitive deficits, a unique challenge facing primary care providers (PCPs) is making specific adaptations in caring for this population. The VA piloted a specialized medical home "Patient-Aligned Care Team" for patients with SMI, called SMI PACT, to address these issues and improve outcomes. We used qualitative analysis to understand patient experiences in comparison to previous medical home experiences.

METHODS: A SMI PACT team was piloted at a VA medical center to provide patient care for 13 months. Patients received integrated primary and mental health care by a PCP, supported by a nurse and consulting psychiatrist. The team was provided training on how to work with this population. Semi-structured interviews were conducted post-implementation with 28 SMI PACT patients. Interviews were recorded, professionally transcribed, and coded prior to qualitative thematic analysis.

RESULTS: Patients mostly described positive experiences with SMI PACT. Many patients (n=16) mentioned caring interpersonal qualities displayed by SMI PACT providers, individualized care (n=11), good follow-up (n=10), and providers using repetition and/or easy-to-understand language (n=8). Caring interpersonal qualities included good listening (undivided attention, eye contact), showing concern, "warmth", being non-judgmental, kind, conveying genuine interest in the patient, and being patient and not pressuring. SMI-PACT providers were described as taking more individualized (not "cookie cutter") approaches than they had experienced with prior providers in the general primary care setting, i.e., asking more questions, taking time to go over apprehensions, and reviewing patient notes prior to the appointment. They recounted experiencing an overall greater amount of communication (e.g., receiving proactive check-in calls in between appointments, post-hospital or emergency room discharge, and after tests). Patients also described appreciating how SMI-PACT providers used simplified language ("explaining everything in laymen's terms"), repeated or rephrased sentences, and gave print-outs, charts, and pamphlets. There were a few instances of negative experiences regarding the SMI PACT model; one patient felt that a psychiatrist signature on paperwork would carry more weight than that of a SMI-PACT PCP, and another patient who chose the integrated model experienced a dip in confidence when the PCP could not answer a psychiatric question and had to confer with the consulting psychiatrist.

CONCLUSIONS: Patients identified provider characteristics and behaviors that informed an overwhelmingly positive impression of the program model and their experiences. Our findings may help with guiding similar primary care models for SMI, as well as other specialized services for patients with SMI.

PATIENT-LEVEL BARRIERS AND FACILITATORS TO COLLABORATIVE CARE ENGAGEMENT: A QUALITATIVE STUDY

Melissa Dong[1]; Ludwing Florez Salamanca[2]; Vivian Medina[6]; Yenilshia Firpo-Greenwood[6]; Eileen Carter[3]; Sujata Malhotra[5]; Nathalie Moise[4]. [1]Center for Behavioral Cardiovascular Health, Columbia University Irving Medical Center, New York, NY; [2]Department of Psychiatry, Columbia University Irving Medical Center, New York, NY; [3]School of Nursing, Columbia University Irving Medical Center, New York, NY; [4]Department of Medicine, Columbia University Medical Center, New York, NY; [5]Ambulatory Care, Columbia University Irving Medical Center, New York, NY; [6]Independent LCSW, Norwalk, CT. (Control ID #3390406)

BACKGROUND: Recent research suggests patient engagement is a key barrier to sustaining collaborative care (CC) models for depression. Few studies have examined patient perspectives of CC in mature programs, particularly among minority patients. We sought to examine patient-level barriers and facilitators to engaging in CC in settings treating minorities already implementing integrated care models.

METHODS: We conducted focus groups and semi-structured interviews with patients (n=12) attending an academic primary care clinic in Northern Manhattan who had been referred to the CC program (enrolled (n=8) and no-show patients (n=4)). The interview guide and preliminary codebook were informed by the Theoretical Domains Framework (TDF). Two independent coders (MD, LS) coded relevant TDF constructs in the context of CC engagement using content analysis in NVIVO 12.

RESULTS: All participants were female and identified as either Hispanic, Black, or both. Patients most often endorsed opportunities as primary drivers of CC engagement, such as social influences and environmental resources. Enrolled patients referred proportionally more to stigma and poor insight as barriers, while no- show patients expressed treatment-related fear/anxiety and beliefs that treatment is ineffective. Enrolled patients referenced accessibility and quality of care (e.g. effective care managers) as facilitators, while no- show patients discussed education of treatment options as a potential facilitator. All participants, including "no shows" described the program as highly acceptable and seemed open to technology-delivered facilitators.

CONCLUSIONS: Any setting implementing CC, specifically those treating minorities, should consider psychoeducation at the time of referral to address barriers e.g., fear of treatment or perceived inefficacy for no-show patients. Emphasizing convenience and quality of care (i.e., effective care management) may be key to increasing long-term adherence for patients already engaged in more mature programs. Leveraging technology may also facilitate engagement and retention.

PATIENT PERCEPTIONS OF FACTORS CONTRIBUTING TO HIGH HOSPITAL UTILIZATION: A QUALITATIVE STUDY OF YOUNG WOMEN ENROLLED IN AN INPATIENT GENERAL MEDICINE HIGH UTILIZER PROGRAM

Mika Schwartz, Gabrielle Mezochow, Judy A. Shea, Kirstin Knox. Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA. (Control ID #3388385)

BACKGROUND: Patients who are frequently admitted to the hospital are a vulnerable population, facing medical, social, and behavioral health challenges that are compounded by discontinuity between hospital admissions and care settings. At the Hospital of the University of Pennsylvania, the multidisciplinary STEP program works intensively with the most frequently admitted patients on the inpatient general medicine service (minimum of 5 but often 10-30 admissions per year). Over half of enrollees are 18-35 years old, and of these, over 80% are women. This study aims to better understand the perceptions and experiences of this important subset of the high utilizer population.

METHODS: In depth, semi-structured interviews were carried out with 11 women ages 18-35 who are currently or previously enrolled in the STEP program. 15 patients were identified as eligible for the study and 11 interviews were completed. Interviews were conducted by two medical students trained in qualitative interviewing. Most interviews took place in-person, during hospital admissions, with the remainder conducted over the phone. Questions were open-ended, designed to identify drivers of frequent

hospitalizations, patients' experiences with transition from pediatric to adult care, and patient perceptions of how their care could improve. Interviews were audio recorded, transcribed, coded, and thematically analyzed.

RESULTS: Of patients interviewed, 64% have a primary diagnosis of sickle cell disease. Two major themes emerged: challenges in communication with inpatient care teams and difficulties with the transition from pediatric to adult care. Patients feel stigmatized by providers, particularly in regard to pain management.

They feel their providers do not adequately involve them in clinical decision making and that they are discharged before their pain is adequately controlled. All but one patient experienced difficulty transitioning from pediatric to adult care. Patients described strong alliances with pediatric providers, who they felt were more understanding of their needs. Study participants experienced fragmentation in care when transitioning to adult providers, facing delays and confusion when establishing a new outpatient team. Over 70% of participants reported 2 or more Adverse Childhood Experiences, with an average of 3.6 experiences.

CONCLUSIONS: Based on the findings in this study, patient centered interventions aimed at improving care for young patients with high rates of readmission should focus on improving communication and shared decision making between patients and providers. Another crucial area for improvement is the transition from pediatric to adult care. This transition represents a vulnerable time, during which these high-risk patients would benefit from additional structure and support to establish a strong relationship with a new care team. A history of adverse childhood experiences may be useful in identifying pediatric patients who require additional support during transition to adult care.

PATIENT PERCEPTIONS OF THE USE AND VALUE OF BLOOD GLUCOSE SELF- MONITORING IN ABSENCE OF INSULIN

Sidra Speaker[1]; Elizabeth Pfoh[2]; Anita D. Misra-Hebert[3]; Michael B. Rothberg[3]. [1]Education, Cleveland Clinic Lerner College of Medicine at Case Western Reserve University, Cleveland Heights, OH; [2]Medicine, Cleveland Clinic, Cleveland, OH; [3]Internal Medicine, Cleveland Clinic, Cleveland, OH. (Control ID #3391170)

BACKGROUND: SGIM has identified self-monitoring of blood glucose (SMBG) for patients with type 2 diabetes not on insulin as low value care. Advocates cite behavior change promotion and patient preference as reasons for SMBG, while clinical trials show SMBG to be associated with psychological burden. We sought to understand how SMBG affects such patients, how they use SMBG, and how they value it.

METHODS: We developed a survey based on interviews with physicians, literature review, and expert opinion. Survey questions included demographic information, diabetes characteristics (e.g. duration of disease), SMBG practices (e.g. frequency of use; who told them to start SMBG), health behaviors (e.g. changing diet in response to blood glucose) and value of SMBG (effect on worry about diabetes; whether they would stop SMBG if a physician said they could). We administered online and in-person surveys in 2018-19 to adults with type 2 diabetes who use SMBG and were seen by a Cleveland Clinic primary care physician in the prior year, excluding patients taking insulin.

We used a logistic regression to evaluate the association between demographic factors, diabetes characteristics, SMBG practices and desire to stop SMBG.

RESULTS: Overall, 249 (98 in-person [response rate 64%] and 151 online [response rate 17%]) patients completed the survey; 51% were female, 46% were ≥65 years, 34% were black, and 44% had at least an associate's degree. Individuals who responded online vs in-person had similar SMBG use characteristics: 57% had diabetes > 5 years and 3% for ≤ 6 months. Most (91%) were instructed by a doctor to initiate SMBG; 57% said a doctor checked their readings and 25% said no one did. Over half (55%) used SMBG at least daily, and 23% used it ≥2x/day. Most used SMBG first thing in the morning (80%), and some did before (24%) or after (21%) meals. In response to SMBG readings, 60% changed eating habits and 26% changed physical activity. Only 5% reported that SMBG worsened their quality of life, while 62% reported that SMBG improved it; 45% felt it reduced their worry about diabetes and 28% that it increased worry.

The most common reasons for using SMBG were "My doctor wants me to" (66%), "To see if my diabetes medication is working" (64%), "To see what the number is" (63%), "To feel more in control of my diabetes" (52%), "To avoid damaging my body" (47%), and "I was told to" (47%). Half of respondents (52%) said they would stop SMBG if their doctor told them they could. In the adjusted regression model, respondents who performed SMBG at least daily were less willing to stop than others (AOR 0.46, 95% CI 0.26-0.82).

CONCLUSIONS: Despite evidence from randomized trials that SMBG does not improve glucose control and reduces quality of life, many patients value it. Letting patients know they can stop might reduce SMBG by half, but many patients, particularly those who check their sugars frequently and incur the highest costs, will need other reasons to stop.

PATIENT PERSPECTIVE OF TARDIVE DYSKINESIA: RESULTS FROM A SOCIAL MEDIA LISTENING STUDY

Leslie Lundt[1]; Mallory Farrar[2]; Erica Franey[2]; Chuck Yonan[2]. [1]Clinical Development, Neurocrine Biosciences, Inc., San Diego, CA; [2]HEOR, Neurocrine Biosciences, Inc., San Diego, CA. (Control ID #3386708)

BACKGROUND: Tardive dyskinesia (TD) is a persistent and potentially disabling movement disorder associated with prolonged exposure to dopamine receptor blocking agents such as antipsychotics. With the expanding use of antipsychotics, research is needed to better understand patient perspectives of TD, which clinical assessments may fail to capture. This is the first study to use a social media listening (SML) analysis of unsolicited patient and caregiver insights from various social media sources to help clinicians understand how patients describe their symptoms, the emotional distress associated with TD, and the impact on caregivers.

METHODS: In this retrospective, observational study, a comprehensive search was performed for publicly available, English-language, online content posted between March 2017 and October 2019 on social media platforms, blogs, and forums. A social media analytics platform, NetBase, identified posts containing patient or caregiver experiences of assumed TD with a set of pre-defined search criteria (inclusion/exclusion). All posts were then manually curated and reviewed to ensure quality and validity of the post and to further classify key symptoms, sentiments, and themes.

RESULTS: A total of 210 posts from patients or caregivers ("patient insights") were identified for manual review; 107 posts were used for these analyses. Posts were from forums (47%), Twitter (33%), Instagram (7%), Tumblr (5%), blogs (5%), and other online

sources (3%). The most common disease characteristics and affected body areas described in posts included: movements, tongue, twitching, face, tremor and tic. A majority of posts (64%) had a negative sentiment; 33% were neutral and 3% were positive. The most common emotional sentiments included: worse/worst, bad, horrible, pain and difficult. Theme analysis revealed that TD often caused patients to feel angry about having TD from a medication that was for a different condition. In addition, patients felt insecure and that TD made them feel ugly, weird, and uncomfortable in their skin.

CONCLUSIONS: The patient perspective generated from analyzing social media can help in understanding the needs of a heterogeneous patient population with TD. The analysis of patients with assumed TD with SML indicated the most common concern for patients are their symptoms which result in strong feelings of anger and insecurity.

PATIENT PERSPECTIVES ABOUT HEALTHCARE SCREENING FOR GUN POSSESSION AND EXPOSURE TO NEIGHBORHOOD VIOLENCE

Madison R. Wilson[1]; Nichole Smith[1]; Monica E. Peek[2]; Elizabeth L. Tung[2]. [1]Pritzker School of Medicine, University of Chicago, Chicago, IL; [2]Section of General Internal Medicine, University of Chicago, Chicago, IL. (Control ID #3379736)

BACKGROUND: Gun violence is increasingly recognized as a social determinant of health, associated with negative patient outcomes, but whether or not physicians should intervene remains fiercely contested. While some states have enacted laws that limit physicians' ability to screen for gun possession, multiple medical associations encourage physicians to do so. Few studies, if any, have examined patient perspectives about healthcare screening for gun possession and exposure to neighborhood violence.

METHODS: 40 patients, aged ≥35 years, were recruited from a Chicago primary care clinic to participate in a one-time, qualitative study. In-depth, semi-structured focus groups and interviews were used to elucidate patients' experiences with and perspectives regarding healthcare screening for gun possession/safety and exposure to neighborhood violence. Focus groups were transcribed verbatim from audio recordings and analyzed for major themes using grounded theory and the constant comparison method.

RESULTS: The mean age was 60.7±10.8 years. Patients were predominantly female (67.5%) and Black (90%). Almost one-quarter (22.5%) reported possession of any firearm. Many reported prior experiences with violence as a direct victim (47.5%), witness (36.8%), or close friend or family member of someone who died violently (42.1%). Very few had discussed gun possession/safety (5.3%) or exposure to neighborhood violence (7.9%) with a healthcare provider. Many barriers to and benefits of screening were identified. Most notably, patients shared concerns about discrimination, stigma, and encounters with the criminal justice system, one stating, "If the doctor asks [about guns], patients will think they're going to get locked up." Other major themes included insufficient time to screen during patient encounters and the providers' ability to effectively intervene. Although themes overlapped, patients voiced stronger concerns about screening for gun possession compared to violence exposure, particularly given fears regarding the sharing of gun possession data between healthcare systems and legal systems. One-third (34.2%) reported that screening for gun possession/safety was never appropriate compared to less than one-quarter (21.6%) for exposure to neighborhood violence. Participants acknowledged some benefits to screening, for instance, identifying patients at risk for trauma, suicide, and other mental health concerns. One noted, "Every illness ain't a physical thing. Some things are mental and sometimes…you have left over feelings from what happened to you from the violence."

CONCLUSIONS: Although patients described important benefits related to healthcare screening for gun possession and violence exposure, many voiced concerns, especially related to screening for gun possession. Emergent themes may serve as targets for making screening more acceptable for all patients.

PATIENT PERSPECTIVES ON RECEIVING TREATMENT FOR TOBACCO, ALCOHOL, OR OPIOIDS IN HIV CLINICS

Kenneth Morford[1]; David A. Fiellin[1]; Philip Chan[3]; Deborah Cornman[4]; Srinivas Muvvala[2]; Benjamin Oldfield[2]; Jessica Yager[5]; E. Jennifer Edelman[1]. [1]Internal Medicine, Yale School of Medicine, New Haven, CT; [2]Yale School of Medicine, New Haven, CT; [3]Infectious Disease, Brown School of Medicine, Providence, RI; [4]University of Connecticut, Hartford, CT; [5]Internal Medicine, SUNY Downstate, New York, NY, Afghanistan. (Control ID #3391809)

BACKGROUND: Screening and treatments for substance use disorders (SUD) involving tobacco, alcohol and opioids are inconsistently provided in HIV clinics. To explore patient perspectives on factors impacting receipt of evidence-based SUD treatment, we conducted focus groups with patients receiving HIV treatment in four HIV clinics in the US northeast.

METHODS: From July 2017–February 2019, we conducted four focus groups at HIV clinics in Brooklyn, NY; New Haven and Hartford, CT; and Providence, RI. We purposefully invited patients with SUD and HIV receiving treatment at the participating clinics. Informed by the *Promoting Action on Research Implementation in Health Services Research (PARiHS)* implementation science framework, we sought to understand patient perspectives on *evidence* supporting SUD screening and treatment and the HIV clinic *context* for treatment delivery to inform future *facilitation* efforts to increase clinic implementation. Focus groups were digitally recorded, professionally transcribed, and independently coded by three investigators. We used directed content analysis to identify consensus-based themes. Participants completed a brief survey to assess demographic, clinical and behavioral characteristics.

RESULTS: Among the 28 participants, the mean age was 58, the majority were African American (61%), and 32% were female. Self-reported current substance use was common: 71% tobacco, 46% alcohol, 39% heroin, and 39% prescription opioids. Overall, 57% reported receiving any treatment for SUD. Regarding *evidence*: 1) patients recognized tobacco and opioid use as harmful, but reported less consistent concerns regarding alcohol's impact on health; 2) barriers to use of addiction treatment medications included lack of knowledge of their availability (i.e. alcohol treatment medications), stigma and misperceptions (i.e., opioid agonist treatment as substitution), and concerns of side effects. Regarding *context*: 1) patients had experiences with being screened for substance use, but this was inconsistently addressed in follow-up; 2) patients had favorable experiences receiving education of and treatment for substance use at their HIV clinics, particularly when provided by their HIV provider; 3) HIV clinics were recognized to include multidisciplinary teams; while patients generally endorsed the HIV clinic as a safe setting for care, educational priorities of training students and residents undermined continuity of care.

CONCLUSIONS: Efforts to implement screening and treatments for tobacco, alcohol and opioid use within HIV clinics will require a multifaceted facilitation approach that involves enhanced patient education regarding evidence, particularly of alcohol's harmful effects and treatment options; stigma reduction around medications for opioid use disorder; provider training on SUD treatments to follow-up positive screening; patient-centered care that incorporates educational training priorities; and an integrated multidisciplinary approach that offers onsite SUD treatment.

PATIENT PERSPECTIVES REGARDING THE SOCIAL AND CULTURAL ACCEPTABILITY OF A BIBLICALLY-BASED HEALTHY EATING AND WEIGHT LOSS INTERVENTION: A MIXED METHODS RESEARCH STUDY

Kirstie A. Finch[4]; Shaquita Starks[1]; Cardella L. Leak[1]; J. Carolyn Graff[2]; Satya Surbhi[3]; Sierra M. Gaffney[4]; Michelle Duncan[4]; James E. Bailey[5]. [1]University of Tennessee Health Science Center, Memphis, TN; [2]College of Nursing, University of Tennessee Health Science Center, Memphis, TN; [3]Center for Health System Improvement, Medicine, University of Tennessee Health Science Center, Memphis, TN; [4]College of Medicine, University of Tennessee Health Science Center, Memphis, TN; [5]Medicine and Preventive Medicine, University of Tennessee Health Science Center, Memphis, TN. (Control ID #3392143)

BACKGROUND: Obesity affects 32% of U.S. adults and is associated with chronic conditions of high mortality. Recent studies have demonstrated the positive impact that plant-forward low-calorie diets can have on such conditions. Memphis, TN is a medically underserved area with obesity occurring in 37% of the population. Further, Tennessee ranks 3rd highest in the nation for religious participation. This study seeks to assess the social and cultural acceptability of a biblically-based healthy eating and weight loss intervention. We specifically wanted to gauge interest in the biblically-based *Daniel Fast* in which a vegan diet is strictly followed for a 21-day initiation period. In addition, we sought to assess whether acceptability of a biblically- based diet is associated with patient religiosity.

METHODS: We used a convergent parallel mixed-methods design to collect quantitative survey and qualitative focus group data. We used a phone script to recruit participants from a regional Diabetes Wellness and Prevention Coalition practice-based research network including all adults with obesity recently seen in a religious affiliated and federally qualified health center in Memphis, TN. We collected demographic data surveys and measured religiosity using a validated scale developed by Lukwago. Participant interest level regarding a biblically-based vegan diet was examined using Likert scale survey items and in-depth semi- structured focus group discussions. All focus groups were audio recorded and transcribed. The data were systematically reviewed using NVivo 12 software to identify common themes.

RESULTS: Most participants (n=17) self-identified as African American (94%), female (65%), and Christian (82%). The mean age of participants was 49 (range 23-78). Mean participant religiosity index score was 0.84 (range .20 to 1, SD=.10). The majority of participants (88%) reported liking the biblical basis of the diet. Many participants were receptive to participating in Bible study (65%) and prayer (94%) in support of healthy eating, and 82% were open to receiving religious health-related text messages. Focus groups demonstrated that participants generally felt comfortable with their providers offering a biblically-based healthy eating program. Some Christian participants expressed uncertainty of whether peers of varying faith traditions would accept this diet. Other identified focus group themes included Parallel Spiritual and Physical Motivation and Need for Religious Inclusivity when Referencing a Clinic-based Diet.

CONCLUSIONS: This study suggests that a biblically-based diet is viewed as socially and culturally acceptable by a majority of patients. Our data indicates that obese patients in medically underserved areas of the Southern U.S. appreciate prayer, religious health-related text messages, and Bible studies as supports for healthy eating. Furthermore, this study suggests that biblically-based healthy eating and weight loss programs may be well-received by patients in many primary care settings.

PATIENT PREFERENCE DOES IMPACT INTENSITY OF CARE

David Zingmond[1]; david powell[3]; Lee A. Jennings[2]; Rachel Louie[1]; Jose Escarce[1]; Li-Jung Liang[1]; Punam Parikh[4]; Neil Wenger[1]. [1]Division of General Internal Medicine and Health Services Research, University of California, Los Angeles, Los Angeles, CA; [2]Geriatrics, University of Oklahoma, Oklahoma City, OK; [3]RAND Corporation, Alexandria, VA; [4]Division of General Internal Medicine, UCLA School of Medicine, Los Angeles, CA. (Control ID #3391743)

BACKGROUND: Patients may be maintained in health states or receive care that they do not want. Physician orders for life sustaining treatment (POLST) capture patient preferences including CPR and DNR orders. Their impact on care intensity is unknown. This study estimates the impact of POLST on one aspect – acute care hospital days.

METHODS: Retrospective study of all nursing home residents enrolled in traditional Medicare in California in 2011 using the Minimum Data Set with California Section S (required reporting of POLST) merged with Medicare hospital claims. In multivariate regression models, we estimate the conditional relationship of preferences marked on a POLST form and inpatient days. We divide each patient's year into "segments," which are defined by days between assessments, and we study the number of inpatient days per segment. Inpatient days are normalized to annual inpatient days by multiplying by 365. We regressed the outcome on whether the patient has a valid POLST and preferences marked on the POLST. Estimates are relative to the excluded category of not having a valid POLST and account for demographics, comorbidity, functional status, cognitive status (BIMS score), type of nursing home, and median household income of the zip code. We estimate using OLS weighted by the number of days in the segment. Standard errors are adjusted for individual-level clustering. We also performed stratified analyses by BIMS category.

RESULTS: 110,921 Medicare nursing home residents were studied. Among these, 42% completed a POLST (21.2% chose CPR and 20.9% chose DNR) across MDS assessments in 2011. In the overall sample, as compared to not completing a valid POLST, patients with a valid CPR order had two more hospital days, while those with a valid DNR order had one fewer hospital day. In stratified analyses, impairment moderated the impact of CPR and DNR with the least impact among the unimpaired and the most with those with the greatest impairment.

CONCLUSIONS: Overall, the specific order (CPR vs. DNR) that is put on the POLST for nursing home patients matters and potentially impacts aggressiveness of care (hospital days) as compared to not completing a POLST. Further investigation should focus on specific care received.

PATIENT RECRUITMENT: INSIGHTS FROM THE GOALS FOR EATING AND MOVING STUDY (GEM); A CLUSTER-RCT OF A HEALTH COACHING TECHNOLOGY-ASSISTED WEIGHT-LOSS INTERVENTION IN PRIMARY CARE

Lorena Velastegui[1,2]; Sandra Wittleder[3]; Alia Dixon[3]; Rosalie Grullon[1,2]; Paul Meissner[2]; Kevin Salinas[1,2]; Victoria Sweat[3]; Judith Wylie-Rosett[1]; Melanie Jay[4,5]. [1]Epidemiology and Population Health, Albert Einstein College of Medicine, Bronx, NY; [2]Montefiore Medical Center, Bronx, NY; [3]Medicine Department, Division of General Internal Medicine and Clinical Innovation, New York University School of Medicine, New York, NY; [4]Veterans Affairs New York Harbor Healthcare System, New York, NY; [5]Medicine and Population Health Department, New York University School of Medicine, New York, NY. (Control ID #3391835)

BACKGROUND: Over one-third of American adults have obesity and are at increased chronic disease risk. The Goals for Eating and Moving (GEM) protocol is a health coaching and technology-

assisted, 5A-based weight management intervention. We describe our insights recruiting and enrolling 454 patients in two different NYC healthcare systems serving diverse populations.

METHODS: This cluster-RCT trial is conducted at the VA NY Harbor Healthcare System Manhattan Campus (VA) and four Montefiore Health System Medical Groups Bronx, NY (MMG) primary care practices with the patient-centered medical home. We randomized 19 primary care teams (11 VA teams with a total of 23 providers and 8 MMG teams with a total of 31 providers) to the GEM intervention or EUC (enhanced usual care). Eligibility criteria include age 18–69 years, obese/overweight with co-morbidity, PCP visit within 2 years, and no physical/mental health contraindications.

To enroll 512 patients, we identify eligible patients via queries of electronic health records. Primary care providers receive a list of their patients and have the opportunity to exclude any patients based on medical/behavioral issues. We mail potential eligible participants a customized opt-out invitation letter and a flyer describing the study. A week later, staff attempts to follow-up with 1-3 telephone calls to assess interest in participation, screen for eligibility and schedule interested eligible patients for the baseline visit at their primary care site, where they complete the informed consent. After 3 unsuccessful telephone calls, a patient is marked as inactive for outreach.

RESULTS: From November 2017- January 2020, we identified 4,386 patients via electronic health records (1,662 VA; 2,724 MMG), mailed 4,237 invitation letters (1,588 VA; 2,649 MMG), completed 8,278 telephone calls (4,676 VA; 3,602 MMG) and enrolled 454 patients (234 VA; 220 MMG). On average, for every patient enrolled, our staff had to identify: 9 records, mail 9 letters and make 18 telephone calls. Eligible patients at the VA and MMG most reported refusal reasons were lack of interest (1) and lack of time (2) to participate in a weight management study. Reflecting the characteristics of the study sites VA (21% Hispanic; 53% non-Hispanic black; mostly male) and MMG (55% Hispanic; 37% non-Hispanic black; 62% women) our recruited sample consisted of VA (30% Hispanic; 52% non-Hispanic black; 26% women) and MMG (51% Hispanic; 49% non-Hispanic black; 83% women). The mean ±SD age of enrolled patients was VA 51.9 ±12yrs and MMG 48.7 ±11yrs.

CONCLUSIONS: Results provide support for the validity to recruit a representative sample. Although this method of recruitment can yield a demographically representative sample, results are likely to differ in unmeasured ways. Also, we provide estimates for efforts needed to recruit a diverse patient sample into a weight management study. Refusal reasons may guide future improvements in recruitment strategies to address barriers and increase intervention uptake.

PATIENTS WHO HAVE NEWLY IDENTIFIED PRE-DIABETES LOSE WEIGHT IN THE FOLLOWING YEAR

Nayyer H. Varghai[1]; Michael B. Rothberg[2]; Cassandra Nathan[2]; Elizabeth Pfoh[3]. [1]family medicine, ccf, Beachwood, OH; [2]Internal Medicine, Cleveland Clinic, Cleveland, OH; [3]Medicine, Cleveland Clinic, Cleveland, OH. (Control ID #3375039)

BACKGROUND: Obesity is the second leading cause of preventable death. Given the difficulty of weight loss, identifying opportunities to capitalize on patients' motivation can help physicians promote a healthier lifestyle. We evaluated whether developing pre-diabetes is associated with weight loss at 6 and 12 months. We chose pre-diabetes due to its close association with obesity.

METHODS: We conducted a retrospective cohort study in a large integrated health system. We included patients who saw a primary care provider between January 2016 and December 2017, were over 18 years, had a body mass index (BMI) ≥30, and Hemoglobin A1c (HbA1c) result within 45 days of a primary care visit (the "index" visit). We excluded patients who were over 65 years, were previously prescribed metformin, had a diagnosis of diabetes or pre-diabetes prior to their index visit, or had bariatric surgery within a year of the index visit. We classified patients into pre-diabetes (HbA1c 5.7 to 6.4) and control (HbA1c<5.7) groups since we hypothesized having a lab result indicating pre-diabetes is a motivating factor for weight loss. The outcomes were percent weight change at 6 and 12 months (with a 60-day window around each outcome). All data were collected from the electronic health record. The multilevel linear regression models were adjusted for patient age, sex, race, smoking and new prescription of an antipsychotic, antidepressant, metformin and/or anti-obesity medication. New prescriptions were required to occur within the first 4 months of the index date for the 6-month outcome, and within 9 months for the 12-month outcome to account for side-effects after starting a new medication. The models were clustered by physician.

RESULTS: Our study included 12,417 participants of which 42% developed pre-diabetes. The pre-diabetes group was older (49 vs 43 years), had a higher initial BMI (38 versus 37) and had a lower percentage of white (66% vs. 75%) and female (54% vs 59%) individuals, and more smokers (16% vs. 13%) ($p<0.01$ for all comparisons). Patients in the pre-diabetes group were more likely to receive metformin (5% vs. 2%, $p<0.01$) and less likely to receive an antidepressant (10% versus 11%, $p=0.02$) in the first 9 months. There was no difference in prescriptions for anti-obesity medication. In the unadjusted regressions, the pre-diabetes group lost a higher percentage of weight at 6 months (β = -0.9% vs -0.3%) and 12 months (β = -0.7% vs 0.1% weight change) ($p<0.01$). The adjusted multilevel regression models produced similar results (β = -0.9% vs -0.3% at 6 months and β = -0.7% vs 0.3% at 12 months).

CONCLUSIONS: We found that individuals with obesity who recently developed pre-diabetes lost more weight than the comparison group in the subsequent 6 and 12 months. Primary care practitioners should view sharing laboratory results indicating pre-diabetes as a "teachable moment" to promote weight loss.

PATTERNS OF INPATIENT HYPERTENSION MANAGEMENT IN OLDER ADULTS HOSPITALIZED IN THE NATIONAL VA HEALTH SYSTEM

Timothy S. Anderson[1]; Bocheng Jing[2]; Kathy Fung[2]; Shoshana J. Herzig[3]; Edward R. Marcantonio[4]; Michael A. Steinman[2,5]. [1]Medicine, Beth Israel Deaconess Medical CEnter, Jamaica Plain, MA; [2]Geriatrics, UCSF, San Francisco, CA; [3]Medicine, Beth Israel Deaconess Medical Center, Brookline, MA; [4]Beth Israel Deaconess Medical Center, Boston, MA; [5]Geriatrics / Medicine, SF VA Medical Center, San Francisco, CA. (Control ID #3391794)

BACKGROUND: Transient asymptomatic elevations of blood pressure (BP) are common in hospitalized older adults, yet no guidelines exist on inpatient management. Unnecessary exposure to antihypertensives, particularly intravenous (IV) medications, may risk adverse drug events including hypotension.

METHODS: We examined all older adults (age >=65) receiving regular care in the Veterans Health Administration (VHA) health system and who were admitted to VHA hospitals between 2015 and 2017. We excluded patients admitted to intensive care units and those admitted for cardiovascular conditions or stroke. Using inpatient VHA pharmacy and vital sign records, we examined the prevalence of elevated inpatient BPs as well as oral and IV antihypertensive administration (excluding loop diuretics). We identified prior BP control as the mean of the 3 most recent ambulatory BP recordings within the prior year. Outcomes included any exposure

to antihypertensives during hospitalization and exposure to antihypertensives within 90 minutes of an elevated BP recording.

RESULTS: We identified 220,964 hospital admissions (98% male, median age 71) to 115 VHA hospitals which met inclusion criteria. Prior to hospitalization, 77% of patients had a diagnosis of hypertension and 28% had an outpatient BP >140/90 mmHg. The majority (61%) of patients with elevated inpatient BPs had well-controlled BP prior to admission (outpatient BP<140/90 mmHg). Among the 51% of patients who had one or more inpatient BP recording >160/100 mmHg, 85% received oral antihypertensives (95,995/113,1965) and 9.5% received IV antihypertensives (7,590/113,195) during their hospital stay. The proportion of patients with elevated inpatient BPs treated with IV antihypertensives varied across hospitals, with hospital rates ranging from 1% to 31%. We next looked at clinical actions taken within 90 minutes of an elevated BP recording. Among 486,134 elevated BP recordings (systolic BP 160-179mmHg or diastolic BP 110-119 mmHg), 11% were repeated, 20% were treated with oral antihypertensives, and 1% were treated with IV antihypertensives. Among 113,112 severe hypertension recordings (systolic BP >180 mmHg or diastolic BP >120 mmHg), 20% were repeated, 27% were treated with oral antihypertensives, and 5% were treated with IV antihypertensives. In total, 39% of IV antihypertensives were given following a severe hypertension recording, 31% following an elevated BP recording, and 30% following a BP<160/90 mmHg.

CONCLUSIONS: The majority of older adults hospitalized for non-cardiovascular conditions in the VHA health system experienced elevated inpatient BPs. Nearly 1 in 10 patients with elevated BPs received IV antihypertensives indicating there is a critical need to understand the benefits and harms of this common practice.

PATTERNS OF MEDICAL CANNABIS USE AMONG ADULTS WITH CHRONIC PAIN AND OPIOID USE

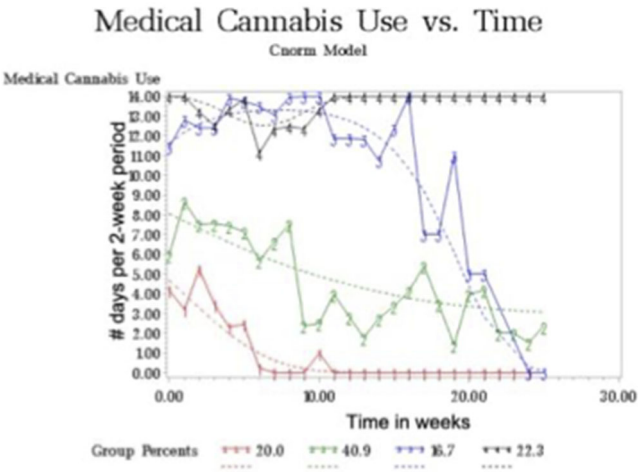
Deepika Slawek[1,2]; Chenshu Zhang[4]; Julia H. Arnsten[1]; Joanna L. Starrels[4]; Frances Levin[3]; Nancy Sohler[7]; Haruka Minami[5]; Chinazo Cunningham[6]. [1]Medicine, Albert Einstein College of Medicine, Bronx, NY; [2]Medicine, Montefiore Medical Center, Bronx, NY; [3]Columbia University, New York, NY; [4]General Internal Medicine, Albert Einstein College of Medicine & Montefiore Medical Center, Bronx, NY; [5]Fordham University, Bronx, NY; [6]Medicine, Albert Einstein College of Medicine & Montefiore Medical Center, Bronx, NY; [7]City University of New York, New York, NY. (Control ID #3391519)

BACKGROUND: Medical cannabis is increasingly used as an alternative to prescription opioids in adults with chronic pain, but little is known about how it is incorporated into their daily lives. Among adults with chronic pain who were taking prescription opioids and were newly certified for medical cannabis in New York, we examined patterns of medical cannabis use over time. We hypothesized there would be two distinct medical cannabis use patterns: near-daily use, and infrequent use.

METHODS: In an ongoing observational study examining how medical cannabis affects prescription opioid use in adults with chronic pain, we enrolled 54 adults from 11/2018-11/2019. Every two weeks participants completed questionnaires to assess days of medical cannabis use. To date, because participants have varying duration of study follow-up (2-52 weeks), we conducted latent class analyses to classify participants into groups based on medical cannabis use over time. Number of medical cannabis use patterns was determined by Bayesian Information Criterion. After extracting latent classes, we assigned participants to groups with the largest Bayesian posterior probability.

RESULTS: Mean age was 53 years, 67% were female, and 42% white. We identified four distinct patterns of medical cannabis use over time. In the most common pattern (41% of participants), participants used medical cannabis about one-half of days, then declined to about one-third of days. In the next most common pattern (22%), participants used medical cannabis daily most of the time. In the third most common pattern (20%), participants used medical cannabis only a few days per two-week period, followed by no use at all. Finally, in the least common pattern (17%), participants used daily most of the time.

CONCLUSIONS: Among adults with chronic pain who take opioids and were newly certified for medical cannabis in New York, four distinct medical cannabis use patterns emerged. Medical cannabis may be used differently and more variably than traditional medications. Medical cannabis cost can be prohibitive, leading adults to reduce frequency of use even if they experience benefit. Finally, adults may moderate medical cannabis use to limit side effects. As medical cannabis use continues to increase, it is important to understand medical cannabis use patterns and the factors that drive them.



PATTERNS OF OSA TESTING IN PRIMARY CARE: ARE HIGH RISK PATIENTS RECEIVING EVIDENCE-BASED CARE?

Christina Mallarino-Haeger[1]; Scott D. Rothenberger[2]; Sanjay R. Patel[2]; Wendy L. Bennett[3]; Carolyn Bramante[4]; Jeanne M. Clark[5]; Molly Conroy[6]; Sharron J. Herring[9]; Jennifer Kraschnewski[10]; Michelle R. Lent[7]; Albert W. Wu[8]; Kathleen Mary Mctigue[2]. [1]Internal Medicine, UPMC - Presbyterian/Shadyside, Pittsburgh, PA; [2]Medicine, University of Pittsburgh, Pittsburgh, PA; [3]Medicine, Johns Hopkins School of Medicine, Baltimore, MD; [4]Internal Medicine & Pediatrics, University of Minnesota, Minneapolis, MN; [5]Medicine, Johns Hopkins University, Baltimore, MD; [6]General Internal Medicine, University of Utah, Salt Lake, UT; [7]Psychology, Philadelphia College of Osteopathic Medicine, Philadelphia, PA; [8]Health Policy & Management, Johns Hopkins University, Baltimore, MD; [9]Internal Medicine, Lewis Katz School of Medicine at Temple University, Philadelphia, PA; [10]Medicine and Public Health Sciences, Penn State College of Medicine, Hershey, PA. (Control ID #3387782)

BACKGROUND: Obstructive sleep apnea (OSA) is associated with cardiovascular disease, decreased quality of life and mortality. Given availability of treatment, the American Academy of Sleep Medicine recommends routine evaluation for symptoms in high risk patients (e.g. BMI>35, type 2 diabetes and hypertension). Data regarding OSA evaluation in primary care is limited. We examined prevalence of sleep study orders across individuals with varying levels of risk and markers of sleep disturbance.

METHODS: We analyzed EHR and survey data collected by the PaTH Cohort Study of Healthy Lifestyles, Body Weight and Health Care. Survey data collected from primary care patients in 5 health systems were linked with de-identified EHR data collected from the PCORnet Common Data Model. Patient vital signs, comorbid conditions and sleep study orders were extracted from the EHR and analyzed in relation to survey responses. We categorized 5-point Likert responses for PROMIS-29 data related to sleep: sleep quality [worse >3]; [more: </=3; less: >3]; and fatigue [more: >48.6; less: </=48.6]. T-scores for PROMIS-29 subscales were calculated for patients overall and by weight class. Linear regression models were used to perform ANOVA and test for trends in t-scores across classes.

RESULTS: EHR data were analyzed from 3,191,225 patients; a subset of 1,070 patients completed the PROMIS-29 survey. Among the EHR cohort, 30% had a normal BMI, 31% had overweight, 29.5% had Class I/II obesity and 7.6% had Class III obesity. Mean age was 52.4 years, 58% were female, 79% were white and 11.7% were African American. The prevalence of weight-related comorbidities increased with increasing weight category; 3.1% of all patients, 6.1% of patients with Class II obesity and 8.9% of those with Class III obesity had a sleep study ordered between 2011 and 2018. Among individuals with BMI<40 (n=892), the proportion of sleep studies ordered in 2017-18 was significantly higher in those with more fatigue (16.7%) vs. those with less fatigue (8.6%;p<0.001). However, that proportion was similar for individuals with better (11.7%) vs. worse (12.6%) self-reported sleep quality (p=0.76). Furthermore, those with greater refreshment from sleep were significantly more likely to have a sleep study ordered (16.2%) vs. those with less refreshment (6.1%,p<0.001). Among individuals with Class III obesity, the percentages with a sleep study order were similar regardless of sleep quality (21.4 vs. 19.2%;p=0.75), refreshment from sleep (21.3 vs. 19.6%;p=0.80) and fatigue (19.4 vs. 22.4%;p=0.62).

CONCLUSIONS: OSA may be underdiagnosed in high risk patients given the low rate of sleep studies ordered compared with the high prevalence of OSA in this population. A lack of correlation between sleep study orders and markers of sleep disturbance suggests that despite guideline recommendations, these tests are not being ordered based on evaluation of sleep-related symptoms.

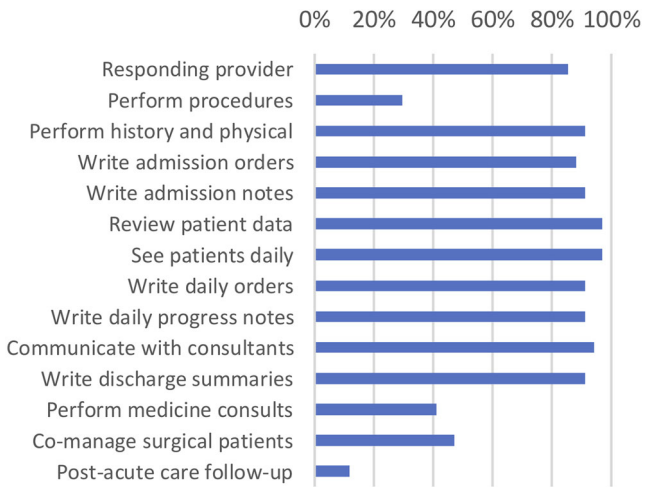
PATTERNS OF UTILIZATION AND EVALUATION OF ADVANCED PRACTICE PROVIDERS ON HOSPITAL MEDICINE TEAMS AT ACADEMIC MEDICAL CENTERS

Evan Shannon[1]; Vineet Chopra[2]; S R. Greysen[3]; James D. Harrison[4]; Shoshana J. Herzig[5]; Sunil Kripalani[6]; Tiffany Lee[4]; Peter K. Lindenauer[7]; Melissa Mattison[8]; Kevin O'leary[14]; Sumant Ranji[9]; Edmondo Robinson[10]; Gregory Ruhnke[15]; Neil Seghal[4]; Eduard E. Vasilevskis[11]; Mark V. Williams[16]; Andrew D. Auerbach[12]; Jeffrey L. Schnipper[13]. [1]Division of General Internal Medicine, Brigham and Women's Hospital, Boston, MA; [2]Internal Medicine, University of Michigan, Ann Arbor, MI; [3]DOM, University of Pennsylvania, Philadelphia, PA; [4]Division of Hospital Medicine, University of California San Francisco, San Francisco, CA; [5]Medicine, Beth Israel Deaconess Medical Center, Brookline, MA; [6]Medicine, Vanderbilt University Medical Center, Nashville, TN; [7]Institute for Healthcare Delivery and Populatin Science, University of Massachusetts medical School - Baystate, Springfield, MA; [8]Medicine, Massachusetts General Hospital, Boston, MA; [9]Medicine, University of California San Francisco, San Francisco, CA; [10]Medicine, Christiana Care Health System, Wilmington, DE; [11]Medicine, Vanderbilt University, Nashville, TN; [12]Medicine, UCSF Division of Hospital Medicine, San Francisco, CA; [13]Division of General Medicine, Brigham and Women's Hospital, Boston, MA; [14]Department of Medicine, Northwestern Medicine, Chicago, IL; [15]Department of Medicine, University of Chicago, Chicago, IL; [16]Department of Medicine, University of Kentucky, Lexington, KY. (Control ID #3390580)

BACKGROUND: Staffing of inpatient medicine services with Advanced Practice Providers (APPs), including physician assistants and nurse practitioners, is becoming increasingly common at academic medical centers across the United States. The purpose of this study is to better characterize how APPs are utilized and to summarize perceptions of APP contributions to inpatient general medicine teams at academic medical centers.

METHODS: We performed a survey of hospital medicine programs at academic medical centers in the United States affiliated with the Hospital Medicine Reengineering Network (HOMERuN), a hospital medicine research collaborative. Questions regarding different APP roles were multiple choice. Questions that rated APP contributions were on a 1-5 Likert scale. Surveys were distributed via email to division/section chiefs and/or senior leaders of unique hospitalist groups between January and August 2019. Responses to questions are reported as proportions or mean/standard deviation (SD).

RESULTS: We received responses from representatives of 43 hospital medicine groups from 86 invitees (50%). Thirty-four (79.1%) programs employed APPs. Respondents stated that APPs perform a wide range of roles (Figure). The following were rated of highest importance in deciding to incorporate APPs within the hospitalist group: allow physicians to focus on "higher level" activities (mean=4.2, SD=1.1), increase efficiency (mean=4.4, SD=0.9), and decrease physician burnout (mean=4.1, SD=1.1). APPs were considered beneficial for the quality of patient care (mean=3.8, SD=0.9) and physician retention (mean=3.7, SD=0.9). The greatest reported challenges to having APPs as part of the service included training requirements and support for new hires (mean=3.4, SD=1.1) and less flexibility in number of hours (mean=3.2, SD=1.1). **CONCLUSIONS:** We found that the majority of surveyed hospitalist groups at academic medical centers employed APPs. APPs performed a variety of roles with substantial heterogeneity across sites. The presence of APPs was generally considered beneficial to hospitalist groups. Additional research is needed to better elucidate the contribution of APPs to clinical outcomes, cost, physician and patient satisfaction.



PERFORMANCE AND DISPARITY PATTERNS: FOLLOW-UP OF ABNORMAL CANCER SCREENING IN CALIFORNIA'S PUBLIC HOSPITAL SYSTEMS

Elaine C. Khoong[1,2]; Natalie Rivadeneira[1,2]; Ma Somsouk[4,2]; David Lown[3]; Dean Schillinger[1,2]; Urmimala Sarkar[1,2]. [1]Division of General Internal Medicine at Zuckerberg San Francisco General Hospital,

University of California - San Francisco, San Francisco, CA; [2]UCSF Center for Vulnerable Populations, San Francisco, CA; [3]California Health Care Safety Net Institute, Oakland, CA; [4]Division of Gastroenterology, Department of Medicine, UCSF, San Francisco, CA. (Control ID #3389480)

BACKGROUND: Little is known about disparities in follow-up of abnormal cancer screening results (e.g., colonoscopy after abnormal fecal immunochemical tests (FITs) or biopsies after high-risk mammograms). Since safety net systems provide a disproportionate amount of care to populations that experience health disparities, we explored whether there are disparities in follow-up of abnormal FITs/mammograms within California's public hospital systems.

METHODS: Using electronic health records (EHRs) from five California safety net systems, we collected data from 7/1/15-6/30/17 for patients with an abnormal FIT from 7/1/15-12/31/16 or BIRADS 4/5 mammogram from 7/1/15-5/31/17. Our primary outcomes were binary: whether a colonoscopy was acquired after abnormal FIT, or tissue biopsy pursued after BIRADS 4/5 mammogram. Controlling for system (sites 1-5), we used a multivariable logistic regression for each outcome to assess if patient characteristics (age, gender, race/ethnicity, preferred language, insurance status) predicted outcomes.

RESULTS: *Abnormal FIT Follow-Up:* Across all sites, 1850/4860 (38%) participants with abnormal FIT received a colonoscopy. We found age, language, and insurance type/coverage status impacted odds of follow-up. Relative to 50-59 years old patients, those that were 70+ years old had lower odds of receiving a colonoscopy (aOR: 0.77; 95% CI: 0.60-0.99). Individuals with Medicare (aOR: 0.68; 95% CI: 0.51-0.91), Medicaid (aOR: 0.69, 95% CI: 0.54-0.89), or uninsured (aOR: 0.33; 95% CI: 0.21-0.50) had lower odds of receiving a colonoscopy than privately insured patients. Patients with a language preference other than English/Spanish (aOR: 1.32; 95% CI: 1.05-1.65) had higher odds of receiving follow-up than English speakers. *Abnormal Mammogram Follow-Up:* Across all sites, 1378/1617 (85%) participants received a biopsy after a BIRADS 4/5 mammogram. We found only that Asian patients had increased odds of biopsy vs non-Hispanic White patients (aOR: 1.92; 95% CI 1.06, 3.46).

CONCLUSIONS: The performance of public systems on follow-up for cancer screening tests is variable; despite these systems' focus on reducing financial barriers, insurance type/coverage status remained a predictor of colonoscopy receipt. This supports assertions that insurance type/coverage status are proxies for social needs that impact longitudinal access to healthcare, a necessity for acquiring follow-up tests months after an encounter. Social needs need to be routinely measured to explore how they mediate associations between sociodemographic traits and health outcomes. These public systems did not generate the race/ethnicity-related disparities documented in other settings. Moreover, some non-English speaking patients had better abnormal FIT follow-up, and Asian patients had better mammogram follow-up. Understanding these systems' performance with respect to race/ethnicity and language-related disparities may shed insights on reducing disparities in other systems.

PERFORMANCE OF COMMON HEALTH LITERACY MEASURES IN YOUNGER ADULT PARENTS

Stephanie Batio[2]; Marina Arvanitis[2]; Laura M. Curtis[2]; Stacy Bailey[2]; Michael S. Wolf[2]; Shonna Yin[1]. [1]Pediatrics, NYU School of Medicine, New York, NY; [2]Center for Applied Health Research on Aging, Northwestern University, Chicago, IL. (Control ID #3391426)

BACKGROUND: Nearly one third of US parents have limited health literacy, therefore lacking the full capability of making appropriate health decisions for themselves, and for their children. Despite the importance of addressing parent health literacy, the most commonly used health literacy instruments utilized in research were developed and validated in older adult populations, and may have reduced discriminative predictive validity in younger adults (40 years old and younger). As part of a larger controlled study of pediatric liquid medication dosing, we examined the performance of three health literacy measures, BHLS (Brief Health Literacy Screen), S-TOFHLA (Short Test of Functional Health Literacy in Adults) and NVS (Newest Vital Sign) in a diverse, younger parent population.

METHODS: We used data from a randomized controlled study of strategies to improve medication label and dosing tools, and reduce parental error in dosing liquid medicines. Parents and legal guardians, 18 years or older, were recruited in pediatric outpatient clinics in New York, NY, Atherton, CA and Atlanta, Georgia. Parents were eligible if they identified as caregivers for their child of 8 years or younger. Kappa statistics were used to assess the agreement between BHLS, S-TOFHLA and NVS. Multivariate logistic regressions were performed to assess the associations between these health literacy measures and making a medication dosing error (>20% deviation from correct dose). Additionally, ROC curves and contrasts were used to compare the predictive validity of these measures.

RESULTS: Of the 1,956 parents, 92% were mothers of young children, with a mean age of 28. Over half of the parents identified as Hispanic, and nearly one-third reported low English proficiency and grade school as their highest educational attainment. According to the BHLS, 98% self-identified as having adequate health literacy, whereas, 85% of them were classified as having adequate health literacy by S-TOFHLA and only 23% by the NVS measure. Weak agreements between NVS and S-TOFHLA (kappa=0.13; 95%CI:0.11-0.14), and NVS and BHLS (kappa=0.03; 95% CI:0.0048-0.02) were observed. Adequate health literacy, by all the measures, was associated with lower probability of making a dosing error (BHLS: aOR=0.52, p<0.001; S-TOFHLA: aOR=0.47, p<0.001; NVS: aOR=0.53, p<0.001). However, ROC contrasts estimates show significant differences between the predictive validity of BHLS and NVS (-0.01; p<0.001), and S-TOFHLA and BHLS (0.01; p<0.001). The ROC contrasts showed no significant differences between S-TOFHLA and NVS (-0.003; p=0.36).

CONCLUSIONS: Our analysis found the BHLS and S-TOFHLA to be poor assessments of health literacy with significant ceiling effects when administered to a younger, ethnically diverse, primarily female, adult parent population. The NVS, an objective health literacy measure, may perform better in younger adults than subjective measures such as BHLS, and measures with questionable discriminative and predictive validity, such as S-TOFHLA

PERFORMANCE OF THE ADA AND CDC DIABETES RISK SCORES USING STRUCTURED EHR DATA VS. PATIENT-REPORTED DATA

Sam Hankins[5]; Matthew J. O'Brien[4]; Ildiko Lingvay[3]; Luigi Meneghini[2,6]; Ethan Halm[2]; Michael E. Bowen[1]. [1]Medicine, UT Southwestern Medical Center, Dallas, TX; [2]Internal Medicine, Univ of TX Southwestern Med Ctr, Dallas, TX; [3]Internal Medicine, UT Southwestern Medical Center, Dallas, TX; [4]Northwestern Feinberg School of Medicine Center for Community Health, Northwestern University, Chicago, IL; [5]Internal Medicine-Pediatrics, UT-Southwestern, Dallas, TX; [6]Parkland Health and Hospital System, Dallas, TX. (Control ID #3391792)

BACKGROUND: The American Diabetes Association (ADA) and Centers for Disease Control (CDC) diabetes (T2D) risk scores are patient-reported instruments to identify individuals in need of T2D screening and/or eligible for the evidence-based Diabetes Prevention Program. Although they have been automated in some EHRs, their performance using EHR data is unknown. We compare risk score performance using EHR data

alone vs. EHR data + patient-reported data on T2D risk factors that are not routinely collected in the EHR.

METHODS: Primary care patients in a safety-net health system ages 18-65 without diagnosed prediabetes (PDM) or T2D and no T2D screening in the past 2 years (N=523) were enrolled in a prospective screening study and classified as normal (HbA_{1c} <5.7% and Fasting glucose (FBG) <100 mg/dL) or having dysglycemia (HbA_{1c} ≥5.7% or FBG≥ 100 mg/dL). We then calculated the ADA and CDC 2018 risk scores in 2 datasets from the same 523 patients: 1) EHR+Patient-reported: EHR data (age, sex, BMI, hypertension) plus prospectively collected patient-reported data (family history of T2D, physical activity, gestational diabetes); 2) EHR-only: all data from structured, retrospective EHR data. For each dataset, we calculate and compare overall discrimination and sensitivity/specificity/predictive values at recommended cut-points (ADA ≥4; CDC ≥9) to detect dysglycemia using the EHR+P^2atient-reported data as the gold-standard.

RESULTS: Of 523 participants (mean age 48 years, mean BMI 30 kg/m^2, 61% female, 68% Hispanic, 23% black) in the screening study, 33% had dysglycemia. Using recommended risk score cut-points for dysglycemia, more patients qualified for screening when patient-reported data were included vs. EHR data alone (ADA 74% vs. 54%; CDC 75% vs. 43%; p<0.001). The c-statistic for discrimination was similar using EHR only and EHR+patient-reported data for ADA [0.69 (0.65-0.74) vs. 0.71 (0.67-0.75)] and CDC [0.67 (0.62-0.71) vs. 0.64 (0.59-0.68)] risk scores. Use of EHR data only underestimated risk compared with EHR+patient-reported data (Table).

CONCLUSIONS: Using patient-reported data to calculate the ADA and CDC diabetes risk scores markedly improved detection of dysglycemia compared with the use of EHR data alone when recommended cut-points were used. In the absence of patient-reported risk data, alternate cut-points are needed to optimize performance of the ADA and CDC risk tests for use with existing, structured EHR data.

PERSPECTIVES ON DECISION-MAKING DURING HOSPITALIZATION AMONG FREQUENTLY HOSPITALIZED PATIENTS IN THE COMPREHENSIVE CARE PROGRAM STUDY

Josef N. Kushner[1]; Erin Y. Rieger[1]; Abbie Klein[2]; Lauren Wiklund[2]; David Meltzer[2]; Joyce W. Tang[2]. [1]Pritzker School of Medicine, The University of Chicago, Chicago, IL; [2]Section of Hospital Medicine, University of Chicago, Chicago, IL. (Control ID #3390514)

BACKGROUND: Research in medical decision-making during hospitalization suggests that patients hold a wide range of preferences for their involvement. Less is known about if patient involvement differs if they are cared for by a physician with whom they have a prior relationship. This work seeks to explore patient experiences with decision-making during hospitalization qualitatively through the lens of the Comprehensive Care Program (CCP) study, a randomized controlled trial that assesses the effects of an interdisciplinary care team led by a physician who serves as both the outpatient PCP and inpatient attending as compared to usual care (ambulatory care for a PCP, hospital care from hospitalists) for patients at high risk of hospitalization.

METHODS: This is a qualitative study embedded within a randomized controlled trial, using semi-structured interviews with 12 CCP patients and 12 standard care (SC) patients. Patients were interviewed near the end of or shortly after a hospitalization, and were asked to describe 1) their communication with doctors during hospitalization and 2) a major decision made during their hospitalization. Interviews were analyzed using general thematic analysis. Each transcript was independently coded by two team members. Common themes were agreed upon by consensus.

RESULTS: Decisions were coded in 3 domains: topic, process (provider-dominant, patient-dominant, collaborative), and preferences. The most frequently described decision topic was discharge timing, with most patients requesting additional days to recover prior to discharge and a few preferring earlier discharge. Other common decision topics included medical procedures, and medication changes; not infrequently, patients stated that there were no major decisions made. When describing the decision-making process, CCP patients more often used collaborative language ("She always asks me if I'm feeling good enough to go, so I appreciate that."); in contrast, SC patients more often used provider-centric language ("She finally came to me and said, 'Mr. H, we need to remove the PD tube'."). The few instances of patient-dominant language were in the setting of refusing recommended care ("I ain't taking no test, I wasn't taking nothing. Just leave me alone.") Patients who had a longitudinal relationship with a physician caring for them during hospitalization (most frequently a CCP physician; occasionally a specialist) often described preference for discussing major decisions with this physician: "Should no other doctor be running nothing or make no decisions because you don't know me."

CONCLUSIONS: Many patients identify discharge timing as the main decision during a hospitalization. Patients who were treated by a physician familiar to them tended to use more collaborative language to describe the decision-making process. Future investigation into inpatient shared decision-making should consider provider continuity and the doctor-patient relationship as a driver for patient involvement.

PERSPECTIVE-TAKING, A NOVEL MECHANISM FOR ENHANCING TRAINEE EMPATHY: A QUALITATIVE ANALYSIS

Brianna Rossiter[2,1]; Melissa McNeil[3]; Gaetan Sgro[4]. [1]General Internal Medicine, UPMC, Pittsburgh, PA; [2]Internal Medicine, VA Pittsburgh Healthcare, Pittsburgh, PA; [3]Medicine, University of Pittsburgh Medical Center, Pittsburgh, PA; [4]Medicine, VA Pittsburgh Healthcare System, Pittsburgh, PA. (Control ID #3392475)

BACKGROUND: Residency is marked both by intense knowledge acquisition, personal growth, and by increasing levels of burnout and cynicism both of which have been shown to erode empathy and undermine the altruistic motivations that led to a medical career path. Interactions with so-called "challenging" patients in the ambulatory setting are often cited as drivers of burnout and cynicism. Perspective-taking (PT) is a cognitive skill defined as "an understanding of other people's mental states" and has been studied as a way to cultivate empathy. We qualitatively assessed internal medicine (IM) residents' response to the implementation of a PT curriculum for enhancing empathy.

METHODS: *Setting and participants*: This curriculum took place during the 2018-2019 academic year within the PGY3 Ambulatory rotation of the UPMC Internal Medicine Residency. All PGY3 residents complete this rotation but could opt-out of our research evaluation. Our curriculum included: 1) a brief introductory session of narrative, medical writing and perspective-taking, 2) a self-directed, written perspective-taking exercise in which all residents were asked to respond to a prompt about a "challenging" patient in their ambulatory clinic, and 3) a de-briefing session in which PT pieces were shared in a facilitator- guided, group reflection.

Evaluation: Residents who completed the PT curriculum were invited to participate in 30-minute phone interviews assessing their attitude of the curriculum. A $30 gift card was offered as incentive. The semi- structured interviews were conducted by an independent research group. Interviews were transcribed and a code book was development. The interviews were independently coded by two coders who then met to adjudicate disagreements. Thematic analysis was achieved.

RESULTS: Four major themes emerged from the interviews: (1) Writing in first-person, from the patient's perspective, was challenging but beneficial, allowing residents to re-examine their judgements

on patient's actions. (2) Residents found discomfort in first-person because they feared making wrong assumptions about their patients. (3) The exercise allowed residents to better identify patients' barriers in the healthcare system. Lastly, (4) trainees almost universally enjoyed the de-brief session despite having initial apprehension. The de-brief allowed for reflection, which the trainees found extremely valuable but rare in medical education.

CONCLUSIONS: First-person writing through the technique of PT beneficially impacted how residents thought about challenging patients but also brought discomfort. De-Briefing of the PT exercise was felt to be essential as it allowed for both self- reflection and the ability to draw realizations from peers' pieces. Discomfort in first-person narration and reflection of patients' challenges are elements of empathy. The novel use of PT may serve as a potential strategy for enhancing empathy in medical training.

PERSPECTIVE-TAKING, A NOVEL MECHANISM FOR ENHANCING TRAINEE EMPATHY: A QUANTITATIVE ANALYSIS

Brianna Rossiter[2,1]; Melissa McNeil[3]; Gaetan Sgro[4]. [1]General Internal Medicine, UPMC, Pittsburgh, PA; [2]Internal Medicine, VA Pittsburgh Healthcare, Pittsburgh, PA; [3]Medicine, University of Pittsburgh Medical Center, Pittsburgh, PA; [4]Medicine, VA Pittsburgh Healthcare System, Pittsburgh, PA. (Control ID #3392483)

BACKGROUND: Residency is marked both by intense knowledge acquisition, personal growth, and by increasing levels of burnout and cynicism both of which have been shown to erode empathy and undermine the altruistic motivations that led to a medical career path. Interactions with so-called "challenging" patients in the ambulatory setting are often cited as drivers of burnout and cynicism. Perspective-taking (PT) is a cognitive skill defined as "an understanding of other people's mental states" and has been studied as a way to cultivate empathy. We evaluated whether implementation of a PT curriculum within an internal medicine (IM) residency could enhance empathy in challenging patient encounters.

METHODS: *Setting and participants*: This curriculum took place from November 2018 until April 2019 within the PGY3 ambulatory rotation of the UPMC Internal Medicine Residency. All PGY3 residents complete this rotation but could opt-out of the research evaluation. Our curriculum included: 1) a brief introductory session on PT, 2) a self-directed, written PT exercise in which residents responded to a prompt about a "challenging" patient in their ambulatory clinic, and 3) a de-briefing session in which PT pieces were shared in a facilitator-guided, group reflection. Residents who completed the curriculum (Nov. 2018-April 2019) were considered the intervention group. Residents who had their rotation prior to the initiation of the curriculum (July-October 2018) were considered the control group.

Methods and Evaluation: Participants in the control group completed a one-time, validated, empathy measure, the Jefferson Empathy Scale (JSE). Participants in the intervention group completed the survey both before and after completion of the PT curriculum. Demographic questions were asked and the analyzed by descriptive statistics. The JSE scoring algorithm was used to process the control group, pre-intervention and post-intervention survey data. Composite scores were compared using paired t-tests.

RESULTS: Both control and intervention groups were similar in respect to age, gender, race and previous experience in narrative writing. There was no statistical difference in baseline empathy between the control and pre-intervention group (p=0.403). There was a statistically significant change towards higher empathy between the pre- and post-invention groups (p = 0.006). When stratified by gender, female residents had higher empathy at baseline than males. The significant difference in empathy between males and females pre- curriculum (p=0.028) closed post-curriculum (p=0.129), with males having a change towards higher empathy (p=0.017).

CONCLUSIONS: Implementation of a brief, novel curriculum that combined aspects of narrative writing and perspective-taking enhanced empathy among IM residents in challenging patient interactions. Our innovative curriculum can serve as a relatively small but actionable strategy to preserve and strengthen trainee empathy.

PHYSICIAN ASSISTANTS' KNOWLEDGE, CONFIDENCE AND COMPETENCY WITH PRESCRIBING PRE-EXPOSURE PROPHYLAXIS

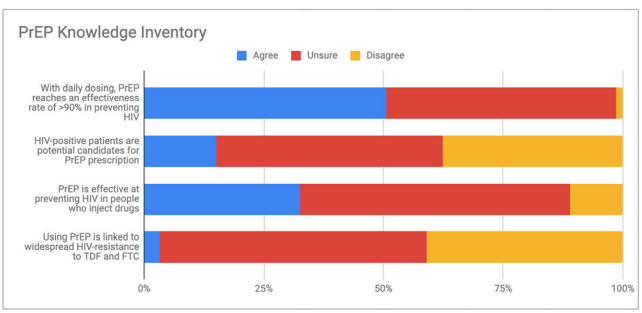
Kathleen Miller[2]; Samuel Bunting[3]; Robert Goldstein[1]. [1]Infectious Disease, Massachusetts General Hospital, Boston, MA; [2]Internal Medicine, Massachusetts General Hospital, Boston, MA; [3]Rosalind Franklin University of Medicine and Science, North Chicago, IL. (Control ID #3370470)

BACKGROUND: Pre-exposure prophylaxis (PrEP) is a safe and effective tool for preventing HIV, but remains significantly underutilized, particularly among primary care providers. Scaling up of PrEP will require engagement of providers at all levels of care in interdisciplinary collaborative practice models.

METHODS: We conducted an online survey of physician assistants (PAs) regarding knowledge of CDC guidelines for PrEP prescribing and confidence prescribing and managing PrEP, counseling patients about PrEP, and educating colleagues about PrEP. Online surveys were completed by 461 PAs who were attending a national conference (Response rate = 36.2%). A 7-point Likert scale was utilized to analyze participant responses.

RESULTS: A significant proportion of respondents were uncertain about PrEP indications and clinical management: 50% were unsure if HIV-positive patients were candidates for PrEP, and 56% were uncertain on whether PrEP prescribing would lead to high HIV-resistance rates. Mean confidence scores for were low (12.1, max = 28). PAs practicing at an academic medical center and those practicing in Family Medicine were more confident in all areas (M = 12.9 vs 9.8, p = .03; M = 15.3 vs 10.0, p < .001).

CONCLUSIONS: We found that there were significant knowledge gaps as well as low confidence with prescribing PrEP among our surveyed sample of PAs. These results highlight the need for increased training and support for PrEP prescribing among PAs.



PHYSICIANS' VIEWS ON UTILIZATION OF AN EHR-EMBEDDED CALCULATOR TO ASSESS RISK FOR VENOUS THROMBOEMBOLISM AMONG MEDICAL INPATIENTS

Stephanie Moss[1]; Michael B. Rothberg[2]; Cassandra Nathan[5]; Elizabeth Pfoh[3]; Kathryn A. Martinez[4]. [1]Hospital Medicine, Cleveland Clinic, Cleveland, OH; [2]Internal Medicine, Cleveland Clinic, Cleveland, OH;

[3]Medicine, Cleveland Clinic, Cleveland, OH; [4]Center for Value-Based Care Research, Cleveland Clinic, Cleveland, OH; [5]Brandeis University, Waltham, MA. (Control ID #3391553)

BACKGROUND: Venous thromboembolism (VTE) is a common cause of preventable morbidity and mortality among hospitalized patients. Pharmacologic prophylaxis is effective in reducing rates of VTE in at risk patients, but indiscriminate use of prophylaxis increases the risk of bleeding. To increase appropriate prescribing of VTE prophylaxis, as part of a randomized clinical trial, a risk assessment calculator was embedded in the electronic health record at Cleveland Clinic. Despite efforts to promote use of the calculator through staff meetings, email reminders, local champions, and weekly audit and feedback, routine use by physicians was low and highly variable among sites. The objective of this research was to understand provider perspectives on using the VTE risk calculator in clinical practice and factors that may hinder its use.

METHODS: We conducted a qualitative study exploring provider perspectives on use of the VTE risk calculator. Eligible participants included attending physicians and advanced practice providers (APPs) in the department of hospital medicine at 10 hospitals who had at least 10 opportunities to use the calculator over a three month period. They were categorized by level of utilization of the calculator, low (<20%), moderate (20-50%), or high (>50%). We sent interview requests via email. We conducted semi-structured interviews from April 2019 to July 2019 either in person or by phone. The semi-structured interview was developed using literature review and expert opinion, and asked respondents about use, relative advantage, and support for the VTE calculator, as well as general VTE prophylaxis questions. Interviews were approximately 30 minutes, audio recorded and transcribed verbatim. Interviews continued until thematic saturation was reached. Transcripts were analyzed using a grounded theory approach to identify themes associated with engagement with the risk calculator.

RESULTS: Fourteen providers participated, including twelve physicians and two APPs. Five providers were high utilizers of the VTE risk calculator, three were moderate utilizers, and six were low utilizers. There were five major themes identified. 1) Regardless of level of utilization, most clinicians overestimated their usage of the VTE calculator. 2) Clinicians felt that the calculator sometimes underestimated the risk of VTE. 3) The calculator validated clinicians' decision to withhold VTE prophylaxis from low risk patients. 4) Trust of the calculator was predicated on clinicians' awareness that it had been validated. 5) The calculator was easy to use and did not take excessive time or hinder work flow.

CONCLUSIONS: The optimal VTE risk assessment tool would be both easy to use and trusted by providers. While providers feel that the VTE risk calculator is easy to use, routine use may be hindered by provider mistrust of the calculator's recommendations. Specifically, providers believe that the calculator underestimates some patients' risk of VTE.

PHYSICIAN VOTING PRACTICES FROM 2006-2018 IN CALIFORNIA, NEW YORK, AND TEXAS

Hussain Lalani[1]; Arthur Hong[2]. [1]Internal Medicine, UT Southwestern Medical Center, Dallas, TX; [2]Department of Internal Medicine, University of Texas Southwestern Medical Center, Dallas, TX. (Control ID #3374932)

BACKGROUND: From 1976 to 2002, physicians voted 43% less often in elections than the general population. Voting has significant implications on health care policy, and physicians are valuable members of society in this regard. It remains unclear how physician voting practices have changed over the last decade in the midst of major health care reform. We characterized physician voting patterns from 2006 to 2018 in California (CA) New York (NY), and Texas (TX) – the three states with the largest numbers of physicians.

METHODS: We merged physician profiles from the National Physician Registry (Centers for Medicare & Medicaid Services) with state voter registration files obtained from L2, a private non-partisan company, using a name matching algorithm, comparing National Physician Identifier enumeration with voter file birth dates, and demographic data on occupation from L2 linked commercial data. We excluded physician trainees. Our primary outcome was voter participation - the percentage of voting eligible physicians (VEP) - who voted in general elections (even-numbered years) from 2006 to 2018. VEP was calculated based on state physician workforce profiles published by the Association of American Medical Colleges. We compared to general population voter participation rates from publicly available data. We then used logistic regression to predict odds of our secondary outcome, voter turnout (percentage of registered physicians who voted), comparing female to male physicians.

RESULTS: We identified 117,478 physicians registered to vote – 50,854 in CA, 39,046 in NY, and 27,578 in TX. Two-thirds (66%) were male with median age 42 in 2006 (IQR: 31 – 52). Internal Medicine was the most represented specialty (17%). Overall, 36% of eligible physicians in these states voted in general elections between 2006-2018, significantly lower than 46% of the general population ($p<0.001$). From 2006 to 2018, physician voter participation was lowest in 2006 (25%) and highest in 2016 (45%), though even in 2016 it was significantly lower than general population voter participation (56%, $p< 0.04$). Registered female physicians generally had lower adjusted odds of turnout than males in midterm elections: 2006 aOR: 0.94 (95% CI: 0.91-0.97); 2010 aOR: 0.89 (95% CI: 0.86-0.91); 2014 aOR: 0.90 (95% CI: 0.88-0.93), but higher odds of turnout than males in 2016 (aOR 1.16, 95% CI: 1.13-1.20) after controlling for age and specialty.

CONCLUSIONS: Our study found that eligible physicians voted approximately 22% less than the general population from 2006-2018, with physicians' highest voter participation in 2016. Voting rates varied between general vs. midterm election, and gender. Although in general, higher income households have higher voter participation rates, physicians consistently had lower voter participation than the general population since 2006. Registered female physicians generally had lower voter turnout than their male colleagues in midterm elections. Barriers to physician voting should be identified and addressed.

PILOT TESTING A BEDSIDE PATIENT SAFETY DISPLAY TO INCREASE PROVIDER AWARENESS OF THE 'HIDDEN HAZARDS' OF CATHETERS AND WOUNDS

Jessica Ameling[1]; M. Todd Greene[1,2]; Martha Quinn[3]; Jennifer Meddings[1,2]. [1]Internal Medicine, University of Michigan, Ann Arbor, MI; [2]Center for Clinical Management Research, Veterans Affairs (VA) Ann Arbor Healthcare System, Ann Arbor, MI; [3]School of Public Health, University of Michigan, Ann Arbor, MI. (Control ID #3391423)

BACKGROUND: We developed and piloted a digital bedside "Patient Safety Display" of catheter and wound information to improve awareness by rounding providers.

METHODS: Display development was informed by clinical observations, interviews, and prototype testing with clinicians. The display reported presence and duration of urinary and vascular catheter use, urinary catheter indication, wound presence and severity, and wound and catheter location on a human outline, from real-time documentation in the electronic medical record (EMR). In a pilot study in a tertiary care medical-surgical step-down unit with 20 private rooms, including a pre-intervention period and a post-intervention period with 10 control rooms without the display and 10 intervention rooms with the display, we surveyed providers directly after rounds to assess awareness of their patients' catheters and wounds, compared to the EMR. We assessed

display utility and usability from clinician interviews, and used an adapted grounded theory approach to identify major themes.

RESULTS: A total of 787 surveys (681 Medicine service with 89% response rate, 106 Surgery service with 47% response rate; 363 pre-, 424 post-intervention) were completed involving 176 unique patients and 47 unique providers. Among all 787 patient encounters, 156 (20%) had a transurethral indwelling urinary catheter (Foley), 314 (40%) had a central venous catheter (CVC, including peripherally inserted central catheters), and 247 (31%) had at least one pressure injury. The Figure summarizes provider awareness of catheters and pressure injuries when present as assessed pre- and post-intervention. Benefits identified from 13 post-intervention clinician interviews included: prompted discussion and increased awareness of catheter and skin issues; limitations reported were: didn't notice display and repetitive to EMR.

CONCLUSIONS: In this pilot study of a Patient Safety Display, although provider awareness of Foleys, CVCs, and pressure injuries appeared higher for patients in the intervention rooms compared to pre- and/or post-intervention control rooms, most comparisons did not meet statistical significance. Clinicians varied in views of the display as useful for improving catheter and wound awareness and prompting discussion.

	Pre-Intervention Period 14 weeks January-April 2019	**Post-Intervention Period** 13 weeks June-September 2019	
	20 rooms **WITHOUT** Patient Safety Display (**Pre-Intervention Rooms**)	10 rooms **WITHOUT** Patient Safety Display (**Control Rooms**)	10 rooms **WITH** Patient Safety Display (**Intervention Rooms**)
Awareness* of Transurethral Indwelling Urinary Catheter (i.e., Foley)	**66.0%** from survey of 50 patients with Foley	**80.4%** from survey of 56 patients with Foley	**86.0%**+, ++, # from survey of 50 patients with Foley
Awareness of Central Venous Catheter (CVC)**	**73.9%** from survey of 138 patients with >=1 CVC	**63.2%** from survey of 76 patients with >=1 CVC	**77.0%**+, ++, # from survey of 100 patients with >=1 CVC
Awareness of Pressure Injury	**51.9%** from survey of 108 patients with >=1 Pressure Injury	**45.5%** from survey of 77 patients with >=1 Pressure Injury	**58.1%**+, ++, # from survey of 62 patients with >=1 Pressure Injury

*Awareness by the rounding physician or advanced practice provider, as assessed by brief paper survey immediately after they rounded on their patients in the unit.
**CVCs in this survey included lines such as subclavian, internal jugular, femoral CVCs, ports, hemodialysis lines, and peripherally-inserted central catheters.

+When comparing awareness results for Intervention Rooms compared to Pre-intervention Period Rooms, Foley awareness increase did meet statistical significance (p=0.02), but there was no statistically significant increase in CVC (p=0.59) or Pressure Injury (p=0.43) awareness.

++When comparing the awareness for Intervention Rooms compared to Post-Intervention Control Rooms, the increase in CVC awareness marginally did meet statistical significance (p=0.045), but there was no statistically significant increase in Foley (p=0.44) or Pressure Injury (p=0.14) awareness.

#When comparing the awareness for Intervention Rooms compared to pooled results from the Pre-Intervention Rooms and Control Rooms, there was no statistically significant change in Foley awareness (p=0.08), CVC awareness (p=0.20), or Pressure Injury awareness (p=0.23).

PILOT TESTING OF THE MYCOG PARADIGM: RAPID DETECTION OF COGNITIVE IMPAIRMENT IN EVERYDAY CLINICAL SETTINGS

Laura M. Curtis[1]; Lauren Opsasnick[1]; Julia Yoshino Benavente[1]; Cindy J. Nowinski[3]; Rachel O'Conor[2]; Vitali Ustsinovich[3]; Marina Arvanitis[1]; Richard Gershon[3]; Michael S. Wolf[4]. [1]General Internal Medicine, Northwestern University, Chicago, IL; [2]Division of General Internal Medicine, Northwestern University, Chicago, IL; [3]Medical Social Sciences, Northwestern University, Chicago, IL; [4]Medicine, Northwestern University, Chicago, IL. (Control ID #3391883)

BACKGROUND: Cognitive impairment (CI) and dementia are significant public health burdens that can have profound social and emotional effects on older adults. Early detection of CI is imperative to identifying potentially treatable underlying conditions and providing supportive services to minimize the effects of CI in cases of Alzheimer's Disease and Related Dementias (ADRD). While primary care settings are ideal places for identifying CI, it frequently goes undetected. DetectCID is a consortium of three institutions funded to develop clinical paradigms to detect CI and dementia in primary care settings. We developed the Northwestern 'MyCog Paradigm' and piloted the brief, technology-enabled, 2-step CI detection assessment in a sample of older adults.

METHODS: In all, 80 participants were recruited from an ongoing cognitive aging study conducted in one academic general internal medicine clinic and six community health centers. Impaired cases were determined based on a diagnosis of dementia or mild cognitive impairment (MCI) in their medical record or an impairment based on performance on a comprehensive cognitive battery within the prior 18 months. During in-person interviews, participants completed the MyCog CI detection assessment via an iPad, consisting of an initial subjective assessment of their memory followed by two objective cognitive assessments from the NIH Toolbox for Assessment of Neurological and Behavioral Function: Picture Sequence Memory (PSM) and Dimensional Change Card Sorting (DCCS). We evaluated of the efficacy of the MyCog paradigm as a detection tool using sensitivity, specificity, and receiver operator characteristic (ROC) curves.

RESULTS: 31 of the 80 participants who were administered the MyCog paradigm were classified as impaired cases. The single self-report item regarding concern about memory or other thinking problems demonstrated high sensitivity (92%, 95% Confidence Interval (CI): 75%-99%) with 23/25 cases expressing concern; yet it yielded low specificity (46%, 95% CI: 33%-60%) with 29/54 controls also expressing a concern. In the subsample of participants who expressed concern, PSM and DCCS assessments were demonstrated exceptional ability in detecting CI (AUC=0.92), with an average administration time of 12 minutes. Only including the first of two PSM trials along with the DCCS reduced this time to an average of <7 minutes, with little change in AUC (0.90).

CONCLUSIONS: Based on our preliminary findings, we plan to continue optimizing our paradigm by 1) examining other self-reported items to improve the specificity in Step 1, 2) include only PSM Trial 1 and the DCCS in Step 2 to reduce administration time, 3) create a self-administered version to optimize use in clinical settings based on clinician feedback. With further validation and feasibility testing, MyCog offers a practical, scalable, primary care paradigm for the routine case finding of cognitive impairment and dementia.

PLEASE FOLLOW UP WITH YOUR PCP: RISK FACTORS ASSOCIATED WITH NOT HAVING A PRIMARY CARE PROVIDER ON HOSPITAL DISCHARGE

Elizabeth Cummings[1]; Erin Yao-Cohen[1]; Yumiko Abe-Jones[2]; Michelle Mourad[1]. [1]Internal Medicine, UCSF, San Francisco, CA; [2]Medicine, Division of Hospital Medicine, University of California at San Francisco, San Francisco, CA. (Control ID #3392284)

BACKGROUND: Despite known benefits of primary care, over 40 million Americans do not have a specific source of ongoing care. Data on risk factors for not having a primary care provider (PCP) are lacking. To explore this gap, we performed a descriptive analysis of patients with no assigned PCP at the time of hospital discharge and followed these patients over one year to determine risk factors for a persistent lack of access to primary care.

METHODS: We analyzed electronic medical record (EMR) data for all patients discharged from the medicine service at a large urban academic medical center for two years (2017-2018), N= 12,675. We used chi squared analysis to compare sociodemographic characteristics and ICD-10 codes in those with and without an assigned PCP in the EMR. We further analyzed patients without an assigned PCP who had subsequent interactions with our health system, examining the rate of acquiring a PCP at 12 months post- discharge and analyzing characteristics of patients who remained without a PCP after one year.

RESULTS: Of 12,675 patients discharged from our academic center, 9645 (76%) had a PCP and 3030 (24%) did not. Not having a PCP was associated with male gender, non-married status, Hispanic ethnicity, White and Black/African American race, having a substance use disorder diagnosis, having a psychiatric diagnosis, and experiencing homelessness (Table). Patients with Asian race and with non-English preferred language were more likely to have a PCP.

After hospital discharge, 2060 (68%) patients without an assigned PCP had further in-person encounters with our health care system in the year after discharge. 887 (43%) of those patients acquired a PCP after one year. Still not having a PCP one year after hospital discharge was most strongly associated with male gender, substance use disorder, and homelessness.

CONCLUSIONS: In our descriptive study, patient with sociodemographic factors traditionally associated with poor access to care were at higher risk of having no assigned PCP at the time of discharge, and most remained without a PCP after one year despite further encounters with the health care system. Targeted interventions need be undertaken to connect these patient groups to primary care and its associated benefits.

Table. Comparison of sociodemographic variables of Medicine discharges with and without an assigned PCP in the EMR

Sociodemographic Variables	PCP Assigned N= 9675 (%)	No PCP N = 3030 (%)	*p* Value
Age (years)	61.9	52.9	**<0.001**
Gender (M)	4685 (48)	1762 (58)	**<0.001**

POOR SLEEP PERSISTS AFTER HOSPITALIZATION AND IS ASSOCIATED WITH MOBILITY IMPAIRMENT: TIME-SERIES ANALYSIS OF A LONGITUDINAL COHORT STUDY

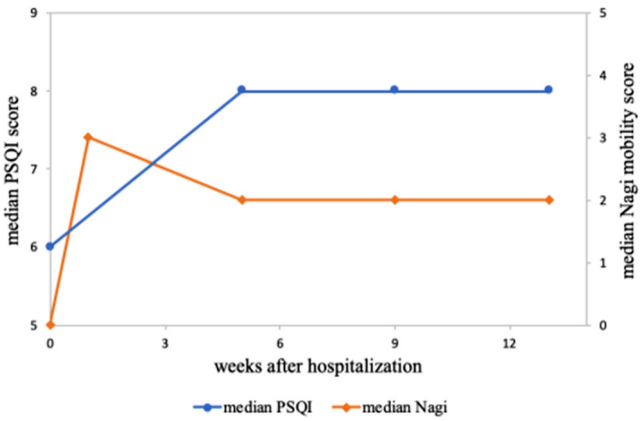
Christine M. Willinger[1]; Charles Rareshide[3,2]; Catherine Reale[3,2]; Ashley Mercede[3,2]; Mitesh Patel[4,3]; S R. Greysen[4,5]. [1]Perelman School of Medicine, University of Pennslyvania, Philadelphia, PA; [2]DOM, University of Pennsylvania, Philadelphia, PA; [3]Nudge Unit, University of Pennsylvania School of Medicine, Philadelphia, PA; [4]Division of General Internal Medicine, University of Pennsylvania, Philadelphia, PA; [5]Section of Hospital Medicine, University of Pennsylvania, Philadelphia, PA. (Control ID #3388257)

BACKGROUND: Poor sleep is robustly associated with morbidity and mortality in the community. However, the health impact of sleep during and after hospitalization is poorly characterized. Our objectives were to describe trends in sleep and physical function during and after hospitalization and evaluate sleep as a predictor of function over time.

METHODS: We conducted a longitudinal observational study of 237 adults hospitalized in 2018-2019, embedded in a randomized controlled trial of an e-health intervention. Patient-reported surveys were collected in the hospital and monthly for 13 weeks post-discharge. Sleep was measured by the Pittsburgh Sleep Quality Index (PSQI) and physical function by the Nagi mobility scale, Lawton-Brody instrumental activities of daily living (IADLs), and Katz basic activities of daily living (BADLs). Changes from baseline to each follow-up time were assessed by Wilcoxon signed-rank tests. Time-series multivariable linear regression was performed with PSQI as the primary predictor and Nagi score as the outcome. Covariates included age, gender, Charlson comorbidity index (CCI), length of stay (LOS), and trial arm.

RESULTS: Participants' mean age was 40, median CCI was 2, and median LOS was 3.8 days. Pre-hospital sleep was poor (median PSQI=6) and persistently worse after hospitalization (p<0.002 at each follow-up) (Figure 1). Pre-hospital mobility was intact (median Nagi score=0), but impairment increased post-discharge and did not recover to baseline (p<0.0001 at each follow-up). Median IADLs and BADLs were unchanged. The final time-series regression model explained 43% of variation in mobility over time (p<0.0001). The model predicted a direct, dose-response relationship between poor sleep and mobility impairment during the study period (beta=0.13, 95% CI 0.09-0.16, p<0.001).

CONCLUSIONS: Even in this relatively young and healthy group of patients, sleep and advanced physical function significantly declined for up to 3 months after brief hospital stays, and poor sleep predicted impaired mobility over this time. This result has important implications for the long-term health of hospitalized patients. Further studies should test the causal nature of this relationship and explore the association of poor sleep with post-hospital healthcare utilization.



POST-ELECTION U.S. TRENDS IN INSURANCE COVERAGE, HEALTH CARE UTILIZATION, AND DISPARITIES AMONG LOW-INCOME HISPANIC ADULTS

June-Ho Kim[1,2]; Megan B. Cole[3]. [1]Division of General Internal Medicine and Primary Care, Brigham and Women's Hospital, Boston, MA; [2]Ariadne Labs, Boston, MA; [3]Health Law, Policy, and Management, Boston University School of Public Health, Boston, MA. (Control ID #3392322)

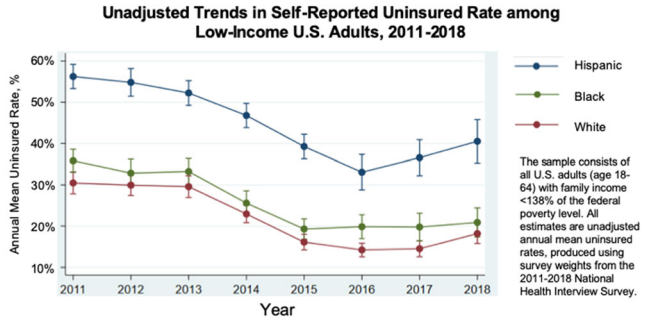
BACKGROUND: The Affordable Care Act was associated with significant decreases in the uninsured rate, especially among low-income and Latinx adults. However, following the 2016 election, there were several changes to national health policy and rhetoric—including the cessation of cost-sharing subsidies to insurers and efforts to enhance immigration enforcement—that may have adversely affected health insurance participation and utilization, particularly among vulnerable, minority populations. We assessed trends in insurance coverage, utilization, and racial/ethnic disparities before and after the 2016 U.S. election.

METHODS: We identified a nationally representative sample of low-income U.S. adults (age 18-64, family income <138% of the federal poverty level) from the 2011-2018 National Health Interview Survey. Our primary outcome of interest was the annual mean uninsured rate while our secondary outcomes were rates of Medicaid coverage, private insurance coverage, people reporting a usual source of care, and delays in care due to cost. We used linear regressions to model each outcome as a function of a linear annual time trend interacted with race/ethnicity and plotted the predicted probabilities.

RESULTS: For low-income Hispanic adults, the annual mean uninsured rate decreased from 56.3% [95% CI 53.3-59.2] in 2011 to 33.1% [95% CI 28.8-37.4] in 2016 but increased to 40.5% [95% CI 35.2-45.8] by 2018 (Figure). In 2011, there was a 26% absolute difference in insurance coverage between Hispanic and non- Hispanic white low-income adults. This narrowed to 19% in 2016 then widened to 22% by 2018. Rates of Medicaid participation among low-income Hispanic adults rose from

2011 to 2016 and continued to rise from 2017-2018. However, rates of private insurance coverage (including insurance exchanges) increased from 13% in 2011 to 20% in 2016 then decreased to 15% in 2018. Similarly, the proportion who reported having a usual source of care peaked in 2016 then declined from 2017-2018 while the rate of delaying care due to cost was at its lowest in 2016.

CONCLUSIONS: Despite large gains in insurance coverage and health care utilization before 2017, there have been significant reversals since then, particularly among low-income Hispanic adults. With the rise in the uninsured rate, there was a concurrent decrease in private insurance coverage without a decline in Medicaid coverage, suggesting that losses occurred primarily from employer or exchange-based insurance.



PRACTICES FOR HUMANISM AND CONNECTION IN MEDICINE: A QUALITATIVE STUDY OF STRATEGIES FROM PRESENCE CIRCLE PHYSICIAN PEER GROUPS TO SUPPORT PRESENCE 5 PRACTICES

Cati Brown-Johnson[1]; Ted Miclau[2]; Mariko Kelly[2]; Nadia Safaeinili[3]; Marie C. Haverfield[4]; Meredith D. Fischer[2]; Donna M. Zulman[5]. [1]Evaluation Sciences Unit, Stanford School of Medicine, Stanford, CA; [2]Stanford University School of Medicine, Stanford, CA; [3]Primary Care & Population Health, Stanford University, Stanford, CA; [4]Health Services Research & Development, Veterans Affairs, Menlo Park, CA; [5]Internal Medicine, Stanford University and VA Palo Alto, Stanford, CA. (Control ID #3391962)

BACKGROUND: The Presence 5 intervention comprises practices derived from a systematic literature review, observation of doctor-patient interactions, qualitative interviews with medical experts and nonmedical professionals, and a review by a panel of expert clinicians, researchers, patients, and caregivers.

Presence 5 practices are: (1) prepare with intention (take a moment to prepare and focus before a patient); (2) listen intently and completely (sit down, lean forward, avoid interruptions); (3) agree on what matters most (find out what the patient cares about and prioritizes for the visit agenda); (4) connect with the patient's story (consider life circumstances that influence the patient's health; acknowledge positive efforts; celebrate successes); and (5) explore emotional cues (notice, name, and validate the patient's emotions).

METHODS: Presence 5 was delivered as a pilot intervention via Presence Circles: peer-facilitated hour-long discussions where physicians (n=15) across three primary care clinics discussed Presence 5 practices and shared specific examples. The discussions were transcribed and coded by Presence 5 practice area.

RESULTS: In the first five circles, 104 discreet Presence 5 practices were shared in Presence Circles (~average 24 per circle).

"Prepare" strategies (n=26) included mental preparation such as mindful handwashing, and physical preparation such as pending the note prior to entering the exam room to seamlessly integrate EMR into the visit, or utilizing the pre-visit briefing with scribes/MAs/students to obtain key information about a patient.

"Listen" strategies (n=17) included avoiding interruptions; non-verbal behaviors such as facing patients, making eye contact, or uncrossing legs to signal openness; and sign-posting – telling patients when providers need to turn attention to the EMR "Give me a second [to write this in the EMR]."

"Agree" strategies (n=21) of interest included eliciting patient priorities ("tell me the whole list first), using alternative appointments (monthly/telephone) to address all priorities over time. Two providers mentioned using MAs to elicit patient top priorities when running behind schedule.

"Connect" strategies (n=26) included focusing on common interests and shared experiences, including family and travel, use of humor, and acknowledgment of patient effort.

"Explore emotion" strategies (n=17) ranged from explicit efforts to notice emotions to naming and eliciting them ("asking about stressors"). Some providers who were less comfortable with managing patient emotions said they put a tissue box in front of patients who were visibly distressed.

CONCLUSIONS: A repository of Presence 5 strategies may serve as a resource to clinicians who seek to try new practices to enhance their communication and relationships with patients. Future research will examine themes within each practice that illustrate variations in how clinicians foster humanism and connection with patients.

PREDICTORS OF PATIENT LOSS TO FOLLOW-UP IN PRIMARY CARE: AN ANALYSIS OF PATIENT RETENTION AT AN ACADEMIC PRIMARY CARE PRACTICE

Erin Duralde[2]; Rebecca Masutani[2]; Maelys Amat[2]; Rebecca Glassman[1]; Kelly L. Graham[1]. [1]General Medicine/Primary Care, Beth Israel Deaconess Medical Center, Boston, MA; [2]Department of Medicine, Beth Israel Deaconess Medical Center, Boston, MA. (Control ID #3387870)

BACKGROUND: Primary care in the United States is undergoing a major transformation toward value-based care, with a new focus on population health. Defining patient panel is the foundation of these efforts. Preliminary analyses from a large academic primary care clinic undergoing such a transition revealed the following: despite acquiring 400 new patients every month, the overall panel size remained at 40,000 patients from 1990 to 2019, suggesting significant patient attrition. Little is published about what drives patient loss. In our current study, we aimed to define patient attrition and identify relevant patient, provider, and practice factors that contribute to this phenomenon.

METHODS: Study Design, Population: We performed a retrospective cohort analysis from 7/2014 - 6/2019 using five years of billing data from a single academic primary care practice, and conducted a qualitative analysis via structured telephone interviews with patients who had left.

Measures: The primary outcome was patient loss to follow-up, defined as a lapse in visits greater than 3 years. Predictors included patient, provider, and practice variables.

Analysis: We compared characteristics of patients lost to follow-up with those who remained in the practice. We used multivariable cox regression analyses to determine significant predictors of loss to follow-up. We identified themes from structured telephone interviews.

RESULTS: We examined 402,415 visits for 41,876 distinct patients. A total of 22% of patients were lost to follow-up, with trainee and departing faculty losing 38% of panel, and stable faculty losing 20% of panel. Patient characteristics associated with loss to follow-up included patient age <40 (HR 2.83 (2.70-2.96)) and limited English proficiency (HR 1.20 (1.10-1.31)). Provider characteristics included trainee status (HR 2.33 (2.22-2.44)) and departing faculty (HR 2.64 (2.50-2.80)). Lower cancer screening rates were noted in the attrition cohort (65% vs 85% for breast, 75% vs 83% for cervical, and 67% vs 88% for colorectal, all p<0.01).

Structured interviews revealed distance, cost, provider turnover, and provider discontinuity within a given year as contributors to loss.

CONCLUSIONS: In this large academic primary care practice, 20% of patients were lost to follow-up. Young patient age and physician transitions were the most powerful predictors of loss, while limited English proficiency had a small but significant effect. Patients lost to follow-up had significantly lower cancer screening rates. Primary care practices, particularly those with trainee and faculty turnover, should dedicate resources to retaining patients and invest in faculty retention. Further efforts should also focus on providing equitable care to patients with limited English proficiency. Further investigation into a more ideal loss to follow-up definition for younger, healthier patients who may engage in primary care in non-traditional ways will better inform panel definition for practices serving these populations.

PREP IN STUDENT HEALTH SERVICES: AN OPPORTUNITY TO EXPAND

Samantha Rawlins-Pilgrim[1,4]; Alyse Wheelock[1]; Carl G. Streed[3]; Margaret Higham[2]; Jessica Taylor[3]. [1]Internal Medicine, Boston Medical Center, Boston, MA; [2]Student Health Service, Tufts University, Medford, MA; [3]Section of General Internal Medicine, Boston University School of Medicine, Boston, MA; [4]Preventive Medicine, Boston Medical Center, Boston, MA. (Control ID #3386548)

BACKGROUND: Despite an overall decline in US HIV incidence, the rate of new infections remains unacceptably high in young men who have sex with men (MSM). HIV pre-exposure prophylaxis (PrEP) is a safe and effective mode of HIV prevention. However, it remains underutilized, and young people ages 16-24 have the lowest rates of PrEP coverage. College and university student health services (SHS) may be a resource for expanding PrEP access to young MSM.

METHODS: We conducted an electronic survey of medical directors of SHS at two and four-year undergraduate institutions in New England (n=143). The primary outcome was availability of PrEP. Secondary outcomes included frequency of PrEP prescribing, barriers and facilitators to offering PrEP, and provider PrEP knowledge. Associations between PrEP prescribing and institutional characteristics were tested using Fisher's exact test.

RESULTS: Thirty-nine percent (N=56) of surveyed institutions responded, the majority of which were private (75%) and four-year (93%) (Table). More than 1 in 3 institutions (n=18, 36%) did not offer PrEP. Those offering PrEP started a mean of 2.0 per 1000 students/year on PrEP (range 0-11.9) and continued a mean of 0.7 per 1000 students/year who had started PrEP elsewhere (range 0-2.7). PrEP was more likely to be offered by four-year schools than two-year schools (68% vs 0%, p=0.042) and by private schools than public schools (73% vs 38%, p=0.043). No differences between religious and secular schools were observed (33% vs 70%, p=0.16). Among institutions not currently offering PrEP (n=18, 36%), the most commonly cited barriers were lack of insurance coverage (n=13, 72%), clinical monitoring requirements (n=12, 67%), and staffing/time constraints (n=10, 56%). Access to on-site support staff (n=11, 61%), institutional willingness for new protocols (n=11, 61%), peer champions (n=11, 61%), and PrEP guidelines and protocols (n=10, 56%), and were identified as potential facilitators of PrEP implementation.

CONCLUSIONS: In spite of strong evidence, PrEP was not available in one in three New England college and university SHS. Absolute prescribing rates among institutions that do offer PrEP are low. Results suggest a substantial opportunity to increase PrEP access to young MSM and others via SHS. Interventions that focus on two-year and public institutions and that support insurance navigation and on-demand provider support may be effective in addressing this gap.

PREP TBL CURRICULUM: IMPROVES IM RESIDENTS PREP KNOWLEDGE

Gina M. Simoncini[2]; Elizabeth Lee[2]; Mica N. Winchester[1]. [1]Internal Medicine, Temple University, Philadelphia, PA; [2]Section of General Internal Medicine, Lewis Katz School of Medicine, Philadelphia, PA. (Control ID #3342830)

BACKGROUND: Pre-exposure prophylaxis (PrEP) is an HIV prevention strategy, but Primary Care Provider (PCP) directed-education has been limited. PCPs have increasing awareness of PrEP, but adoption of PrEP services has been slow. Lack of education is cited as a major barrier.

METHODS: The primary outcome is to improve knowledge of PrEP among Temple University Hospital Internal Medicine categorical residents (N = 97) by implementing a PrEP team-based learning (TBL) curriculum in the academic year 2017-2018. The categorical program is composed of 53 men (55%) and 44 women (45%), 55% self-identifying as white (53/97). Ninety-three residents met eligible criteria, excluding residents on vacation or away rotations. The study was conducted over 5 outpatient clinic weeks to account for the 4 + 1 schedule. Residents were provided with preparatory material regarding PrEP including iPrex study. Residents answered completed a five-question individual readiness assessment test (IRAT) followed by the group readiness assessment test (GRAT). At the end of the PrEP TBL curriculum, residents completed a post PrEP knowledge survey to assess PrEP knowledge acquisition. Thirty-three residents (35% of eligible pool) completed the IRAT and GRAT, including 11 interns, 13 junior residents, and 9 senior residents. Thirty- one residents completed the post-PrEP knowledge survey, including 14 interns, 9 junior residents, and 8 senior residents.

RESULTS: Based on IRAT analysis, 52% of residents did not know the appropriate test for HIV screening. Forty-five percent of residents had difficulty identifying patients who should be counseled on PrEP based on CDC guidelines. Twenty-five percent of residents did not know the recommended immunizations nor sexually transmitted infection tests they should offer men who have sex with men. Thirty-nine percent of residents did not correctly choose the recommended clinical follow-up and monitoring of patients on PrEP. Overall, residents did well on Post-PrEP knowledge survey compared to IRAT and GRAT results. Eighty-eight percent of senior residents answered all five questions correctly compared to 79% of interns and 78% of junior residents. However, 19% of residents still had difficulty determining appropriate testing for acute retroviral syndrome.

CONCLUSIONS: Implementing PrEP TBL curriculum is an important educational tool in order to expand PrEP provider adoption. Based on survey results, resident knowledge of eligible patients and recommended schedule of testing and follow-up for individuals on PrEP improved. Residents need further education on appropriate testing for HIV screening and acute retroviral syndrome.

PRESCRIBING NRT IN HOSPITALIZED PATIENTS WHO SMOKE

Alanna Tieman[1]; Brittany Bass[1]; Le Zhong[1]; Rebecca Mazurkiewicz[2]. [1]Internal Medicine, Northwell, New York, NY; [2]Medicine, Lenox Hill Hospital, New York, NY. (Control ID #3389925)

BACKGROUND: Studies have shown that prescribing nicotine replacement therapy (NRT) to hospitalized patients who smoke increases the rate of successful smoking cessation after discharge. As NRT is not part of our standard admission orders, we hypothesized that many of our patients who smoke are not being prescribed NRT within 24 hours of admission to our hospital.

METHODS: We performed a chart review of all patients admitted to the inpatient general medicine service at our academic community hospital in NYC from November 1st 2017 through October 31st 2018, who answered yes to the question on the provider admission note: "Has the patient used tobacco in the past 30 days?" We excluded patients with admissions to step-down units or intensive care units, as well as patients with lengths of stay one day or less. We evaluated whether NRT was prescribed to these patients during their hospitalization, and if so, whether it was prescribed within 24 hours of admission. NRT was defined as either the nicotine patch, gum or lozenge. For those who were not prescribed NRT, we looked for documented refusal of NRT within the admission note.

RESULTS: Of the 1,289 patients admitted to the regional medicine service during this time period, 762 patients had the question "Has the patient used tobacco in the past 30 days?" answered on their admission note. Of these 762 patients, 100 (13.1%) answered "yes." Of these 100, 17 had lengths of stay one day or less, resulting in 83 patients. Of those 83, 24 (29%) had NRT prescribed at some point during the admission. Of those 24, 19 (79%) were within the first 24 hours of admission, and one patient had documented refusal within the first 24 hours, that was later prescribed NRT, resulting in a 23% (19/82) rate of prescribing NRT within the first 24 hours without documented refusal. Of the initial 83 charts reviewed, 59 (71%) were never prescribed NRT during their hospital stay but only 13 (22%) of these had documented refusal in the admission note. This results in 46 (55%) of the original 83 patients who should have been prescribed NRT, as they did not refuse (or were without documentation of such refusal) but no NRT was prescribed.

CONCLUSIONS: Based on our chart review, we are not sufficiently prescribing NRT within the first 24 hours of admission to patients who smoke, likely because NRT is not a part of our standard admission orders. Prescribing NRT in hospitalized patients who smoke has proven benefits. We can do a better job of prescribing NRT to our patients while they are admitted to the general medicine service. We plan to make a list of general medicine admission orders and add consideration of smoking status and need for NRT as part of that list, and disseminate it to our fellow residents. We have also partnered with the pharmacist on the medical floor, who will follow up with the medical residents regarding patients documented as smokers that do not have NRT ordered.

PRESCRIBING PATTERNS OF ANTIHYPERTENSIVE AND ANTIDIABETIC DRUG THERAPY IN PATIENTS WITH COMORBID HYPERTENSION AND TYPE 2 DIABETES

Adam Attaar, Stacie Schmidt. Internal Medicine, Emory University, Atlanta, GA. (Control ID #3376037)

BACKGROUND: Hypertension when co-occurring with type 2 diabetes doubles the risk of death from cardiovascular disease. Blood pressure and glucose control are strong modifiable risk factors. We studied prescription patterns of antihypertensive and anti-diabetic drug therapy and their adherence with published guidelines.

METHODS: We performed a cross sectional, observational study of patients with hypertension and diabetes followed in our primary care clinic within a large public teaching hospital. Included patients were seen in the prior year with data collected from medical records through 12/2019.

RESULTS: A total of 533 patients were included (mean age 61 ± 10, 43% men, and 91% black patients). Prevalent comorbidities were CHF (14% of patients), CKD (24%), CAD (8%), and obesity (59%). At their last clinic visit, 53% and 28% of patients had achieved blood pressure targets of <140/80 vs. BP <130/80, respectively, and 75% and 56% achieved HgbA1c<8 vs. HgbA1c<7, respectively.

As shown in table 1, anti-hypertensive polytherapy (70%) was more common than monotherapy with 2.3 ± 1.3 mean number of drugs prescribed. ACE or ARBs were the most prescribed drugs followed by calcium channel blockers (CCB). For antidiabetic agents, the majority were on monotherapy with 1 ± 0.9 mean number of oral anti-diabetics prescribed. The oral anti-diabetics prescribed included metformin (59% of patients), dipeptidyl peptidase 4 inhibitors (16%), glucagon-like peptide-1 agonists (9%), sulfonylureas/meglitinides (9%), sodium-glucose transport protein 2 inhibitors (6%), and thiazolidinediones (1%).

Regression analysis revealed higher BMI, lower eGFR, and a diagnosis of CHF were independent predictors of antihypertensive polytherapy (significance level $p<0.05$). Higher eGFR, no diagnosis of CHF, and current non-smoking status were independent predictors of antidiabetic polytherapy. Other significant patterns (significance level $p<0.05$) were increased age positively associates with thiazide and CCB use and higher BMI associates with GLP1, loop diuretic and thiazide use, and negatively associates with DDP4 use.

CONCLUSIONS: Antihypertensive drug utilization at our clinic generally follows guidelines with preferential use of renin-angiotensin inhibitors. Areas of improvement include increasing the proportion of patients achieving blood pressure and glucose control, which commonly requires multi-drug therapy, and further increasing use of renin-angiotensin inhibitors whenever indicated.

Table 1- Antihypertensive drug utilization by drug class in mono- and poly-therapy

Drug Class, N (%)	Overall N= 533	No Drug n=31 (6%)	Mono-therapy n= 126 (24%)	Polytherapy n=376 (70%)			
				2 drugs n=168 (32%)	3 drugs n=116 (22%)	4 drugs n=72 (14%)	5 or More Drugs n=20 (4%)
ACE or ARB	368		66	125	98	63	16
Thiazides	166		12	47	67	32	8
CCB	303		38	110	83	56	16
Beta blocker	192		10	40	63	61	18
Loop diuretic	79		0	12	22	35	10
Spironolactone	35		0	1	5	18	11
Other Hypertensives	47		1	4	8	19	15

PREVALENCE AND COST OF CASCADES AFTER LOW-VALUE ROUTINE TESTING DURING THE MEDICARE ANNUAL WELLNESS VISIT

Ishani Ganguli[1]; Claire Lupo[1]; Alexander J. Mainor[2]; Qianfei Wang[2]; E. John Orav[1]; Meredith Rosenthal[3]; Thomas D. Sequist[4]; Carrie H. Colla[2]. [1]Division of General Internal Medicine and Primary Care, Brigham & Women's Hospital, Cambridge, MA; [2]The Dartmouth Institute for Health Policy and Clinical Practice, Geisel School of Medicine, Lebanon, NH; [3]Harvard TH Chan School of Public Health, Boston, MA; [4]Quality and Safety, Partners Healthcare System, Boston, MA. (Control ID #3391366)

BACKGROUND: For healthy adults, routine testing during annual check-ups is considered low-value and may trigger cascades of further

medical services that are of unclear benefit. We do not know how often routine tests are performed during Medicare Annual Wellness Visits (AWVs) nor whether they are associated with cascades (ie, downstream laboratory tests, imaging/cardiac tests, procedures, hospitalizations, and new diagnoses).

METHODS: Using national 20% Fee-for-Service Medicare claims, we identified patients 66 years and older who received an AWV in 2014, had no prior Elixhauser or Charlson comorbidities, had not gotten one of the routine tests of interest (urinalysis, thyroid stimulating hormone (TSH), or electrocardiogram (EKG)) in the 6 months before their AWV, and had no symptoms or conditions in the AWV testing period that would suggest a non-"preventive" indication for a routine test. Within this cohort, we compared patients who received a given routine test between 7 days before and 1 day after the AWV to those who did not. Our primary outcome was cascade-attributable event rates and associated charges in the 90 days after the AWV test period, using Poisson and linear regression models adjusted for visit, patient, and area-level characteristics and physician random effects. We also examined patient, physician, and area-level predictors of receiving routine tests.

RESULTS: Among 62,531 AWV recipients, 17.5% (n=10,952) received at least one routine test including an EKG (6.9%, n=4,321), urinalysis (9.3%, n=5,817), or TSH (8.0%, n=4.987). Patients who were younger (Adjusted Odds Ratio (AOR) 1.84 for 66-74 years old vs >85 years old [95%CI, 1.64-2.07]), white (AOR 1.21 vs black [95%CI, 1.05-1.39]), and lived in urban areas (AOR 1.55 vs rural [95%CI, 1.36-1.76]) and higher income areas (AOR 1.73 for >400% above federal poverty level vs 0-200% FPL [95%CI, 1.60-187]) were more likely to get any routine test. We identified 7.8 [95%CI, 5.9-9.6] cascade-attributable events per 100 beneficiaries in the 90 days following routine EKGs, 2.4 [95%CI, 0.0-4.7] following urinalyses, and 4.2 [95%CI, 2.1-6.2] following thyroid tests, with cascade-attributable cost per beneficiary of $152.6 [95%CI, $6.5-$298.6], -$25.2 [95%CI, -$109.2-$58.9], and $24.8 [95%CI, -$62.7-$112.3] respectively.

CONCLUSIONS: A sizable minority of healthy Medicare beneficiaries received routine EKGs, urinalyses, or thyroid tests during their annual wellness visits – more often those who were younger, white, and lived in urban, high income areas. All 3 tests were associated with downstream cascades while only EKGs demonstrated significant downstream cost, suggesting clinicians and policymakers might weigh both financial and non-financial effects of low-value testing cascades when prioritizing efforts to reduce them.

PREVALENCE OF ADVERSE CHILDHOOD EXPERIENCES AND POST TRAUMATIC STRESS DISORDER SYMPTOMS IN AN AMBULATORY SAFETY-NET POPULATION

Danielle F. Loeb[1]; Michael J. Durfee[4]; Samantha Pelican Monson[4]; Elizabeth A. Bayliss[2]; Danielle M. Kline[3]; Deborah Rinehart[4,1]. [1]General Internal Medicine, University of Colorado Denver, Aurora, CO; [2]Institute for Health Research, Kaiser Permanente and University of Colorado, Denver, CO; [3]Medicine, University of Colorado Denver School of Medicine, Aurora, CO; [4]Health Services Research, Denver Health, Denver, CO. (Control ID #3392471)

BACKGROUND: Adverse childhood experiences (ACEs) have a strong linear relationship with common causes of adult illness, death, and disability. The burden of ACEs and lifetime trauma among ambulatory patients in safety-net healthcare systems and the association of ACES with population health risk stratifications measuresis less well-understood. We sought to evaluate the burden of ACES and association of ACES with Tier; evaluate the incidence of lifetime trauma and presence of PTSD symptoms in patients seeking primary care at Denver Health Hospital Administration (DHHA).

METHODS: We conducted a cross-sectional survey of patients attending primary care visits at DHHA, a safety-net healthcare system that utilizes a 4-tiered population health risk stratification method, based on ICD-10s and health service utilization. We recruited patients 18 to 65 years old whose primary language was English or Spanish. We used a pseudo-random sampling method that included features of systematic and multistage sampling. Outcome measures included: ACEs measured using the 10-question survey, Adverse Childhood Experiences Questionnaire. Each item scored as the presence or absence of exposure with a summary score of 0 to 10. Primary Care Posttraumatic Stress Disorder for DSM 5 (PC-PTSD5) used to screen for current symptoms of posttraumatic stress disorder. Series of trauma informed care interventions and treatments rated on a scale of "not helpful at all" to "extremely helpful" to assess treatment preferences. Data collected from DHHA EHR included patient tier (range of 1-4) and presence of a trauma-related diagnosis. In multivariable analysis of association of ACES with Tier, we controlled for age, race, ethnicity, gender, and SES.

RESULTS: 303 of 481 approached participated for a response rate of 63%. Of 289 respondents who completed ACES, 148 (51.2%) scored 3 or greater and 117 (40.4%) with score 4 or higher. 172 of 300 participants who responded (57.3%) had positive response to lifetime presence of a traumatic event on the PC-PTSD. Of those 172,88 (51.2%) had a score of 3 to 5. 20 (22.7%) of those with a positive score had a trauma-related diagnosis in their chart. Odds of ACES ≥ 4 if PC-PTSD $\geq 3 = 4.2$ (95% CI 2.3-7.7). In multivariable analysis, ACES score was not significantly associated with tier ($p = 0.3150$) when controlling for age, race, ethnicity, gender, and socioeconomic status. People with trauma history were significantly more likely to endorse "Does going to a doctor's visit at this clinic make you feel stressed?" ($p < 0.01$). Patients with trauma expressed preferences for changes to their primary care provider's behavior over changes to team behavior or clinic built environment.

CONCLUSIONS: Rates of ACES and positive PC-PTSD were higher than the general population and past studies of primary care populations. In next steps, we will include the Chronic Illness and Disability Payment System (CDPS) in the multivariable analysis to risk adjust for severity of illness.

PREVALENCE OF FINANCIAL CONFLICTS OF INTEREST AMONG NON-INDUSTRY FUNDED TRIALS

Haley R. Martin[1,3]; Wylie M. Barker[1,3]; Ann Abraham[1,3]; Emily Lum[1,3]; Deborah R. Korenstein[2]; Salomeh Keyhani[3]. [1]NCIRE, San Francicsco VA Medical Center, San Francisco, CA; [2]Department of Medicine, Memorial Sloan Kettering Cancer Center, Pelham, NY; [3]Department of Medicine, University of California at San Francisco, San Francisco, CA. (Control ID #3390519)

BACKGROUND: Randomized controlled trials (RCTs) are considered the most reliable form of evidence in evaluating the safety and efficacy of drugs. Because results of RCTs shape the evidence

base, objectivity in the conduct of clinical trials has important implications for clinical practice and the health and safety of patients. Previous studies have demonstrated that financial ties are common among trial principal investigators (PIs). However, the prevalence of financial ties has not been examined among non-industry funded studies. We examined the prevalence of financial ties among PIs of non-industry funded drug efficacy studies.

METHODS: We conducted a cross sectional study examining the prevalence of financial ties among PIs in non-industry funded published RCTs registered in clinicaltrials.gov between 01/01/2015 and 12/31/2017. We included studies examining drug efficacy. We excluded studies of generic drugs, head-to-head studies, and dosing studies. We defined financial ties as the direct compensation of PIs by the manufacturer of the drug of interest in the form of speakers' fees, honorariums, consultant and advisor fees, employee relationships, patents, travel fees, or food/beverage fees. We designated PIs as first and last authors. We searched each study for declaration of financial ties and regardless of disclosure, we searched for ties using Open Payments Data and Disclosure UK. Searches were limited to the two years prior to online study publication. If any of the PIs had a financial tie, we considered the publication as having a financial tie.

RESULTS: Our search yielded 755 studies, of which 90 met inclusion criteria. First authors were predominately based in North America (80%), followed by Europe (9%), then Asia (8%). Best represented specialties included Cardiology (16%), OBGYN (13%) and Anesthesiology (10%). The most common funding sources included NIH (44%), Foundations (24%), and Other Government Agencies (14%). Among 90 studies, 16 (18%) had PIs with financial ties and 74 (82%) had no PIs with financial ties. Among the 40 studies with some NIH funding, 21 (53%) had financial ties. Among the 18 PIs with financial ties identified, 56% had not disclosed them in the paper. Types of financial ties included food/beverage (32%), unspecified (28%), honorariums (12%), consultant/advisor (12%), travel (12%), and employee relationship (4%).

CONCLUSIONS: Among non-industry funded studies, financial ties are common. There is a high prevalence of nondisclosure of financial ties. A larger sample size with a more diverse geographic authorship would provide greater generalizability.

PREVALENCE OF RISK FACTORS FOR COGNITIVE IMPAIRMENT AMONG MIDDLE AGE AND OLDER ADULTS: THE LITCOG STUDY

Morgan Eifler[1]; Lauren Opsasnick[2]; Julia Yoshino Benavente[2]; Laura M. Curtis[2]; Michael S. Wolf[3]. [1]General Internal Medicine and Geriatrics, Northwestern University, Chicago, IL; [2]General Internal Medicine, Northwestern University, Chicago, IL; [3]Medicine, Northwestern University, Chicago, IL. (Control ID #3391522)

BACKGROUND: Investigations into cognitive changes have typically focused on older adulthood, as Alzheimer's disease and related dementias (ADRD) are most prevalent among people 65 years and older. However, evidence has emerged suggesting that clinically meaningful cognitive decline may present earlier on. Several known or suspected risk factors for cognitive impairment/ADRD manifest during middle age, including chronic conditions that may be newly acquired or inadequately managed, entrenched lifestyle behaviors such as obesity or smoking, and psychosocial stressors (e.g. employment, finances, depression). Using an existing cohort study of older adults, we explored these risk factors by age.

METHODS: Patients ages 55-74 were recruited from an academic internal medicine clinic and six federally qualified health centers in Chicago (N=900). In-person structured interviews were conducted every 2.5 years to investigate changes in cognitive function, health literacy (HL), and health self-management (SM). We examined behavioral characteristics by age group (ages 55-59 (n=279); 60-64 (n=284); 65-69 (n=182); 70+ (n=155)). Patients self-reported chronic conditions, employment/income status, and Body Mass Index (BMI). Smoking habits were assessed via the Behavioral Risk Factor Surveillance System (BRFSS), and health literacy was measured by the Newest Vital Sign (NVS). Global health, physical function, and mental health symptoms were assessed using the PROMIS short forms. For this analysis, we used Chi-square statistics and one-way ANOVA, as necessary, to evaluate associations between behavioral and psychosocial characteristics and age groups.

RESULTS: Participants mean age was 63 years; 69% were female, 47% were African American, and approximately half had limited health literacy. When comparing age groups, the late middle age adults (ages 55-59) were more likely to work full time (33.5% vs. 19.5%, 9.4%, 3.9%, $p<0.001$) and to support a greater number of individuals on their income (M=1.9 (1.1) vs. 1.8 (1.1), 1.6 (0.8), 1.6 (0.9), p=0.01). They had significantly higher rates of obesity (45.4% vs. 38.8%, 35.8%, 29.0%, p=0.01) and were more likely to self- report "fair" or "poor" overall health (30.2% vs. 26.1%, 18.1%, 17.4%, p=0.004). Additionally, they reported a significantly greater number of anxiety (M=54.7 (9.1) vs. 53.6 (8.3), 51.8 (9.1), 51.6 (8.9), p=0.001) and depressive symptoms (M=49.0 (9.8) vs. 48.5 (9.1), 46.6 (8.4), 46.0 (7.9), p=0.001). Smoking status, total number of chronic conditions, and physical function were consistent across age groups.

CONCLUSIONS: Late middle age adults were associated with higher rates of specific lifestyle behaviors and psychosocial stressors, including obesity, anxiety, depression and worse health status than older adults in this sample. Further exploration of risk factors for cognitive impairment among middle age and older adults may inform health system strategies to prevent, better detect or manage cognitive impairment.

PRIMARY CARE MEDICAL STAFF ATTITUDES TOWARD SUBSTANCE USE: RESULTS OF THE SUBSTANCE ABUSE ATTITUDES SURVEY (SAAS)

Noa Appleton[1]; Leah Hamilton[1]; Sarah E. Wakeman[2]; Timothy WIlens[3]; Joseph Kannry[5]; Richard N. Rosenthal[6]; Keith Goldfeld[1]; Angeline Adam[1]; Sarah Farkas[4]; Carmen Rosa[7]; John Rotrosen[4]; Jennifer McNeely[1]. [1]Population Health, NYU School of Medicine, New York, NY; [2]Medicine, Massachusetts General Hospital, Charlestown, MA; [3]Psychiatry, Massachusetts General Hospital, Boston, MA; [4]Psychiatry, NYU School of Medicine, New York, NY; [5]Division of General Internal Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; [6]Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY; [7]Center for the Clinical Trials Network, National Institute on Drug Abuse, Bethesda, MD. (Control ID #3390654)

BACKGROUND: Under-treatment of drug and alcohol use in primary care settings has been attributed, in part, to medical providers' negative attitudes toward substance use. As a part of an implementation study of electronic health record-integrated substance use screening in primary care clinics, conducted in the NIDA Clinical Trials Network, we assessed baseline attitudes among medical staff.

METHODS: Eligible participants were primary care providers and medical assistants in 4 urban academic primary care clinics. Prior to implementation of a substance use screening program, participants completed the Substance Abuse Attitudes Survey (SAAS), a validated 50-item self-administered survey that measures attitudes to substance use in 5 domains: permissiveness, non-moralism, non-stereotyping, treatment intervention, and treatment optimism. Participants were asked to rate their level of agreement with each item on a five-point Likert scale.

RESULTS: In total, 131/191 (69% response rate) eligible staff completed the survey. Participants had mean age 42; 76% were female; 11% Hispanic/Latino, 6% Black, 25% Asian. The majority of the sample was physicians (78%), while 11% were nurse practitioners, and 11% were medical assistants. Participants had an overall average of 13.2 years in practice. Approximately one-third reported moderate to high satisfaction treating patients with drug problems (35.1%) and alcohol problems (33.6%). The proportion of participants having positive attitudes in each of the following domains were: non-moralism (64.1%); non-stereotyping (55.7%); treatment intervention (47.3%); treatment optimism (48.9%); and permissiveness (44.3%). Negative attitudes toward permissiveness reflect responses to items addressing health effects of substance use, especially among teens.

CONCLUSIONS: While most primary care staff did not endorse moralistic or stereotyping statements about alcohol and drug use, attitudes toward addiction treatment were mixed, with less than half endorsing positive attitudes toward treatment effectiveness. These results suggest a need to improve attitudes, particularly toward addiction treatment. This could be accomplished through education and increased exposure to effective interventions that can be delivered by primary care providers, including office-based treatment for alcohol and opioid use disorder.

PRIMARY CARE NEEDS AMONG PATIENTS RECEIVING OFFICE BASED OPIOID TREATMENT (OBOT) WITH BUPRENORPHINE

Jeanette M. Tetrault[1,2]; Cindy X. du[3]; Julia M. Shi[1,2]; Lynn M. Madden[2,1]; Declan Barry[1,2]. [1]Internal Medicine, Yale University School of Medicine, New Haven, CT; [2]APT Foundation, New Haven, CT; [3]Yale School of Medicine, New Haven, CT. (Control ID #3392441)

BACKGROUND: Opioid use disorder (OUD) is a chronic disease. Integrating OUD treatment and primary care is feasible, effective, and promotes retention. Integrated models of care are effective when several chronic conditions can be treated in one setting. This is important for older patients or patients with other conditions or who are prescribed multiple medications. Little is known about the primary health care needs of patients with OUD and how this differs by age or treatment retention. The purpose of this study is to characterize the primary care conditions and prescription medications among patients treated with office-based opioid treatment (OBOT) with buprenorphine.

METHODS: Our retrospective study was conducted at an integrated outpatient primary care clinic within the APT Foundation, a non-profit opioid treatment program in CT. We included all patients enrolled in OBOT in the electronic health record as of an index date of 4/29/2019. Patients were excluded if they were not prescribed buprenorphine or if they did not have urine toxicology testing for the three months prior. Variables extracted included demographics, chronic pain management and other primary care practitioner status. Urine testing was reviewed for presence of buprenorphine or substance use. Descriptive statistics were calculated using R and Microsoft Excel. P- values were calculated using an independent 2-group Mann-Whitney U Test and Fischer's Exact Test. We stratified results by older vs. younger patients (defined as <50 vs.> or = to 50) and by patients retained vs. not retained in OBOT for >or = 1 year.

RESULTS: 355 patients were included. 33.7% of patients were > or =50 years old, 71.5% male, 89% White/Caucasian, and 7.3% Latino/Hispanic. 42.0% of patients had another primary care practitioner. Comorbid conditions included chronic pain (24.5%), psychiatric diagnosis (38.5%), and other SUDs (54.8%). 3.65% had chronic viral hepatitis and zero had HIV. Patients reported taking a median of 4 medications (IQR: 2-6), and 59.6% used 1 or more psychoactive medications (PAM). Common classes of medications were cardiovascular (36.62%) and non-opioid pain (22.54%). Older patients used more medications than younger patients (Median: 5 vs Median: 3, p-value 1.3×10^{-7}). Older patients, patients with chronic pain, and patients prescribed PAMs were not more likely than their counterparts to have a urine toxicology test positive for opioids (OR 0.93, OR 0.88, OR 1.3, p-value= 0.83, p-value= 0.81, p-value=0.68 respectively). Patients retained in treatment <1 year were more likely than those retained > or = 1 year to have a urine toxicology test positive for opioids (OR 2.44, p-value= 0.03).

CONCLUSIONS: Our findings underscore the importance of incorporating OBOT into integrated primary care settings. Primary care practitioners should be encouraged to offer OBOT as they are well equipped to treat the most commonly occurring conditions among patients.

PRIMARY CARE PHYSICIAN EXPERIENCE WITH SINGLE-LEAD ECG SCREENING FOR UNDIAGNOSED AF: RESULTS FROM THE VITAL-AF STUDY

Jeffrey M. Ashburner[1]; Aimee K. Lin[2]; Colin M. Rivet[2]; Priscilla R. Lee[2]; Courtney E. Leonard[2]; Margaret Bussineau[2]; Ana T. Trisini Lipsanopoulos[3]; Leila H. Borowsky[4]; Wyliena Guan[2]; Xinye Li[2]; Yuchiao Chang[1]; Shaan Khurshid[2]; Patrick T. Ellinor[2]; Daniel E. Singer[1]; David D. McManus[5]; Steven A. Lubitz[2]; Steven J. Atlas[1]. [1]Division of General Medicine, Massachusetts General Hospital, Boston, MA; [2]Division of Cardiology, Massachusetts General Hospital, Boston, MA; [3]Cardiology, Massachusetts General Hospital, Boston, MA; [4]General Medicine Division, Massachusetts General Hospital, Boston, MA; [5]University of Massachusetts Medical School, Worcester, MA. (Control ID #3367686)

BACKGROUND: Atrial fibrillation (AF) is a common arrhythmia associated with a 5-fold increased risk of stroke. Since AF may be asymptomatic and related strokes may be preventable with anticoagulation, we conducted a pragmatic cluster-randomized trial (VITAL-AF, ClinicalTrials.gov NCT03515057) in a large primary care network in the United States to assess the efficacy of population-based screening for AF in older patients using a 30-second handheld single-lead ECG as part of routine care. We examined primary care provider (PCP) experience with screening at study completion.

METHODS: We randomized practices to AF screening (n=8) or to usual care (n=8). All patients ≥ 65 years attending an outpatient

visit with a physician or nurse practitioner were eligible. Intervention sites embedded screening by medical assistants as part of routine vital signs assessment at each clinic encounter. Control practices continued with usual care that may have included rhythm assessment as determined by each PCP. Following the 1-year screening period, intervention PCPs (88 physicians and 16 nurse practitioners) were sent a survey that asked about AF screening practice prior to the study, experience with screening during the study, and preferences for future practice.

RESULTS: During the 1-year screening period, 17,645 unique subjects had 45,406 encounters in an intervention practice. Overall, 16,105 (91%) patients completed at least one single-lead ECG tracing and screening was completed at 35,080 (77%) encounters. The PCP survey response rate was 81% (84/104) among intervention PCPs. PCPs rated integrating AF screening into clinical practice favorably (81% easy/very easy to integrate). 71% of PCPs reported ordering more ECGs, and 34% reported ordering more Holter/patch monitors during the study period. All but 1 PCP reported being informed about one of their patients screening as "Possible AF," and 62% indicated AF screening led to a new true diagnosis of AF for at least one patient (27% 1 patient, 26% 2 patients, 8% ≥3 or more patients). However, PCPs estimated that the false positive rate of screening was high (57% estimated that <30% of "Possible AF" screening results were true positives). Most PCPs stated that they performed pulse palpation to screen for AF prior to the study. When asked about future use PCPs said they favored screening (86%), either annually (36%) or at each visit (45%), preferentially with a single lead ECG (73%). PCP reported occurrence of true positive cases or estimated false positive rates did not affect preference for single lead ECG screening.

CONCLUSIONS: Screening and survey data suggest that adding automated AF rhythm assessment as a new vital sign with a single-lead ECG among older adults at primary care visits is feasible and accepted by patients and PCPs. PCPs viewed single-lead ECG screening for AF favorably despite a low true positive rate and the need for additional ECGs or ambulatory rhythm monitoring that were prompted by the screening.

PRIMARY CARE PHYSICIANS FAIL TO RECOGNIZE DEPRESSIVE SYMPTOMS AMONG MOST CHINESE AND LATINO PATIENTS DURING ROUTINE PRIMARY CARE VISITS

Maria E. Garcia[1]; Ladson Hinton[2]; Steven Gregorich[3]; Jennifer Livaudais-Toman[4]; Celia P. Kaplan[5]; Mitchell D. Feldman[6]; Leah S. Karliner[6]. [1]General Internal Medicine, University of California, San Francisco, San Francisco, CA; [2]Psychiatry, UC Davis, Sacramento, CA; [3]UCSF, San Francisco, CA; [4]Division of General Internal Medicine, University of California, San Francisco, Greenwich, CT; [5]Medicine, University of California San Francisco, San Francisco, CA; [6]Medicine, UCSF, San Francisco, CA. (Control ID #3391891)

BACKGROUND: Poor recognition of depressive symptoms may contribute to racial and ethnic minorities disparities in depression treatment. Primary care physicians fail to recognize depressive symptoms in half their non-Latino white patients, yet little is known about rates of under-recognition in Chinese and Latino patients. We sought to determine whether physicians recognize and treat Chinese and Latino patients with depressive symptoms during routine primary care visits.

METHODS: This cross-sectional study included Chinese and Latino primary care patients with a preferred language of English, Cantonese, Mandarin or Spanish and no documented prior diagnosis of depression in a large academic practice in San Francisco, California prior to implementation of universal screening. We recruited and interviewed participants within 1 week of a primary care visit. The study questionnaire included the Patient Health Questionaire-2 (PHQ-2) to assess depressive symptoms in the prior 2 weeks. For patients with current depressive symptoms (PHQ-2 score ≥3), we conducted chart reviews to determine if the physician had documented discussion of symptoms, initiated an antidepressant, or referred the patient for therapy. We further determined whether the patient had a follow-up visit within 30 days that addressed depression.

RESULTS: Among 1171 Chinese and Latino participants, 118 patients (mean age 68) had current depressive symptoms. In total, only 11 unique participants (9% of those with PHQ-2 score ≥3) had their depressive symptoms recognized and addressed. Physicians initiated antidepressants for four participants (2.5%) and referred 6 participants (5.0%) for services. Eight participants (6.7%) received an antidepressant and/or a referral. Twenty-three participants (19%) had follow-up appointments within 30 days; of those a further three participants (2.5%) had a discussion with their physician about their depressive symptoms and all were referred to therapy. We found no significant differences in recognition and treatment initiation by race/ethnicity (Chinese vs Latino) or English proficiency, though the number of patients with recognized symptoms was small.

CONCLUSIONS: Physicians recognized and addressed depressive symptoms in only a small proportion of Chinese and Latino patients with no history of depression during routine visits in a large academic primary care practice. Low rates of physician recognition of depressive symptoms in Chinese and Latino patients likely contribute to significant disparities in depression treatment for these populations. Universal depression screening followed by targeted follow-up may help address unmet mental health needs in these patients.

PRIMARY CARE PHYSICIANS THAT PRACTICE IN A SINGLE CARE SETTING: A COHORT STUDY OF US PHYSICIANS TREATING OLDER ADULTS 2014-2017

Kira Ryskina[1]; Mark Unruh[2]; Yuting Qian[2]; Lawrence P. Casalino[2]; Hye-Young Jung[2]. [1]Medicine, University of Pennsylvania, Philadelphia, PA; [2]Public Health, Weill Cornell Medical College, New York, NY. (Control ID #3390548)

BACKGROUND: As US health care shifts to delivery models that place emphasis on improving population health and controlling costs, primary care has become a target of investment. By directing resources toward primary care, these models recognize the important role that primary care physicians play in care coordination and continuity between settings. However, some primary care physicians are increasingly limiting their scope of practice to a single setting defined by the type of facility where they practice (e.g., hospital, skilled nursing facility, office). We examined recent trends in the prevalence of primary care physicians treating older adults who focus their practice on a single setting and of physician groups that contain different types of setting-based primary care 'specialists'.

METHODS: We used 2014-2017 billing data for Medicare fee-for-service beneficiaries to measure the proportion of all patient visits by primary care physicians (family medicine, internal medicine, geriatrics, and general practice) in the physician office, inpatient hospital, outpatient hospital department, and other settings (e.g., skilled nursing facility, assisted living facility, etc). Outpatient hospital department visits included visits to patients in observation units and ambulatory hospital-based clinics. A 'setting-based specialist' was defined as a physician who had at least 90% of all their professional services performed in a single setting. To describe regional trends in primary care physician setting-based specialization during the study period, we calculated the proportion of all physicians who focused their practice in a single setting. We also measured the proportion of primary care physician groups that included different types of setting-based specialists.

RESULTS: 141,404 primary care physicians were included in the analyses. From 2014 to 2017, the proportion of primary care physicians who narrowed their practice to a single setting increased by 6.7% (from 62.8% to 67.0%, $p_{for\ trend}<0.001$). The greatest relative increase occurred among physicians who practiced in the hospital outpatient department (15.7% increase from 5.1% to 5.9%; $p_{for\ trend}<0.001$). The proportion of primary care physicians who practiced in an office not affiliated with a hospital increased by 5.1% (from 43.0% to 45.2%; $p_{for\ trend}<0.001$), in a hospital by 8.5% (from 9.4% to 10.2%; $p_{for\ trend}<0.001$), and in other settings by 7.5% (from 5.3% to 5.7%; $p_{for\ trend}<0.001$). This trend was not accompanied by growth among primary care physician groups that include different types of setting-based specialists (4.6% of physician groups included more than one type of setting-based specialist).

CONCLUSIONS: Two-thirds of US primary care physicians treating older adults focus their practice on a single type of health care setting or facility. These findings raise concerns regarding increasing fragmentation of primary care delivery across different health care settings.

PRIMARY CARE PHYSICIANS' PERSPECTIVES ON LOW-VALUE PRESCRIBING IN OLDER ADULTS

Eric Walter[1]; Alicia Dawdani[2]; Megan E. Hamm[2]; Aimee N. Pickering[1]; Carolyn T. Thorpe[4,5]; Joseph T. Hanlon[3,6]; Walid Gellad[2,4]; Thomas R. Radomski[2,6]. [1]Internal Medicine, University of Pittsburgh Medical Center, Pittsburgh, PA; [2]Division of General Internal Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA; [3]Department of Geriatric Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA; [4]Center for Health Policy Research and Promotion, VA Pittsburgh Medical Center, Pittsburgh, PA; [5]Division of Pharmaceutical Outcomes and Policy, University of North Carolina Eshelman School of Pharmacy, Chapel Hill, NC; [6]Center for Pharmaceutical Policy and Prescribing, University of Pittsburgh, Pittsburgh, PA. (Control ID #3391775)

BACKGROUND: Health systems are increasingly implementing interventions to reduce older patients' use of low-value medications. However, prescribers' perspectives regarding medication value and views of such interventions are poorly understood. Our objective was to identify the characteristics that affect the perceived value of a medication and those factors that incentivize or disincentivize low-value prescribing from the perspective of primary care physicians.

METHODS: We conducted 16 semi-structured interviews of primary care physicians from academic and community settings. We elicited their views on definitions and examples of low-value prescribing in older adults, the factors that incentivize or disincentivize them to engage in such prescribing, and the characteristics of interventions that make them more or less likely to deprescribe low-value medications. Interviews were audio-recorded and transcribed verbatim. We developed a codebook that 2 members of the research team applied to each transcript. To identify salient themes, we conducted a thematic analysis of 5 transcripts, with analyses of the remaining transcripts 4We identified 3 key preliminary themes. First, physicians viewed low-value prescribing among older adults as prevalent and described factors such as patients' limited life expectancy and the increased risk of side effects like falls and bleeding as reducing or eliminating the value of certain medications. Second, physicians consistently described the concept of "prescriber inertia", defined as the continuation of medications that were once appropriate but are no longer safe or effective, as the driving force behind low- value prescribing. Reasons for this inertia included insufficient time, the cognitive burden of performing medication reconciliation, and the subtle nature of shifting patient characteristics over time. As one participant described, "patients accumulate these medicines and it's just easier to continue than it is to think critically and have the discussion about discontinuing." Third, providers believed that interventions to address low-value prescribing must address the cognitive load and time pressures that drive "prescriber inertia." Examples included sending targeted messages alerting providers to potentially low-value medications and shifting responsibility for medication reconciliation to ancillary staff. Conversely, initiatives that would increase time pressure or cognitive load, such as increased documentation, were less acceptable.

CONCLUSIONS: Our preliminary findings demonstrate that low-value prescribing is a well-recognized phenomenon among primary care physicians, and that interventions to facilitate the deprescribing of low- value medications must address the time pressures and cognitive burden that result in prescriber inertia. Our findings will allow health systems to design interventions in ways that are acceptable to physicians by accounting for their views and values regarding low-value prescribing in older adults.

PRIMARY CARE PRACTITIONER AWARENESS OF AND REFERRAL TO NATIONAL DIABETES PREVENTION PROGRAMS: A LOCAL ASSESSMENT

Diana Thiara[1]; Meghana D. Gadgil[2]. [1]General Internal Medicine, University of California at San Francisco, San Francisco, CA; [2]Department of Medicine, University of California, San Francisco, San Francisco, CA. (Control ID #3375085)

BACKGROUND: Thirty-four percent of US adults have prediabetes.[1] The burden of disease is even higher in California at forty-six percent. Those with prediabetes have a forty percent risk of developing diabetes within five years. The Diabetes Prevention Program (DPP) is an evidence-based, CDC-accredited program focusing on lifestyle change to prevent diabetes in patients with prediabetes. However, few providers are aware of and refer to the DPP. According to a national survey of one thousand two hundred thirty-six primary care providers, thirty-eight percent were aware of the DPP and only twenty-three percent referred prediabetic patients to

the DPP.[2] Concerningly, a larger deficit exists as only four percent of prediabetic patients report being referred to DPP.[3]

METHODS: To assess knowledge of and referral to DPPs, an anonymous questionnaire including a subset of questions from the 2016 DocStyles web-based survey was sent to all one hundred forty providers (attending physicians, resident physicians, and nurse practitioners) within the Division of General Internal Medicine at UCSF.[2] The five questions measured providers self-reported prediabetes screening practices, awareness of DPP, referral patterns, as well as EMR panel management habits for prediabetic patients.

RESULTS: Of the 140 providers, we had 73 complete responses (52%). 42 (58%) were attending physicians, 26 (35%) were resident physicians, and 5 (7%) were nurse practitioners. 33% of respondents had heard of the National DPP. 8% had referred to an in-person or online CDC-recognized DPP, and those responses were all from attending physicians. 10% used the EMR panel management tool to identify pre-diabetic patients in their panels.

CONCLUSIONS: Rates of provider awareness of and referral to DPP at our institution are much lower than national averages. Furthermore, clinicians are not using built-in EMR panel management tools to help identify pre-diabetic patients which could help increase and streamline referral practices. Overall, addressing these gaps in practice through provider education interventions as well as creating a partnership between our institution and the local YMCA-led DPPs has the potential to increase patient referrals and improve health outcomes.

PRIMARY CARE PROVIDER INVOLVEMENT DURING HOSPITALIZATION: PERSPECTIVES OF FREQUENTLY HOSPITALIZED PATIENTS IN THE COMPREHENSIVE CARE PROGRAM VERSUS USUAL CARE

Erin Y. Rieger[1]; Josef N. Kushner[1]; Veena Sriram[3]; Abbie Klein[2]; Lauren O. Wiklund[2]; David Meltzer[2]; Joyce W. Tang[2]. [1]Pritzker School of Medicine, University of Chicago, Chicago, IL; [2]Department of Medicine, University of Chicago, Chicago, IL; [3]Center for Health and the Social Sciences, University of Chicago, Chicago, IL. (Control ID #3388416)

BACKGROUND: As hospitalized patients are increasingly cared for by hospitalist physicians with whom they have no prior relationship, discontinuities in care and communication may arise. These problems may be magnified for frequently hospitalized patients with complex medical and social conditions. Involvement of primary care physicians (PCPs) could mitigate these discontinuities; however, patients' experiences and preferences related to PCP involvement in the hospital setting are not well studied. The goal of this study was to explore patient perspectives within the context of the Comprehensive Care Program (CCP) study, a randomized controlled trial which assesses the effects of an interdisciplinary care team led by a physician who serves as both the outpatient PCP and inpatient attending as compared to usual care (ambulatory care from a PCP, hospital care from hospitalists) for patients at high risk of hospitalization.

METHODS: This is a qualitative study embedded within a randomized controlled trial. In-depth interviews were conducted with a purposive sample of 12 CCP and 12 usual care patients to better understand patients' experiences and preferences surrounding the role of their PCP during hospitalization. Data were analyzed by the research team using general thematic analysis. Each transcript was coded by two researchers; themes and representative quotes were agreed upon through discussion in face-to-face meetings.

RESULTS: Four primary themes emerged: 1. PCP continuity (CCP patients described longitudinal relationships with their PCP which improved over time. Usual care patients reported frequent turnover of PCP); 2. PCP involvement during hospitalization (CCP and usual care patients valued PCP involvement during hospitalization. While most usual care patients did not interact with their PCP during hospitalization, CCP patients described active involvement of their PCP in decision-making: *"You ask about your discharge plans, you talk to your doctor about what I've gotta do to get better."*); 3. Communication between PCP and hospital providers (CCP patients emphasized PCP's role aligning the knowledge and goals of the providers: *"She's my main doctor, so she makes sure everybody gets the email when I'm in the hospital."* Most usual care patients were not aware of communication between PCP and hospital providers: *"I don't know for sure that they're calling him…or if he's getting the reports or any of that."*); and 4. Shared trust (CCP patients valued PCP's clinical judgement, but also felt their PCP empowered them to make decisions: *"We have this really good relationship, and she knows that I am an informed patient…so she trusts me the same way I trust her."* No mention of shared trust with PCP among control group patients).

CONCLUSIONS: Patients at high risk of hospitalization value PCP involvement during hospitalization. Active involvement of PCPs during hospitalization may increase longitudinal PCP continuity, and improve shared decision making and care coordination.

PRIMARY CARE PROVIDERS' AWARENESS AND ATTITUDES TOWARD MASKED HYPERTENSION: A QUALITATIVE STUDY

Rebekah Boyd[1]; Eileen Carter[2]; Nathalie Moise[1]; Carmela Alcantara[3]; Thais Valaderas[1]; David E. Anstey[1]; Ian M. Kronish[1]. [1]Center for Behavioral Cardiovascular Health, Columbia University Irving Medical Center, New York, NY; [2]School of Nursing, Columbia University, New York, NY; [3]School of Social Work, Columbia University, New York, NY. (Control ID #3390042)

BACKGROUND: Masked hypertension (MHT) is blood pressure (BP) phenotype defined as non-elevated BP in the office setting but elevated BP out of the office setting. MHT confers a similar level of cardiovascular risk as sustained hypertension. MHT is also common, present in approximately 12% of US adults with non-elevated office BP. Hypertension guidelines now recommend that patients with non-elevated office BP undergo screening for MHT through 24-hour ambulatory BP monitoring (ABPM) or home BP monitoring (HBPM), with lifestyle and/or medication treatment for patients who screen positive. Yet, few primary care providers (PCPs) are screening for or treating MHT, and little is known about the attitudes of PCPs toward MHT.

METHODS: Three focus groups were conducted with 30 PCPs affiliated with 3 academic medical centers in New York City. Focus groups explored awareness of MHT and attitudes toward MHT screening and treatment. Two researchers (R.B., I.K.) independently analyzed transcripts using a conventional content analysis to identify attitudes that represented barriers or facilitators to implementing MHT guidelines.

RESULTS: There was wide variation in familiarity with MHT, and only 2 PCPs had ever diagnosed or treated MHT. Common barriers to screening for MHT included lack of knowledge about the prevalence and impact of MHT, distrust of the accuracy of HBPM to detect MHT, inaccessibility of ABPM, discomfort with labeling patients with non-elevated office BP as hypertensive, perception of inadequate evidence in support of screening and treatment (i.e., no randomized screening or treatment trials, no cost-effectiveness studies), and reluctance toward adding to the long list of screening guidelines. While few had heard of MHT prior to the focus group, PCPs were receptive to MHT screening after being educated about its prevalence and impact. Other screening facilitators included opportunities for office visits dedicated to MHT screening, nurses and medical assistants trained to help PCPs follow MHT screening protocols, and easily accessible testing for MHT through ABPM. There was broad agreement with guidelines recommending lifestyle changes for treatment of patients with MHT, but PCPs had low confidence patients would comply. While some PCPs agreed with prescribing BP medications for MHT, prominent barriers to medication treatment were concerns that BP medication could induce harm (e.g., falls, side-effects) and the lack of randomized trials testing BP medication in patients with MHT.

2**CONCLUSIONS:** Lack of awareness of prevalence and impact of MHT on cardiovascular health were major barriers to implementation of MHT guidelines. Prior to broad uptake of guidelines by PCPs, randomized clinical trials and cost-effectiveness studies demonstrating the net benefits of screening and treatment may be needed, coupled with greater accessibility of ABPM for MHT screening.

PRIMARY CARE PROVIDERS' PERCEPTIONS ABOUT PARTICIPATING IN LOW-RISK PROSTATE CANCER TREATMENT DECISION MAKING

Archana Radhakrishnan[1]; Lauren P. Wallner[2]; Ted A. Skolarus[3]; Paul Abrahamse[4]; Adam Kollipara[1]; Steven Katz[1]; Sarah Hawley[1]. [1]Internal Medicine, University of Michigan, Ann Arbor, MI; [2]Internal Medicine, University of Michigan, Ann Arbor, MI; [3]Urology, University of Michigan, Ann Arbor, MI; [4]Biostatistics, University of Michigan, Ann Arbor, MI. (Control ID #3390573)

BACKGROUND: Primary care provider's (PCP) role in cancer care is expanding and may include supporting patients in their treatment decision making. This is important in low-risk cancers where patients are being managed with active surveillance. Because active surveillance involves management similar to any other chronic disease, it is well-aligned with PCP expertise. However, the degree to which PCPs engage in this role for low-risk prostate cancer is unknown.

METHODS: We surveyed 1000 PCPs randomly sampled from the American Medical Association between July and September 2018 (N=347, response rate 56%). For patients with low-risk prostate cancer, PCPs reported their: 1) confidence to engage in low-risk prostate cancer treatment decision making (based on a 4-item scale, categorized as high vs. low based on median cutoff); and 2) intended participation in active surveillance treatment decision making including reviewing all treatment options, discussing worry, and reviewing risks and benefits (dichotomized into less (not at all/little/some) vs. more (much/a great deal) participation). We examined associations between PCP confidence and physician and practice characteristics. We then examined associations between PCP confidence and intended participation for each of the four aspects of active surveillance using multivariable logistic regression.

RESULTS: Half of the PCPs (50.3%) reported high confidence in engaging in low-risk prostate cancer treatment decision making. The odds of high confidence were greater among those in solo practice (vs working with > 1 PCP) (OR 2.18; 95% CI 1.14-4.17) and with higher volume of prostate cancer patients (>15 vs. 6-10 in past year) (OR 2.16; 95% CI 1.02-4.61). PCP intended participation in active surveillance treatment decision making varied: discussing worry (62.4%), reviewing risks (41.8%) and benefits (48.5%), and reviewing all treatment options (34.2%). PCPs who reported high confidence had increased odds of reporting more participation in all aspects of active surveillance treatment decision making: reviewing all treatment options (OR 3.11; 95% CI 1.82-5.32), discussing worry (OR 2.12; 95% CI 1.28-3.51), and reviewing the risks (OR 3.20; 95% CI 1.91-5.36) and benefits of active surveillance (OR 3.13; 95% CI 1.89-5.16).

CONCLUSIONS: The majority of PCPs reported having high confidence in engaging in low-risk prostate cancer treatment decision making and were also more likely to participate in four key aspects of active surveillance treatment decision making. With active surveillance being considered as a management strategy for other low-risk cancers (such as breast and thyroid), PCPs may be increasingly engaging in not only cancer treatment decision making, but also in management of their patients on active surveillance. Understanding factors influencing PCP involvement and their ability to provide coordinated care will be instrumental towards defining the optimal team-based care delivery model for low-risk cancers.

PROBLEMS WITH THE CMS MORTALITY MEASURES AND VALUE-BASED PURCHASING

John Hughes[1]; Richard Fuller[2]. [1]Medicine, Yale University School of Medicine, New Haven, CT; [2]3M Health Information systems, Silver Spring, MD. (Control ID #3391489)

BACKGROUND: The Center for Medicare and Medicaid Services (CMS) publishes measures of risk- adjusted hospital mortality rates that are meant to and to contribute to Value-Based Payment (VBP) quality ratings used to redistribute up to $2 billion in Medicare payments annually. Despite the well-recognized association of comorbidities and complication codes (CCs) present on admission (POA) with risk of mortality, the CMS mortality rating method does not include POA CC diagnoses for risk adjustment, and only allows CC codes that occurred in the 12 months before the index admission. The VBP mortality measure includes 3 cohorts: Acute Myocardial Infarction (AMI), Heart Failure (HF), and Pneumonia (PN). Our objective was to examine if hospital mortality ratings, which account for 25% of Medicare's VBP ratings, could be improved by allowing POA CC codes to be used for risk adjustment. Addition of POA CC codes could make a hospital's actual to expected mortality ratio more accurate, which in turn could affect its VBP rewards or penalties.

METHODS: We used data for calendar year 2016 from the CMS Fee-for-Service claims file for diagnosis codes and admission dates and used the Medicare Master Beneficiary Summary File to identify all deaths within 30 days of hospital admission. There were 1.032 million admissions from the 3 VBP cohorts, of whom 116,315 died (11.3%). We excluded all transfer-in cases. We created 2 logistic regression models, in which the dependent variable was death within 30 days of admission, and the independent variables were the CC groups designated by CMS. Model 1 was based on the CMS method that only allows CCs recorded in the previous 12 months ("Lagged" Model), while Model 2 used CC codes

recorded as POA and did not include historical CC codes ("POA" model). We compared the number of times a CC diagnosis group was identified for each model for each of the 3 VBP cohorts. Also, for all 3 VBP conditions and both models, we calculated the coefficients for each CC group, which served as a measure of effect size, and calculated C-statistics.

RESULTS: There were dramatic differences between the POA and Lagged models, all of which contributed to increased predictive power for the POA model. The POA model identified many more CCs, ranging from 2 to 12 times as many as in the Lagged model. The estimated effect sizes for the CC groups were almost uniformly larger, ranging from 30% higher to 4 times as high in the POA model. C-statistics were higher for the POA model for all 3 VBP cohorts: 0.74 vs. 0.51 for AMI, 0.63 vs 0.54 for HF, and 0.71 vs 0.52 for PN.

CONCLUSIONS: The use of CC secondary diagnoses codes present on admission could substantially improve the accuracy of the CMS mortality rating component of VBP. Hospitals' reputations and sizeable payment distributions can depend upon publicly reported evaluations such as VBP. While the goal of evaluating hospitals based on their mortality outcomes is important, it is also important to reflect those differences accurately and fairly.

PROJECT CONNECTIONS: A LOW THRESHOLD BUPRENORPHINE MODEL FOR EXPANDING ACCESS TO BUPRENORPHINE TO MARGINALIZED POPULATIONS

Courtney Nordeck[2]; Deborah Agus[2,3]; Megan Buresh[1]. [1]Addiction Medicine, Johns Hopkins School of Medicine, Baltimore, MD; [2]Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [3]Behavioral Health Leadership Institute, Baltimore, MD. (Control ID #3392765)

BACKGROUND: The opioid epidemic continues to disproportionately affect marginalized populations and people of color, particularly black men. Buprenorphine is a highly effective treatment for opioid use disorder, however, disparities in access to care remain, with lower rates for African Americans. The *Project Connections (PC)* program is a low-threshold treatment program operated by the Behavioral Health Leadership Institute that provides buprenorphine to the most marginalized and vulnerable populations in Baltimore City. The program also provides case management and peer recovery services to individuals who are unable to access the traditional health care system due to systematic barriers such as lack of insurance or ID and stigma. The population served by the PC program often have complex histories and comorbidities, including recent involvement with the criminal justice system, psychiatric disease and lack ID, insurance and stable housing. The goal of the program is to meet individuals where they are and engage them in low- threshold, high-quality buprenorphine treatment and eventually transition them to ongoing care throughout the community.

METHODS: The Project Connections program includes three sites that are co-located with community partners and Project Connections to Re-Entry (PCARE), a van located directly outside of the Baltimore City jail. Clinical teams at each site initiates buprenorphine and provides linkage to ongoing care. This analysis describes the demographics characteristics and initial follow-up and 30 day retention in treatment for individuals served through the PC program between November 2018 through October 2019.

RESULTS: Between November 2018 and October 2019, 290 patients completed an intake assessment across the PC sites and 242 (83.4%) began treatment with a buprenorphine/naloxone prescription. Those who initiated buprenorphine were primarily male (69.8%), African American (73.1%), had a mean age of 44.4 years (SD = 12.6), and a mean of 21.9 years (SD = 12.9) of opioid use. The majority had previous criminal justice involvement (72.7%), were unemployed (66.9%), and were unstably housed (73.6%). Over half of patients had reported a previous overdose event (52.1%). Of those who were initiated on buprenorphine, 90.9% returned to the treatment sites for a second visit, and 62.8% remained in treatment after 30 days.

CONCLUSIONS: The Project Connections program offers a viable treatment model to provide low- threshold treatment to vulnerable and marginalized populations, by addressing systematic barriers that typically can exacerbate health disparities, including providing access to African Americans and justice- involved individuals who are less likely to access care in traditional treatment models. Further work is needed to scale-up access to low threshold buprenorphine and develop sustainable funding mechanisms for these programs.

PROMOTING ACADEMIC WOMEN THROUGH RECOGNITION: NOMINATIONS ARE ESSENTIAL

Valerie G. Press[1]; Megan H. Scheetz[2]; Julie Oyler[3]. [1]Medicine, University of Chicago, Chicago, IL; [2]Medicine, University of Chicago Medicine, Chicago, IL; [3]General Internal Medicine, University of Chicago Medical Center, Chicago, IL. (Control ID #3363763)

BACKGROUND: The majority of academic award recipients across medical specialties have been men, a phenomenon documented across multiple fields. Award recognition is critical to promotion, funding, and an indication of regional and national status. Therefore, gender disparities in awards may impact work place inequities. We evaluated gender distribution among award recipients at our hospital fater piloting an award nomination intervention to increase female awardees.

METHODS: For this pre/post evaluation we obtained historical lists from our Department of Medicine (DOM) and Biological Sciences Division (BSD) of award recipients and piloted a nomination intervention to identify eligible female nominees. Gender distribution among award recipients was compared pre- intervention and post-intervention years using chi square tests. To account for national trends of decreasing gender disparities, we conducted a sensitivity analysis limiting our pre-intervention period to the same number of years as the post-intervention period.

RESULTS: Historical awardee lists were available from 2006-2016 (DOM) and 2011-2017 (BSD). Pre-intervention, 39% (range=25-58%) and 38% (18-57%) of awardees were women in the DOM and BSD, respectively. The intervention was implemented in 2018 (DOM) and 2017 (BSD). The percent of women awardees significantly increased to 56% (25-50%; p=0.02) and 56% (55-65%; p=0.02), in the DOM and BSD post-intervention, respectively. Results remained significant when restricting to similar pre and post number of years (DOM pre-intervention: 33%, [29-37%], p=0.045) (BSD pre-intervention: 34%, [18-43%], p=0.02) in a sensitivity analysis.

CONCLUSIONS: We found that a simple, easily reproducible, low resource intervention significantly increased the number of deserving women receiving awards within our Department and Division. Because we only increased the number of nominated woman and did not implement any interventions with regard to the decision process, it is possible that the low proportion of women awardees prior to our intervention was due, in part, to qualified women being over looked, perhaps due to implicit bias. It is important to note, however, that implicit bias could still impede deserving women from receiving recognition for other awards, such as those that rely on clinical productivity and/or trainee evaluations. Future work can establish whether interventions can successfully address these factors. Since nomination bias, however, is likely pervasive, other programs, sections, departments, and/or divisions could easily develop low-cost, feasible nominating processes at their institutions.

PROMOTING COLLABORATIVE GOAL SETTING FOR CANCER PREVENTION AMONG PRIMARY CARE PATIENTS: PILOT TESTING A NEW APPLICATION

Daniel Resnick[1]; Allison Bautista[4]; Jazmine Smith[4]; Liz Jones[5]; Chang Xu[6]; Marilyn M. Schapira[3]; Jaya Aysola[2]. [1]Internal Medicine, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; [2]Medicine, Division of General Internal Medicine, University of Pennsylvania, Philadelphia, PA; [3]Internal Medicine, University of Pennsylvania, Philadelphia, PA; [4]Department of Medicine, University of Pennsylvania, Philadelphia, PA; [5]Design, Transmogrify, Conshohocken, PA; [6]Medicine, UPenn, Lansdale, PA. (Control ID #3391177)

BACKGROUND: Evidence suggests up to 80% of the cancer burden is related to modifiable lifestyle behaviors, such as diet, exercise, smoking cessation, and maintaining a healthy weight. Yet we lack primary care interventions that promote cancer prevention behaviors. In this pilot study, we evaluate the feasibility, acceptability, and preliminary effectiveness of a mobile application to engage primary care patients in cancer prevention goal setting, tracking, and progress sharing with known and unknown social ties.

METHODS: For 8 weeks we provided primary care patients (n=41) with a cancer prevention mobile app that allowed them to choose and track cancer prevention goals, as well as share goal progress and encouragements with others. We recruited non-Hispanic black patients, as the application was conceived to help reduce the disproportionate cancer burden in racial and ethnic minority communities. We conducted semi-structured interviews to assess cancer prevention knowledge and behaviors at baseline and after the study. Exit interviews also assessed app usability and acceptability, using the validated System Usability Scale (scored 0 to 100) and open-ended questions. We captured app use data including the frequency of participant weekly check-ins, goal selections, whether participants achieved their goals, and whether participants shared their goal progress with known and/or unknown users.

RESULTS: The mean age of participants was 51 (SD: 12) and 31 (76%) were women. App use data was captured for all participants and 35 (85%) completed the exit interview. On average, participants checked in with the app during 59% of all weekly opportunities (SD: 30%). Thirty-one participants (76%) checked in during at least 4 of the 8 weeks. The mean goal achievement rate was 53% (SD: 29%). Participants selected diet goals most frequently (35%), followed by weight tracking (28%), physical activity (25%), and smoking cessation (13%). Regular users (n=31) on average set 2.1 goals during the 8 weeks. Thirty-four (82%) opted to share their goal progress with invited social ties and 18 (44%) opted to share progress with all app users. The median SUS score was 90 (IQR 77.5-95), indicating a highly acceptable app. Cancer prevention knowledge, a 0 to 4 score indicating people's understanding of how behaviors can reduce cancer risk, improved (2.35 to 2.65, p=0.17). User feedback illustrated a pattern of the app motivating behavior change, with comments including: "…had to really work on me to stop smoking but I did it;" "it helped me do new things that I would have never done…;" it kept me focused and looking forward to the check in…;" and "I saw I was losing weight… [The app] kind of changed my lifestyle."

CONCLUSIONS: The implementation of a mobile cancer prevention goal setting application in a primary care setting was feasible with high uptake and usability ratings. Cancer prevention knowledge increased and qualitative user feedback revealed an influence on healthy behaviors.

PROVIDER PERCEPTIONS OF MEDICATION FOR OPIOID USE DISORDER FROM QUALITATIVE INTERVIEWS IN ALLEGHENY COUNTY, PENNSYLVANIA

Nicole Paul[1]; Amy J. Kennedy[2]; Simone Taubenberger[3,4]; Judy Chang[1,3]. [1]School of Medicine, University of Pittsburgh, Pittsburgh, PA; [2]Department of Internal Medicine, University of Pittsburgh Medical Center, Pittsburgh, PA; [3]Magee-Womens Research Institute, Pittsburgh, PA; [4]Allegheny County Health Department, Pittsburgh, PA. (Control ID #3385971)

BACKGROUND: Medication for Opioid Use Disorder (MOUD) has been shown to be safe, cost-effective, and lower the risk of opioid overdose. However, access to and use of MOUD, as well as expansion of MOUD prescribers, in Allegheny County, PA, has been limited. Our objective was to explore attitudes, opinions, and beliefs of MOUD among healthcare and social service providers.

METHODS: As part of an ethnographic study focusing on neighborhoods of Allegheny County with the highest opioid overdose death rates, we conducted semi-structured qualitative interviews with key stakeholders living or working in these communities. For this analysis, we focused on a subset of interviews with physicians, nurses, care managers, peer-support specialists, and other professionals who provide treatment for persons with opioid use disorders. We collaboratively developed a coding scheme using a grounded theory approach and subsequently validated results via data triangulation and investigator triangulation.

RESULTS: Thirty-eight provider interviews were included in our analysis. We identified the following major themes related to MOUD from the perspectives of our provider participants. Among concerns and challenges, participants noted: 1) lack of uniformity and quality control of MOUD, especially with respect to buprenorphine/naloxone treatment; 2) referrals to MOUD centers or providers is a "word of mouth insider system"; 3) lack of a centralized source for the public to navigate and assess county MOUD services; 4) challenges optimizing timing of MOUD service access with patient motivation for treatment, and 5) stigma as a barrier to MOUD care. Providers also described different opinions about the centrality and duration of MOUD; some providers believed that MOUD was a "tool" for achieving complete abstinence from opioid- containing substances, while others viewed it as a long-term treatment for a chronic medical condition.

CONCLUSIONS: Quality control of MOUD delivery and referrals to care is a major concern for healthcare and social service providers. The dissonance among providers regarding the centrality and duration of MOUD, as well as community stigma surrounding persons who use MOUD, may also contribute to the lack of uniformity among MOUD centers within Allegheny County. Understanding the structural barriers and community biases regarding MOUD will better inform the design of referral systems and delivery of MOUD in clinical practice.

PROVIDER PERCEPTIONS OF SOCIAL COMPLEXITY AMONG VA HOME-BASED PRIMARY CARE PATIENTS

Elizabeth Hulen[1,2]; Avery Z. Laliberte[1]; Sarah S. Ono[1]; Somnath Saha[3,1]; Samuel T. Edwards[1,3]. [1]Health Services Research & Development, VA Portland Health Care System, Portland, OR; [2]Department of Sociology, Portland State University, Portland, OR; [3]Section of General Internal Medicine, Portland VA Medical Center, Portland, OR. (Control ID #3377775)

BACKGROUND: The U.S. Department of Veterans Affairs (VA) Home-Based Primary Care (HBPC) program is designed to provide Veterans with complex, chronic disease comprehensive primary care services in their homes using an interdisciplinary model. The objective of this research is to describe

HBPC providers' knowledge of social complexity among HBPC patients and how this knowledge impacts care delivery.

METHODS: This study utilizes a qualitative study design. The data-set includes 14 semi-structured interviews with HBPC providers representing multiple disciplines (nursing, medicine, physical therapy, pharmacy, psychology, and social work) and seven field observations of HBPC team meetings. Interview domains are: patient selection and care delivery patterns, core functions of HBPC, and barriers and facilitators to HBPC performance. All data have been coded and analyzed using a content-driven approach

RESULTS: Four thematic categories are identified. First, HBPC patients have dynamic overlapping layers of medical and social complexity that compromises their ability to utilize clinic-based care and additionally, are vulnerable and socially isolated. Second, HBPC providers having "eyes in the home" yields essential information that cannot be obtained in outpatient clinic visits. Third, HBPC fills in instrumental care gaps, many of which are not medical and are typically performed by families and caregivers in other contexts. Fourth, addressing social complexity requires flexibility in care design which the HBPC model can provide. Potential limitations to the current work include limited generalizability because data were collected from one HBPC site in the VA

CONCLUSIONS: Medical and social complexities overlap in unique ways among HBPC patients and HBPC, as a care model, functions as a proxy for social support for vulnerable, home-bound and nearly home-bound patients. The flexible nature of the HBPC program supports the ability of providers to tailor care and address needs beyond traditional scope of practice.

PROVIDING HIV PRE-EXPOSURE PROPHYLAXIS TO PATIENTS WITHIN AN OPIOID TREATMENT PROGRAM: A QUALITATIVE STUDY

Amy J. Kennedy[5]; Iman F. Hassan[1]; Flor de Abril Cameron[5]; Valerie Gobao[3]; E. Jennifer Edelman[2]; Ken Ho[4]; Stuart Fisk[6]; Megan E. Hamm[5]; Jessica S. Merlin[5]. [1]Internal Medicine, Montefiore Medical Center, Bronx, NY; [2]Internal Medicine, Yale University, New Haven, CT; [3]University of Pittsburgh School of Medicine, Pittsburgh, PA; [4]Infectious Disease, University of Pittsburgh, Pittsburgh, PA; [5]Internal Medicine, University of Pittsburgh, Pittsburgh, PA; [6]Center for Inclusion Health, Allegheny Health Network, Pittsburgh, PA. (Control ID #3389944)

BACKGROUND: Although the US incidence of HIV is declining, infection rates remain high in certain risk groups, including people who inject drugs (PWIDs). Despite guidelines recommending use of HIV pre-exposure prophylaxis (PrEP) for HIV prevention among PWIDs, it remains underutilized. Opioid treatment programs may be an ideal setting to reach PWIDs for PrEP as individuals may not access routine primary prevention services elsewhere. The objective of this study was to qualitatively explore provider knowledge, attitudes, and practices regarding PrEP use for PWIDs among outpatient medication for opioid use disorder (MOUD) treatment providers in Pittsburgh, PA.

METHODS: We conducted semi-structured qualitative interviews with MOUD treatment providers in Pittsburgh, PA in the fall of 2019. The interview script was structured based on an implementation science framework and covered providers' knowledge of PrEP and barriers/facilitators to PrEP use within their practice. We inductively developed a codebook based on the content of the interviews, coded the interviews, and performed a thematic analysis. Preliminary themes were identified by the primary investigator and shared with co-investigators as a form of investigator triangulation.

RESULTS: A total of 13 MOUD providers (6 internal medicine, 2 family medicine, 2 psychiatry, 1 palliative care, 1 obstetric/gynecology, 1 nurse practitioner) from 5 MOUD practices in Pittsburgh, PA were included in the analysis. The majority of participants (n=11) prescribed buprenorphine while 2 prescribed both buprenorphine and methadone. All participants reported that their patient population was at high risk for HIV acquisition and all included harm reduction protocols (HIV screening, naloxone distribution, access to clean needles) within their practice. Few had considered prescribing PrEP within their MOUD practice, and only 2 individuals had prescribed PrEP for a patient receiving MOUD. Barriers to PrEP use included provider lack of knowledge of PrEP indications and guidelines, discomfort in discussing PrEP with this population (i.e. discussion of PrEP might undermine the recovery process), concern for patient adherence to once daily dosing, competing priorities (i.e. greater emphasis on hepatitis C screening and treatment) and lack of time and support to implement a PrEP program. Participants suggested facilitators to PrEP use would include integration of reminders into the electronic medical record, standardization of clinic protocols, and different formulations of PrEP (i.e. a long-acting injection would be preferable).

CONCLUSIONS: MOUD providers recognize the increased risk of HIV among their patient population, but lack knowledge and strategies for implementing PrEP within their practice. Interventions that increase MOUD provider knowledge of PrEP and strategies to easily implement PrEP use within a MOUD treatment program are needed to improve PrEP uptake and decrease risk of HIV acquisition among PWIDs.

PSYCHOMETRIC EVALUATION OF MULTI-ITEM SCALES ASSESSING BARRIERS TO CARE AND UNMET SOCIAL NEEDS AMONG HIGH-NEED HIGH-COST MEDICAID BENEFICIARIES

Jacob K. Quinton[1]; Ning Li[1]; Carol Mangione[1]; Tannaz Moin[1,3]; Jessica Harwood[1]; Ron D. Hays[1]; Karen L. Spritzer[1]; Patrick Y. Liu[2]; O. Kenrik Duru[1]. [1]General Internal Medicine / Health Services Research, David Geffen School of Medicine UCLA, Los Angeles, CA; [2]Medicine, David Geffen School of Medicine at UCLA, Los Angeles, CA; [3]Medicine, UCLA/VA Greater Los Angeles, Los Angeles, CA. (Control ID #3390714)

BACKGROUND: High-need high-cost (HNHC) patients in Medicaid likely experience significant barriers to care and unmet social needs which may drive excess utilization. Survey instruments that are psychometrically sound are needed to assess these constructs. We used a multi-trait scaling analysis to evaluate barriers to care and unmet social need scales. The screening tool analyzed was used by a major health insurer to guide a community health worker (CHW) led intervention in a national program to improve the care of HNHC patients receiving Medicaid.

METHODS: HNHC patients were defined as those in the top 5% of spending by administrative claims. Beneficiaries were administered a health risk assessment survey at the time of enrollment into the CHW intervention. After completing the survey, patients were assigned a CHW to coordinate unmet medical, behavioral, and social needs. We grouped questions into two constructs: barriers to care (7 items) or unmet social needs (4 items). Item convergence within scales were summarized using coefficient alpha. Item discrimination across scales was assessed by comparing the correlation of each item with the scale it is hypothesized to represent against the other scale.

RESULTS: A total of 50,368 HNHC patients were screened, among which 43,344 had complete data on all 11 questions considered in the multi-trait scaling analysis. Patients screened had a mean (+/-SD) age of 51.5yrs (+/- 12.8), were more likely to be female (58%), and varied by race race/ethnicity (48% White, 21% Black, 7% Hispanic, 19% missing). The median within-scale correlation was 0.32 for barriers to care and 0.37 for unmet social needs (Table 1). Coefficient alphas were 0.52 for barriers to care and 0.62 for social needs. The two scales were significantly positively correlated (0.23, $p < 0.0001$).

CONCLUSIONS: The internal consistency reliabilities of the scales were low and item discrimination across scales was moderate. This

psychometric evaluation of the barriers to care and unmet social needs scales indicates a need for improvement in these survey measures. This represents an area of potential improvement in social need screening.

PUBLIC HEALTH CARE SYSTEMS PARTICIPATING IN CALIFORNIA'S GLOBAL PAYMENT PROGRAM ADOPTED DIVERSE STRATEGIES TO PROVIDE CARE TO THE REMAINING UNINSURED

Denise Quigley[2]; Maria DeYoreo[2]; Justin W. Timbie[3]; Jodi Liu[2]; Alina Palimaru[2]; Mary Slaughter[2]; Katherine L. Kahn[1,2]. [1]Medicine, David Geffen School of Medicine at UCLA, Los Angeles, CA; [2]RAND Corporation, Santa Monica, CA; [3]RAND Health, RAND, Arlington, VA. (Control ID #3392282)

BACKGROUND: California's county-based Public Health Care Systems (PHCSs) implemented the Global Payment Program (GPP) to provide more cost-effective and higher-value care to California's uninsured. GPP is structured with strong financial incentives to shift the focus of care for the uninsured toward primary and preventive services and expand service-use related to prevention, mental health, patient education, and non- traditional services (e.g., nurse advice-lines).

METHODS: We surveyed GPP-implementation teams at the 12 participating PHCSs in February 2018 and February 2019 about infrastructure investments and implementation strategies to achieve goals across six domains of care transformation: data collection and tracking, coordination of care, access, staffing, team- based care, and the delivery system. Survey items were identified through review of documents describing health system changes relevant to GPP and other safety net initiatives.

RESULTS: The six domains aggregate 49 individually assessed strategies with generally high reliability: Cronbach's alpha was >0.90 for four domains; 0.88 for data collection/tracking, and 0.78 for the delivery system. Each PHCS adopted a combination of the 49 strategies spanning all domains. Across the 12 PHCSs, the mean number of strategies adopted within domains ranged from 4 to 10. Across the two years, the total number of strategies used ranged from 57 to 98. The two most frequently used domains were improving coordination of care (88% of strategies in 2018; 95% in 2019), and improving data collection and tracking (88% and 91%, respectively). The two domains found to be most successful in achieving GPP goals were: (1) improving team-based care (including new positions or roles and delivery of more non-traditional services and (2) collecting and tracking data.

CONCLUSIONS: Although GPP provides flexible funding streams to PHCSs to transform practice, it leaves the mechanism of practice change to each health care system to decide how to provide better care for the remaining uninsured. PHCSs reported using a wide range of strategies across the six domains to improve care for their remaining uninsured. The large variability of specific strategies implemented by PHCSs within the given domains suggests that PHCSs are considering their unique contexts, such as baseline capacities, local resources, costs and benefits associated with strategy implementation, and patient needs as they strive to achieve GPP goals. PHCS-reported adopting multiple, diverse strategies for improving infrastructure to support cost-effective and higher-value care to California's remaining uninsured. GPP's payment policies that provide flexibility in how resources can be used, allowed PHCSs to pursue both statewide goals and local needs/priorities. These findings support the notion that transformation of care delivery and practice may entail more than a singular focus area of improvement.

PUBLIC HEALTH INSURANCE, GESTATIONAL DIABETES, AND THE RISK OF TYPE 2 DIABETES IN PAROUS WOMEN

Kathryn Corelli, Sarah Hsu, Kaitlyn E. James, Wei He, Jessica S. Tangren, Mark Clapp, James B. Meigs, Camille E. Powe. Massachusetts General Hospital, Boston, MA. (Control ID #3392048)

BACKGROUND: A history of gestational diabetes (GDM) increases the risk of type 2 diabetes (T2D). Prior studies have shown that public health insurance is associated with reduced postpartum diabetes screening in women with GDM. We assessed the relationship between GDM and T2D in parous women with different types of health insurance. Our study was conducted in Massachusetts, where near universal health care coverage was implemented in 2006.

METHODS: We conducted a retrospective cohort study in 17,154 women who delivered infants at an academic medical center between 1998 and 2016. Women were free of T2D during the index pregnancy (the last pregnancy in the dataset) and for at least 1 year postpartum. We included women who were followed for >1 year after delivery in any affiliated primary care practice. Pregnancies with GDM (Carpenter-Coustan criteria) were identified using laboratory data. T2D diagnosis at least 1 year after delivery was ascertained with a validated algorithm using laboratory and administrative data (sensitivity 0.99, specificity 0.93). We excluded a small number of women with limited (N=797, 4.3%) or no insurance (N=494, 2.9%) from subsequent analysis. We used Cox-proportional hazard models to evaluate the association between insurance type at the time of pregnancy and incident T2D. We adjusted for GDM, age, race, body mass index, language, marital status, parity, and education. Women were censored at their last primary care visit. We tested for effect modification of the association between GDM and T2D by insurance type, using a GDM-insurance interaction term and insurance type-stratified models.

RESULTS: Of 15,923 included women, 32% had public insurance and 68% had private insurance, each with a mean of 7.8 and 8.1 years of primary care follow up since delivery, respectively. Women with public insurance were more likely to have GDM in the index pregnancy than those with private insurance (6.4% vs 4.0%, P<0.001). In follow up, 383 women developed T2D. Both public insurance and GDM were independently associated with increased risk of T2D (Public Insurance: HR 1.60 95% CI 1.25-2.06, GDM HR 8.85 95% CI 7.05-11.12) in adjusted models. There was a significant interaction between insurance type and GDM on the risk of T2D (P-interaction= 0.02). GDM appeared to have less effect on T2D risk among women with public insurance (Public: HR 6.98 95% CI 5.07-9.63, Private: HR 11.40 95% CI 8.19- 15.87). In a post-2006 sensitivity analysis, both public insurance and GDM remained independently associated with T2D diagnosis (Public Insurance HR 1.91 95% CI 1.26-2.89, GDM HR 11.45 95% CI 8.44-16.29).

CONCLUSIONS: In parous women, having public health insurance is associated with an increased risk of T2D, independent of GDM history. Differences in the effect of GDM on T2D risk in women with different insurance types may be due to disparate screening practices.

QUALITATIVE STUDY ON HEALTHCARE PROVIDERS PERSPECTIVES ON PERSONALIZED TRIALS AMONG MINORITY PATIENTS: A PILOT STUDY

Lyndonna M. Marrast[1]; Joseph Conigliaro[2]; camille chan[3]; negin hajizadeh[3]; Michael Diefenbach[3]; Renee Pekmezaris[3]; karina davidson[3]. [1]General Internal Medicine, Zucker School of Medicine at Hofstra/Northwell, Kew Gardens, NY; [2]Internal Medicine, Zucker School of Medicine, New Hyde Park, NY; [3]Feinstein Institute for Medical Research, Manhasset, NY. (Control ID #3391662)

BACKGROUND: Personalized (N-of-1) trials, one-person studies conducted to determine the best treatment for that individual, are increasingly used to inform the treatment decisions for providers and patients in primary care. Patients from racial and ethnic minority backgrounds have historically been underrepresented in research trials and they face unique challenges in the healthcare system such as mistrust. Understanding the viewpoints of minority patients and their providers regarding participation in N-of-1 trials is imperative as we design and implement these studies in clinical practice.

METHODS: We conducted 3 focus groups of health care providers in the Division of General Internal Medicine at a large academic medical center in the northeast. Providers included multidisciplinary team members: physicians, pharmacists, nurses and a clinical psychologist. They were asked questions about how they think minority patients would respond to personalized trials in the following domains: priority conditions for this population, benefits, barriers, and strategies for improved communication. Transcripts were audio recorded, professionally transcribed and manually analyzed for major themes. We used inductive analysis to identify themes across the three focus groups.

RESULTS: We uncovered the following themes regarding racial and ethnic minority patient views on personalized trials. Chronic conditions such as type 2 diabetes mellitus, hypertension, hyperlipidemia and symptoms of pain and GI upset would be priority to study. Benefits include patients feeling more empowered by having a choice in the final decision and the tailoring of treatment. Barriers for participating include mistrust, language (for non-English speakers) and lengthy travel outside of the United States. Other considerations for racial and ethnic minority participants are inclusion of family/friends and/or caregivers in the trial, desire for non-evidence based treatments, and the role of cultural foods in the outcomes and disease being studied. Use of telehealth in data collection was frequently mentioned but also the need to ensure adequate and appropriate familiarity with smart phone technology in collecting data. Mindfulness of patient's level of health literacy and awareness of the research process are other factors to consider. Providing dedicated education about their disease and treatment options were noted as strategies to engage minority patients in participation of personalized trials.

CONCLUSIONS: Personalized trials have the potential to change the way we deliver primary care. It is essential to consider racial and ethnic minority patient perspectives in the design and conduct of these trials as they have the potential to improve disparities by improving patient adherence and trust in the treatment decision process.

QUANTIFYING THE BURDEN OF HOSPITALIZED DAYS IN MEDICARE BENEFICIARIES WITH MULTIMORBIDITY

Melissa Y. Wei[1,2]; Nicholas Tilton[1]; Kenneth J. Mukamal[3]. [1]Internal Medicine, University of Michigan, Ann Arbor, MI; [2]Institute for Healthcare Policy and Innovation, University of Michigan, Ann Arbor, MI; [3]Medicine, Beth Israel Deaconess Medical Center and Harvard Medical School, Brookline, MA. (Control ID #3391318)

BACKGROUND: Multimorbidity impacts several downstream health consequences including physical, cognitive, and social functioning and mortality risk. Multimorbidity is also associated with greater healthcare utilization based on a simple disease count. We aimed to study the association between multimorbidity and healthcare burden using a patient-centered multimorbidity measure that weights conditions by their impact on physical functioning.

METHODS: Health and Retirement Study participants were continuously enrolled in Medicare Parts A and B 1-year before and after the 2012-2013 HRS interview. Medicare claims were used to compute the ICD-coded multimorbidity-weighted index (MWI-ICD) by summing physical functioning-weighted conditions. The outcome was number of hospitalized days per year. Given the excess observations of zero hospital days (78.1%), we used zero-inflated Poisson regression to examine the association between multimorbidity and hospitalized days. First, logit models predicted membership into the zero-coded "no hospitalizations" group. Second, Poisson models predicted hospital days for participants not in the zero-coded group. We converted adjusted regression coefficients to odds ratios to report odds of zero hospitalized days. To compare model fit between MWI-ICD and simple disease count we used the Akaike Information Criterion (AIC). Models were adjusted for age, sex, race/ethnicity, education, household net worth, and living arrangement/marital status.

RESULTS: The final sample of 5,201 participants had mean ± SD age of 77.6 ± 11.6 years, MWI-ICD score of 16.5 ± 11.6, and 1.9 ± 6.0 (range 0-90) hospitalized days. Each 1-point increase in MWI-ICD was associated with a 4.3% decreased odds of zero hospitalized days (OR = 0.96, 95% CI: 0.95-0.96) and 2% increased number of expected hospitalized days (IRR = 1.02, 95% CI: 1.01-1.03) over one year in adjusted models. MWI-ICD had a lower AIC than simple disease count.

CONCLUSIONS: Among Medicare beneficiaries, multimorbidity using a new validated ICD-coded multimorbidity-weighted index is monotonically associated with an increased risk of hospitalized days and greater number of expected hospitalized days. Multimorbidity contributes greatly to patient burden through increased hospitalization and is better captured through an index weighting conditions to physical functioning. MWI-ICD appears to be a valid measure of multimorbidity that embeds physical functioning and thus presents an opportunity to incorporate functional data into administrative claims.

QUANTIFYING THE PROBLEM: PENICILLIN ALLERGY TESTING AT THE SAN FRANCISCO VETERANS AFFAIRS MEDICAL CENTER

Alex Ge[1]; Ishan Kanungo[1]; Michelle Leung[1]; Angela Lu[1]; Deepa Rajan[1]; Alexander Vesprey[1]; Geoffrey V. Stetson[1,2]. [1]School of Medicine, University of California, San Francisco, San Francisco, CA; [2]Internal Medicine, San Francisco VA Medical Center, San Francisco, CA. (Control ID #3390534)

BACKGROUND: Penicillin has been instrumental in combating bacterial infections since its discovery in 1928. Yet, a significant proportion of patients do not receive penicillin, or other β-lactam antibiotics, as first-line therapy due to a documented penicillin allergy. 6-25% of patients in the U.S. are labeled with a penicillin allergy, however, it is estimated that 90% of these patients can receive the drug safely (NEJM, 2019).

The clinical implications of a penicillin allergy are numerous: increased rate of nosocomial and antibiotic resistant infections, increased clinical failure and mortality when treating bacteremia, increased surgical site infections, and increased cost to patients and health systems.

The San Francisco Veterans Affairs Medical Center (SFVAMC) currently lacks a CDC recommended protocol for evaluating and diagnosing false penicillin allergies. Before implementing a testing program, it was important to measure the number of SFVAMC patients with allergies to penicillin and other β-lactam antibiotics who could potentially benefit from antibiotic allergy testing.

METHODS: We performed a retrospective chart review of patients admitted to the SFVAMC inpatient medicine service during September 2019. For each patient with a β-lactam allergy, we noted the name of the drug, the nature of the reaction, the antibiotic history, and whether the allergy was observed by the documenting provider or self-reported by the patient (i.e. historical). We also defined each patient's eligibility for allergy testing (low-risk, medium-risk, or high-risk) using previously published, peer-reviewed protocols for penicillin allergy testing.

RESULTS: In September 2019, 32/207 (15.4%) admitted patients at the SFVAMC had a documented β-lactam allergy. Only 1/32 (3.1%) β-lactam allergies were observed by the documenting provider while the other 31/32 (96.9%) allergies were historical. 29/32 (90.6%) patients were allergic to penicillin or its derivatives, while the remaining 3/32 (9.4%) patients were allergic to a carbapenem, cephalosporin, or clavulanic acid. Notably, 6/29 (20.7%) patients with a penicillin allergy had previously received a penicillin derivative while hospitalized, suggesting these patients had tolerated penicillin in the past, even with a persistently documented allergy.

For patients with penicillin allergies, 18/29 (62.1%) patients had an unknown reaction or rash with no other symptoms (low-risk of anaphylaxis upon allergy testing), 7/29 (24.1%) patients had urticaria, angioedema, dyspnea, and/or gastrointestinal symptoms (medium-risk), and 4/29 (13.8%) patients had anaphylaxis or abnormal liver enzymes (high-risk). Overall, 25/29 (86.2%) patients would be eligible for a testing protocol, with eligibility defined as being low-risk or medium-risk.

CONCLUSIONS: There is sufficient eligibility (86.2% of patients) to justify implementation of a penicillin allergy testing protocol at the SFVAMC, with the goal of de-labeling false penicillin allergies and improving antibiotic stewardship.

RACE AND SEX DIFFERENCES IN SOCIAL DETERMINANTS OF HEALTH AMONG PATIENTS ON CHRONIC OPIOID THERAPY FOR NON-CANCER PAIN

Eboni Price-Haywood[1,4]; Jeffrey Burton[1]; Jewel Harden-Barrios[1]; Alessandra Bazzano[2]; Robert Jamison[3]; Lizheng Shi[2]; John Lefante[2]. [1]Center for Outcomes and Health Services Research, Ochsner Health System, New Orleans, LA; [2]Tulane University School of Public Health and Tropical Medicine, New Orleans, LA; [3]Harvard Medical School, Boston, MA; [4]Ochsner Clinical School, University of Queensland, New Orleans, LA. (Control ID #3373760)

BACKGROUND: Epidemiologic surveillance of the opioid crisis has demonstrated that race/ethnicity, gender, age, family composition, socioeconomic status, family stress, social isolation are correlates of substance use, misuse and mortality. In addition to safe opioid prescribing practices, providers must assess social determinants of health (SDoH) and tailor case management to mitigate risks.

METHODS: This retrospective observational study examined race and sex differences in SDoH among chronic opioid users within an integrated delivery health system in Louisiana. The cohort included patients on opioid therapy for non-cancer pain seen within the health system between January 2017 and November 2019. Chronic opioid use was defined as have been prescribed an opioid for three of the last four months. Patients are included in the chronic opioid health maintenance registry if they are age 18 and older and do not have cancer or enrolled in hospice or palliative care. Registry patients with the SDoH questionnaire completed within Epic electronic health records and opioid prescriptions documented within 12 months of joining the registry were included in the data analysis. Chi-squared tests for association between questionnaire items by race and sex were conducted.

RESULTS: Among 27,747 registry patients, 1,644 were included in the analysis. Among the 1644, most patients were white, non-Hispanic (76%), female (69%) with an average age of 56.6 years; had depression (41%), anxiety (44%), or substance abuse disorder (19%); 18% were prescribed high-dose opioids with an average morphine equivalent daily dosage >50; and 21% were co-prescribed benzodiazepines. A larger proportion of black patients compared to whites reported major financial strain (9% vs 5%), worry about food insecurity (10% vs 7%), have medical transportation needs (15% vs 8%) and have phone communications relatives/friends more than 3x/week (74% vs 61%, all P<0.001). Among white patients, a higher percentage of females compared to males reported financial strain (7% vs 3%), food insecurity (8% vs 5%), medical transportation needs (9% vs 5%), and frequent phone communications (65% vs 55%, all P<0.02); however, among black patients, there were no statistically significant sex-related differences in SDoH. Compared to all other groups, a higher proportion of black females reported difficulties with financial strain (10%), food insecurity (10%) and transportation needs (16%) but reported more frequent social connection with relatives/friends through phone communication (77%).

CONCLUSIONS: This study confirmed race and sex differences in SDoH among patients on chronic opioid therapy for non-cancer pain within a single healthcare institution. To combat the opioid crisis, it is imperative that health systems collect measures of SDoH to inform risk mitigation and population health management strategies.

RACE AND THE PRECLINICAL MEDICAL CURRICULUM: A CONTENT ANALYSIS

Christina Amutah[1]; Kaliya Greenidge[3]; Adjoa Mante[1]; Sanjna Surya[1]; Jaya Aysola[2]. [1]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; [2]Medicine, Division of General Internal Medicine, University of Pennsylvania, Philadelphia, PA; [3]University of Pennsylvania, Philadelphia, PA. (Control ID #3372338)

BACKGROUND: Implicit bias in medicine has recently attracted growing attention. The role that medical education plays in perpetuating or instilling biases is yet to be understood. The objective of this study was twofold. First, to analyze the medical school preclinical curriculum content to characterize the presentations and discussions of race/ethnicity. Second, to develop evidence-based recommendations to correct inaccurate uses of race/ethnicity.

METHODS: We did a content analysis of the course materials within the preclinical medical curriculum at one academic institution to identify and characterize errors in the use of race/ethnicity. We analyzed the lecture and case-based learning materials for key terms relating to race/ethnicity. Uses of race/ethnicity were flagged as errors when content deviated from evidence-based terminology or failed to adequately reflect the current evidence base. If necessary, we reviewed recorded lectures for additional context or to capture lecturer's intention. The team jointly analyzed 20% of the content to develop a codebook. All identified errors were then coded and classified by theme with some errors identified within multiple themes.

RESULTS: There were 115 errors, categorized into 5 themes, that were identified across 20 courses. We describe the following five themes in order of prevalence: 1) The presentation of racial/ethnic disparities in disease prevalence without adequate explanation thus implicating genetic susceptibility as the sole etiology for observed differences (n=74). 2) The use of inaccurate semantics, where imprecise and non-biological terms were used to convey biological information (n=57). 3) Among diseases where there is a strong genetic predisposition based on ancestry, a lack of discussion of antecedent risk factors and exceptions, which can perpetuate harmful diagnostic bias resulting in diagnostic errors (n=15). 4) Pathologizing race by either using dehumanizing language or by unnecessarily drawing attention to an increased disease burden in Black or African-American patients, perpetuating the notion that these groups are inherently predisposed to disease (n=5). 5) Presentation of disputed race-based clinical guidelines, without discussion of the consequences of and evidence-based challenges against them (n=4).

CONCLUSIONS: Our analysis aimed to reveal the extent and nature of the misuse of race in a preclinical medical curriculum and we found that the misuse of race in medical education is common. The analysis of these errors and the themes generated can be applied by medical schools to evaluate and optimize their curricula. Correcting such errors may contribute to combating implicit biases amongst medical students and, as a consequence of that, potentially attenuate health care disparities.

RACIAL/ETHNIC DIFFERENCES IN UNCONTROLLED TYPE 2 DIABETES MELLITUS AMONG PEOPLE WHO TAKE DIABETES MEDICATION

Nazleen Bharmal[1]; Phuc H. Le[2]; Anita D. Misra-Hebert[3]; Michael B. Rothberg[3]. [1]Cleveland Clinic Community Care, Cleveland Clinic, Cleveland, OH; [2]Center for Value-based Care Research, Medicine Institute, Cleveland Clinic, Cleveland, OH; [3]Internal Medicine, Cleveland Clinic, Cleveland, OH. (Control ID #3390847)

BACKGROUND: Racial/ethnic minorities have a disproportionately higher burden of diabetes prevalence and have a greater prevalence of uncontrolled diabetes compared to White patients. This may reflect access to care or cultural norms of diet and activity. Less is known about uncontrolled diabetes among patients taking diabetes medication. Our objective was to examine factors associated with uncontrolled type 2 diabetes (T2D) among adults taking at least one diabetes control medication in a national sample.

METHODS: We performed an analysis of the National Health and Nutrition Examination Survey (NHANES) 2011-2016 cohort, limited to non-pregnant persons aged ≥18 years with T2D who reported using at least one prescription diabetes medication.

The outcome of interest was uncontrolled diabetes, defined as a HbA1c ≥ 8%. Race/ethnicity was categorized as non-Hispanic Whites, non-Hispanic Blacks, non-Hispanic Asians, Hispanics, and other. Covariates included age, sex, body mass index, educational attainment, income, birth country, health status, health insurance status, and having a routine place for medical care.

Multivariable logistic regression analysis was performed to estimate the odds of having uncontrolled diabetes despite medication as a function of race/ethnicity, adjusted for socio-demographic characteristics, health status, and health care access (model 1). In a second model, we also adjusted for healthy eating (index) and physical activity (METS). Analyses were conducted using Stata 14.2 and accounted for complex survey design.

RESULTS: There were 1806 people with T2D who reported taking a diabetes medication; 31% had uncontrolled diabetes with a mean HgA1c of 9.6%. Among those with uncontrolled diabetes on medication, the majority were male (55%) with a mean age of 57 years old and mean BMI of 34 kg/m2. Fifty-three percent were White patients, 21% were Hispanic, 17% were Black, 4% were Asian, and 5% were other race/ethnicity.

Having health insurance and self-reporting good/very good/excellent health status were significantly associated with lower odds of uncontrolled diabetes on medication. After adjustment for these factors in model 1, Hispanic patients were more likely to have uncontrolled diabetes than Whites (OR 1.72; 95% CI 1.09, 2.72). After adjustment for healthy eating and physical activity, this association disappeared. Asian patients were less likely to have uncontrolled diabetes than Whites (OR 0.44; 95% CI 0.21, 0.95). There was no association with Black race and uncontrolled diabetes.

CONCLUSIONS: Hispanics taking diabetes medication are more likely to have uncontrolled diabetes, and this appears due to diet and sedentary lifestyle, affirming the need for culturally tailored nutrition and physical activity approaches for diabetes education and treatment.

RACIAL/ETHNIC VARIATIONS IN DISCHARGE DESTINATION AFTER INPATIENT CARE: A RISK-ADJUSTED ANALYSIS OF A LARGE REGIONAL DATASET

Arnab K. Ghosh, Said Ibrahim. Medicine, Weill Cornell Medical College, New York, NY. (Control ID #3377732)

BACKGROUND: While there are many well-documented factors for racial/ethnic variation in discharge destination, less is known about the role hospital processes play. We hypothesize that variation in hospital processes -defined as the patient length of stay (LOS) adjusted for known confounders - explains racial/ethnic variation in discharge destination.

METHODS: We used the 2014 New York State Inpatient Database from the Healthcare Cost and Utilization Project merged with the 2014 American Hospital Association Annual Survey, which contained all inpatient discharges, their demographic, clinical characteristics and some social characteristics. We excluded patients under 18 years, those with LOS of zero, patients who are homeless, those who died in hospital, those admitted to critical access hospitals, and patients from hospitals that lacked sufficient number of minority patients. We used a generalized linear model with gamma link function to create an in-hospital risk-adjusted average LOS (RA-LOS) by modelling the relationship between the interaction of race and discharge destination with LOS, controlling for known confounders such as patient socio-demographic factors, disease characteristics, and time, DRG and hospital fixed-effects.

RESULTS: There were 1,668,675 observations from 165 hospitals. Mean age of patients was 57.25 years, 57.95 % were female; 58.24% were non-Hispanic white, 17.25% were Black and 11.30% were Hispanic; 43.84% had Medicare, 23.39% had Medicaid and 27.3% had commercial insurance. Patients had a mean 4.87 medical conditions. Almost 80% of patients were discharged home, 20.08% were discharged to non-home destinations

After adjusted analysis, White patients discharged had a 5.60 day RA-LOS regardless of discharge destination (95% CI: 5.59-5.61) while Black patient RA-LOS was 5.90 days (95% CI: 5.88-5.92), representing a significant 0.3 day difference (95% CI: 0.29-0.31, $p < 0.001$). Results were significant for Black compared to White patients discharged to non-home destinations (0.3 day difference in RA-LOS, 95% CI: 0.25-0.32, $p < 0.001$). However compared to White patients, Hispanic patients (5.59 day RA-LOS, 95% CI: 5.56-5.62) did not have a significant difference in RA-LOS overall (-0.01 days, 95% CI: -0.02-0.00) nor in non-home discharge destinations (difference in RA-LOS -0.02 days, 95% CI: -0.08-0.02).

CONCLUSIONS: We show a persistent difference in LOS by discharge destination between Black and White adult inpatients patients after controlling for between-hospital, disease and patient factors using New York 2014 discharge data. However, we saw no difference between Hispanic and White patients. LOS is a function of hospital processes and organizational structure, and is an important metric for hospital efficiency. This suggests a potential role for hospitals themselves to help reduce existing racial disparities in their inpatient processes.

RACIAL AND ETHNIC DIFFERENCES IN OPIOID PRESCRIBING ON HOSPITAL DISCHARGE FROM AN INTERNAL MEDICINE SERVICE

Aksharananda Rambachan[1]; Margaret Fang[1]; Priya A. Prasad[2]; Nicholas Iverson[3]. [1]Medicine, University of California, San Francisco, San Francisco, CA; [2]Division of General Internal Medicine, Department of Epidemiology and Biostatistics, UCSF, San Francisco, CA; [3]Medicine, Zuckerberg San Francisco General Hospital, San Francisco, CA. (Control ID #3388351)

BACKGROUND: Prior studies have found racial disparities in how patients are assessed for pain and prescribed opioids from emergency department and surgical settings. However, we do not know whether similar disparities exist among general medicine inpatients. We examined opioid prescriptions at discharge among adults admitted to the general medicine service at our medical center, with a focus on whether there were differences by race and ethnicity.

METHODS: We identified all adults hospitalized on the general medicine service from 2012-2018 at a 600- bed urban academic teaching hospital. Using electronic health databases, we identified two cohorts of

patients: first, patients who received opioids during their last 24 hours of hospitalization and second, all patients who were discharged with an opioid prescription, and collected data on their demographics, diagnoses codes, and medications. We excluded patients with diagnoses of cancer-related pain, sickle cell disease pain crises, patients discharged on hospice, or who were followed by palliative care. Patient self- reported race/ethnicity was categorized as White, Black, Hispanic (for patients who reported Hispanic ethnicity), Asian, or Other/Unknown.

We used multivariable logistic regression to examine the likelihood of receiving an opioid prescription at discharge based on whether they had received opioids in the 24 hours prior to discharge. We then developed a second multivariable linear regression model, this time examining disparities in the total opioid days prescribed at discharge, calculated as the total morphine milligram equivalents (MME) prescribed divided by the MME administered during the last 24 hours of hospitalization. Models were adjusted for patient demographics (age, gender, limited English proficiency status), hospitalization factors (including length of stay, intensive care unit management, opioids received during the total stay and in the last 24 hours), and medical diagnoses (including adjusted Elixhauser comorbidity index and cancer).

RESULTS: We identified 10,953 patients who received opioids during the last 24 hours of hospitalization and 5,541 patients discharged on opioids. We found statistically significant differences by race/ethnicity in mean opioid days prescribed at discharge, in both univariate and multivariable analyses. In unadjusted univariate analysis, Black patients were prescribed fewer opioid days (14.1 days) compared to White patients (17.6 days). Adjusting for covariates, Black patients were less likely to receive opioids on discharge (OR 0.77, 95% CI 0.64 to 0.91, p = 0.003) compared to White patients. Moreover, Black patients discharged on opioids received 2.5 fewer days of opioids (95% CI -4.5 to -0.1 days, p= 0.044).

CONCLUSIONS: We found Black patients were less likely to be prescribed opioids on discharge. Black patients discharged on opioids received fewer days of opioids compared to other racial/ethnic groups.

RACIAL AND ETHNIC DISPARITIES IN 7-DAY READMISSIONS FROM AN INTERNAL MEDICINE SERVICE

Aksharananda Rambachan, Yumiko Abe-Jones, Yalda Shahram. Medicine, Division of Hospital Medicine, University of California at San Francisco, San Francisco, CA. (Control ID #3388348)

BACKGROUND: Health equity will only be achieved when health care outcomes do not vary based on patient social characteristics, such as gender, race, ethnicity, geographic location, and socioeconomic status. Readmission is a significant outcome for patients and health systems, and 30-day readmission has been associated with racial disparities. However, less is known about disparities in 7-day readmissions. Previous studies have demonstrated that 7-day readmissions reflect a similar patient mix to 30-day readmissions, but that 7-day readmissions may be a better measure of hospital care. In the realm of health equity, studying 7-day, as opposed to 30-day readmissions, may better capture modifiable factors, diagnostic error, clinical decision making, and implicit bias from the provider.

METHODS: Using electronic health databases, we identified all adults discharged from the general medicine service between July 2016 and June 2019 from a 600-bed urban academic teaching hospital. Given the primary outcome of readmission, we excluded patients who died during hospitalization, were under observation status, or were transferred to a psychiatric facility. The primary predictor was self-reported race/ethnicity, categorized as White, Black, Hispanic, Asian, or Other/Unknown. The primary outcome was 7-day readmission back to the discharging hospital. Multivariable logistic regression was used to assess for factors associated with 7-day readmission adjusted for patient demographics (age, gender, Limited English Proficiency (LEP status), housing status, payor status), hospitalization and health system factors (including length of stay, intensive care unit management, teaching vs. hospitalist service, discharge disposition), and medical comorbidity index.

RESULTS: We identified a total of 18,808 patients in this dataset. A total of 1,297 (6.9%) of patients were readmitted within 7 days. We found a statistically significant association between race/ethnicity and 7-day readmission. Black patients (8.9%) and Asian patients (7.2%) had a higher 7-day readmission rate compared to White patients (6.4%). Using multivariable logistic regression, controlling for confounding variables, the Odds Ratio for 7-day readmission for Black patients was 1.35 (95% CI 1.15-1.58, p <0.001) and for Asian patients was 1.24 (95% CI 1.05-1.48, p = 0.014). The readmission odds for Hispanic and Other/Unknown patients did not differ significantly from White patients.

CONCLUSIONS: Black and Asian patients experienced higher rates of 7-day readmission than White patients, confirmed on adjusted analysis. Racial disparities in 7-day readmissions from general medicine services have not been previously characterized, but these findings align with known racial disparities in 30- day readmissions. Because 7-day readmissions may be more modifiable and impacted by factors like clinician bias, these results require further investigation into causal pathways and the development of tools to mitigate bias.

RACIAL AND ETHNIC DISPARITIES IN ANTICOAGULANT CHOICE FOR ATRIAL FIBRILLATION IN THE VETERANS HEALTH ADMINISTRATION: RESULTS FROM THE REACH-AF STUDY

Utibe R. Essien[1,2]; Nadejda Kim[1]; Leslie R. Hausmann[1]; Maria K. Mor[1]; Chester Good[1]; Walid F. Gellad[1]; Michael J. Fine[1]. [1]Center for Health Equity Research and Promotion, VA Pittsburgh Healthcare System, Pittsburgh, PA; [2]Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA. (Control ID #3389630)

BACKGROUND: Atrial fibrillation (AF) affects nearly 1 million patients in VA, causing morbidity and mortality that disproportionately affects racial/ethnic minorities. Anticoagulation reduces stroke risk in AF, yet non-VA studies show that warfarin and safer, more effective direct oral anticoagulants (DOACs) are underused in minorities. We compared anticoagulant initiation by race/ethnicity for patients with AF in VA— which facilitates access to medications through a uniform national drug formulary.

METHODS: Using data from the VA Corporate Data Warehouse, we identified patients enrolled in VA from January 1, 2014 to December 31, 2018 with an outpatient diagnosis of AF and a confirmatory diagnosis ≦180 days of their initial (index) AF diagnosis. To restrict the cohort to incident AF cases, we excluded patients with an AF diagnosis or anticoagulant therapy in the 2 years prior to their index AF diagnosis. We excluded those with pre-existing valvular heart disease, receiving hospice care or who died within 180 days of index AF diagnosis, or had missing or "other" race/ethnicity. We categorized our independent variable as non- Hispanic white (NHW), non-Hispanic black (NHB), and Hispanic. Our primary outcome was receipt of any anticoagulant ≦180 days of index AF diagnosis; we also assessed the type of anticoagulant (warfarin, DOAC) initiated. We used logistic regression to compare these outcomes by race/ethnicity, adjusting for year of diagnosis, renal disease, and stroke risk with $CHADS_2VA_2Sc$ score (categorized as low risk; 0-1, or moderate to high risk; ≧2).

RESULTS: We identified 148,062 patients with incident AF: 8.6% were NHB, 3.4% Hispanic, mean age was 72.5 years, and 88.9% had a $CHADS_2VA_2Sc$ score ≧2. Overall, NHBs (57.7%) and Hispanics

(58.4%) were less likely than NHWs (61.4%) to initiate any anticoagulant therapy (p <0.01), driven largely by lower DOAC initiation for minorities (36.8% NHBs, 36.5% Hispanics, 43.0% NHWs; p <0.01). Compared to NHWs, the adjusted odds ratios (AORs) for receiving any anticoagulant or DOACs were significantly lower for NHBs and Hispanics (Table); in contrast, AORs for receiving warfarin were significantly higher among minorities. As DOAC initiation increased from 16.8% (2014) to 60.3% (2018), disparities in initiation increased from 1.7 to 9.1% points for NHBs vs. NHWs and from 0.9 to 9.4% points for Hispanics vs. NHWs.

CONCLUSIONS: In a national incidence cohort of AF in VA, we identified significant racial/ethnic disparities in anticoagulant initiation, driven largely by growing disparities in DOAC initiation. Understanding the reasons for these differences is essential to improving outcomes in an increasingly diverse patient population with AF managed in the largest U.S. integrated health care system.

RACIAL DIFFERENCES IN MECHANICAL VENTILATION USE FOR PATIENTS WITH ADVANCED DEMENTIA OVER TIME

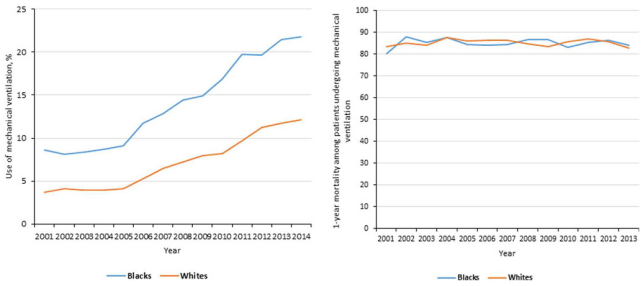
Rashmi K. Sharma[1]; Hyosin Kim[2]; Donald R. Sullivan[2]; Pedro Gozalo[3]; Jennifer Bunker[2]; Joan Teno[2]. [1]Medicine, University of Washington, Seattle, WA; [2]OHSU, Portland, OR; [3]Brown University, Providence, RI. (Control ID #3368296)

BACKGROUND: Racial/ethnic minorities are more likely than Whites to receive intensive care at the end of life. In patients with advanced dementia, use of invasive interventions such as mechanical ventilation may be burdensome without associated benefits in longevity. While use of feeding tubes in patients with advanced dementia has declined by 50% among both White and Black patients over the last decade, little is known about whether a similar reduction has occurred in use of mechanical ventilation.

METHODS: We conducted a retrospective analysis of Medicare beneficiaries with advanced dementia who were hospitalized between 2001 and 2014 for pneumonia and/or septicemia and had been in a nursing facility during the 120 days preceding hospitalization. The study sample was restricted to patients of Black or White race. Invasive mechanical ventilation (IMV) was identified by ICD procedure codes. We used multivariate logistic regression analyses to examine the association between race and the likelihood of receiving IMV, controlling for patients' demographics, function, and comorbidities. We used a fixed effect model to examine the association of race within a hospital and a robust clustering model to examine the overall association between race and IMV across hospitals.

RESULTS: A total of 301,925 nursing home residents with advanced dementia were hospitalized for pneumonia or septicemia between 2001 and 2014. Of these hospitalizations, 63,143 occurred for patients identified as Black and 216,874 for patients identified as White yielding a study sample of 280,017 hospitalizations. Use of IMV increased from 3.7% to 12.1% in Whites and from 8.6% to 21.8% in Blacks. Among those ventilated, one-year mortality rates remained high at 76.1% for Whites and 75.6% for Blacks dying in 2014. Compared to Whites, Blacks had a higher odds of receiving IMV in the fixed effect (within hospital) model (AOR 1.34; 95% CI 1.29-1.39) and in the robust clustering model (AOR 1.84 95% CI 1.71-1.97).

CONCLUSIONS: Use of IMV in patients with advanced dementia has substantially increased with Black patients having a larger increase than Whites despite no significant improvement in mortality. These racial differences are based, in part, on the hospitals where Black patients receive care.



RANDOMIZED TRIAL OF AN EMBEDDED RISK CALCULATOR FOR DETERMINING VTE PROPHYLAXIS IN HOSPITALIZED MEDICAL PATIENTS

Michael B. Rothberg[1]; Aaron Hamilton[2]; Jacqueline Fox[3]; Alex Milinovich[4]; Bo Hu[4]; Toyomi Goto[1]; Stephanie Moss[2]; Sidra Speaker[5]; Daniel Moussa[6]; Matthew A. Pappas[7]. [1]Internal Medicine, Cleveland Clinic, Cleveland, OH; [2]Hospital Medicine, Cleveland Clinic, Cleveland, OH; [3]Medicine Institute, Cleveland clinic, Cleveland, OH; [4]Quantitative Health Sciences, Cleveland Clinic, Cleveland, OH; [5]Education, Cleveland Clinic Lerner College of Medicine at Case Western Reserve University, Cleveland Heights, OH; [6]Lerner College of Medicine, Cleveland Clinic, Cleveland, OH; [7]Medicine Institute, Cleveland Clinic Foundation, Cleveland, OH. (Control ID #3391999)

BACKGROUND: Venous thromboembolism (VTE) is a serious source of hospital morbidity and mortality. Chemoprophylaxis with heparin has been shown to reduce VTE, but it increases the risk of bleeding and heparin induced thrombocytopenia. It should therefore be reserved for patients at high risk of VTE. We conducted a randomized trial to assess the impact of a VTE risk calculator embedded in an electronic health record (EHR) on prophylaxis prescribing and patient outcomes.

METHODS: We embedded a locally derived and validated risk calculator in our EHR. Ten hospitals were randomized to implement the calculator (one per month) using a stepped-wedge design. Most calculator fields were autopopulated, but required physician confirmation. Physicians were encouraged to use the calculator but to prescribe prophylaxis according to their clinical judgment. We included all patients 18 years and older who were admitted to a medical service, including intensive care, but not observation status, between October 1, 2018 and February 28, 2019. We excluded patients not eligible to receive VTE prophylaxis because they were already receiving anticoagulation for another purpose, terminal patients receiving comfort care only, and surgical patients temporarily housed on a medical floor. Outcomes were determined through review of the EHR. Our primary outcome was proportion of patients receiving appropriate prophylaxis (high risk receiving + low risk not receiving/total patients). High risk patients were defined as those whose predicted VTE risk exceeded 0.6% at 14 days based on an updated risk calculator. Secondary outcomes included total proportion of patients receiving prophylaxis and rate of VTE among high risk patients at 14 and 45 days after admission. Outcomes were compared using mixed-effect models to account for the stepped-wedge design.

RESULTS: The final sample included 32,560 patients (13,413 prior to the intervention and 19,147 during the intervention). Of these, 29% were high risk for VTE. During the intervention phase, physicians used the calculator for 13% of high risk and 12% of low risk patients. Physicians prescribed prophylaxis to 73% of patients designated high risk and 28% designated low risk by the calculator. Appropriate prophylaxis was prescribed to 41% of patients pre-intervention and to 45% of patients during the intervention ($p<0.001$). The total proportion of patients receiving prophylaxis declined from 61% pre-intervention to 54% during the intervention ($p<.001$). The rate of VTE among high risk patients was 3.1% in the pre-intervention phase and 2.3% in the intervention phase ($p=0.13$) at 14 days and 4.9% vs. 4.0% at 45 days ($p=0.43$). Overall rates of VTE at 14 and 45 days also did not differ between the groups.

CONCLUSIONS: A locally validated risk calculator embedded in the EHR was used infrequently, but improved the rate of appropriate prophylaxis and decreased overall use of prophylaxis without impacting the rate of VTE among high risk patients.

RATES OF LABOR AND DELIVERY COMPLICATIONS IN PATIENTS WITH ANXIETY AND DEPRESSION

Joanna Rowe[1]; Kenneth S. Johnson[2]; Victoria Gordon[2]; Clayton Marolt[2]; Adam Lewis[2]; Kanwalgeet Hans[2]; Barth Wright[2]. [1]Anatomy, Kansas City University, N Kansas City, MO; [2]Anatomy, Kansas City University of Medicine and Biosciences, Kansas City, MO. (Control ID #3391816)

BACKGROUND: Depression and anxiety are complex, overwhelming diagnoses and influence many aspects of a patient's life and health care. Maternity has not escaped this influence. This study aims to elucidate the impact of specific mental health diagnoses on maternity. Particularly, we analyzed the connection between depression and anxiety on labor and delivery complications.

METHODS: This retrospective cohort study used the Nationwide Inpatient Sample to identify patients from 2012-2015 admitted for labor and delivery. ICD-9 codes were then used to identify patients who also carried a diagnosis in the categories of depression or anxiety. Chi-square was used to analyze rates of labor and delivery complications in these patients including premature rupture of membranes (PRROM), obstetrical pulmonary embolism, retained placenta or membranes without hemorrhage, postpartum hemorrhage, obstructed labor, umbilical cord complications, and other complications not elsewhere classified including maternal distress, material shock, maternal hypotension syndrome, acute kidney failure, as well as mortality.

RESULTS: A total of 2,540,087 patients with a labor and delivery diagnosis were identified. Of those patient encounters, 147,270 also carried a diagnosis within the categories of depression or anxiety. When compared to deliveries without a concurrent mental health diagnosis, these patients had increased rates of complication diagnoses including obstetrical pulmonary embolism (13.7% vs. 5.8%, $p<0.0005$), PRROM (7.3% vs. 5.7%, $p<0.0005$), retained placenta or membranes without hemorrhage (7.9% vs. 5.8%, $p<0.0005$), postpartum hemorrhage (7.4% vs. 5.7%, $p<0.0005$), and other complications not elsewhere classified including maternal distress, material shock, maternal hypotension syndrome, acute kidney failure. (9.6% vs 5.8%, $p<0.0005$). Additionally, there was an increase in mortality (6.9% vs. 5.8%, $p<0.0005$). There was no statistically significant difference in rates of umbilical cord complications, and obstructed labor was diagnosed 0.2% more often in women without concurrent mental health diagnosis. (5.8% vs 5.6%, $p=0.002$)

CONCLUSIONS: This analysis is the first to examine rates of these complications for pregnant patients with depression or anxiety between the years 2012-2015. It serves to support previous research on maternal depression and identify more specific statistical correlations. Maternal depression is negatively effecting delivery and labor outcomes. Future research should attempt to develop methods for identifying pregnant patients who may need greater intervention and support in order to decrease rates of complications and give them their best chance at beginning a life.

READMISSION RELATED HEALTH CARE UTILIZATION AND FACTORS ASSOCIATED WITH HOSPITAL READMISSION IN PATIENTS WITH COCAINE RELATED DISORDER: A US POPULATION COHORT STUDY

Palakkumar Patel[1]; Pranavi Patel[1]; Eric Lam[1]; Yichen Wang[2]; Jiten Desai[1]; Chris Elsayad[1]. [1]Internal medicine, Nassau University Medical Center, East Meadow, NY; [2]Internal medicine, The Wright Center for Graduate Medial Education, Scranton, PA. (Control ID #3392149)

BACKGROUND: Cocaine related disorders (CRD) are a growing burden on the US Healthcare system. We aim to identify factors associated with 30-days CRD related readmission and to evaluate its impact on health- care utilization.

METHODS: This is a retrospective cohort study using the 2016 and 2017 National Readmission Database. Inclusion criteria were: patient age >18 and urgent admissions with principal ICD-10 codes for CRD. A readmission was defined as the first admission to any hospital for any non-trauma diagnosis within 30 days of the index admission. Independent risk factors for readmission were identified using multivariate cox regression analysis.

RESULTS: CRD disorder most common in males, age group 50-65 years with a mean age of 43, Insured by Medicaid, has lower comorbidity burden and being treated at large, urban teaching hospital.

The total number of index CRD admissions were 18,167, of which 3,026 (16.7%) were readmitted within 30 days. Most Common cause of readmission: Major Depressive disorder (4.9%), Schizoaffective disorder (bipolar type,3.8%, Unspecified,3.1%), Schizophrenia (3.3%), Cocaine dependence with mood dosorder(3.0%), and Bipolar disorder(2.6%). The in-hospital mortality rate (0.3% vs. 0.1%, $p<0.001$), mean cost of hospitalization ($6,279 vs. $5,570, $p<0.001$) for readmitted patients was higher than that in index admissions with no difference in length of stay(LOS). The total in-hospital economic burden associated with readmission was $ 19 million. Table-1 shows independent predictors of 30 days readmission.

CONCLUSIONS: We found that 16.7% of hospitalized patients with CRD were readmitted within 30 days. Readmissions had higher in-hospital mortality, and resource utilization compared to index admission and was associated with a significant health-care burden with total hospitalization cost of $ 19 million. We identified risk factors associated with 30-days readmission. Patients with known risk factors to cause readmission needs special attention to improve outcomes and provide optimum care.

Table 1:- Independent Predictors for 30-day Readmission for Cocaine Related Disrder(CRD)

Variables	Adjusted Hazard ratio	P value
Age Group		
18- 30 years	reference	reference
30-40 years	1.14 (0.93- 1.39)	0.18

REDUCING HIGH-RISK GERIATRIC POLYPHARMACY VIA ELECTRONIC HEALTH RECORD NUDGES

Tiffany Brown[1]; Stephen Persell[1]; Ji Young Lee[1]; Jeffrey A. Linder[1]; Mark W. Friedberg[2]. [1]Department of Medicine; Division of General Internal Medicine and Geriatrics, Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Blue Cross Blue Shield of Massachusetts, Boston, MA. (Control ID #3392479)

BACKGROUND: Inappropriate polypharmacy, prescribing more drugs than clinically necessary, is highly prevalent among geriatric patients and is associated with adverse drug events (ADE). Our objective was to develop and pilot test electronic health record (EHR) clinical decision support (CDS) alerts using behavioral economics informed strategies to nudge clinicians toward safer prescribing for older patients.

METHODS: This pilot study occurred during February-May 2019 within three primary care clinics affiliated with an integrated academic health system. Alerts were triggered for patients aged 65 or greater who had ≥ 5 medications, at least one of which was on the Beers list, met Screening Tool of Older Persons' Potentially Inappropriate Prescriptions (STOPP) criteria, or was targeted by the National Action Plan for ADE Prevention. Participating clinics (all attributed clinicians) were randomized to one of three arms to receive CDS alerts when triggering criteria were met within the chart: (1) a 'commitment nudge' which offered prescribers a chance to create an EHR reminder to commit to addressing high-risk polypharmacy at the next patient encounter, (2) a 'justification nudge' which asked clinicians to write a justification or reason for ordering medications when high-risk polypharmacy was present, or (3) to receive both the 'commitment' and 'justification' nudges. We developed and validated seven measures of high-risk polypharmacy and extracted data from the EHR analyzing data from before and after the study period. Pilot clinics, for each measure, had between 4 and 1197 patients prescribed high-risk polypharmacy for each measure.

RESULTS: On average, physicians (n=70) received 1.6 commitment nudges per week and 0.6 justification nudges per week. Justification nudge frequency fell from 1.2 nudges per week in the first four weeks to below 0.5 nudges per week in the later weeks of the intervention period. No physicians asked to leave the pilot. All seven measures of polypharmacy either decreased during the study period (e.g., increased fall risk and prescribed drug associated with increased falls rate from 32.8% to 31.6%) or remained stable (e.g., heart failure and NSAID use rate from 3.6% to 3.5%).

CONCLUSIONS: This pilot study shows that two EHR-based nudges to address high-risk polypharmacy are feasible to implement in a commercial EHR and were tolerated by practicing primary care physicians. The observed decline in justification nudge firing frequency suggests that this nudge might have begun to influence prescribing, despite the short duration of the study. We plan to evaluate the effectiveness of these nudges with a large randomized controlled trial.

REDUCING NIGHTTIME INTERRUPTIONS AND IMPROVING SLEEP FOR HOSPITALIZED PATIENTS BY RESTRUCTURING NIGHTTIME CLINICAL WORKFLOW

Minna Holleck[3]; Kei Tikkanen[4]; Cynthia Frank[2]; Nick Falcone[1]; Jennifer McDonald[1]; Noyes Annamarie[1]; Marie Mann[1]; Sukeisha Davis[1]; John J. Chang[1,2]. [1]Medicine, VA Connecticut Healthcare System, West Haven, CT; [2]Medicine, Yale School of Medicine, New Haven, CT; [3]Georgetown University, Washington DC, DC; [4]Yale School of Public Health, New Haven, CT. (Control ID #3392099)

BACKGROUND: Noise and interruptions at night negatively impact the experience of hospitalized patients. We prospectively implemented a change in nighttime clinical workflow for hospitalized patients and determined the impact on disruptions and sleep of this new intervention.

METHODS: We administered surveys to hospitalized patients on a 23-bed general medical ward at the CT VA Hospital. The survey asked the following questions about the sleep in the hospital the night before: time to fall asleep; number of times of waking up; reasons for waking up; and overall quality of sleep in the hospital compared to that of sleep at home. The first round of surveys (Feb to Mar of 2018) measured the baseline level of interruptions. Two major sources of interruptions were identified: blood pressure (BP) check at 4 am for telemetry patients and medication administration before 6 am (most commonly heparin SQ injection 4:30 - 6 am for DVT prophylaxis). The clinical workflow was restructured to eliminate these disruptions: 4 am BP check was moved to 6 am and the heparin SQ Q8H order which had prompted an injection between 4:30 and 6 am was replaced with daily 9 am enoxaparin injection order. The impact of these changes was assessed in a second round of surveys (July to Aug of 2019). Comparisons between pre and post-intervention groups were made by using the Z-test.

RESULTS: 149 pre-intervention surveys completed by 97 patients (of whom 32 surveyed twice and 10 thrice) confirmed frequent interruptions and excessive noise at night. The most common interruptions were BP check [56% of surveys (84/149)], medication administration [40% (59/149)], hallway noise [39% (58/149)] and phlebotomy [35% (52/149)]. 39% of patients reported taking longer to fall asleep in the hospital than at home, while 46% reported waking up more frequently in the hospital.

44% of patients reported sleeping worse in the hospital than at home. After restructuring the nighttime clinical workflow (see Methods), 99 post-intervention surveys were completed by 55 patients (of whom 24 surveyed twice and 10 thrice). Medication administration as a cause of nighttime disruption decreased significantly from 40% (59/149) pre- to 4% (4/99) post-intervention ($p < 0.01$). BP check became a less frequent cause of interruption [56% (84/149) pre vs 42% (42/99) post, $p = 0.033$]. Fewer patients reported taking longer to fall asleep in the hospital vs home (39% pre vs 25% post, $p = 0.021$). Similarly, fewer patients woke up more frequently in the hospital vs home (46% pre vs 32% post, $p = 0.036$). Finally, fewer patients reported sleeping worse in the hospital (44% 39% pre vs 39% post, NS) though not statistically significant. No adverse outcome has resulted from checking BP 2 hours later at 6 am and changing from heparin to enoxaparin for DVT prophylaxis.

CONCLUSIONS: Nighttime interruptions in hospitalized patients frequently interfere with sleep. Restructuring the clinical workflow significantly reduced interruptions and improved sleep.

REDUCING NO CARDS AND IMPROVING TRANSITIONS IN CARE AT HOSPITAL DISCHARGE

Caleb Melancon[1]; Stephen A. Petty[1]; Paul Ehrlichman[1]; Alex Song[1]; Ronald Ng[1]; Matthew Sechler[1]; George Waits[2]; Nancy M. Denizard-Thompson[1]. [1]Internal Medicine, Wake Forest Baptist Medical Center, Winston Salem, NC; [2]Cardiology, Houston Methodist, Houston, TX. (Control ID #3391444)

BACKGROUND: Given the complexities of current healthcare systems, transitions of care at discharge are crucial to ensure appropriate standard of care. Follow up with primary care providers is a major component of care transition from the inpatient setting, though this can be challenging to arrange. Our institution utilizes a dedicated team, dubbed "Gold Card" (GC), to assist in securing follow up appointment scheduling, who are contacted through the use of an order in the EHR. Unfortunately, if the GC group is not engaged at discharge, this may result in patients not having a follow up visit scheduled. We wanted to better characterize this process and hypothesized there was opportunity for improvement to more reliably secure follow up appointments for our patients in this crucial care transition period.

METHODS: We examined discharges from a general medicine ward for 1 month to evaluate frequency of usage of the GC at discharge. Patients who were discharged without a GC were further examined for appropriateness. It was considered a "no card," if there was no appropriate reason for not placing a GC for discharge follow up. Appropriate reasons included patients discharging to hospice or skilled facility, patients who had follow up previously scheduled or scheduled through other means, and patients who passed away. Subsequently, the GC order was added to the default discharge order set and 1 month of discharges were examined. Finally, a "hard stop," that would not allow providers to proceed without selecting whether or not the patient needed a GC at discharge was added and an additional 1 month of discharges were examined from the same unit for comparison in "no cards."

RESULTS: In the initial month of observation, there were 127 patients discharged, of these, 14 (11%) were "no cards," with no appropriate reason for not ordering follow up at the point of care transition. In the month after the GC order was added to the discharge order set, there were 121 discharges, with 22 (18%) identified "no cards." Finally, following the addition of the hard stop, there were 144 patients discharged in the subsequent month, of these, 4 (2%) were "no cards," representing a significant decrease ($p<0.0001$).

CONCLUSIONS: The addition of a hard stop in a default discharge order set prompting providers to consider securing discharge follow up has the potential to improve care transition follow up and patient outcomes. Through our intervention we were able to dramatically reduce the number of patients that were not engaged for follow up scheduling. This benefit was not observed without prompting direct consideration by the discharging provider.

RE-FRAMING HEPATITIS C DECISION-SUPPORT ALERTS: A PILOT PROJECT IN HUMAN- CENTERED DESIGN

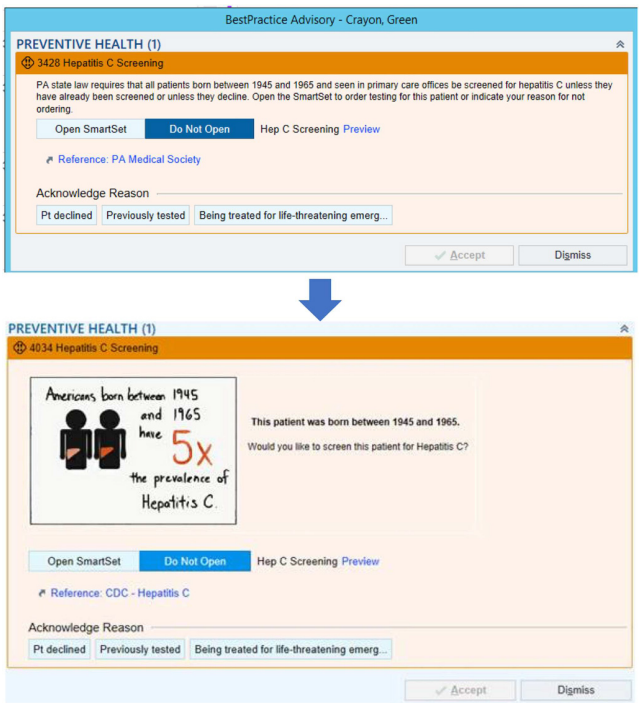
Michelle-Linh T. Nguyen[1]; Gary Fischer[2]. [1]Medicine, University of Pittsburgh Medical Center, Pittsburgh, PA; [2]Medicine, University of Pittsburgh, Pittsburgh, PA. (Control ID #3391562)

BACKGROUND: Decision-support alerts (DSA) within electronic health records (EHRs) have become a common way to remind physicians to comply with regulatory and quality mandates, but they are often ignored. Hepatitis C (HCV) is known to be five times more prevalent among people born between 1945 and 1968, and PA state law requires PCPs to offer their patients screening. In the University of Pittsburgh Medical Center EHR (EpicCare), a DSA prompts physicians to screen for HCV among this population. A majority of physicians ignore this DSA. We hypothesized that a DSA designed with a human-centered approach would be more effective.

METHODS: We designed a new DSA by refocusing the message to emphasize clinical rather than regulatory purpose, streamlining the text to make it easier to read, and inserting a graphic. We identified ambulatory medical practices that had 10 or more ignored alerts over a one-month period (n=132) and randomly assigned the new DSA to 62 of these practices without changing the DSA for the rest. We used the Mann-Whitney test to compare mean percent action taken on the old versus new DSA. Pre and post analyses are ongoing and will include a difference-in-differences analysis.

RESULTS: 12,290 old DSAs and 6,551 new DSAs were deployed over two months. There was no stastically significant difference between mean percent action taken by practices assigned to the old versus new DSA by Mann-Whitney test (23.6% and 27.6%, respectively). Within the intervention group, there was an increase in action after the new DSA was deployed ($p<0.001$; paired Wilcoxon signed rank test). This needs to be validated using a difference-in-differences analysis.

CONCLUSIONS: There may be a small increase in action taken on DSAs designed with a human-centered approach, but if present, the difference is modest. Physicians' interactions with DSAs are complex. More mixed-methods studies are needed to better understand the effect of DSAs on medical practice and inform health information system decisions.



REJECTION OF PATIENTS WITH OPIOID USE DISORDER REFERRED FOR POST-ACUTE MEDICAL CARE BEFORE AND AFTER AN ANTI-DISCRIMINATION SETTLEMENT IN MASSACHUSETTS

Simeon D. Kimmel[1,2]; Sophie J. Rosenmoss[1]; Benjamin Bearnot[3,4]; Marc Larochelle[1,2]; Alexander Y. Walley[1,2]. [1]Department of Medicine, Boston Medical Center and Boston University School of Medicine, Boston, MA; [2]Grayken Center for Addiction, Boston Medical Center, Boston, MA; [3]Department of Medicine, Massachusetts General Hospital, Boston, MA; [4]Mongan Institute, Massachusetts General Hospital, Boston, MA. (Control ID #3386114)

BACKGROUND: Patients with opioid use disorder (OUD) may be referred to post-acute medical care facilities for ongoing care following an acute hospitalization. Massachusetts Department of Public Health guidelines prohibit facilities from rejecting patients on the basis of treatment with medications for opioid use disorder (MOUD). Furthermore, in May 2018 the United States Attorney reached a discrimination settlement with a Massachusetts facility for violating the Americans with Disabilities Act by rejecting patients due to MOUD. We are unaware of studies which systematically evaluate this practice. Our objective was to determine how commonly individuals with OUD at a safety net hospital in Boston were rejected due to substance use or treatment with MOUD and if practices changed following the United States Attorney's settlement.

METHODS: We linked electronic referrals to private Massachusetts post-acute medical care facilities from Boston Medical Center in 2018 with clinical data. These referrals frequently include electronically transmitted comments from facilities detailing reasons for rejecting a referral. We restricted the cohort to hospitalizations for individuals with OUD, which we identified using ICD-10 diagnostic codes or inpatient or discharge MOUD receipt. Two reviewers assessed comments for substance use or MOUD content as reasons for rejection and classified these as discriminatory. We used segmented regression to assess for changes in proportions of referrals rejected for any reason and rejected explicitly due to substance use and MOUD before and after the settlement.

RESULTS: In 2018, 219 OUD-associated hospitalizations resulted in 1648 referrals to 285 facilities, an average of 7.5 referrals per hospitalization; 81.8% of referrals (1348) were rejected. Hospitalized individuals referred to private post-acute medical care facilities had a mean age of 50.2, were mostly male (71.7%), white (54%) or black (29%), English speaking (92%), insured by Medicaid (53%), and treated with MOUD (87.7%). Among hospitalizations, 37.4% (82) received at least one discriminatory rejection. Among rejections, 15.1% (203) were discriminatory (105 for MOUD and 98 for substance use). Among facilities, 29.1% (83) had at least one discriminatory rejection. We found no differences in the proportion of OUD referrals rejected for any reason or explicitly due to MOUD or substance use before and after the settlement.

CONCLUSIONS: Individuals hospitalized with OUD frequently experience explicit discrimination when rejected from post-acute care despite federal and state protections. Amidst rising morbidity and mortality associated with OUD and OUD-associated hospitalizations, there is increased need for high-quality and equitable post-acute medical care. Enhanced enforcement of anti-discrimination laws, regulations, and policies and efforts to identify and address barriers to post-acute medical care for patients with OUD are needed to achieve this goal.

RELIGION AND WORKFORCE BURNOUT

Robert G. Badgett[1]; Madhu V. Sharma[4]; Harold G. Koenig[2,3]. [1]Internal Medicine, KU School of Medicine- Wichita, Wichita, KS; [2]Psychiatry and Behavioral Sciences, Duke University School of Medicine, Durham, NC; [3]Internal Medicine, Duke University School of Medicine, Durham, NC; [4]Duke University, Durham, NC. (Control ID #3392320)

BACKGROUND: Prior research suggests that spirituality and religious beliefs may protect against burnout. This effect may be due to the guidance from the world's religions regarding our work lives. We compare burnout across major religions in the workforce in all English Trusts.

METHODS: Our data source was the National Health Services (NHS) Staff Surveys, available for all English hospital Trusts from 2012 to 2018. Burnout was measured with "During the last 12 months have you felt unwell as a result of work-related stress." The analysis focused on the year 2018, but trends were confirmed across all years. Prevalences and heterogeneity in burnout across religious groups were measured with a random-effects model. Modulators of burnout were explored with meta-regression. In addition, an individual-level dataset was recreated and analyzed by logistic regression.

RESULTS: In 2018, there were 471,886 respondents. The pooled rate of burnout across all religious affiliations was 39% with substantial heterogeneity (I^2 = 100%). After excluding the 6% of staff who withheld a response, the rates of burnout among staff reporting any versus no religious affiliation were 37% versus 40%. The rate of burnout among Hinduism, 29%, was statistically lower than in all other religions surveyed. For all years surveyed, Hindus had the lowest burnout. This significance remained after using logistic regression to control for the presence of any religion, a western religion, or a Dharmic religion. Regarding harassment or discrimination as modulators, while these rates varied significantly across religions (I^2 > 99%) and the rates for harassment tended to correlate with rates of burnout across religions, the associations did not reach statistical significance.

CONCLUSIONS: Religious affiliation is associated with lower burn out in the NHS workforce. Among the world's major religions, Hinduism is associated with significantly less burn out compared to other religions. The substantial heterogeneity in rates of workforce burnout suggests an opportunity for mutual learning across religions.

REMOTE GLUCOSE MONITORING LEADS TO HEMOGLOBIN A1C REDUCTION AT 12 MONTHS, INDEPENDENT OF SOCIODEMOGRAPHICS, AND SUSTAINED UP TO 18MONTHS AMONG LOW-INCOME ADULTS WITH DIABETES

Elizabeth B. Kirkland[2]; Jingwen Zhang[1]; Justin Marsden[2]; Patrick D. Mauldin[1]; William P. Moran[2]. [1]Medicine, Medical University of South Carolina, Charleston, SC; [2]General Internal Medicine, Medical University of South Carolina, Charleston, SC. (Control ID #3383998)

BACKGROUND: Evidence suggests that remote patient monitoring (RPM) improves short-term diabetes control. We seek to determine whether RPM of glucose, with provider engagement to allow for medication changes in the intervisit period, will produce sustained improvements in hemoglobin A1c (A1c) over 12 and 18 months. Additionally, we examine the impact of patient-level variables on A1c change in the setting of RPM participation.

METHODS: Over 800 underserved patients with an A1c of 8% or higher have been enrolled in an RPM program, transmitting home glucose and blood pressure readings to a secure server for healthcare provider review. Enrolled patients agreed to participate for 12 months, and those who continued to transmit data were invited to extend to 18 months. Providers were encouraged to adjust treatment plans based on incoming glucose data.

Baseline demographic and clinical variables are obtained at enrollment. A1c measurements are repeated 6, 12, and, for extended patients, 18 months after enrollment and compared to baseline values via paired t-tests. Two multivariable regression models were developed with primary outcomes of a) A1c change at 12 months and b) absolute 12 month A1c accounting for the RPM intervention and demographic variables.

RESULTS: Compared to baseline, RPM was associated with an A1c reduction of 1.8% at 6 months, 1.3% at 12months, and 2.0% at 18months (Table 1). A significant reduction in A1c was achieved at 6 and 12 months for all clinic types: academic, FQHC, and free/volunteer (Table 1).

Our regression model for A1c change showed no statistically significant difference for patient age, gender, race, household income, insurance, or clinic type. A higher baseline A1c was associated with a greater reduction at 12 months (β= -0.64; $p < 0.01$). In a pre- and post-intervention regression model, the RPM intervention was associated with an A1c reduction of 1.29 ($p < 0.01$). Increasing age was associated with a slightly lower A1c at baseline and 12 months (β= -0.04; $p < 0.01$), while male gender was associated with a higher A1c ($\beta = 0.70$; $p = 0.02$).

CONCLUSIONS: RPM leads to improved diabetes control at 6 months, which is sustained at 12 months, yet to a lesser degree. Although subject to selection bias, extension data suggests the A1c reduction can be sustained to 18 months.

Our pre- and post-intervention regression model for hgbA1c confirms the A1c reduction that we find in our t-test comparison. Further, our regression model for change in A1c over time suggests that sociodemographic variables do not significantly alter the likelihood of patients to benefit from this type of technology.

RESIDENT OBESITY MANAGEMENT: COMFORT CORRELATES WITH ACTION

Mita Hoppenfeld[1]; Nadeem E. Abou-Arraj[1]; Michelle Hauser[2]. [1]Internal Medicine, Stanford University, Palo Alto, CA; [2]Primary Care and Population Health, Stanford University School of Medicine, Palo Alto, CA. (Control ID #3391070)

BACKGROUND: The projected prevalence of obesity in the US is 50% by 2030. Little data exists on resident physician obesity management in their primary care clinics. We aimed to explore internal medicine (IM) resident comfort, knowledge, and treatment practice of obesity in primary care.

METHODS: IM residents at one academic medical center (N=125), at 5 primary care sites were anonymously surveyed about knowledge, comfort, and practice behaviors around obesity management. In this exploratory analysis, respondents self-reported comfort with lifestyle counselling and weight management medication (WMM) prescription on 4-point Likert scales; scores were combined into an overall Comfort Score (CS). Correlation analysis (Pearson's correlation) compared CS with the following Clinical Actions: referral to lifestyle specialists, lifestyle counseling, WMM prescription, and bariatric surgery referral.

RESULTS: The response rate was 70/125 (56%). Most residents (91%) reported discomfort with prescribing WMMs and most (84%) had never prescribed one. While most residents (81%) were "comfortable" or "somewhat comfortable" with lifestyle counseling, only 33% reported consistently providing it. Of the 31% of residents that correctly identified indications for bariatric surgery, only 9% reported referring appropriate patients for bariatric surgery. Notably, higher CS was significantly correlated with more frequent bariatric surgery referrals, lifestyle counselling, WMM prescription, and lifestyle specialist referral (Table 1). Reported barriers to lifestyle counseling were lack of time (93%), poor familiarity with resources (50%), and lack of training in motivational interviewing (36%). Barriers to WMM prescription were unfamiliarity with the medications (84%) and side effect concerns (61%). Finally, 90% desired more training in pharmacotherapy, and 77% wanted more information on referral processes for surgical and medical interventions.

CONCLUSIONS: Most IM residents surveyed do not feel adequately prepared to provide evidence-based management of obesity via conselling on lifestyle changes, WMM prescription, or specialty care referral. Comfort and knowledge of system processes/resources and WMMs are critical to resident management of obesity. These are potential targets for educational intervention in residency curricula that may improve care for patients with obesity.

RESIDENT PHYSICIAN PERSPECTIVES OF HEALTH DISPARITIES EDUCATION

Khushboo S. Gala, Suzanne McGee, Nancy T. Kubiak. Internal Medicine, University of Louisville, Louisville, KY. (Control ID #3386331)

BACKGROUND: Health disparities within the United States are well-documented and continue to grow given the growing diversity of the population. The Accreditation Council for Graduate Medical Education has prioritized education on social determinants of health, health disparities, and health equity for all residency trainees. Prior to implementation of such a curriculum, we evaluated internal medicine trainees' background knowledge of these topics and performed a needs assessment to determine future directions of the curriculum.

METHODS: We conducted a web-based survey of categorical and preliminary internal medicine and medicine-pediatrics residents in an urban academic Internal Medicine residency program. Residents were asked demographic information, source and extent of prior knowledge of and education in health disparities, ability to define health disparities and related terms and future learning interests on this topic. Using a 5-point Likert scale, trainees were asked to rate their knowledge (1-not at all to 5-very knowledgeable) of various social determinants of health and opinions (1-strongly disagree to 5-strongly agree) regarding importance of factoring in these determinants into patient care. In fall 2018, the anonymous survey was e-mailed to 112 residents.

RESULTS: Survey response was 60% (n=68); 66% were male. Respondents identified as Caucasian (59%), 24% as Asian, 4% African American and 4% Arabic. 63% reported previous training in health disparities and social determinants of health, primarily in medical school (93%). Respondents rated themselves least knowledgeable about the relationship of physical/intellectual/sensory disabilities (2.69) and gender orientation (2.82) and health. Residents were least likely to rate gender (3.71) or race/ethnicity (3.96) as a healthcare determinant, and most likely to rate access to healthcare (4.74) and poverty (4.63) as determinants of health. Without looking up the definition, 41(60%) of respondents felt able to explain the concepts of health disparity and 18(26%) could explain health equity. 77% of respondents reported factoring healthcare disparities into their medical decision-making more than half of the time. Respondents were most interested in learning more about immigrant/refugee status (46%) and socioeconomic status (44%) affecting health.

CONCLUSIONS: Internists frequently care for patients negatively affected by health disparities and social determinants of health. We believe that the first step to helping patients attain health equity is to recognize that these disparities exist. Our survey indicated that many of our respondents have baseline knowledge in health disparities and social determinants of health, and desire further education on this topic, particularly relating to ethnicity and immigrants. We recommend a more standardized curriculum to address the needs of learners and the communities they will serve.

RESIDENTS VALUE FREQUENT AND STRUCTURED FEEDBACK FROM ATTENDINGS WHO HAVE OBSERVED MULTIPLE EPISODES OF CARE

Tyra Fainstad[1]; Adelaide McClintock[2]; Bradley Anawalt[1]. [1]Internal Medicine, University of Washington, Seattle, WA; [2]Internal Medicine, UW Medicine, Seattle, WA. (Control ID #3391213)

BACKGROUND: Residents report feedback as one of the most important components of their ambulatory care experience but remain highly dissatisfied with feedback provision. We hypothesized that resident satisfaction with feedback in a primary care clinic would increase with a structured intervention aimed to improve feedback frequency and attending continuity.

METHODS: In a university-affiliated internal medicine residency continuity clinic, we randomized residents to a control group (standard feedback process) and an intervention group. In the intervention group, resident and attending pairs were created based on frequency of overlapping clinic schedules. Prior to a clinic day with their matched attending, each intervention resident was requested by e-mail to identify a goal for improvement for their upcoming clinic day and to and seek observation and feedback around this goal from that attending. Participants were all asked to complete pre- and post-intervention surveys regarding satisfaction around feedback and clinic experience. Kruskal-Wallis tests were used to determine associations in survey questions.

RESULTS: 78 residents participated in the study with response rates of 76% and 75% for the pre- and post- surveys, respectively. There was increased satisfaction with overall feedback, usefulness of feedback, and frequency of feedback in the intervention resident group ($p < 0.001$, 0.02, <0.001, respectively). There was also trend towards greater satisfaction with overall clinic experience ($p=0.09$), and towards increased desirability of primary care as a profession ($p=0.05$) in the intervention resident group.

CONCLUSIONS: Implementation of frequent and structured feedback sessions with a focus on attending/resident continuity increases resident satisfaction with feedback in the outpatient continuity clinic setting. Our study suggests that this frequent, structured feedback by a paired attending might improve resident satisfaction with primary care clinic, likelihood of choosing primary care as a career, and could ultimately improve resident competency and

RESILIENCE AND BURNOUT AMONG PHYSICIANS AND THE GENERAL U.S. WORKING POPULATION

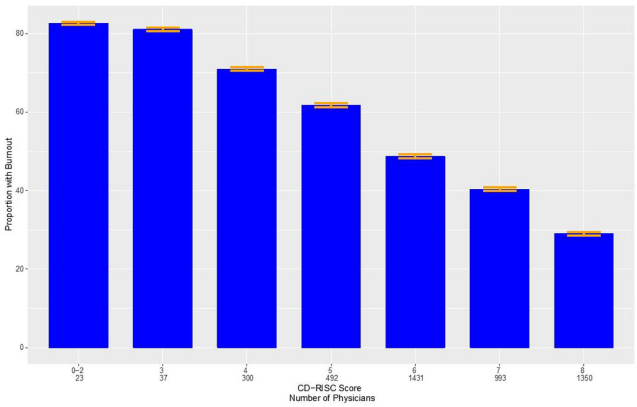
Colin P. West[1]; Liselotte Dyrbye[2]; Christine Sinsky[3]; Mickey Trockel[4]; Michael Tutty[5]; Laurence Nedelec[4]; Lindsey E. Carlasare[5]; Tait Shanafelt[4]. [1]Internal Medicine, Mayo Clinic, Rochester, MN; [2]Medicine, Mayo Clinic, Rochester, MN; [3]Professional Satisfaction, American Medical Association, Chicago, IL; [4]Stanford University, Palo Alto, CA; [5]American Medical Association, Chicago, IL. (Control ID #3382722)

BACKGROUND: The prevalence of physician burnout is well documented, and resilience training has been proposed as one means to support physician well-being. However, the resilience of physicians relative to that of the U.S. working population is not established, and the relationship between resilience and physician burnout is not well understood.

METHODS: Between October 2017 and March 2018 we conducted a national survey of U.S. physicians and a probability-based sample of the non-physician U.S. working population. Resilience and burnout were measured using the 2-item Connor-Davidson Resilience Scale and full Maslach Burnout Inventory, respectively. Multivariable regression models compared resilience scores of physicians with those of the employed general population, as well as the relationship between resilience and physician burnout, adjusting for sex, age, relationship status, hours worked per week, and burnout status.

RESULTS: 5445 physicians and 5198 members of the U.S. working population completed surveys. Resilience scores were higher among physicians (6.49 vs. 6.25 on the 0-8 scale, adjusted mean difference 0.25, 95% CI 0.19-0.32, p<0.001). Among physicians, resilience was strongly associated with burnout. Physicians without overall burnout had higher resilience scores than physicians with burnout (6.82 vs. 6.13, adjusted mean difference 0.68 points, 95% CI 0.61-0.76, p<0.001). Each 1-point higher resilience score was associated with a 36% lower odds of overall burnout (OR 0.64, 95% CI 0.60-0.67, p<0.001), with similar results for high emotional exhaustion and high depersonalization. More than 80% of physicians with resilience scores of 3 or less had burnout symptoms. However, 29% of physicians with the highest possible resilience score of 8 had burnout (Figure).

CONCLUSIONS: In this national study in the United States, physicians exhibited higher levels of resilience than the general working population. Resilience was inversely associated with burnout symptoms, but burnout rates were substantial even among the most resilient physicians. Although maintaining and strengthening resilience is important, physicians as a profession do not have a resilience deficit. Additional solutions, including efforts to address system issues in the clinical care environment, are needed to reduce burnout and promote physician well-being.



RESOURCED FOR RESPONSIVENESS: HOW RIMARY CARE INTENSIVE MANAGEMENT FOSTERED GOOD PAIN CARE

Karleen Giannitrapani[1,2]; Jesse Holliday[1]; Matthew McCaa[1]; Susan E. Stockdale[3]; Alicia Bergman[3]; Marian L. Katz[3]; Lisa V. Rubenstein[3]; Donna M. Zulman[3,2]; Evelyn T. Chang[3]. [1]U.S. Department of Veterans Affairs Palo Alto Health Care System, Menlo Park, CA; [2]Division of Primary Care and Population Health, Stanford University School of Medicine, Stanford, CA; [3]U.S. Department of Veterans Affairs Greater Los Angeles Healthcare System, Los Angeles, CA. (Control ID #3390372)

BACKGROUND: High-risk Veterans experience high rates of chronic pain and/or arthritis. In 2014-2018, the Veterans Health Administration (VHA) piloted a quality improvement program to augment standard primary care (Patient Aligned Care Team, or PACT) with PACT-Intensive Management (PIM) to improve management of high-risk patients.

METHODS: The PIM evaluation included 102 semi-structured interviews with stakeholders: including physicians, nurses, nurse practitioners, physician assistants, social workers, and patients participating in the PIM program. Text related to pain was subcategorized according to key stakeholder type: PACT providers/staff (21 pain mentions), PIM leaders (31 pain mentions) and PIM patient (37 pain mentions). Each of the three data sets were then evaluated using a consensus qualitative method to identify themes.

RESULTS: Themes varied across interviewee type. PACT providers themes: 1) WORKLOAD REDUCTION. PACT providers felt PIM provided a resource for the workload associated with providing pain care in

the context of mental illness and substance use. They also highlighted PIM's allowance of longer visits to accommodate needs of complex pain concerns. 2) ACCESS TO EXPERTISE. PACT providers described benefiting from access to expertise for complex patients, specifically how PIM helped strategize "creative processes" for minimizing risk of negative side effects and ER visits. PIM leader themes: 1) PAIN CARE COORDINATION IS AN APPROPRIATE FOCUS OF PIM. PIM providers indicated that pain is one of the reasons providers consider patients for PIM and that chronic pain management was an area they would emphasize if given more time with patients. In particular, navigating system complexity and coordinating chronic pain management is something PIM can help with. 2) FACILITATE TRYING NON-OPIOID APPROACHES. By creating a trusting relationship and "rapport building", PIM helped patients try non- opioid pain management strategies. 3) MITIGATE PROVIDER COMPASSION FATIGUE. PIM offered an extra level of support, which may be critical in mitigating compassion fatigue some providers experience when treating high-need patients with pain. PIM patient themes: 1) COMMUNICATION. Patients felt the PIM program reduced frustration by giving them someone to talk to about pain and quality of life. PIM helped with facilitating challenging communication around pain care and experience. 2) RESPONSIVE TO REAL TIME PATIENT PAIN CONSIDERATIONS. Patients reported PIM helped them navigate more timely access to pain care, receive "validation" of their pain experience, and develop a mutually agreed upon pain care plan.

CONCLUSIONS: An intensive management quality improvement program in primary care facilitated effective pain care for high-risk patients by offering access to clinicians with dedicated time and expertise to communicate effectively, build rapport, and address time-intensive and time-sensitive issues around chronic pain management.

RESOURCE USE AND CARBON FOOTPRINT OF INPATIENT STAYS IN A US HOSPITAL

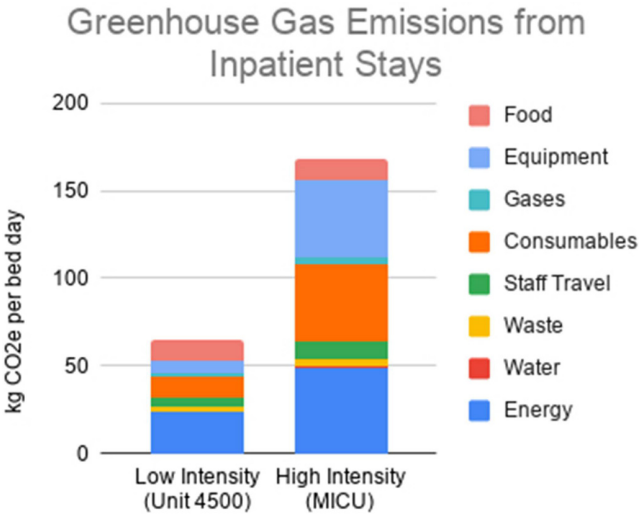
Cassandra L. Thiel[1]; Purnima A. Prasad[2]; Dhruvi Joshi[2]; Jenna Agins[3]; Robin Allen[3]; Michael Collins[4]; Foohel Pena[3]; Joan Velletri[3]. [1]Population Health, NYU Langone Health, New York, NY; [2]Civil Engineering and Urban Planning, New York University, New York, NY; [3]NYU Langone Health, New York, NY; [4]Environmental Resources Management Ltd., London, United Kingdom. (Control ID #3358779)

BACKGROUND: Environmental sustainability is a growing concern to healthcare providers, given the health impacts of climate change and air pollution and the sizable footprint of healthcare delivery itself. In 2017, 17.9% of the United States (US) Gross Domestic Product, or $3.5 trillion, was from the healthcare sector (1). In addition,10% of US greenhouse gas emissions (GHGs) and 9% of air pollutants that adversely affect the lives of the public(2,3) come from the healthcare sector. Though many studies have focused on environmental footprints of operating rooms, few have quantified emissions from inpatient stays.

METHODS: This study analyzes resources required for care activities of a regular inpatient unit (Unit 4500) with 49 beds and 14,427 bed days and a medical intensive care unit (MICU) with 12 beds and 2,536 bed days in a tertiary, private hospital in Brooklyn, NY, USA. Through the use of hybrid Environmental Life Cycle Assessment (LCA), average emissions associated with resource use in an inpatient setting for one calendar year and per bed day were quantified. Retrospective data collected included purchasing of supplies, pharmaceutical, utilities (gas, water, electricity), and linens used over a calendar year, and staffing levels in both units. A 5-day period of manual waste auditing in each unit was also conducted.

RESULTS: Unit 4500 generates 5.5kg of solid waste and 65kg CO2-e per bed day, shown in the Figure. The MICU generates 7.1kg of solid waste and 168kg CO2-e per bed day. Most emissions originate from purchase of consumable goods, building energy consumption, purchase of capital equipment, food services, and staff travel.

CONCLUSIONS: As expected, the MICU generates more solid waste and GHGs per bed day than Unit 4500. With resource use and emissions data, sustainability strategies, like energy efficiency upgrades, renewable energy sources, minimizing single-use consumables, and optimizing care pathways, can be effectively targeted and tested. Medical device and supply manufacturers should also aim to minimize life cycle waste and GHGs.



RETENTION OF WOMEN IN ACADEMIC MEDICINE AND EFFECTS OF MENTORSHIP

Chavon Onumah[2]; Anne Cioletti[1]; Sara Wikstrom[3]. [1]Internal Medicine/Population Health, University of Texas Dell Medical School, Austin, TX; [2]General Internal Medicine, George Washington University, Washington, DC; [3]Internal Medicine, George Washington University, Potomac, MD. (Control ID #3392484)

BACKGROUND: Despite entering medical school and academic medicine at higher rates, rates of women faculty are not commensurate with men. Literature has shown that women leave or intend to leave academic medicine for multiple reasons. Gender leadership gaps in academic medicine are well documented in the literature more-so than gender gaps in retention. Lack of women in leadership roles equates to lack of female role models and potential losses related to organizational effectiveness given the importance of diversity within teams and organizations. To address the gender gaps in leadership in academic medicine, we must address the leaky pipeline. The goal of the study is to provide descriptive information regarding relationships between specific institutional factors and interventions and women's intent to remain in academic medicine.

METHODS: To better identify what factors are associated with women's retention or intent to remain in academic medicine, we surveyed women faculty with appointments in U.S. Departments of Medicine. The survey consisted of a series of questions rated on a Likert scale, demographic questions, and qualitative write- in questions derived from the literature. Participants voluntarily completed the survey by links posted on public listservs. Using the Statistical Package for the Social Sciences (SPSS), descriptive and discriminant analyses were performed.

RESULTS: At the close of the survey, 429 survey responses analyzed after removing incomplete surveys and respondents that that did not meet inclusion criteria. The sample included women faculty across all ranks, across all regions, and various ethnicities. The largest number of responses were from women in general internal medicine.

Of the participants, 43% were satisfied with the current level of mentorship provided at their institution. More participants agreed if there was a formal mentorship program at their institution, but rates were lower if it was through an outside program or formal peer mentorship. Institutional interventions to address gender inequities varied. A number of factors were found to have a positive association with intention to remain in academic medicine including opportunities to integrate work and life identities, flexible work options, paid parental leave, and professional development. Over 80% of women responding plan to stay in academic medicine over the next five years.

CONCLUSIONS: While gender bias training for leaders and committee members and faculty development programs may be important steps in addressing gender inequities in academic medicine, these initiatives alone are unlikely to fix the leaky pipeline. Despite the lower rates of women climbing the leadership ladder, most are satisfied with their current opportunities of formal mentorship and plan to stay in academic medicine over the next five years. Limitations of this study include selection bias as those opting to take the survey may be more engaged and proactive in seeking mentorship and retention in medicine.

RETENTION STRATEGIES FOR MEDICATIONS FOR OPIOID USE DISORDER IN ADULTS: A RAPID REVIEW

Brian Chan[1]; Emily Gean[3]; Irina Arkhipova-Jenkins[3]; Jennifer Gilbert[2,3]; Jennifer Hilgart[3]; Celia V. Fiordalisi[3]; Kimberly Hubbard[3]; Robin Paynter[3]; Philip T. Korthuis[4]; Jeanne-Marie Guise[3]. [1]Internal Medicine, OHSU, Portland, OR; [2]Scientific Resource Center for AHRQ, Portland, OR; [3]Scientific Resource Center, Portland VA Research Foundation, Portland, OR; [4]Medicine, Oregon Health & Science University, Portland, OR. (Control ID #3392245)

BACKGROUND: Almost 50,000 Americans die annually from opioid overdose. While medications for addiction treatment (MAT) of opioid use disorder (OUD) effectively improve mortality, retaining patients in MAT programs remains challenging. Patients with OUD are adversely affected by social determinants of health that may make accessing traditional treatment settings difficult. Policymakers and research agencies have an interest in identifying potential interventions for further study and evaluation. The U.S. Agency for Healthcare Research and Quality, on behalf of the U.S. Department of Health and Human Services, commissioned a rapid evidence review on the effectiveness of interventions to improve MAT retention among adults with opioid use disorder.

METHODS: We searched MEDLINE and the Cochrane Library from February 2009 through June 2019. Systematic reviews and randomized controlled trials (RCTs) reporting retention in MAT for at least 3 months for the following interventions were included for analysis: care settings/logistical support, contingency management (CM), health information technology (HIT), extended-release (XR) MAT formulations, and psychosocial interventions. One investigator abstracted data; two investigators independently assessed quality.

RESULTS: Two systematic reviews and 39 primary studies were included. Interventions initiating MAT in soon-to-be-released incarcerated patients improved retention following release (1 prior review and 2 additional RCTs, n=1,062, positive). Integrating primary care services (3 RCTs, n=631, 1 positive, 2 no difference), or logistical interventions (4 RCTs, n=709, no differences) reported similar retention compared to usual specialty treatment. CM may improve retention on antagonist MAT (3 RCTs, n=140, all positive). Early trials suggest that retention in MAT may be no worse with HIT approaches than with in-person approaches (3 cohort studies, n=3965, 4 RCTs, n=1,688, no differences). Retention was comparable with implant or injectable XR buprenorphine compared with daily formulations (2 RCTs, n=605, no differences). Retention varied for XR naltrexone injection compared with daily buprenorphine (2 RCTs, n=729, no differences). Most psychosocial interventions did not improve retention (1 SR, n=3124, 9 RCTs, n=2483, no differences). There was limited data on harms and subgroups.

CONCLUSIONS: We found limited evidence suggesting MAT initiated in pre-release criminal justice populations and CM interventions with antagonist MAT may aid in MAT retention. HIT interventions may be equivalent to in-person MAT; similarly, integrating health services with MAT warrant further investigation. Most intervention types had few trials that reported retention outcomes. Studies lacked standard definitions of retention, had methodological shortcomings, and limited generalizability. Future research on interventions to improve MAT retention should focus on identifying and addressing the unique needs of the OUD population.

REWRITING THE RULES INSTEAD OF THE NOTES: IMPACTS OF CMS DOCUMENTATION UPDATES ON STUDENT CLERKSHIP NOTE WRITING

Marie McKinnon[1]; Amber Pincavage[2]. [1]Internal Medicine, University of Chicago, Chicago, IL; [2]Medicine, University of Chicago, Chicago, IL. (Control ID #3347626)

BACKGROUND: In 2018, the Center for Medicare & Medicaid Services (CMS) updated their documentation regulations to expand utilization of medical student documentation. This study aims to evaluate the impact of this change on medicine clerkship student documentation.

METHODS: Medicine clerkship student documentation from the 2017 summer quarter (prior to the CMS regulation change) was compared to documentation during the 2018 summer quarter (after documentation changes were implemented) at a single site through assessment of electronic health record (EHR) data. Numbers of notes in the EHR, cosignature by attending physicians, and timing of note writing was assessed in both the inpatient and ambulatory settings during both time periods. Note quantity in each category was compared before and after the CMS documentation changes were implemented.

RESULTS: A total of 46 third-year medical students were included in this study (23 from 2017 and 23 from 2018). Over the 11-week medicine clerkship, the mean number of inpatient notes students wrote before and after implementation was similar (81 prior vs. 68 after, p=0.19). There was also no difference in the mean number of inpatient notes signed by attendings (51 vs. 36, p=0.045), H&Ps signed by attendings (3 vs 5.8, p=0.064) or progress notes signed by attendings (11 vs 17, p=0.33). The mean number of inpatient notes written between 6pm-4am was also unchanged (47 vs 39, p=0.32).

However, in the outpatient setting, the mean total number of notes written by medical students increased from 2 to 12 per student (p<0.001). In addition, the average number of notes signed by the attending increased from 1 to 5 (p<0.001) and the average number of notes written from 6pm-4am decreased from 48 to 7 (p<0.001).

CONCLUSIONS: After implementation of the new CMS medical student documentation regulations, more ambulatory notes were written by medical students and signed by their attendings. In the inpatient setting, the number of notes and those signed by attendings remained stable. Despite these changes, documentation after hours didn't increase. These documentation changes could lead to more integration of medical students into ambulatory clinical care and enhanced preparedness for ambulatory practice.

RIFAXIMIN IS EFFICACIOUS FOR THE TREATMENT OF IRRITABLE BOWEL SYNDROME WITH DIARRHEA IN PATIENTS RECEIVING CONCOMITANT ANTIDEPRESSANTS

Adam P. Laitman[2]; Zeev Heimanson[1]; Philip S. Schoenfeld[3]. [1]Medical Affairs, Salix Pharmaceuticals, Bridgewater, NJ; [2]N/A, Salix Pharmaceuticals, Bridgewater, NJ; [3]Gastroenterology Section, John D. Dingell VA Medical Center, Detroit, MI. (Control ID #3391838)

BACKGROUND: A high prevalence of comorbid psychiatric disorders, such as depression, has been reported in patients with irritable bowel syndrome (IBS). Rifaximin, a nonsystemic antibiotic, is indicated in the United States for the treatment of adults with IBS with diarrhea (IBS-D). In the current post hoc analysis, rifaximin for the treatment of IBS-D (TARGET 3 study) was assessed in a subgroup of adults receiving concomitant antidepressants.

METHODS: Adults diagnosed with IBS received placebo for 10 ± 3 days and completed a daily symptom diary during a single-blind screening phase. During the placebo screening phase, patients who rated their abdominal pain ≥3 (scale range, 0-10) and bloating ≥3 (scale range, 0-6) and had mushy/watery stool (Bristol Stool Scale [BSS] type 6/7) for ≥2 days in a week (ie, IBS-D) were eligible to receive open-label rifaximin 550 mg three times daily for 2 weeks. In the original protocol, patients could continue taking antidepressants if they were on a stable dose for ≥6 weeks before study entry. Efficacy response was defined using a composite as well as individual assessment of abdominal pain (≥30% decrease from baseline in mean weekly pain score) and stool consistency (≥50% decrease from baseline in number of days/week with BSS type 6/7) during ≥2 of the first 4 weeks post-treatment. Additional symptoms response assessments included bloating (≥1-point decrease in weekly average bloating score), bowel movement urgency (≥30% improvement in percentage of days with urgency), and daily global IBS symptoms (≥1-point decrease in weekly average IBS symptoms score) during ≥2 of the first 4 weeks post-treatment.

RESULTS: 500 of 2579 patients with IBS-D were taking stable doses of antidepressants during the 2-week rifaximin treatment phase; 2438 in the overall group and 473 patients in the concomitant antidepressant subgroup were evaluable for efficacy. A total of 44.1% (1074/2438) and 44.6% (211/473) of patients in the overall group and concomitant antidepressant subgroup, respectively, were abdominal pain plus stool consistency (composite) responders, 56.8% (1384/2438) and 61.3% (290/473), respectively, were responders for the individual component of abdominal pain, and 60.1% (1466/2438) and 57.9% (274/473), respectively, were responders for the individual component of stool consistency. In addition, 56.2% (1369/2438) and 57.5% (272/473) for the overall group and concomitant antidepressant subgroup, respectively, were bloating responders, 52.3% (1276/2438) and 56.4% (267/473), respectively, were bowel movement urgency responders, and 57.5% (1401/2438) and 61.5% (291/473), respectively, were daily global IBS symptom responders. Adverse events reported in ≥2.0% of patients in the concomitant antidepressant subgroup were sinusitis (2.8% [14/500]) and urinary tract infection (2.0% [10/500]).

CONCLUSIONS: A 2-week course of rifaximin 550 mg three times daily improved symptoms in adults with IBS-D taking concomitant antidepressants, and rifaximin was well tolerated.

RISK AND POTENTIAL MAMMOGRAPHY HARMS DISCUSSION IN BREAST CANCER COUNSELING: PERSPECTIVES FROM PATIENTS WITH LOW HEALTH LITERACY AND PRIMARY CARE PROVIDERS

Ariel Maschke[1]; Tracy A. Battaglia[2]; Mara A. Schonberg[3]; Michael Paasche-Orlow[2]; Nancy R. Kressin[2]; Christine Gunn[2]. [1]Department of Medicine, Boston Medical Center, Boston, MA; [2]Medicine, Boston University Medical Center, Boston, MA; [3]Medicine, Beth Israel Deaconess Medical Center, Boston, MA. (Control ID #3387433)

BACKGROUND: While breast cancer screening guidelines promote informed decision-making, how mammography information, especially personal risk and mammography harms, is perceived by those with low health literacy (LHL) is relatively unknown. This study: 1) Characterized breast cancer risk and potential mammography harm discussions among women 40-54 with LHL and primary care providers (PCPs); and 2) Explored perceptions of existing decision aid (DA) samples.

METHODS: Eligible women were ages 40-54; had LHL(<7 on the Health Literacy Skills Instrument-10); no mammogram within 9 months; and no prior breast cancer. Women were approached prior to a well-visit at an academic safety-net hospital. PCPs practicing at this site were eligible for PCP interviews. Qualitative interviews explored mammography counselling experiences, including discussions of breast cancer risk and potential mammography harms. Patient interviews included feedback on sample mammography DAs. Two individuals developed a codebook, independently coding 6 transcripts and establishing consensus. One individual coded remaining transcripts with second coder review. Thematic analysis identified themes related to breast cancer risk, mammography harms, and DA feedback.

RESULTS: Of 25 patients, 18 identified as black, 3 as Hispanic/Latina, 2 as non-Hispanic white, and 3 did not disclose. Average age was 46.5 years; 12 had a prior mammogram. Of 20 PCPs, 15 were female; 12 had practiced >5 years. Seven PCPs reported conducting risk assessment routinely during mammography counseling, 8 did so for suspected strong family history, and 5 did not assess risk. Most patients did not recall discussing their personal risk with PCPs, but cited family history as the primary breast cancer risk. In DA review, patients desired more details about other risk factors, simpler risk visualizations, and information about how personal risk is calculated. PCPs reported limited comfort with risk calculators; concern about patients' numeracy impeded their use. Three PCPs believed discussing harms would deter mammography and avoided addressing them. About half of PCPs reported discussing false positives, but found the concept challenging to describe. Patients expressed confusion about false positives after viewing DAs, but valued harms information. Both groups sought materials with simpler language, like analogies rooted in patients' daily life. PCPs recommended priming patients via interactive tools that elicited family history in waiting rooms to facilitate targeted discussions during clinic visits.

CONCLUSIONS: Breast cancer risk and mammography harms were challenging concepts for PCPs to describe and for patients with LHL to understand. Family history was the most cited breast cancer risk factor acknowledged by both patients and providers. Time-limited visits and complicated support materials impeded robust counseling. Interactive education and risk elicitation provided in the waiting room were suggested to facilitate in-clinic discussions.

RISK OF CARDIOVASCULAR EVENTS AND SERIOUS HYPOGLYCEMIA COMPARING PATIENTS WITH TYPE 2 DIABETES INITIATING A GLP-1 RECEPTOR AGONIST OR BASAL INSULIN: A PROPENSITY-SCORE MATCHED COHORT STUDY

Jing Luo[1]; Ajinkya Pawar[2]; Deborah J. Wexler[2]; Seoyoung Kim[2]; Dae Kim[2]; Elisabetta Patorno[3]. [1]Medicine, University of Pittsburgh, Pittsburgh, PA; [2]Medicine, Brigham and Women's Hospital, Boston, MA; [3]Medicine, Pharmacoepidemiology, Brigham and Women's Hospital and Harvard Medical School, Boston, MA. (Control ID #3390666)

BACKGROUND: Prior head-to-head open label trials comparing selected GLP-1RA(s) versus basal insulin(s) did not evaluate cardiovascular outcomes.

3**METHODS:** Using 2 large U.S. commercial claims databases (Optum and Truven MarketScan) from 01/2012 to 12/2017, we assessed the risk of a composite cardiovascular outcome (MI, stroke) and serious hypoglycemia defined by validated claims-based algorithms comparing 26,308 patients with type 2 diabetes (mean age 58, mean HbA1c 8.6%) with prior or concurrent metformin therapy newly initiating an injectable GLP-1RA or basal insulin.

RESULTS: We estimated pooled incidence rates, meta-analyzed hazard ratios and 95% CI adjusting for >140 baseline clinical characteristics, including HbA1c. Baseline clinical characteristics were well-balanced in the two groups after 1:1 propensity score matching. In an as-treated analysis, the median follow-up was 148 days. Compared to basal insulin, initiating a GLP-1RA was associated with a lower risk of MI or stroke (HR 0.68 [95% confident interval (CI), 0.51 to 0.90]) and lower risk of serious hypoglycemia (HR 0.38 [95% CI, 0.25 to 0.57]).

CONCLUSIONS: These results support recent clinical treatment guidelines that recommend starting a GLP-1RA before basal insulin for patients with type 2 diabetes with inadequate glycemic control despite metformin.

Table: Baseline clinical characteristics and outcomes in a 1:1 propensity-score matched study comparing patients with type 2 diabetes newly initiating an injectable GLP-1RA or basal insulin.

	GLP-1RA (n=13,154)	Basal Insulin (n=13,154)	Stand. Diff.***

MI or stroke (primary)	61 (6.75)	82 (10.43)	0.68 (0.51-0.90)
Myocardial Infarction	36 (3.98)	43 (5.46)	0.69 (0.48-1.00)
Stroke	29 (3.21)	49 (6.23)	0.62 (0.40-0.95)
Serious hypoglycemia****	24 (2.65)	66 (8.40)	0.38 (0.25-0.57)

*Baseline characteristics were measured 180 days (6 months) before the index date (i.e. new prescription claim for a GLP1RA or a basal insulin).
**CKD 4 and 5 were excluded. We defined CKD 3 based on ICD-9 and ICD-10 diagnosis codes.
***Standardized difference <10% has been suggested to represent good balance between treatment groups.
****Serious hypoglycemia was defined as hospitalization or ED encounter with primary diagnosis of hypoglycemia.
*****HR = hazard ratio. Reference group = basal insulin.

RIVAROXABAN VERSUS WARFARIN FOR TREATMENT AND PREVENTION OF RECURRENT VENOUS THROMBOEMBOLISM IN AFRICAN AMERICAN PATIENTS

Olivia S. Costa[1,2]; Stanley Thompson[3]; Veronica Ashton[4]; Michael Palladino[5]; Thomas J. Bunz[6]; Craig I. Coleman[1,2]. [1]Department of Pharmacy Practice, University of Connecticut School of Pharmacy, Storrs, CT; [2]Evidence-Based Practice Center, Hartford Hospital, Hartford, CT; [3]TeamHealth LifePoint Group, Southaven, MS; [4]Real World Value and Evidence, Janssen Scientific Affairs LLC, Titusville, NJ; [5]Medical Affairs, Janssen Pharmaceuticals Inc., Titusville, NJ; [6]Department of Pharmacoepidemiology, New England Health Analytics LLC, Granby, CT. (Control ID #3358572)

BACKGROUND: African Americans have an increased risk of venous thromboembolism (VTE) and poorer outcomes vs other racial groups. Despite these race-based differences, African Americans have been under- represented in randomized trials evaluating anticoagulants for acute VTE treatment. We sought to evaluate the effectiveness and safety of rivaroxaban vs warfarin for treatment and prevention of recurrent VTE in African Americans.

METHODS: We performed a retrospective cohort analysis using Optum® De-Identified Electronic Health Record data from 11/1/2012-9/30/2018. We included African Americans admitted to the hospital, emergency department or observation unit for deep vein thrombosis or pulmonary embolism, who received rivaroxaban or warfarin as their first oral anticoagulant within 7-days of the acute event and had ≥1 provider visit in the 12-months prior. We excluded patients with another indication for oral anticoagulation. Differences in baseline characteristics between cohorts were adjusted using inverse probability-of-treatment weighting based on propensity scores (standard differences <0.10 were achieved for all covariates). Our primary outcome was the composite incidence of recurrent VTE or major bleeding at 6-months (intention-to-treat approach). Three- and 12-month timepoints were also assessed. Risk was compared using Cox regression and reported as hazard ratios (HRs) with 95% confidence intervals (CIs).

RESULTS: We identified 2097 rivaroxaban and 2842 warfarin users with incident VTE. At 6-months, no differences in the composite endpoint (HR=0.96, 95%CI=0.75–1.24), recurrent VTE (HR=1.02, 95%CI=0.76–1.36) or major bleeding (HR=0.93, 95%CI=0.59–1.47) were observed between cohorts. Analysis at 3- and 12-months provided similar findings (Table).

CONCLUSIONS: In African Americans experiencing an acute VTE, no significant difference in the incidence of recurrent VTE or major bleeding was observed between rivaroxaban or warfarin users.

	Rivaroxaban N=2,097 n (%)	Warfarin N=2,842 n (%)	HR (95%CI)
3-Month			
Composite	96 (4.58)	130 (4.57)	1.08 (0.82–1.42)
Recurrent VTE	74 (3.53)	96 (3.38)	1.07 (0.78–1.46)
Major Bleed	27 (1.29)	40 (1.41)	1.19 (0.72–1.97)
6-Month			
Composite	105 (5.01)	166 (5.84)	0.96 (0.75–1.24)
Recurrent VTE	81 (3.86)	115 (4.05)	1.01 (0.76–1.36)
Major Bleed	30 (1.43)	59 (2.08)	0.93 (0.59–1.47)
12-Month			
Composite	122 (5.82)	208 (7.32)	0.93 (0.74–1.16)
Recurrent VTE	89 (4.24)	140 (4.93)	0.95 (0.72–1.2)
Major Bleed	39 (1.86)	80 (2.81)	0.92 (0.62–1.36)

ROLE EXPANSION IS CULTURE CHANGE: LESSONS FROM EVALUATING THE VA'S NATIONAL IMPLEMENTATION OF THE LIFE-SUSTAINING DECISIONS TREATMENT INITIATIVE

Jessica Ma[1]; Marie C. Haverfield[2,3]; Cati Brown-Johnson[4]; Karl Lorenz[3,4]; Karleen Giannitrapani[3,4]. [1]Durham Center of Innovation to Accelerate Discovery and Practice Transformation, Durham VA Health Care System, Durham, NC; [2]Department of Communication Studies, San José State University, San José, CA; [3]Center for Innovation to Implementation, Veterans Health Administration, Menlo Park, CA; [4]Division of Primary Care and Population Health, Stanford University School of Medicine, Stanford, CA. (Control ID #3386722)

BACKGROUND: The Department of Veterans Affairs (VA) implemented the Life Sustaining Treatment Decisions Initiative (LSTDI) throughout all VA institutions in 2017. This policy was to encourage goals of care (GOC) discussions regarding life-sustaining treatments

among veterans with serious illnesses. A key component of the initiative was allowing nurses and social workers to participate in goals of care conversations. Level of implementation of the LSTDI varied among different sites. We conducted a secondary analysis of LSTDI implementation evaluation interviews to understand how sites facilitated newly expanded roles.

METHODS: We purposively sampled 31 interdisciplinary providers from 12 geographically diverse high and low performing sites in terms of implementation of LSTDI (defined as GOC conversation documentation via a structured note-template). We then used a combination of inductive and deductive approaches. Specifically, we first reviewed 6 transcripts to develop a code list based on role theory and provider descriptions of education and training about roles. We then applied codes to all transcripts and summarized higher-level themes.

RESULTS: 1) Initiative educational champions were key in readying providers for LSTDI implementation. "Turnover" and lack of educational champions slowed implementation. 2) A diverse variety of educational materials and approaches to training assisted in provider readiness for the implementation. 3) Leadership acknowledgement of role overload and its effect on role readiness helped facilitate implementation. Providers were "feeling overwhelmed, it was just one more thing on their plate", leadership had "been pretty supportive of it … [and] willing to give them an extra half hour to have the life-sustaining treatment discussion". 4) Development or expansion of existing roles was reinforced by initiative education and leadership alignment with implementation goals. This support readied providers to take GOC conversations as a "role specific versus person specific" task. 5) Role expansion to take on LSTDI components represents a culture change. "Our culture has been, and we have had many, many people tell our social workers you don't touch this DNR thing. You don't touch it. It's out of your scope, you have nothing to do with it. And they told the nurses the same thing … a really difficult thing for us and we still are working on that is how to get people to understand that this is everyone's job". Multiple high performing LSTDI sites successfully integrated non- clinicians for goals of care conversations into their teams' practice.

CONCLUSIONS: Role expansion is never straightforward and may benefit from being described as culture change. Fostering role readiness and expanding multidisciplinary roles was important to LSTDI implementation, and initiative educational training and leadership reinforcement facilitate successfully negotiating and undertaking expanded roles.

ROOM OF HAZARDS: AN INTERPROFESSIONAL EVALUATION OF SAFETY RISKS IN A SIMULATED PATIENT ROOM

Melinda Wang[1]; Victor Bilan[1]; Megan B. McCullough[2,1]; Naseema B. Merchant[3]; Benjamin Rodwin[1]. [1]Internal Medicine, Yale School of Medicine, New Haven, CT; [2]Center for Healthcare Organization and Implementation Research, VA Health Services Research & Development, Bedford, MA; [3]Medicine, VA Connecticut health Care and Yale School of Medicine, Middlefield, CT. (Control ID #3355502)

BACKGROUND: As many as 3.7% of patients experience preventable adverse events in health care facilities nationwide. The "Room of Hazards" is a simulation developed to assess knowledge of health care staff in identifying safety hazards in clinical settings. While prior studies focused on nursing and medical students, few have assessed its use for interprofessional health care professionals in a hospital setting. Our study aims to assess the use of this simulation among many different disciplines across the hospital.

METHODS: In our simulation, we set up a simulated inpatient hospital room with a patient mannequin and multiple safety hazards. Participants walked around the room, documenting all observed safety hazards. Answer sheets were analyzed, transcribed, and grouped into five hazard categories (patient, medications, equipment, environment, and care processes). Results were analyzed using ANOVA with a Tukey post hoc test (homogeneity of variance) or a Games-Howell test (no homogeneity of variance).

RESULTS: There were 115 participants in the simulation, including 70 nursing staff, 5 nursing students, 3 medical students, 11 physicians, 5 social workers, 6 pharmacists, 9 Certified Nursing Assistants (CNAs), 4 psychologists, and 2 others. On average, participants identified 20.8 out of 34 hazards: 2.9/6 in patient, 3.4/5 in medications, 5.8/9 in equipment, 6/8 in environment, and 2.7/6 in care processes. There was a significant difference among different professionals in how many hazards they identified in each category: environment ($p=0.020$), equipment ($p<0.001$), medications ($p=0.003$), patient ($p=0.041$), and total hazards identified ($p<0.001$). Within the medications category, nurses and pharmacists identified more hazards than CNAs (3.86 vs. 1.67, $p=0.018$; 4.83 vs. 1.67, $p=0.025$). In the equipment category, nurses identified more hazard than social workers (7.01 vs. 1.80, $p=0.002$), pharmacists (7.01 vs. 1.17, $p<0.001$), or physicians (7.01 vs. 4.00, $p=0.019$), and CNAs identified more hazards than pharmacists (5.67 vs. 1.17; $p=0.044$). In the environment category, nurses identified more hazards than medical students (6.31 vs. 3.67, $p=0.018$). Overall, nurses found more hazards than medical students (23.30 vs. 12.67; $p<0.001$) or pharmacists (23.30 vs 14.33, $p=0.045$). Nursing students also identified more hazards than medical students (21.00 vs. 12.67, $p=0.042$).

CONCLUSIONS: While all participants identified hazards in all categories, there were significant differences among health care professionals in ability to identify safety hazards from different categories. This finding suggests that each professional's unique training and job responsibilities can result in varying degrees of ability to identify different types of safety hazards. To maximize identification of patient safety hazards in our health system, interdisciplinary teaching and collaboration is crucial. Our study provides a starting point to include a diverse group hospital staff members in safety training with simulation techniques.

RURAL VS URBAN HOSPITAL LOCATION AND THE IMPACT ON SURGICAL COMPLICATIONS AND IN-HOSPITAL OUTCOMES FOR PATIENTS UNDERGOING APPENDECTOMY

Victoria Gordon, Adam Lewis, Kenneth S. Johnson, Clayton Marolt, Kanwalgeet Hans, Joanna Rowe, Sarah A. Keim. Anatomy, Kansas City University of Medicine and Biosciences, Kansas City, MO. (Control ID #3390652)

BACKGROUND: It is well-known that patients in rural areas are more likely to have poorer outcomes than those in urban areas due to a variety of reasons including access to care and quality of care. However, most studies in this area focus on long-term complications and health outcomes for these patients and little is known about the in-hospital outcomes. An appendectomy is one of the most frequently performed surgical procedures and is known for being a lower-risk procedure. This study aimed to elucidate if patients in more rural areas had worse in-hospital outcomes and more frequent surgical complications than those who live in urban areas.

METHODS: This retrospective cohort study utilized the Nationwide Inpatient Sample (NIS) to identify patients from 2012-2015 who had undergone an appendectomy as coded for by ICD-9. Next, patient location data was dichotomized into two categories, those living in an area with 250,000 or more people (urban) or an area with less than 250,000 people (rural). Independent t-tests assessed length of stay (LOS) and total charges. Chi-squared analyses assessed mortality and surgical complications. Patients missing data for any of these variables or under the age of 18 at admission were excluded.

RESULTS: We identified a total of 90,351 patients who underwent an appendectomy during this time period. 19,960 of these patients had their

surgeries in a rural area and 70,391 of these patients had their surgery in an urban area. Those in a rural area had statistically significant increases in mortality (12.5% vs 7.64%, p <.0005) and LOS (3.4 days vs 3.14 days, p <.0005) as compared to patients who underwent an appendectomy in an urban area. Patients who underwent an appendectomy in an urban area had statistically significantly more charges ($41,897 vs $34,307, p<.0005). Those in rural areas also were statistically significantly more likely to have a surgical complication specifically related a pulmonary issue (1.3% vs .95%, p<.0005), the digestive tract (5.35% vs 4.13%, p<.0005), an infection (.67% vs .55%, p=.028), or a complication during the surgery itself (.63% vs .45%, p=.001). Between the two groups, there were no statistical differences regarding systemic, mechanical wound, cardiac, and urinary complications.

CONCLUSIONS: This study's results support previously published literature focused on long-term outcomes for patients in rural areas. Those in rural areas who underwent an appendectomy were much more likely to experience a surgical complication, had longer lengths of stay, and higher rates of mortality even in a routine surgical procedure such as an appendectomy. Physicians should investigate ways to alleviate this problem in areas where access and quality of care are an issue. Additionally, further studies should try and elucidate why outcomes were worse and length of stay was longer for patients in rural areas but total charges were decreased.

SAFE PRESCRIBING PRACTICES AMONG CLINICAL PROVIDERS IN A LARGE NY STATE ACADEMIC CENTER

Sreekala Raghavan[5]; Keren M. Paul[2]; Christina Ventura DiPersia[2]; Johanna Martinez[3]; Alice Sardell[4]; Lyndonna M. Marrast[1]. [1]General Internal Medicine, Zucker School of Medicine at Hofstra/Northwell, Kew Gardens, NY; [2]Physician Assistant Department, Hofstra Northwell School of Graduate Nursing and Physician Assistant Studies, Middletown, CT; [3]Medicine, Northwell Health, Lake Success, NY; [4]Urban Studies, Queens College, Flushing, NY; [5]Medicine, Zucker School of Medicine at Hofstra/Northwell, Glen Oaks, NY. (Control ID #3392454)

BACKGROUND: New York State (NYS) implemented a safe prescribing law (SafeRx) that requires translation of prescription labels to non-English languages for limited English proficiency (LEP) patients. Few studies have assessed provider awareness of this law, LEP documentation practices in the medical record, or LEP communication to pharmacies. This study sought to assess awareness of SafeRx and provider practice regarding LEP documentation that impacts their safe-prescribing practices for LEP patients.

METHODS: From October to November 2018, we invited 935 prescribing providers (physicians, physician assistants and nurses) across specialties within Northwell Health to complete a 38-item cross-sectional online survey regarding preferences for mode of interpretation, practices regarding LEP status documentation, communication with pharmacists on patients' LEP status, and awareness of safe prescribing laws. We performed descriptive statistics and chi-square analyses.

RESULTS: We received responses from 113 participants (12.1%). Most respondents were in training programs, having graduated professional schooling less than 5 years previously (52.8%) and reported English as their first language (86.7%), but spoke more than one language (54%). The majority had not had any training on providing linguistically appropriate care within the past 5 years (69%). In the past year, 91% had used interpreter services. Bilingual in-facility professional interpreters were most preferred (46.9%) and were perceived to be the most accurate by over half of respondents (55.8%). Though telephonic interpretation was used most frequently (60.2%), it was considered to be the most time consuming (62.8%). Respondents were largely unaware of New York State SafeRx policies (74.8%). Though 44% reported "always" and 51% reported "sometimes" documenting LEP status in the chart, 71% reported they "never" notify pharmacists of patients' LEP status and cited time as the most limiting factor for doing so.

CONCLUSIONS: A large proportion of providers are unaware of the NYS safe prescribing law that allows prescription labels to be printed in non-English languages. Though this was a pilot study at a single institution with a low response rate, the results suggest the need to improve provider awareness of this legislation while employing an efficient system to increase non-English medication labeling. Though SafeRx is intended to help LEP patients access better care, poor implementation of this policy reduces its impact. In the long term, improved execution would have benefits for both team-based communication and medication adherence for a vulnerable population.

SAFETY AND EFFECTIVENESS OF INTRAUTERINE CONTRACEPTION COMPARED TO LAPAROSCOPIC TUBAL LIGATION FOR PREGNANCY PREVENTION AMONG CALIFORNIA MEDICAID CLIENTS

E. Bimla Schwarz[1]; Melanie S. Dove[1]; Carrie Lewis[1]; Diana Zuckerman[2]; Claudia Nunez-Eddy[2]; Aileen Gariepy[3]. [1]Division of General Medicine, University of California, Davis, Sacramento, CA; [2]National Center for Health Research, Washington DC, DC; [3]ObGyn, Yale University, New Haven, CT. (Control ID #3391900)

BACKGROUND: Many couples appreciate the convenience of long-acting contraception. However, real- world data on the comparative safety and effectiveness of contraceptive options is limited, and misconceptions are common among patients and some clinicians. In the US, laparoscopic tubal ligation remains more common than use of intrauterine contraception (IUC), particularly among low income women.

METHODS: We conducted a retrospective cohort study of California Medicaid claims for contraceptive procedures performed for women aged 18-50 years, between January 2008 and August 2014. We excluded procedures performed within 4 weeks of birth. We identified pregnancy-related claims after index contraceptive procedures, as well as claims for procedural complications.

RESULTS: We identified 24,228 women who underwent laparoscopic tubal ligation, 35,714 women who had a hormonal IUC placed, and 23,700 women who had a copper IUC placed. Within the year following the contraceptive procedure, rates of pregnancy were similar for women who had tubal ligation and those who had a hormonal IUC placed (p=0.78). Rates of pregnancy at 12 months post-procedure were significantly higher following placement of a copper IUC than a hormonal IUC or tubal ligation, but still low (3.34% vs. 2.70% vs 2.66%, respectively).

Complications were significantly more common following laparoscopic tubal ligation than IUC placement (either copper or hormonal), both on the day of the procedure and over the next 12 months. Specifically, on the day of procedure, acute hemorrhage affected 3.76% vs. 0.007%, anesthetic complications affected 0.24% vs. 0.0001%, an abdominal injury affected 1.25% vs. 0.0009%, and infection affected 0.52% vs. 0.0004% of those who had laparoscopic tubal ligation compared to IUC placement. Hysterectomy occurred for 3.97% vs. 0.000% of those having a tubal ligation or IUC placement. Acute myocardial infarction or cerebrovascular accident complicated 0.06% of tubal ligation procedures vs 0.0000% of IUC placements. Although risks of complications following tubal ligation decreased with time since surgery, they remained significantly higher than those among women who had an IUC placed for over one year of follow up.

CONCLUSIONS: Laparoscopic tubal ligation incurs significantly greater risk of complications than placement of an IUC, both on the day of procedure and over 1 year of follow-up. Women considering permanent contraception should be counseled about the potential advantages of an IUC, which offers similar contraceptive effectiveness in the first year of use.

SAFETY REPORTING IN RANDOMIZED CONTROLLED TRIALS

Rubaya Yeahia[1]; Renee Gennarelli[2]; DANIEL J. MORGAN[3]; Deborah R. Korenstein[2]. [1]Student, New York Medical College, Valhalla, NY; [2]Center for Health Policy & Outcomes, Memorial Sloan Kettering Cancer Center, New York, NY; [3]Epidemiology and Public Health, University of Maryland School of Medicine, Baltimore, MD. (Control ID #3372901)

BACKGROUND: Physicians rely on accurate reporting of both efficacy and safety in randomized controlled trials (RCTs). Completeness of results and their unbiased framing are critical to accurate estimates of potential benefits and harms that inform clinical decision-making. Poor reporting of safety data in the form of adverse events (AE) has been described, but studies have not evaluated the framing of AE information in relative vs. absolute terms. We set out to evaluate current patterns of reporting efficacy and AEs in high- impact RCTs and to determine the influence of funder, region, clinical area, or intervention type. We hypothesized that AE reporting would be less complete than efficacy reporting and more likely to use absolute terms.

METHODS: We identified all RCTs published within the first three months of 2019 in the 10 highest impact medical journals. We included phase III-IV RCTs of efficacy with sample size > 50 patients, and ≥2 treatment arms. We classified each RCT by clinical area and treatment type (drug, therapeutic procedure, other) and collected information on primary region and funder(s). Chi-square and Fisher's exact tests were used to examine univariate associations between AE reporting and study characteristics. A multivariate logistic regression was used to examine the relationship between complete AE reporting and funder and clinical area.

RESULTS: We identified 121 studies. Most were from Europe (53%) followed by N America (40%); 64% evaluated drugs and 26% evaluated procedures. Funding was from industry (35%), government (31%), or others (34%). Hematology/oncology (31%), cardiology (15%) and infectious diseases (15%) predominated. Nearly all specified a 1° efficacy outcome (99%) and reported efficacy in both absolute and relative numbers (96%). In contrast, only 21% specified a 1° safety outcome and most reported AEs using absolute numbers only (68%). AE reporting was complete in 17% of studies; 24% reported only severe AEs, 20% only common AEs, and 12% did not quantify AEs. There was a significant univariate association between AE reporting and funder (p<.001), but this association did not hold in multivariate analyses (p=0.28). AE reporting did not differ meaningfully based on region, clinical area, or treatment type.

CONCLUSIONS: Efficacy outcomes are well reported in RCTs, while safety reporting is inconsistent and complete in only 17% of studies, regardless of funding, region, specialty, or type of intervention. Presentation of AE data often focuses on absolute event rates while efficacy data is presented in absolute and relative terms, which may bias clinical interpretation. More transparent safety reporting in RCTs is needed to enable clinicians to accurately perceive and describe the balance of benefits and harms.

SAME-DAY VS. DELAYED BUPRENORPHINE TREATMENT AND PATIENT RETENTION IN AN OFFICE-BASED BUPRENORPHINE TREATMENT PROGRAM

Andrea Jakubowski[1]; Tiffany Y. Lu[1]; Frank Direnno[2]; Angela G. Giovanniello[3]; Chinazo Cunningham[4]; Aaron D. Fox[5]. [1]General Internal Medicine, Montefiore Medical Center, Bronx, NY; [2]Albert Einstein College of Medicine, Bronx, NY; [3]Montefiore Medical Center, Bronx, NY; [4]Medicine, Albert Einstein College of Medicine & Montefiore Medical Center, Bronx, NY; [5]Medicine, Montefiore Medical Center, Bronx, NY. (Control ID #3391675)

BACKGROUND: Buprenorphine is a safe and effective treatment for opioid use disorder (OUD), yet a small fraction of people with OUD receive it, and rates of retention in treatment are suboptimal. Drop-out most commonly occurs within 30 days of treatment initiation. Therefore, investigating modifiable factors contributing to early drop-out is critical. Requiring multiple visits for evaluation prior to providing an initial buprenorphine prescription (delayed prescription) may lead to excess early drop out when compared with prescribing at the first medical visit (same-day prescribing). Our objective was to determine whether same-day (vs. delayed) buprenorphine prescription was associated with 30-day retention in treatment.

METHODS: This is a retrospective cohort study of 220 patients who initiated buprenorphine treatment at an urban federally qualified community health center (FQHC) between June 1,2015 and December 31,2017. We measured prescription delays by determining the time between patients' first request for buprenorphine treatment (by calling, presenting to the FQHC in-person, or requesting treatment during a visit) and when buprenorphine prescriptions were written. We examined whether patients who received same-day prescriptions had different sociodemographic and clinical characteristics than patients who received delayed prescriptions. We built a multivariable logistic regression model to evaluate the independent association between same-day vs. delayed prescription receipt and odds of 30-day retention in treatment.

RESULTS: 220 patients were included in the study. The mean age was 46 (SD 10.4). The majority were Hispanic (n=159, 72%), male (n=173, 79%), and publicly insured (n=164, 75%). The majority of patients experienced delayed buprenorphine prescription receipt (n=127, 58%). The median delay was 3 days (IQR 0-8). Compared to those with same-day prescription receipt, a larger percentage of those with delayed prescription receipt were white (11% vs. 2%, p<0.05) and had a history of alcohol use (43% vs. 24%, p<0.05) and/or benzodiazepine use (22% vs. 10%, p<0.05). Same-day prescription receipt was not significantly associated with 30-day treatment retention in the primary analysis (AOR 1.93, 95% CI 0.90-4.14) after adjusting for age, race, sex, and benzodiazepine use.

CONCLUSIONS: In this cohort, there were differences between patients who received buprenorphine prescriptions on the same day as their initial evaluation and those who received delayed prescriptions; however, same-day prescription was not significantly associated with higher 30-day treatment retention after adjustment for these differences. Nonetheless, given that same-day prescription was not associated with worse retention, it is reasonable to avoid delays in buprenorphine prescription. Prospective studies of same- day vs. delayed buprenorphine receipt would elucidate the association between delays and retention more definitively.

SCOPE OF PRACTICE REGULATIONS AND NURSING HOME VISITS BY NURSE PRACTITIONERS: 2012-2017

Kira Ryskina[1]; Ashley Ritter[3]; Joanne E. Spetz[2]; Hilary Barnes[4]. [1]Medicine, University of Pennsylvania, Philadelphia, PA; [2]Institute for Health Policy Studies, University of California, Los Angeles, San Francisco, CA; [3]SONursing, UPenn, Philadelphia, PA; [4]School of Nursing, UDelaware, Newark, DE. (Control ID #3390371)

BACKGROUND: Nurse practitioners (NPs) have been recommended as a way to address care delivery challenges in settings that struggle to attract physicians. This is especially relevant for nursing homes (NHs), which face physician shortages. Our objective was to evaluate the impact of state scope of practice (SOP) regulations on NP practice in NHs.

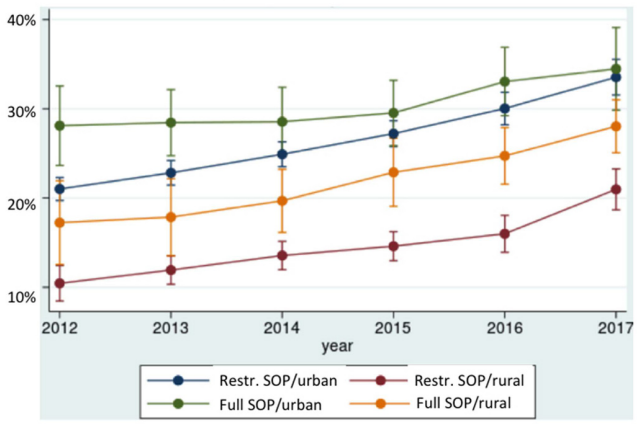
METHODS: We used Medicare Physician/Other Supplier Public Use Files, containing all Part B fee-for- service billings, to identify internal medicine, geriatrics, general practice, or family medicine physicians and

NPs who provided NH visits in 2012-2017. NH visits are excluded from "incident-to" billing and must be submitted under the performing clinician's identifier. Thus, we capture all visits provided by NPs to patients in NHs. For each county, we calculated the proportion of NH visits performed by NPs vs. physicians. Written collaborative agreement with a physician was required for practice in restrictive SOP states; no agreement was required in full SOP states. Using linear regression, we estimated the proportion of NP-delivered care in NHs as a function of state SOP regulations interacted with year, including state fixed effects and year indicators. Other county-level variables included were demographics and an indicator for rural location. We also tested whether the effect of SOP differed in rural vs. urban counties. Confidence intervals were clustered at the state level.

RESULTS: Billings for 40,670 clinicians in 2,680 counties were analysed: 47.8% were NPs and 52.2% physicians. The proportion of NH visits by NPs increased from 2012 to 2017 (Figure). Nine states adopted full SOP regulations during the study period. The adoption of full SOP regulation was associated with a 1.6 percentage point higher proportion of NH visits by NPs (from 21.2% to 22.8%; 95% CI -0.5%-3.7%, p=0.13). Compared to urban counties, rural counties in full SOP states had a slightly greater increase in the proportion of NP-delivered NH care (1.3% vs. 1.9%, respectively).

CONCLUSIONS: The lower proportion of NH visits by NPs in restrictive SOP states may be due to the barriers caused by SOP regulations. However, removing regulations that limit NP practice might not produce significant increases in NPs' practice in NHs.

Figure. Trends in the Proportion of Nursing Home Visits Conducted by Nurse Practitioners by Scope of Practice for Rural vs. Urban Counties



SCOPING REVIEW: THE SCIENCE OF PHYSICIAN CARING

David Burstein[5]; Faith Svigos[3]; Akash P. Patel[3]; Neha K. Reddy[3]; Kelly N. Michelson[2]; Linda C. ODwyer[6]; Mark Linzer[1]; Jeffrey A. Linder[5]; David Victorson[4]. [1]Medicine, Hennepin County Medical Center, Minneapolis, MN; [2]Pediatrics, Northwestern Univeristy, Chicago, IL; [3]Feinberg School of Medicine, Northwestern University, Chicago, IL; [4]Medical Social Sciences, Northwestern University, Chicago, IL; [5]Division of General Internal Medicine and Geriatrics, Northwestern University Feinberg School of Medicine, Chicago, IL; [6]Galter Health Sciences Library & Learning Center, Northwestern University, Chicago, IL. (Control ID #3387821)

BACKGROUND: The physician's ability to care for patients is often limited by onerous job demands, external economic and regulatory factors, and information technology. The study of this problem, and the creation of evidence-based solutions, requires the use of strong conceptual models. Our goal is to identify existing conceptual models, frameworks, and research definitions of physician caring in clinical practice.

METHODS: We defined physician caring as having concern for or commitment to a patient's well-being while using one's experience and resources to promote the patient's health. We searched PubMed and Embase using 32 key words, Medical Subject Headings (MeSH), and EMTREE terms for articles that focused on three domains: 1) caring in clinical practice, 2) conceptual models and frameworks, and 3) physicians and clinicians. We included articles on physician, physician trainee, or advanced practice provider roles, perspectives, and experiences with caring. We excluded articles focused on patients' experience of caring or perceived care needs. We excluded studies focused on related, distinct constructs (e.g., empathy, compassion, humanism, patient-centered care, shared-decision making, etc.) that were clearly-defined. A pilot title and abstract screen of 500 randomly selected articles from 1966-2019 was performed by four authors to test the appropriateness of our inclusion and exclusion criteria, and results were discussed with all authors. Four reviewers then screened and discussed titles and abstracts of articles from 1990-1999 and 2017-2018 for inclusion. Articles that met inclusion criteria, and key references within those articles, were reviewed in full.

RESULTS: Out of 1,976 articles, 72 met inclusion criteria and were reviewed in full; 16 of these articles had conceptual models, frameworks, or research definitions of caring in the medical profession. The Moral Intuitionist Model of Virtuous Caring was used in three articles. Caring models from nursing literature (e.g. models by Gilligan, Nodding, Kohlberg) were used in three articles. Three articles proposed frameworks that had new conceptualizations of caring. Three offered research definitions ("concern for another's well-being," "conveying individualized or person-to-person concern or regard through a specific set of behaviors," "caring reflects the extent to which the respondent sees the patient's expectations, feelings, and life circumstances as critical elements in the treatment process"). Four articles incorporated physician caring into an adapted version of previously defined constructs (e.g., humanism).

CONCLUSIONS: There are a variety of models, frameworks and research definitions of caring in medical literature. The concept of physician caring can be further explored and developed as an aspect of clinician-patient interactions in clinical medicine.

SCREENED SOCIAL NEEDS AND ACCEPTABILITY OF SCREENING AMONG CANCER PATIENTS IN PHILADELPHIA UNDERGOING TREATMENT

Jessica Davis[3]; Lindsey Zinck[2]; Sheila Kelly[1]; Hareena Sangha[3]; Lawrence Shulman[2]; Erin Aakhus[2]; Krisda H. Chaiyachati[1]. [1]General Internal Medicine, The University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]The University of Pennsylvania Health System, Philadelphia, PA; [3]The University of Pennsylvania, Philadelphia, PA. (Control ID #3391912)

BACKGROUND: Despite having a cancer diagnosis, patients miss potentially life-saving outpatient treatment appointments. Reasons for missed appointments may be related to patients' social determinants of health (SDOH) as treatment costs are financially destabilizing with nearly 30% of cancer survivors facing long-term financial hardships. Missed appointments are strongly associated with worse cancer treatment outcomes. How often patients encounter SDOH challenges while undergoing cancer treatment and whether patients believe social needs screening is acceptable during a tenuous phase of their life are understudied questions. To fill this research gap, we are screening patients undergoing cancer treatment for social needs and measuring the acceptability of screening.

METHODS: Since October 2019, we have an ongoing cross-sectional survey of adults age 18 or older, diagnosed with any type of cancer, and

receiving systemic cancer therapy or radiation treatment from two outpatient cancer centers in the University of Pennsylvania Health System (UPHS). To date, 65 patients have been individually approached to complete the survey and 54 patients have consented (response rate: 83%), with a target goal of 500 patients. The survey consists of a 9-question, pilot-tested, social screening tool adapted to our cancer-specific populations, covering the following domains: food insecurity, unaffordable utilities, housing instability, lack of neighborhood safety, caretaker burdens, transportation challenges, social isolation, and financial concerns. Participants were additionally surveyed about the appropriateness of screening cancer center patients for social needs, their own comfort with being screened, and their expectations of clinical staff who are made aware of patients' social needs.

RESULTS: Of the 54 patients who completed the survey, the five domains most commonly reported included future financial concerns (41%), social isolation (35%), current financial strain (30%), housing instability (20%), and unaffordable utilities (13%). The majority of patients undergoing cancer treatment felt neutral (54%) or thought that being screened for social needs was appropriate (39%). Most patients were neutral (41%) or felt comfortable (50%) with being screened for social needs. Many patients wanted cancer center staff to be aware of social needs (55%) or expected staff to connect them to resources (34%).

CONCLUSIONS: Cancer patients are a vulnerable population, clinically, financially, and socially. We identified key social needs among patients undergoing cancer treatment and the majority of patients felt the social screening tool was appropriate, they felt comfortable with the assessment and wanted staff to be aware or connect them to resources. Our findings are a critical first step for policymakers, payers, and provider organizations as they continue to imagine interventions for identifying and addressing social needs experienced by vulnerable patient populations.

SCREENING FOR HEPATITIS C REINFECTION AMONG PATIENTS WITH ONGOING RISK AFTER ACHIEVING SUSTAINED VIROLOGIC RESPONSE IN A PRIMARY CARE HEPATITIS C TREATMENT PROGRAM

Alyssa Patterson[1]; Rachel Daws[2]; Kristen S. Lee[3,2]. [1]Boston University School of Public Health, Boston, MA; [2]Boston Medical Center, Boston, MA; [3]Department of Medicine, Boston University School of Medicine, Boston, MA. (Control ID #3391082)

BACKGROUND: Patients with chronic hepatitis C (HCV) infection who achieved sustained virologic response (SVR) can be reinfected if they are re-exposed to the virus. The current guideline recommends annual testing for HCV reinfection among individuals with ongoing risk, such as injection drug use. Existing literature on the screening rate for HCV reinfection among patients with ongoing risk in a primary care setting is limited. The goal of this study is to understand the population at risk of reinfection and assess the current state of retesting HCV after achieving SVR for those at risk within an urban, hospital-based primary care HCV treatment program.
