METHODS: We reviewed the electronic medical records of all living patients who had achieved SVR in the Adult Primary Care HCV treatment program at Boston Medical Center (BMC) from January 1, 2015 to July 1, 2018. BMC is the largest safety-net hospital in New England. We identified patients at risk of reinfection by reviewing urine toxicology (UTOX) results obtained after achieving SVR. We considered patients to be at risk if the UTOX was positive for non-prescribed opiates, fentanyl or cocaine. We determined that retesting was done if there was a follow up HCV viral load completed after achieving SVR.

RESULTS: 235 patients achieved SVR during the study period. The mean age of these patients was 52 years (standard deviation 13.0) with majority of patients being male (67.2%), non-Hispanic black (42.6%), and with a diagnosis of substance use disorder (80.9%). 19.6% (n=46) of patients were identified as at risk of re- infection based on positive UTOX after achieving SVR. Among patients identified at risk of reinfection, 43.5% (n=20) had a follow up HCV viral load, and 17.4% (n=8) had the retesting done within the recommended 1-year period after achieving SVR. Of those who were retested, 15.0% (n=3) had detectable HCV viral load, indicating reinfection.

CONCLUSIONS: About a fifth of patients who have achieved SVR at the Adult Primary Care HCV treatment program at BMC are known to be at risk of reinfection due to illicit substance use based on UTOX, but the rate of retesting is low. We estimate that the actual number of patients at risk of reinfection may be higher since not all patient returned to BMC or had a UTOX done. In addition, a positive UTOX result does not confirm that the drugs were used via injection. It is imperative to develop and implement a system that can provide guideline concordant HCV reinfection monitoring.

SCREENING FOR INTERPERSONAL VIOLENCE: POTENTIAL HARM OF MODIFYING TOOLS

Emilia De Marchis[1]; Alicia Cohen[2]; Caroline Fichtenberg[3]; Eric Fleegler[4]; Danielle Hessler[5]; Amy G. Huebschmann[6]; Stacy T. Lindau[7]; Brigid McCaw[8]; Elizabeth L. Tung[9]; Laura M. Gottlieb[10]. [1]Family & Community Medicine, University of California, San Francisco, San Francisco, CA; [2]Primary Care, Providence VA Medical Center, Providence, RI; [3]Center for Health and Community, UCSF, San Francisco, CA; [4]Emergency Medicine, Boston Children's Hospital, Boston, MA; [5]Family and Community Medicine, University of California, San Francisco, San Francisco, CA; [6]Medicine, University of Colorado School of Medicine, Aurora, CO; [7]Ob/Gyn and Geriatics and Palliative Care, University of Chicago, Chicago, IL; [8]Family Violence Prevention Program, Kaiser Permanente, Oakland, CA; [9]Section of General Internal Medicine, University of Chicago, Chicago, IL; [10]Family and Community Medicine, UCSF, San Francisco, CA. (Control ID #3385976)

BACKGROUND: HITS, the Hurt Insult Threat Scream tool, was developed to detect intimate partner violence (IPV) in primary care settings. CMMI modified the tool to screen more broadly for interpersonal violence—rather than restricting to IPV—and integrated it into a multidomain social risk screening tool in an ongoing national demonstration project. HITS includes 4 questions: 1 on physical abuse and 3 on verbal abuse. The physical abuse question asks: "How often does anyone, including family and friends, physically hurt you?" The 3 verbal abuse questions ask about being insulted, threatened, or screamed at, respectively. Questions are scored based on frequency (1= "Never"; 5= "Frequently"). Scores range from 4 to 20. A scoring system for the original tool was validated in adult female survivors of IPV, with a score ≥11 signaling a safety concern. In the current demonstration, CMMI recommends using the original HITS scoring cutoff, despite having broadened the scope of the questions. The objective of this study was to evaluate the use of the original scoring system for detecting rates of reported physical and verbal interpersonal violence.

METHODS: Cross-sectional survey analysis of a convenience sample of adult English and/or Spanish speaking/reading patients or caregivers of pediatric patients at 7 primary care and 4 emergency department settings across 9 states. Descriptive analyses using chi-square with 2-sided Fisher's exact.

RESULTS: Of 1,014 participants, 66 (6.5%) screened positive for any frequency of physical abuse. Using the recommended score cutoff of ≥11, 12/66 (18.2%) screened positive for a safety concern. Of those with scores <11, 3/54 participants (5.6%) reported experiencing physical abuse "fairly often" or "frequently" and 14/54 (25.9%) "sometimes." 394/1014 participants (38.9%) screened positive for any frequency of verbal abuse; 344/

1014 (33.9%) screened positive for verbal abuse without physical abuse. 18/394 (4.6%) scored ≥11; 3/394 (7.6%) had total scores <11 and reported "sometimes" or "often" being threatened with harm, while 286/394 (72.6%) reported "rarely" or "sometimes" being insulted or screamed at.

CONCLUSIONS: Using the original scoring criteria for the modified HITS, patients reporting physical violence often did not reach the recommended score cutoff to signal a safety concern. Patient abuse disclosure that lacks adequate follow-up may result in or exacerbate patient mistrust in the health care system, in addition to being a safety risk for patients. Screening for interpersonal violence should at a minimum identify patients experiencing abuse. Identifying patients at risk for abuse can enable interventions to prevent escalation. Given that over 30% of patients in this study reported verbal abuse in the absence of physical abuse, and each question is scored with equal weighting, a more nuanced scoring system may be necessary to identify patients at highest risk. More stakeholder input is needed on how to best score the modified HITS to improve patient safety.

SCREENING FOR SOCIAL AND BEHAVIORAL DETERMINANTS OF HEALTH IN CLINICAL SETTINGS: PATIENT SCREENING RATES, COMFORT LEVEL, AND VIEWS ON APPROPRIATENESS 5 YEARS AFTER THE NATIONAL ACADEMY OF MEDICINE'S RECOMMENDATIONS

Matthew S. Pantell[1]; Laura M. Gottlieb[2]; Emilia De Marchis[3]. [1]Pediatrics, University of California, San Francisco, San Francisco, CA; [2]Family and Community Medicine, UCSF, San Francisco, CA; [3]Family & Community Medicine, University of California, San Francisco, San Francisco, CA. (Control ID #3389582)

BACKGROUND: In 2014, the National Academy of Medicine (NAM) endorsed screening for and documenting several social and behavioral determinants of health (SBDOH) in clinical settings. We investigated rates of screening 5 years later, whether patients feel uncomfortable being screened, whether they feel comfortable having their SBDOH information recorded in their electronic health record (EHR), and whether they think it is appropriate to be screened.

METHODS: Cross-sectional survey of 251 adults recruited from 3 primary care clinics in San Francisco, Chicago, and Boston. Patients were asked whether they were screened for the following NAM-endorsed domains in healthcare settings during the past year: race/ethnicity, education, financial strain, stress, social isolation, mood, smoking, alcohol, and safety. Surveys also asked whether they were uncomfortable being screened for each domain, how comfortable they were having SBDOH information in general documented in their EHR, and whether or not it was appropriate to be asked these questions in clinical settings. Rates of prior SBDOH screening, discomfort with screening (yes/no), comfort (completely uncomfortable, somewhat uncomfortable, neither comfortable nor uncomfortable, somewhat comfortable, completely comfortable) having SBDOH information recorded within the EHR, and appropriateness (very appropriate, somewhat appropriate, neither appropriate nor inappropriate, somewhat inappropriate, very inappropriate) were calculated.

RESULTS: The majority of patients were between the ages of 35-64 (54.2%), female (68.9%), and Hispanic (31.1%). Rates of SBDOH screening varied by domain (Table), ranging from 12.7% (financial strain) to 38.9% (stress); only 2.8% of patients were screened for all domains in the last year. Few patients felt uncomfortable with being asked about SBDOH domains, ranging from 1.2% (smoking) to 6.4% (race/ethnicity). Overall, 84.5% of reported no discomfort with screening for *any* SBDOH. While 24.1% felt uncomfortable having this information documented in the EHR, most patients (79.8%) thought asking SDBOH questions was appropriate.

CONCLUSIONS: Screening rates of the NAM-endorsed SBDOH domains are low despite patients generally feeling comfortable with screening, and that screening is appropriate.

SCREENING FOR SOCIAL RISK FACTORS: A COMPARISON OF TWO MULTI-DOMAIN SOCIAL RISK SCREENING TOOLS

Emilia De Marchis[1]; Nancy E. Adler[2]; Cheryl R. Clark[3]; Alicia Cohen[4]; Eric Fleegler[5]; Danielle Hessler[6]; Stacy T. Lindau[7]; Matthew S. Pantell[8]; Aric Prather[9]; Mark J. Ommerborn[10]; Elizabeth L. Tung[11]; Laura M. Gottlieb[12]. [1]Family & Community Medicine, University of California, San Francisco, San Francisco, CA; [2]Psychiatry, UCSF, San Francisco, CA; [3]General Medicine & Primary Care, Brigham and Women's Hospital, Boston, MA; [4]Primary Care, Providence VA Medical Center, Providence, RI; [5]Emergency Medicine, Boston Children's Hospital, Boston, MA; [6]Family and Community Medicine, University of California, San Francisco, San Francisco, CA; [7]Ob/Gyn and Geriatics and Palliative Care, University of Chicago, Chicago, IL; [8]Pediatrics, University of California, San Francisco, San Francisco, CA; [9]Psychiatry, University of California, San Francisco, San Francisco, CA; [10]Brigham & Women's Hospital, Boston, MA; [11]Section of General Internal Medicine, University of Chicago, Chicago, IL; [12]Family and Community Medicine, UCSF, San Francisco, CA. (Control ID #3385936)

BACKGROUND: Amidst growing interest in identifying patients' social risks in the context of health care delivery, many organizations have developed recommendations for social risk screening. A 10-item instrument developed by CMMI includes 6 questions on material hardship (housing stability and quality, food security, transportation access, utilities security) and 4 on interpersonal violence. A set of measures recommended by the National Academy of Medicine (NAM) includes 1 question on financial strain (difficulty paying for basic needs) and 4 on intimate partner violence (IPV), in addition to behavioral topics like smoking and stress. We field tested both the CMMI and NAM measures to compare: 1) rates of screening positive for material hardship, financial strain, personal safety; and 2) patient acceptability.

METHODS: Cross-sectional study comparing responses to surveys with the CMMI versus NAM questions in a convenience sample of adult English and/or Spanish speaking/reading patients at 3 participating primary care clinics in San Francisco, Chicago, and Boston. Descriptive analyses were done using chi-square with two-sided Fisher's exact tests.

RESULTS: Of 457 respondents, 56.2% (127/226) screened positive for any material hardship on the CMMI tool; 51.1% (118/231) screened positive for the single comparative NAM question on financial strain (p=0.302). Using the recommended screening rubrics from each agency, 1.3% screened positive on the CMMI interpersonal violence measure vs. 10.0% on the NAM IPV measure (p<0.001). More patients indicated interest in assistance with material hardship compared to those indicating interest in assistance for financial strain (38.7% vs. 21.2%, respectively, p<0.001). Differences in interest in assistance with safety did not reach statistical significance (1.8% vs. 5.2%, p=0.072). There were no statistically significant differences in the perceived appropriateness of screening (85.8% vs. 79.3%, respectively, p=0.072). Patient comfort incorporating social risk factor results into the electronic health record was also similar (65.6% vs. 63.4%, p=0.631). Few patients reported discomfort answering specific questions on either questionnaire: 4.9% reported discomfort answering questions about material hardship vs. 5.7% reported discomfort with the question about financial strain (p=0.841). Similarly, 1.6% reported discomfort answering the CMMI safety measure vs. 2.9% on the NAM (p=0.544).

CONCLUSIONS: Acceptability of the CMMI and NAM recommended social risk factor measures was high. Rates of positive screens for socioeconomic risks were similar, though more patients indicated interest in assistance when answering the CMMI items asking about specific social risks. There were significantly lower rates of positive screens for personal safety using the CMMI tool. More research is warranted on the validity and comparative validity of each set of measures. Measure selection should depend on the population served, screening goals and resources available.

SCREENING FOR UNDIAGNOSED ATRIAL FIBRILLATION IN PRIMARY CARE: PRIMARY CARE PHYSICIAN PERCEPTIONS ABOUT CURRENT AND FUTURE PRACTICE

Jeffrey M. Ashburner[1]; Priscilla R. Lee[2]; Colin M. Rivet[2]; Aimee K. Lin[2]; Courtney E. Leonard[2]; Margaret Bussineau[2]; Ana T. Trisini Lipsanopoulos[2]; Leila H. Borowsky[1]; Wyliena Guan[2]; Xinye Li[2]; Yuchiao Chang[1]; Shaan Khurshid[2]; Patrick T. Ellinor[2]; Daniel E. Singer[1]; David D. McManus[3]; Steven A. Lubitz[2]; Steven J. Atlas[1]. [1]Division of General Medicine, Massachusetts General Hospital, Boston, MA; [2]Division of Cardiology, Massachusetts General Hospital, Boston, MA; [3]University of Massachusetts Medical School, Worcester, MA. (Control ID #3367672)

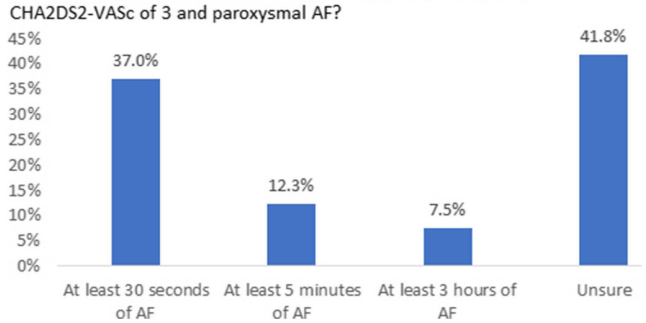
BACKGROUND: Atrial fibrillation (AF) is the most common cardiac arrhythmia and is associated with a 5-fold increased risk of stroke. AF may be asymptomatic, so screening for undiagnosed AF is appealing. Pulse palpation by primary care providers (PCPs) during clinic visits is common, but hand-held devices represent an opportunity for more systematic screening. The U.S. Preventive Services Task Force found insufficient evidence to support electrocardiogram (ECG) screening, while European and Australian/New Zealand guidelines recommend screening.

METHODS: We conducted a large (n=35,309) pragmatic cluster-randomized trial (VITAL-AF, ClinicalTrials.gov NCT03515057) in a U.S. primary care network to assess the efficacy of population-based AF screening in older patients using a handheld single-lead ECG as part of routine care. Following the trial, we surveyed PCPs about how they assessed heart rhythm and opinions about AF screening.

RESULTS: The survey response rate was 76% (81% intervention; 71% control) among 170 physicians and 28 nurse practitioners. Intervention and control responses were similar, so were combined except as noted. 93% of PCPs reported routinely assessing pulse pattern at visits, for ≤ 10 seconds (66%). Most PCPs (85%) believe AF screening should be done during primary care visits. Intervention PCPs exposed to use of a handheld ECG during the trial favored this as a screening method (86%), while control PCPs favored pulse palpation (65%). PCPs were less certain whether screening should be done outside of office visits with patch monitors (17% yes, 36% no, 47% unsure) or consumer devices (22% yes, 24% no, 54% unsure). Of PCPs who support screening with personal devices, 71% believed patients should be able to share results via a patient portal. PCPs were uncertain about the burden of AF required to treat paroxysmal AF with anticoagulation, though many had a low threshold (Figure).

CONCLUSIONS: Clinic-based AF screening, which will largely detect undiagnosed persistent AF, is widely supported by PCPs. PCPs exposed to a handheld ECG device strongly preferred it over pulse palpation. PCPs appear less certain about screening done outside of clinic visits with patch monitors or personal devices. In part, this may be due to recognition that more paroxysmal AF may be detected and the burden of AF at which to recommend oral anticoagulation is unclear.

Figure: What is the minimum duration of a single AF episode that would lead you to recommend oral anticoagulation (OAC) for a patient with a CHA2DS2-VASc of 3 and paroxysmal AF?



SECURE AND INTEGRATED: ENHANCING THE EDUCATIONAL EXPERIENCE OF MEDICAL STUDENTS THROUGH ELECTRONIC MEDICAL RECORD (EMR) SECURE CHAT

Laura Nichols, Dubert Guerrero, Devendranath Mannuru, Dinesh Bande. Internal Medicine, University of North Dakota, Fargo, ND. (Control ID #3391314)

BACKGROUND: Both messaging applications and texting are used in communicating with and educating medical students. However, these platforms present patient privacy concerns. Additionally, students are frequently absent from care coordination conversations. Secure messaging can be used to include students on these conversations and enhance team involvement. Integration into the EMR and availability on devicess such as smartphones presents an opportunity to investigate secure messaging impact on medical education.

METHODS: Between July through December 2019, we performed a mixed methods study to investigate 3rd and 4th year medical student perceptions of secure messaging effect on their internal medicine (IM) rotation. Study components included a pre and post-rotation survey. The third component was a review of secure message threads and categorization of content to evaluate use of secure messaging with students.

RESULTS: A total of 19 students completed the pre-rotation survey, and 15 completed the post-rotation survey between July and December 2019. Ten (53%) students reported the quality of communication with faculty was good or very good prior to IM rotation versus 13 (87%) at IM rotation conclusion. A total of 5 (26%) reported the same towards ancillary staff prior with increase to 10 (67%) at end of rotation. Additionally, 11 (73%) students noted secure messaging either somewhat or significantly improved communication with ancillary staff on their IM rotation. On other rotations, students reported using direct communication and texting most frequently; whereas, direct communication and secure messaging were most frequently used on IM. Fourteen (93%) students reported that secure messaging resulted in either somewhat or significantly improved ease of communication, and 13 (87%) felt it improved their educational experience on IM. On review of 512 secure message threads, 203 (40%) contained logistical communication. Daily management (29%), admissions (12%) and discharge (11%) communications were the next most frequent. Other categories together (20%) included education, clerkship activity and scholarly activity conversations.

CONCLUSIONS: Our mixed methods study suggests that integrated EMR secure messaging is a promising medium to enhance medical student education and team communication and involvement. Additional study should focus on how we can promote faculty use of this tool for educational purposes and to continue to work to ensure students are included on important patient communications.

SELF-ACTUALIZATION SKILLS IN YOUNG ADULTS WITH AUTISM TO IMPROVE QUALITY OF LIFE

Megumi J. Okumura[1]; sarah Selling[1]; Susanne Martin-Herz[1]; Roberta S. Rehm[2]. [1]Pediatrics, UCSF, San Francisco, CA; [2]School of Nursing, UCSF, San Francisco, CA. (Control ID #3392605)

BACKGROUND: Young adults with autism spectrum disorder (YAASD) often lack the skills needed for successful adult living and subsequently achieve lower quality of life in adulthood. Therefore, the purpose of this project is to develop a framework to support resilience and improve quality of life in YAASD and use this framework to generate a life-skills curriculum for YAASD.

METHODS: We conducted in-depth semi-structured interviews with YAASD, parents of YAASD and service providers recruited from

agencies that serve YAASD. We focused our interviews on supports and skills needed to enhance quality of life in adulthood. We performed a multi-step qualitative analysis process including coding, development of categories, and development of a theoretical code.

RESULTS: A total of 23 individuals (over age 19) were interviewed. We developed the major theoretical code of "self-actualization skills in young adults with autism to improve quality of life". This code recognized the neurodiversity of YAASD as well as comorbid intellectual disability and mental health needs, which often were a barrier to achieving life goals. We identified the need for YAASD to develop skills to facilitate both independence and greater insight, including self-care, self-awareness, self-advocacy, and social integration. This also included the concept of personal safety while developing social skills, and the ability to identify one's interests, goals, and strengths. Factors identified that would facilitate development of self- actualizing skills included resources that promote structure in an unstructured adult world. YAASD struggled in developing resiliency skills, which improve adaptation to a constantly changing environment common in adult life. Communication between family and service agencies was considered a critical aspect to support YAASD skill development. Finally, the need for technologies that could facilitate social and vocational engagement across the spectrum of YAASD (e.g. communication assistance) was also highlighted.

CONCLUSIONS: Self-actualization for adults requires skills for independence, self-care, decision making, and effective communication. Unfortunately, most adult programs for YAASD emphasize vocational and simple task performance and focus less, if at all, on these key areas. YAASD need support to develop ways to cope with demands inherent in living as adults in the community. Our framework identifies domains that facilitate self-actualization skills which, though challenging to teach and support, promote health and wellness to enhance quality of life for YAASD.

SELF-EFFICACY AND READINESS TO CHANGE AMONG WOMEN WITH RECENT GESTATIONAL DIABETES ENGAGING IN A WEB-BASED LIFESTYLE INTERVENTION: THE BALANCE AFTER BABY INTERVENTION TRIAL

Cara E. Saxon[1]; Ellen W. Seely[2]; Geraldine Skurnik[2]; Andrea Roche[2]; Claire Schultz[4]; Krithika Suresh[5]; Rachel Blair[2]; Jacinda M. Nicklas[3]. [1]Internal Medicine, University of Colorado, Denver, CO; [2]Endocrinology, Diabetes and Hypertension Division, Brigham and Women's Hospital, Boston, MA; [3]General Internal Medicine, University of Colorado School of Medicine, Aurora, CO; [4]Obstetrics and Gynecology, Denver Health and Hospital Authority, Denver, CO; [5]Biostatistics and Informatics, Colorado School of Public Health, Denver, CO. (Control ID #3390870)

BACKGROUND: Women with gestational diabetes (GDM) have a 30-70% risk for developing type 2 diabetes (T2DM). Postpartum weight loss and physical activity reduce the risk for developing T2DM, however, few evidence-based programs exist to help mothers reduce their risk in the critical postpartum period. Self-efficacy is the belief in one's ability to succeed at a task despite encountering obstacles. We sought to characterize the change in perceived self-efficacy for change in physical activity and diet, and perceived readiness to change among women with recent GDM participating in a web-based diabetes prevention program.

METHODS: Women with recent gestational diabetes were randomized at ~6 weeks postpartum to engage in a 12-month web-based lifestyle intervention with support from a lifestyle coach (BABI group) or to a control website (control group). At the baseline postpartum study visit we administered behavioral questionnaires, including the Self-Efficacy Survey for Diet and Exercise Behaviors and the Readiness to Change Questionnaire. We obtained questionnaire data at 12 and 24 months postpartum. Questionnaire data consisted of 5-point Likert scale questions that were averaged to obtain a mean score for self-efficacy and readiness to change, with 5 the highest. Our study included 181 women (mean 33±5.3 years; 48% White, 22% Asian, 17% African-American, 13% other race, with 35% Hispanic).

RESULTS: The baseline 6-week mean self-efficacy survey scores for physical activity for the BABI vs. control group were 3.6 (SD 0.9) and 3.8 (SD 0.8), respectively. The self-efficacy for diet scores at baseline for BABI vs. control were 4.4 (SD 0.7) and 4.4 (SD 0.5), respectively. The baseline readiness to change mean scores in the BABI vs. control group were 3.1 (SD 0.6) and 3.1 (SD 0.5), respectively. Using a mixed effects model, women in the BABI group experienced a larger increase in reported self-efficacy for physical activity scores compared to the control group at 12 months (difference between groups 0.23, 95% CI: -0.06 to +0.52, p=0.13) and significantly at 24 months (difference between groups 0.38, 95% CI: 0.06 to 0.69, p=0.02). There was no significant difference between groups for increase in self-efficacy for diet at 12 months (difference between groups 0.09, 95% CI: -0.14 to +0.32, p=0.44) or at 24 months (difference between groups 0.07, 95% CI: -0.16 to 0.29, p=0.57). The change in readiness to change was not significantly different between groups at 12 months (difference between groups of 0.09, 95% CI: -0.12 to +0.30, p=0.43) or at 24 months (difference between groups 0.06, 95% CI: -0.19 to +0.30, p=0.66).

CONCLUSIONS: At 24 months postpartum, women randomized to the web-based Balance After Baby intervention program demonstrated a greater change in self-efficacy for exercise than those randomized to the control website. Further analysis will address the relationship between self-efficacy and readiness to change and the adoption of healthy lifestyle behaviors and weight loss.

SEXUAL HARASSMENT AND REPORTING FOR PHYSICIANS (SHARE): USING INCIDENT REPORTING TO UNDERSTAND THE CHARACTERISTICS, RESPONSE AND IMPACT OF INCIDENTS WHERE PHYSICIANS ARE SEXUALLY HARASSED BY PATIENTS

Shirin Hemmat[1]; Elaine C. Khoong[1,2]; Anjana Sharma[3,1]; Sarah Lisker[1,2]; Gabriela Reed[1]; Kristan Olazo[1,2]; Urmimala Sarkar[1,2]. [1]Division of General Internal Medicine, University of California San Francisco, San Francisco, CA; [2]Center for Vulnerable Populations, University of California San Francisco, San Francisco, CA; [3]Department of Family and Community Medicine, University of California San Francisco, San Francisco, CA. (Control ID #3391723)

BACKGROUND: Previous studies have shown a third of physicians encounter sexual harassment from patients, with these rates nearly double for women. Sexual harassment of women in the workplace, including by patients, has been identified as a challenge to the recruitment and advancement of women physicians. The nature of these encounters has not been previously described. Using incident reporting, we aimed to characterize encounters where physicians were sexually harassed by patients.

METHODS: The anonymous SHARE tool used a web-based questionnaire for physicians to report incidents of sexual harassment by patients. The questionnaire included structured questions about respondent traits, incident characteristics, individual and institutional response to the incident, and impact on respondent. Respondents also described the incident in free text which was coded inductively.

RESULTS: As with all incident reporting, data collection is ongoing. *Respondent traits:* 36 respondents from 10 states and seven medical specialties initiated the survey. 30 respondents were women. *Incident traits:* Nineteen occurred in the outpatient setting, 11 inpatient and four in the emergency department. Seventeen had met the patient on at least one prior incident. Most harassment was verbal (n=25), which included inappropriate or flirtatious remarks (i.e. commenting on the physician's

attractiveness or breast size, asking the physician on a date or to engage in sexual activity). There were five incidents of physical harassment, including inappropriate touching or exposure. Three reported stalking or threats from patients. *Physician Response:* Ten respondents ignored the harassment, nine addressed the patient directly, eight told a supervisor or colleague and six formally reported the incident. Many did not formally report because they felt their experience was not significant enough to report (n=17). Others feared negative repercussions (n=9), felt shame about the experience (n=9) or uncertain about the reporting process (n=18). *Institutional/Supervisor response:* 6 patients were reassigned or dismissed from the clinic, two addressed the behavior with the patient, two normalized or minimized the patient's behavior, two discouraged formal reporting and there was one instance of retaliation after reporting. *Physician Impact:* 21 said the incident negatively impacted their mental health, 12 said they withdrew from an aspect of their job or organization as a result of the incident, nine had decreased job satisfaction and three changed their behavior (dressed differently or took a different route to work).

CONCLUSIONS: Sexual harassment of physicians is common with a wide range of incidents. Many do not formally report despite having negative experiences that impacted their ability to perform their job. When reported, many institutional/supervisor responses were inadequate. Next steps include helping physicians, supervisors and institutions better address and prevent incidents of physician sexual harassment by patients.

SHORTER WAIT TIMES FOR BEHAVIORAL HEALTH APPOINTMENTS ASSOCIATED WITH SIGNIFICANTLY HIGHER RATES OF APPOINTMENT ATTENDANCE

Alexandra C. Knitter[2]; Erin M. Staab[2]; Nancy Beckman[1]; Fabiana Araújo[1]; Lisa M. Vinci[2]; Mim Ari[2]; Daniel Yohanna[1]; Neda Laiteerapong[2]. [1]Psychiatry & Behavioral Neuroscience, University of Chicago, Chicago, IL; [2]Medicine, University of Chicago, Chicago, IL. (Control ID #3391655)

BACKGROUND: In any given year, mental health conditions affect about 20% of primary care patients. Due to this high demand for behavioral health services and the nationwide shortage of behavioral health care providers, most patients referred for these services wait for many months before they initiate care. However, long wait times for behavioral health services may increase the rates of cancellations and no shows further exacerbating lack of access to behavioral health services.

METHODS: We examined referrals from the University of Chicago Medical Center internal medicine/internal medicine-pediatrics clinic to psychotherapy and psychiatry services in the Department of Psychiatry for a 3-year period (March 1, 2016-February 28, 2019). We used multivariate logistic regression to analyze the association between the wait time (i.e., time interval between behavioral health referral and the scheduled appointment) and attendance at the appointment. Age, gender, race/ethnicity (non-Hispanic/Latinx white (white), non-Hispanic/Latinx black (black), Hispanic/Latinx, non-Hispanic/Latinx Asian (Asian)), and insurance type were included as covariates.

RESULTS: During the study period, 1587 behavioral health referrals were scheduled. Seventy-two percent (n=1148) of referred patients were women, 55% (n=868) were black, and 31% (n=494) were white. Over half (55%, n=867) of referred patients attended their first scheduled appointment. In multivariate analyses, appointments scheduled for less than one week after the referral date were associated with 87% higher odds of attendance compared to appointments with a longer than one week wait time (OR, 1.87; 95% CI, 1.30-2.72). A waiting time of one month or less was associated with a 61% higher odds of attendance compared to a wait of more than a month (OR, 1.61; 95% CI, 1.22-2.15). A similar increase in attendance was associated for a wait of 3 months or less compared to a more than 3-month wait (OR, 1.62; 95% CI, 1.30-2.03). Among covariates across models, black patients and Hispanic/Latinx patients had consistently lower odds of attendance compared to white patients (e.g., 1 week, black: OR, 0.38; 95% CI, 0.29-0.50. Hispanic/Latinx: OR, 0.63; 95% CI, 0.40-0.99). Other covariates were not consistently associated with attendance.

CONCLUSIONS: We found that a shorter waiting time between a behavioral health referral and the scheduled appointment was associated with significantly higher rates of attendance. Scheduling patients with short waiting times decreases administrative work and provides greater value to patients. Developing alternative resources for excess behavioral health referrals and implementing strategies to triage patients would provide better value to patients and the healthcare system than scheduling patients with long wait periods. Additionally, resources for black and Hispanic/Latinx patients that encourage behavioral health appointment attendance may be important to reduce inequities in access to mental health care.

SIGNIFICANCE OF ADVERSE SOCIAL DETERMINANTS OF HEALTH ON THE DIAGNOSIS AND CONTROL OF DIABETES AND HYPERTENSION: NHANES 2011-2014

Eun Ji Kim[1]; Sara Abrahams[2]; Lyndonna Marrast[1]; Johanna Martinez[1]; Amresh D. Hanchate[3]; Joseph Conigliaro[1]. [1]Internal Medicine, Zucker School of Medicine, New Hyde Park, NY; [2]Medical School, Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY; [3]Social Sciences and Health Policy, Wake Forest School of Medicine, Winston-Salem, NC. (Control ID #3390516)

BACKGROUND: Individual social determinants of health (SDH) have been associated with health outcomes. For example, food insecurity and low educational attainment have been associated with poorly controlled diabetes and hypertension. However, few studies have simultaneously examined multiple domains of SDH and their significance in disease diagnosis and control. This study examines the significance of multiple adverse SDH in diagnosis and control of diabetes and hypertension. Among diabetic patients, we further examined associations between adverse SDH and diabetic standards of care.

METHODS: We conducted a retrospective, cross-sectional study of the National Health and Nutrition Examination Survey 2011-2014 that included 9,609 adult respondents with non-missing responses to key surveyed measures, including blood pressure and hemoglobin A1c (HbA1c) levels. The primary outcomes were diagnosis and control of diabetes and hypertension. We examined seven domains of adverse SDH, which are low education, low income, lack of health insurance, food insecurity, poor housing, unemployment or underemployment, and limited English proficiency (LEP), and their associations with the primary outcomes. For diabetic participants, we additionally examined having a diabetic foot examination, a pupil dilation examination, daily glucose level check, and/or measurement of HbA1c level within the past year.

RESULTS: The presence of food insecurity, poor housing, and LEP were associated with undiagnosed diabetes (p-values<0.05). Prevalence of low income (26.4% vs 23.4%), a lack of health insurance (16.5% vs 12.3%), and food insecurity (31.6% vs 26.4%) were higher among those with uncontrolled diabetes compared to those with controlled diabetes (p-values<0.05). In multivariable logistic regression models, low education (OR = 0.56 [0.34-0.93]), low income (OR = 0.36 [0.28-0.57]), and lack of health insurance (OR = 0.35 [0.21-0.59]) were associated with decreased odds of having an HbA1c test in the past year. Having food insecurity (OR =0.59 [0.40-0.86]) or poor housing (OR=0.73 [0.54-1.00]) was associated with decreased odds of having a dilated pupil exam in the prior year. Respondents with multiple adverse SDH (3 adverse SDH OR=0.18 [0.11-0.29] and 5+ adverse SDH OR=0.16 [0.05-0.51]) had lower odds of

having HbA1c checked in the past year compared to those with one adverse SDH (OR=0.49 [0.27-0.88]), adjusting for covariates.

CONCLUSIONS: We found adverse SDH to have a significant role in the diagnosis and control of diabetes but not hypertension. This suggests that adverse SDH have varying roles in diagnosis and management, depending on medical conditions. Presence of multiple adverse SDH had an inverse relationship with having a dilated pupil exam, HbA1c level measured in the past year, and checking a daily glucose level. For diseases that are associated with adverse SDH, disease process measures could potentially serve as tools to examine the success of interventions addressing adverse SDH.

SIMULTANEOUS COCAINE AND ALCOHOL USE IN WOMEN USING MULTIPLE SUBSTANCES IS ASSOCIATED WITH ELEVATIONS IN BLOOD PRESSURE WHILE INDIVIDUAL SUBSTANCES ARE NOT

Leslie Suen[1]; Eric Vittinghoff[2]; Alan H. Wu[3]; Phillip Coffin[5]; Priscilla Hsue[4]; Kara Lynch[3]; Elise Riley[6]. [1]Internal Medicine, UCSF, San Francisco, CA; [2]Epidemiology and Biostatistics, UCSF, San Francisco, CA; [3]Laboratory Medicine, UCSF, San Francisco, CA; [4]Cardiology, UCSF, San Francisco, CA; [5]San Francisco Department of Public Health, San Francisco, CA; [6]Medicine, University of California, San Francisco, San Francisco, CA. (Control ID #3390456)

BACKGROUND: The impact of polydrug use on traditional cardiovascular risk factors has not been well characterized among homeless women. This population is especially high risk with high rates of polydrug use and cardiovascular events being a leading cause of death. We evaluated associations between substances and blood pressure in a cohort of homeless and unstably housed women in San Francisco.

METHODS: We recruited 245 women from San Francisco community venues, including homeless shelters, free meal programs, low-income hotels and street encampments, to participate in a prospective study examining the influence of toxicology-confirmed polydrug use on cardiovascular health. Participants completed six monthly visits between 2016 and 2019, including vital sign assessment, interview, and lab testing to assess drug use. We used linear mixed models to determine longitudinal associations of substances used with log-transformed diastolic and systolic blood pressure over time.

RESULTS: The median participant age was 53 years and 74% were women of color. At baseline, the prevalence of toxicology-confirmed substance use included cocaine (52.7%), methamphetamine (30.2%), heroin (2.0%), tobacco (69.0%) and alcohol (29.0%). Prior myocardial infarction or stroke were reported by 8.2% and 11.5%, respectively, and 60.4% had systolic blood pressure ≥ 140mm Hg or diastolic ≥ 90 mmHg at baseline. Systolic blood pressure was independently associated with older age (1.03-fold increase per 10 years; 95% CI: 1.02-1.05), African American race (1.11-fold vs Whites; 95% CI: 1.05-1.16) and the presence of cocaethylene (1.05-fold; 95% CI 1.00-1.11). Diastolic blood pressure was independently associated with LDL cholesterol (1.03-fold per SD increase; 95% CI 1.01, 1.05), HDL cholesterol (1.02-fold per SD increase; 95% CI 1.00, 1.04), the presence of cocaethylene (1.05-fold; 95% CI 1.10, 1.11), and the presence of methadone (0.95-fold; 95% CI 0.91, 0.99).

CONCLUSIONS: Cocaethylene is a metabolite created from simultaneous use of cocaine and alcohol within the same hour. Among homeless and unstably housed women, cocaethylene showed a significant effect on blood pressure while individual substances like cocaine, ethanol, methamphetamine, and nicotine did not. Acknowledging that alcohol and cocaine co-use increases cardiovascular risk more than individual substances may improve risk stratification in this population, prompting providers to assess patients for co- use of alcohol and cocaine. While abstinence is often the ultimate goal, for those who have difficulty achieving long-term cessation, counseling against simultaneous use of cocaine and alcohol may reduce blood pressure and overall cardiovascular morbidity.

SINGLE CENTER REVIEW OF APPROPRIATENESS AND UTILIZATION OF UPPER ENDOSCOPY IN DYSPEPSIA

kamesh gupta[1]; Rohit Singhania[2]. [1]Internal medicine, Baystate medical center, East windsor, CT; [2]Gastroenterology, UMMS- Baystate Medical Center, Springfield, MA. (Control ID #3361888)

BACKGROUND: Dyspepsia is estimated to cost the US health care service over $18 billion per annum and the majority of the cost is due to endoscopies performed. ACG published new guidelines in 2017 for the management of dyspepsia which clearly laid down non interventional, effective and affordable steps to undertake before undergoing endoscopy, as the endoscopy was found to be of low yield in true dyspepsia patients.

METHODS: Using administrative data, we retrospectively studied the charts of all adult patients who were referred for Esophagogastroduodenoscopy (EGD) from 3 health clinics with dyspepsia as the primary indication for the study in 2018. Dyspepsia was defined by Rome III criteria. We excluded patients who had pathological diagnosis made on a previous endoscopy. Steps for Dyspepsia management undertaken before performing the endoscopy were recorded. These were compared to the ACG guidelines and appropriateness of EGDs was classified into two categories: Likely Appropriate and Probable Overuse.

RESULTS: Out of the 122 EGDs performed for dyspepsia, 30 of them (24.5%) were performed in patients > 60 years of age. Out of the remaining 92 patients <60 years of age, only 13 (14.1%) patients had undergone both H. pylori test-and-treat and proton pump inhibitor for at least a month before undergoing endoscopy. Of this group <60 years of age, 19 of them had alarm symptoms (13 weight loss, 3 malena, 1 early satiety, 1 dysphagia), 3 had documented family history of gastric cancer and none had any information on belonging to a high risk region. In total, only 30 procedures (24.5%) were deemed to be appropriate per ACG guidelines. 30 patients (25%) had H. pylori testing, out of which 12 (10%) were positive and 6 completed treatment before undergoing endoscopy. 72 patients (59%) were trialed on PPi, but 24 had treatment for less than one month. 26 patients (21.3%) had positive findings on endoscopy, which included gastritis (N=20), Barrett's esophagus (N=2) and celiac disease (N=1). 11 patients tested positive on endoscopic biopsies for H. Pylori. None of the patients had gastric/esophageal cancer detected on EGD.

CONCLUSIONS: Our study shows that there is a high rate of overutilization of EGDs for management of dyspepsia. The rate of inappropriate UGI endoscopy is higher than some of the recent studies, likely because of the stricter use of EGD in patients <60 years wherein ACG guidelines recommends that endoscopy is of high yield in this patient group if they have a family history of gastric cancer or spent their childhood in a high risk region, mainly east asia. Only one in eight patients underwent H. Pylori testing and trial of Ppi for a month, which have been shown to be higher yield than EGD for management of dyspepsia. There were no cases of gastric cancer, which is the primary concern for performing EGD in dyspepsia patients.

SMOKING CESSATION IN THE DIGITAL AGE: EVALUATING THE USABILITY AND APPEAL OF TWO CESSATION APPS AMONG YOUNG ADULTS WITH SERIOUS MENTAL ILLNESS

Minda Gowarty[1,2]; Nathan Kung[2]; Ashley Maher[2]; Mary Brunette[3,2]. [1]Internal Medicine, Dartmouth Hitchcock Medical Center, Lebanon, NH; [2]Geisel School of Medicine, Hanover, NH; [3]Psychiatry, Dartmouth Hitchcock Medical Center, Lebanon, NH. (Control ID #3391715)

BACKGROUND: Young adults with serious mental illness (SMI) are over twice as likely to smoke than the general population, and are less likely to seek treatment or achieve abstinence. Scalable interventions such as smartphone apps created with evidence-based content by the National Cancer Institute (NCI; QuitGuide – QG, or quitSTART – qS) could increase access to behavioral treatment for this group, but have yet to be tested.

METHODS: We enrolled 22 daily smokers with SMI, aged 25-35, who were stable in community mental health treatment in 2019. We conducted five focus groups to identify facilitators and barriers to app use for smoking cessation, as well as desirable and undesirable app features. Three members of the research team coded transcriptions of the focus groups using thematic analysis.

Twelve participants were randomly assigned to use QG or qS on their smartphone and were evaluated using a laboratory-based task-completion protocol, the System Usability Scale (SUS), and semi-structured interviews at baseline (V1) and after two weeks of unstructured app use (V2). Qualitative analysis and descriptive statistics were completed.

RESULTS: Focus Groups: Participants were 45% female, and 41% were diagnosed with psychotic disorders. Facilitators to app use included convenience and ability to self-pace cessation activities. Barriers to app use included busy lifestyle, lack of accountability, and limited phone storage. Desirable app features included cigarette and money tracking functions, distraction tools, and motivational messages. References to cigarettes were perceived as undesirable, as they could trigger smoking.

Usability Testing: Participants were 42% female, and 42% were diagnosed with psychotic disorders. Participants smoked 17±7.3 cigarettes per day, and 80% used smartphone apps at least twice daily. While task completion rates remained high for QG at both V1 and V2 (96%), SUS scores decreased from V1 to V2 (66 to 60). In contrast, both task completion rates and SUS scores for qS improved from V1 to V2 (79% to 84%; 55 to 64). Qualitative feedback supported the SUS scores: initial interest in QG at V1 diminished by V2; initial difficulty navigating qS at V1 resolved by V2, with a corresponding increase in appeal. Participants using both apps were challenged by 4 tasks at both visits: tracking cigarettes, setting a quit date, uploading a photo, and connecting to social media. Participants rated these tasks as important, and stressed the importance of tracking daily cigarette use to their ongoing interest in the apps.

CONCLUSIONS: Young adults with SMI indicated that mobile apps are an appealing vehicle for tobacco treatment, but their concerns about lack of accountability suggest that clinical support for app use is warranted. While overall usability of both apps was high by Visit 2, several desirable features in both apps remained difficult to use. Teaching smokers how to use the apps may be necessary to promote initial engagement.

SOCIAL AND DEMOGRAPHIC PATTERNS OF HEALTH RELATED INTERNET USE AMONG ADULTS IN THE UNITED STATES: AN ANALYSIS OF THE HEALTH INFORMATION NATIONAL TRENDS SURVEY

Argelis Rivera[1]; Christopher Gonzalez[3]; Marlene Camacho-Rivera[2]. [1]Medicine, Mount Sinai St. Luke's Hospital, Brooklyn, NY; [2]Community Health Sciences, SUNY Downstate Health Sciences University, Brooklyn, NY; [3]Weill Cornell Medicine, New York, NY. (Control ID #3392380)

BACKGROUND: National surveys of U.S. adults have documented significant increases in health-related internet use (HRIU), but there are disparities by race/ethnicity, SES, age, gender, urbanicity. Objective: The study aims to identify social and demographic patterns of HRIU among U.S. adults.

METHODS: Data for this study came from the HINTS 4 cycle 3 and HINTS 5 cycle 1. To assess differences in eHealth usage, we used 8 eHealth tasks are divided into 3 domains relevant to health communication: use of internet for healthcare purposes; health information seeking for oneself or someone else; and use of social networking sites to access health information, participate in a health-related support group, or maintenance of an online health diary. Primary predictors of interest were gender, race/ethnicity, age, education, income, and nativity with adjustments for smoking, health insurance, and survey year. We conducted multivariable logistic regression models to identify independent predictors of eHealth usage, with all analyses weighted to provide nationally representative estimates.

RESULTS: Of the 4,817 respondents, 44% of participants had used the internet to look for a healthcare provider and 22% had used the internet to purchase medicine vitamins online. 80% of respondents have used the internet to seek health information for themselves, while 67% have used the internet to seek health related information for someone else. The user generated content domain was less frequently reported among participants.

In multivariable models, in the healthcare use domain, participants 35 years and older were significantly less likely to use the internet to look for a healthcare provider when compared to those in the 18-34 range. Non-Hispanic Blacks were 44% less likely to report purchasing medicine or vitamins online when compared to non-Hispanic Whites (adjusted OR = 0.56, 95% CI 0.38, 0.84). In the health information seeking domain, women were significantly more likely to look for health information for others when compared to men (adjusted OR = 1.74, 95% CI 1.39, 2.18). In the social media and user generated content domain, women were nearly twice as likely to visit a social networking site to read and share health information (adjusted OR = 1.93, 95% CI 1.43, 2.60) and also more likely to participate in an online social support group when compared to men (adjusted OR = 1.62, 95% 1.05, 2.50).

CONCLUSIONS: Given the potential of the internet to increase health disparities due to evidence of the digital divide, this study has important implications for modifying health-related information and the methods by which it is shared to particular groups of the U.S. adults. Understanding how the internet is used by the populations most difficult to reach provides insight into potential targets for health communication.

SOCIAL DETERMINANTS OF HEALTH AND 30-DAY READMISSIONS AMONG ADULTS HOSPITALIZED FOR HEART FAILURE IN THE REASONS FOR GEOGRAPHIC AND RACIAL DIFFERENCES IN STROKE (REGARDS) STUDY

Madeline R. Sterling[1]; Joanna Bryan[1]; Laura C. Pinheiro[1]; Monika M. Safford[1]; Emily B. Levitan[2]; Erica Phillips[3]; Todd Brown[4]; Oanh K. Nguyen[5]; Jacklyn Cho[1]; Parag Goyal[1]. [1]Medicine, Weill Cornell Medicine, New York, NY; [2]Epidemiology, University of Alabama at Birmingham, Birmingham, AL; [3]Medicine, Weill Cornell Medical Medicine, New York, NY; [4]Division of Cardiovascular Disease, University of Alabama at Birmingham, Birmingham, AL; [5]Internal Medicine, University of California, San Francisco, San Francisco, CA. (Control ID #3391332)

BACKGROUND: Researchers and policy makers are increasingly interested in the role that social determinants of health (SDOH) have on post-discharge outcomes in heart failure (HF), since these factors may determine which patients are most vulnerable to readmission. We examined the association of SDOH with 30-day readmission after a HF hospitalization.

METHODS: REasons for Geographic and Racial differences in Stroke (REGARDS) Study is a national longitudinal cohort study of black and white adults ≥ 45 years. Baseline interview and in-home visit data were collected between 2003-2007 and follow-up is ongoing. We examined Medicare-linked REGARDS participants discharged alive after a first adjudicated HF hospitalization. Guided by the HealthyPeople 2020 Framework, we assessed 9 SDOH: race, education, income, social

isolation, social network, high poverty residential area, Health Professional Shortage Area (HPSA), rural residence, and state public health infrastructure. The primary outcome was all-cause 30-day readmission, assessed through Medicare claims. For each SDOH, we calculated incidence per 1000-person years and multivariable-adjusted hazard ratios of readmission.

RESULTS: Over 11 years, 690 participants were hospitalized for HF of whom 155 (22.4%) were readmitted within 30 days. Overall, participants had a median age of 76 years (IQR 71 – 82) and 44.3% were female, 36% were black, 24% had low educational attainment, 63% had low income, 21% had zip code-level poverty, 43.5% resided in HPSAs, 39.3% lived in states with poor public health infrastructure, 13% were socially isolated with poor social networks, and 10% lived in rural areas. Except for HPSA, the incidence of 30-day readmission did not differ by any of the SDOH examined. In a model that adjusted for all SDOH, demographic, clinical, and hospitalization factors, none of the 9 SDOH were independently associated with readmission risk

CONCLUSIONS: In this national cohort, none of the 9 SDOH we examined were associated with 30-day readmission after a HF hospitalization. Our findings suggest that other factors, not assessed here, may be more influential and that policies or interventions that broadly target SDOH alone after a HF hospitalization among Medicare beneficiaries are unlikely to reduce readmission rates.

SOCIAL DETERMINANTS OF HEALTH AND GENETICS IN THE UK BIOBANK

Michael Cantor[1,2]. [1]Clinical Informatics, Regeneron Genetics Center, Tarrytown, NY; [2]Medicine, NYU Grossman School of Medicine, New York, NY. (Control ID #3371585)

BACKGROUND: Social determinants and genetics are considered independent categories when examining the broad set of influences on health. The sequencing of large populations, however, allows for investigation of the interplay between these sets of determinants. Recent studies, for example, have shown the influence of education on blood pressure levels in genetically similar populations. The UK Biobank (UKB), a database of 500,000 people with extensive phenotypic and genetic information, is an excellent resource in which to examine other potential interactions between genetics and social determinants of health.

METHODS: We performed genome wide association studies (GWAS) for phenotypes that were part of the UKB's category 76 "Indices of Multiple Deprivation." Higher scores in all categories meant more deprivation. We used the publicly available imputed genotype dataset of all UKB participants. We focused on potential loss-of-function variants that were associated with a specific gene and reached genome-wide significance ($p<=10^{-8}$).

RESULTS: Few phenotypes showed associations that met our criteria; however, certain associations were both significant and biologically plausible, particularly in rare variants. For example, Income Score was associated with a missense mutation in MYH8, a gene associated with skeletal muscle development as well as a rare Mendelian disorder. Additionally, Crime Score was associated with a missense mutation in CCR2, a gene associated with inflammation that has also been shown to mediate the effects of juvenile stress on adult immune responses. Variants in two oncogenes (MACC1, DENND1A) were negatively associated with the Living Environment score (not the expected direction).

CONCLUSIONS: Data from the UKB revealed some preliminary findings linking genetic variants to an increased risk of deprivation, but these are generally due to an increased risk of disease states that may increase one's social risk (e.g. muscle diseases and the ability to work). The UKB is mainly a European population, so findings may not be applicable across other ethnicities who are generally over-represented in more deprived areas. One must consider that associations do not prove causation, and that the findings are preliminary and would require confirmation through both replication in other datasets and further exploration of the biology they represent. Genetics do not explain social determinants of health, but may begin to explain how they affect different people or populations or how those populations react to or adapt to adverse social situations. Sequencing larger and more diverse populations should help make these explanations clearer.

SOCIAL DETERMINANTS OF HEALTH IN A FEDERALLY QUALIFIED HEALTH CENTER: SCREENING, IDENTIFICATION OF NEEDS, AND DOCUMENTATION OF Z CODES.

Iman Sharif[1]; Jennifer Norton[4]; Judd H. Anderman[2]; Isaac Dapkins[3]. [1]Pediatrics, NYU Langone, Brooklyn, NY; [2]Quality Improvement, Family Health Centers at NYU Langone, Brooklyn, NY; [3]Family Health Centers at NYU Langone, NYU, Brooklyn, NY; [4]Population Health, NYU Langone Health, New York, NY. (Control ID #3391093)

BACKGROUND: Payors are increasingly recognizing that social determinants of health(SDH) impact on health outcomes and healthcare costs. Z codes can be used to document and stratify patients into risk pools according to SDH. We report on the impact of SDH screening implementation in a federally qualified health center network on the use of Z codes to document SDH. In this study, we describe the prevalence of SDH screening by department, the prevalence of documented SDH, and the prevalence of documented Z codes for each SDH.

METHODS: In October 2017, we initiated SDH screening throughout, but focusing on the internal medicine and women's health departments of a large FQHC network (12 service delivery sites) using the OCHIN tool embedded in the elecrtonic health record. In November 2019, we retrieved the following variables from record: % of all patients who were screened, number of patients screened annually by department, % of positive screens (+ response to any question), % abnormal screens(response that triggers a best practice alert to the treating provider), and documentation of a Z code for positive or abnormal screens.

RESULTS: There were 624,007 encounters over a 2 year study period; 2,844 patients were screened: 194 in 2017, 1068 in 2018;1644 in 2019. Overall, there were 3052 screening events (some patients received multiple screens). The majority of screening events occurred in women's health [1961(64%)], followed by adult medicine[874(29%)]. Overall, 2350(77%) of screens were "positive", of which 433 had no "abnormal" results and hence did not trigger a best practice alert. Of these 433, the most common positive items were: social isolation(63%), stress(44%), financial resource strain(8%), moved 2+ times(7%). There were 1923(63%) abnormal screens. The top 10 abnormal items in Women's Health and Adult Medicine were: Education less than high school(36% and 37%), physical activity <140 minutes(23% and 25%), hard to pay for medicine/medical care(13% and 26%), hard to pay for utilities(14% and 23%), hard to pay for food(13% and 21%), hard to pay for health insurance(11% and 22%), concerns about housing quality(3% and 9%), hard to pay child care(5% and 5%), exposure to violence(4% and 3%), never get together with family/friends(3% and 3%). Overall, encounters with an SDH screen were more likely to have a documented Z code:26% vs. 1%. Z codes were documented for the following documented needs: insufficient social insurance(53%); lack of access to health care(51%), homelessness(49%), inadequate family support(40%), lack of physical exercise(37%), underachievement in school(34%), personal history of abuse(31%), lack of assistance for care at home(29%), inadequate food supply(1%).

CONCLUSIONS: Presence of a documented SDH screen was associated with documentation of Z codes, however documentation was missing more than half the time for most documented needs. The drivers of Z

code documentation deserve further exploration. Qualitative interviews and focus groups with providers may be useful.

SOCIAL DETERMINANTS OF HEALTH PREDICT HEALTH CARE UTILIZATION AND QUALITY OF CARE AMONG INSURED PATIENTS.

Ana M. Palacio[1,2]; Stephen DeGennaro[1]; David Seo[1]; Leonardo Tamariz[1,2]. [1]Medicine, University of Miami, Miami, FL; [2]GRECC, Miami VA Health System, Miami, FL. (Control ID #3392108)

BACKGROUND: Social determinants of health (SDoH) have been associated with worst clinical outcomes prompting calls for health systems to collect and address social risk. There is less evidence on the impact that SDOH have on health care utilization and quality of care among insured patients. The purpose of this study is to fill these knowledge gaps and assist in the understanding of how health systems could address SDoH.

METHODS: We conducted a retrospective cohort study of insured patients seen at a primary care clinic at UHealth University of Miami Health System who answered a SDoH survey between September 2016 and April 2019 and had at least 12 months of follow up data. The survey included SDoH domains recommended by the AHA position statement and by the National Academy of Science, including demographic variables, education, financial strain, stress, social isolation, health literacy, health behaviors. We collected clinical and health care utilization variables from the UHealth data warehouse. Using co-factorial analysis and linear regression we calculated a SDoH score that included survey and zip code-based income data and divided the score into quartiles. We used linear regression adjusted for age, gender and charlson score to evaluate the relationship between the SDoH score and mean hospital admissions, mean number of no shows, outpatient visits in 12 months, length of stay, HbA1C, and blood pressure.

RESULTS: The table below summarizes the results amongst the 7,226 UHealth patients who met eligibility criteria. In adjusted models, increasing social risk was independently associated to belonging to a racial/ethnic minority, to higher number of hospital admissions and longer length of stay and to higher probability of no showing for outpatient visits. In addition, the SDoH score was associated to quality of care metrics for diabetes and blood pressure control.

CONCLUSIONS: Conclusions: Increasing social risk score is associated to being female, being a racial/ethnic minority, to underutilize outpatient services and to overutilize in-patient services. The SDoH score identifies patients at risk of poor quality of care. Future analyses should continue to evaluate the mediators of poor health care utilization amongst patients with high social risk.

SOCIAL FACTORS CONTRIBUTE MORE MORTALITY THAN GENETIC OR CLINICAL FACTORS

Leonardo Tamariz[1]; Douglas Conway[2]; Lea Davis[2]; Ana M. Palacio[1]. [1]Medicine, University of Miami, Miami, FL; [2]Vanderbilt, Nashville, TN. (Control ID #3392072)

BACKGROUND: Cardiovascular diseases are prevalent and costly. To develop a preventive strategy it is imperative to identify the contribution of the different factors. There is paucity of data combining clinical, social and genetic factors. Our aim was to evaluate the contribution of cardiovascular risk, social and genetic factors on all-cause mortality.

METHODS: We conducted a retrospective cohort study of primary care patients from a large academic institution. At baseline we estimated the census-based area deprivation index (ADI) as a measure of social risk, genome wide association studies to calculate a coronary artery disease polygenic risk score and measured prevalent cardiovascular disease as well as traditional cardiovascular risk factors. Our primary outcome was all-cause mortality defined as a death flag from the electronic health record or social security death index. We calculated the relative hazard (RH) of each factor in a multivariate model adjusted for prevalent cardiovascular diseases.

RESULTS: We included a total of 38,322 primary care patients with a mean age of 64+/-11 of whom 62% were female and 20% were Black. Increasing ADI was associated with high probability of being Black, having prevalent heart failure and coronary artery disease ($p<0.01$) and increasing cardiovascular risk factors ($p<0.05$). Increasing ADI was associated with a higher polygenic risk score. The table shows the RH and corresponding 95% confidence interval (CI), the ADI was associated with the highest RH of all cause mortality compared to clinical and genetic factors.

CONCLUSIONS: Social factors play a more significant role on all-cause mortality when compared to genetics and clinical factors.

SOCIAL NETWORK CHARACTERISTICS OF PRIMARY CARE PATIENTS ASSOCIATED WITH TOBACCO USE

Jeffrey Rewley[1,2]; Marilyn M. Schapira[5]; Chang Xu[4]; Jaya Aysola[3]. [1]Department of General Internal Medicine, University of Pennsylvania, Philadelphia, PA; [2]Center for Health Equity Research & Promotion, VA Medical Center, Philadelphia, PA; [3]Medicine, Division of General Internal Medicine, University of Pennsylvania, Philadelphia, PA; [4]Medicine, UPenn, Lansdale, PA; [5]Internal Medicine, University of Pennsylvania, Philadelphia, PA. (Control ID #3391491)

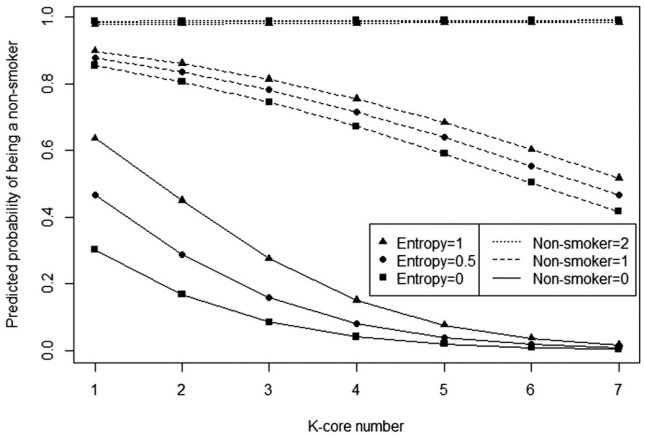
BACKGROUND: Tobacco use is the single most preventable cause of death and is susceptible to social influence. There remains a need to better understand how social network structure relates to tobacco use. This study examined how network measures relate to tobacco use among primary care patients.

METHODS: We conducted enrolled 55 primary care patients (egos) and 153 of their nominated friend/family (alters) through respondent driven sampling. We assessed their demographic and socioeconomic characteristics, the nature and structure of their social ties, self-efficacy, perceived social supports, social norms, and tobacco use. We calculated network metrics for each participant based on their reported network: density, maximum k-core number, and entropy of communication frequency between social ties. Low entropy and high k-core number collectively indicate a network structure that exhibits high cliquishness. We fit a generalized estimating equation, clustered on a participant's original recruiting ego, to estimate whether a participant *did not smoke*.

RESULTS: Participants nominated an average of 5.7 alters (SD=3.1) and 0.87 (SD=1.0) of an ego's enrolled alters, on average, self-identified as smokers. We observed significant effects of k-core number (OR = 0.6 95% CI: 0.5,0.8), entropy (OR = 1.9 95% CI: 1.1,3.5), and the number of alters self-identified as non- smokers (OR = 4.4 95% CI: 2.1,9.4). When we include interactions between k-core number and entropy with the number of non-smokers we find that all three main effects disappear, and both interaction effects are significant. We find that when one nominates two or more alters who are non-smokers, entropy and k-core number does not affect the likelihood of being a non-smoker. However, when one nominates 1 or 0 non- smokers, increasing k-core number and decreasing entropy are strongly associated with a decreasing likelihood of being a non-smoker.

CONCLUSIONS: Having two or more ties to non-smokers, protects one from smoking. When one has 1 or more ties to smokers, one's susceptibility to smoking can be overcome by having a less-cliquish social

network. Network characteristics may help identify individuals at-risk of smoking as well as inform interventions that leverage network structure to promote smoking cessation.



SOCIAL SUPPORT IS ASSOCIATED WITH LOWER ODDS OF HCV-COINFECTION AMONG PEOPLE LIVING WITH HIV WITH POOR RETENTION IN CARE IN LOS ANGELES

Sae Takada[2]; Terry Nakazono[2]; Debika Bhattacharya[3]; Susan Ettner[2]; Danielle Seiden[2]; Robert Weiss[1]; William E. Cunningham[2]. [1]Biostatistics, UCLA Fielding School of Public Health, Los Angeles, CA; [2]Medicine, University of California, Los Angeles, Los Angeles, CA; [3]Infectious Diseases, University of California, Los Angeles, Los Angeles, CA. (Control ID #3392238)

BACKGROUND: Social support is a social determinant of health that can mitigate adverse effects of other risk factors for health. Hepatitis C virus (HCV) coinfection affects up to a quarter of people living with HIV (PLWH) in the US as they share multiple predisposing factors such as substance use and material deprivation. It results in increased morbidity and low antiretroviral therapy adherence. We assessed whether social support may be associated with lower risk of HCV co-infection among a diverse and vulnerable cohort of PLWH in Los Angeles.

METHODS: We analyzed cross-sectional data collected in the CHAMPS cohort from adult PLWH experiencing poor retention in care (defined as having viral load >200 copies/mL and three or fewer routine HIV care visits in 12 months) in community-based clinics in Los Angeles County between 2016 and 2018. We assessed (1) social support using a validated scale and (2) whether the participant had been diagnosed with HCV per participant report. We used multivariable logistic regression to estimate the association between HCV co-infection and social support, adjusting for sociodemographics, substance use, competing needs, and SF12 mental health composite score.

RESULTS: Of 567 participants, 457 (81%) identified as cisgender men, 80 (14%) as cisgender women, 23 (4%) as transgender women, and 3 (0.5%) as transgender men. Mean age was 49 (SD 11.7), 210 (46%) identified as Black/African American and 185 (40%) identified as Latino/Hispanic, 189 (34%) reported any substance use and 9 (2%) reported injection drug use. Ninety-six (17%) reported HCV co-infection. Participants reported a mean social support score of 2.8 (SD 1.2) and mean of 1.3 (SD 0.6) out of five competing needs. In the adjusted model, those reporting higher social support scores were less likely to have HCV co-infection (aOR=0.77, 95%CI=0.62 – 0.97).

CONCLUSIONS: Among racially/ethnically diverse PLWH experiencing poor engagement in care, those reporting higher social support were less likely to be co-infected with HCV. Our results suggest that social support may be a critical component for prevention and management HIV/HCV co-infection and has implications for HCV-related comorbidities, including cirrhosis and end stage liver disease.

SOCIODEMOGRAPHIC AND HEALTH DIFFERENCES OF MONOLINGUAL AND BILINGUAL MEXICAN AMERICANS

2Stephanie Denise Sison[1]; Stephanie Large[2]; Marcela Davila[2]; Esther Oh[3]; Sid O'Bryant[2]; Leigh Johnson[2]. [1]Department of Internal Medicine, Johns Hopkins Bayview, Baltimore, MD; [2]Institute for Translational Research, University of North Texas Health Science Center, Fort Worth, TX; [3]Division of Geriatric Medicine and Gerontology, Johns Hopkins University School of Medicine, Baltimore, MD. (Control ID #3365814)

BACKGROUND: One in three Latinos living in the United States (US) are not fluent in English and consider themselves Spanish speakers only. Lack of English proficiency has been recognized as a factor associated with decreased access to health care, poorer reported health outcomes and increased mental health issues. The objective of this study was to examine social, demographic and health differences among Mexican Americans living in the US based on their linguistic proficiency (monolingual versus bilingual).

METHODS: Data from 558 Mexican Americans enrolled in the Health and Aging Brain among Latino Elders (HABLE) study were analyzed. Participants aged 50 years or older, who were interviewed in either English or Spanish based on language of preference, were grouped into "monolinguals" (Spanish-speaking only) and "bilinguals" (spoke both English and Spanish). Participants who only spoke English were excluded. T-tests and Chi-Square tests were used to compare differences between monolingual (n=255) and bilingual (n=303) participants.

RESULTS: Compared to bilinguals, monolinguals were older (62.1 (9.0) vs 60.6 (7.8) years old; t(556)=2.06; p=0.043), lived in the US for a shorter period (27.4 (16.8) vs 44.6 (17.8) years; t(546)=-11.54; p<0.001), had fewer years of education (5.7 (3.9) vs 9.5 (4.1) years; t(557)=-11.24; p<0.001), and had lower annual household income ($19,730 (18,223) vs $26,064 (20,984); t(505)=-3.78; p<0.001). Chi-Square tests indicated that more bilinguals owned their place of residence (χ^2_{2df} (N=559)=9.79; p=0.007), received a high school diploma (χ^2_{2df} (N=553)=70.03; p<0.001), and had health coverage (χ^2_{2df} (N=558)=15.12; p<0.001). Interestingly, despite a difference in health coverage, having a primary care physician and affording to go to a doctor were not statistically different between the two groups. In terms of health, monolinguals had higher Beck Anxiety Inventory Scores (6.7 (8.2) vs 5.2 (8.3); t(543)=2.11; p=0.035) and higher Geriatric Depression Scale scores (10.5 (6.9) vs 8.3 (7.2); t(551)=3.734; p<0.001) compared to bilinguals. There was also a statistical difference in self-reported health status among two groups with monolinguals reporting poorer health (χ^2_{2df} (N=558)=14.07; p=0.007) but there was no difference in personal medical history of diabetes, hypertension and high cholesterol.

CONCLUSIONS: The results of this study indicated that monolinguals were older, had fewer years of education, had fewer resources, and had higher anxiety and depression scores compared to bilinguals. Spanish-only speakers, whose language may represent inherent and potential social barriers, may experience more mental health issues than Latinos who speak both Spanish and English.

SOCIOECONOMIC DISPARITIES AFFECTING THE TRANSITION FROM HOSPITAL TO HOME: A MIXED METHODS ANALYSIS

Muskaan Sachdeva[1]; Lianne Jeffs[4]; Chaim M. Bell[3,1]; Karen Okrainec[2,1]. [1]Faculty of Medicine, University of Toronto, Toronto, ON, Canada; [2]General Internal Medicine, University Health Network, Toronto, ON, Canada; [3]Medicine, Sinai Health System, Toronto, ON, Canada; [4]Lunenfeld-Tanenbaum Research Institute Sinai Health, Toronto, ON, Canada. (Control ID #3392352)

BACKGROUND: Socioeconomic differences due to low income has been found to disadvantage patients during care transitions in the United States but evidence remains limited among Canadian patients with publicly funded health-care coverage. The objectives of this study were to 1) measure the association between socioeconomic status (SES) and health outcomes following discharge from hospital and to 2) explore patient and caregiver perspectives on the role of income related disparities on care transitions.

METHODS: A mixed methods secondary analysis was conducted among individuals enrolled in a randomized control trial. Participants were discharged home from 5 hospitals in Ontario, Canada with congestive heart failure (CHF), chronic obstructive pulmonary disease, pneumonia, stroke, hip fracture, hip or knee replacement. Individuals were classified as low income if the annual salary was below $29,000 CND, or between $30,000 to $50,000 CND and supported three or more individuals. Data collected included demographics such as sex, age, diagnosis, disability or language barrier, role of family in caregiving and presence of home care. The association between SES and the following outcomes were evaluated using Chi- square and multivariable analyses: patient experience measures, self-reported patient understanding and adherence to discharge instructions, and unscheduled visits, readmission rates and death up to 3 months post- discharge. Lastly, the influence of income and income-related disparities was analyzed through a deductive direct content analysis of patient and caregiver experiences from post-discharge telephone interviews.

RESULTS: Our cohort of 443 participants included 111 (26%) low income, 120 (27%) who were not considered low income and 212 (48%) who did not want to respond. Most participants had an admission diagnosis of CHF (28%), pneumonia (22%), and hip replacement (21%). Compared to the higher income individuals, those in the low SES category were disproportionately non English or French speaking (28% vs. 6%, $p<0.0001$), prior immigrants (51% vs. 34%, $p<0.0116$), reported limited health literacy (58% vs. 23%, $p<0.0001$), and physical disability (62% vs. 38%, $p<0.0004$). Individuals with low SES were just as likely to report highly on patient experience measures and experience an unscheduled visit or death. However individuals with low SES were less likely to adhere to post-discharge follow-up appointments (39% vs. 52%, $p=0.0480$). Themes identified among the 44 participant interviews included personal finances taking priority over health, difficulties with scheduling and transportation to appointments, inability to afford medications, and the costs involved with family support.

CONCLUSIONS: SES plays an important role during the transition home from hospital, particularly in regards to post-discharge follow-up appointments. Further study is needed to better identify opportunities for supporting patients and their families with transportation, medications, and costs associated with caregiving.

SOMATIC, ANXIETY AND DEPRESSIVE (SAD) SYMPTOMS IN YOUNG ADULT LATINX IMMIGRANTS

Carrie A. Leathers[2,1]; Savina B. Diaz[1]; Rachel N. Gruber[2]; Gloria E. Tran[2]; Daniel J. Driver[2]; Mindy E. Flanagan[2]; Kurt Kroenke[2]. [1]Eskenazi Health, Indianapolis, IN; [2]Medicine, Indiana University, Indianapolis, IN. (Control ID #3390971)

BACKGROUND: Several studies have examined mental health and somatization in Latinxs, but few have looked at symptoms specifically in those living undocumented in the United States. Discrimination and acculturation have previously been linked to worse mental health in immigrants, and somatization, anxiety, and depression are linked to poorer health-related quality of life. Young adult Latinx immigrants may be particularly prone to distress and greater understanding of this vulnerable patient population will guide physicians providing care in the outpatient setting.

METHODS: A self-administered questionnaire was completed by 107 persons from Mexico, Guatemala, El Salvador, and Honduras ages 18-29 in an outpatient primary care setting of a large safety-net healthcare system in the Midwest. Participation rates (> 90% of eligible patients) were high. Somatic, anxiety, and depressive symptoms were measured by the PHQ-14, GAD-7 and PHQ-8, respectively. A composite SAD score (sum score of the 3 scales; range, 0 to 69) was the primary outcome. Acculturation and immigration contextual factors including legal status were measured by additional questions including the Brief Acculturation Scale for Hispanics. Factors associated with SAD symptoms were examined using multivariable linear and logistic regression models.

RESULTS: Most participants had some degree of legal marginalization (83%). Threshold level scores for moderate somatization (37%), anxiety (20%), and depression (25%) were common. Multivariable analyses revealed that 5 factors related to the social context of immigration (worries about discrimination, health care access, employment, deportation of self, and deportation of family) predicted a higher composite "SAD score" (sum of the 3 scales, range 0 to 69). Each additional factor increased the SAD continuous score by 3 points (effect size of 0.21) and increased the likelihood of a high SAD score $\geq$ 20 (OR=1.7; 95% CI, 1.1 to 2.5). Participants who immigrated at a younger age also had higher SAD scores ($p=0.04$). An immigration distress index (IDI), which was a simple count of the 5 factors, predicted distress in a dose-response fashion, with SAD scores in patients with 0, 1, 2, 3, 4, and 5 IDI factors being 8.3, 10.5, 14.8, 17.1, 21.7, and 29.3, respectively. Elevated SAD scores were not associated with patient sex, marital status, education, income, country of origin, degree of acculturation, or DACA status.

CONCLUSIONS: Specific immigration contextual factors and earlier age upon arrival to the U.S. increase somatic, anxiety, and depressive (SAD) symptoms in Latinx young adult primary care patients. SAD and IDI measures are brief and can identify symptoms and concerns potentially amenable to treatment. These may include patient-centered culturally sensitive treatment strategies, symptom focused behavioral and medication therapies, and targeted referrals to community resources.

SPILLOVER EFFECTS OF HIP AND KNEE REPLACEMENT SURGERY BUNDLES IN MEDICARE

Robin H. Wang[1]; Joshua M. Liao[2,3]; Akriti Mishra[1]; Ezekiel J. Emanuel[1,3]; Jingsan Zhu[1,3]; Deborah Cousins[1]; Amol S. Navathe[1,3]. [1]Department of Medical Ethics and Health Policy, University of Pennsylvania, Philadelphia, PA; [2]Department of Medicine, University of Washington School of Medicine, Seattle, WA; [3]Leonard Davis Institute of Health Economics, University of Pennsylvania, Philadelphia, PA. (Control ID #3375825)

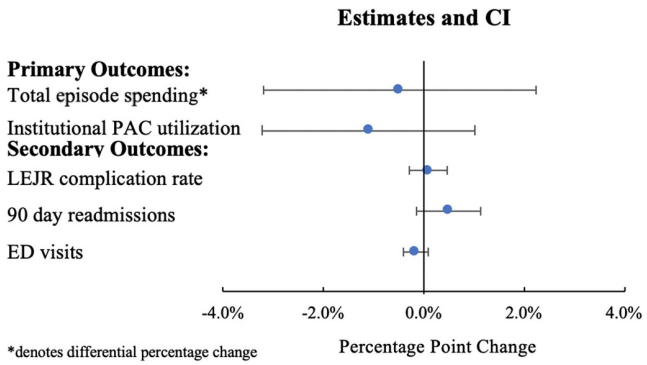
BACKGROUND: As a strategy to improve health care value for joint replacement surgery, mandatory bundled payments have produced 3-4% in episode cost savings with stable quality in the Comprehensive Care for Joint Replacement (CJR) Model. Though CJR targets Medicare fee-for-service patients, it may prompt broad organizational care delivery changes that "spill over" to other patients, such as those insured through private health plans. However, previous literature reporting evidence of spillovers has only used data on a subset of hospitals, thereby potentially compromising the randomized study design of CJR. We addressed these limitations in examining the impact of CJR participation on quality, utilization, and spending outcomes for commercially insured and Medicare Advantage (MA) patients.

METHODS: Our analysis used 2011-2016 Health Care Cost Institute claims encompassing 418,016 MA or commercially insured patients who underwent lower extremity joint replacement (LEJR) surgery at hospitals in 75 CJR markets and 121 non-CJR markets across the US. We leveraged the randomized design of CJR at the market-level to evaluate changes in

LEJR outcomes among CJR hospitals, compared to changes at non- CJR hospitals. Primary outcomes were changes in 90-day total LEJR episode spending and discharge to institutional post-acute care. Additional quality outcomes included the LEJR complication rate, 90-day readmissions rate, and emergency department visit rate. All models were adjusted for patient and market- level factors, and incorporated time fixed-effects and hospital and market random effects.

RESULTS: Patient characteristics, including prior health care utilization, varied between CJR and non-CJR markets, though they were not clinically meaningful. In adjusted analysis, patients who underwent LEJR surgery in CJR and non-CJR markets did not differ with respect to episode spending (difference of -$157, 95% CI -$1,043 to $728, p=0.73) or probability of discharge to institutional post-acute care (difference of -1.1%, 95% CI -3.2% to 1.0 %, p=0.31). Patients in CJR and non-CJR markets also did not differ with respect to changes in other quality outcomes. Stratified and sensitivity analyses yielded similar findings.

CONCLUSIONS: In contrast to findings from previous literature, there was a lack of evidence of program- wide CJR spillovers to patients insured through private health plans. Mandatory payment reforms may have limits in their effects.



STAKEHOLDER PERSPECTIVES ON INCREASING ACCEPTABILITY OF A WEB-BASED HEALTHY LIFESTYLE INTERVENTION FOR OLDER CANCER SURVIVORS

Jessica Adams[1]; Laura Q. Rogers[1]; Wendy Demark-Wahnefried[1]; Yu-Mei Schoenberger[1]; Dorothy Pekmezi[1]; Michelle Martin[2]; Ivan Herbey[1]; Colleen Anusiewicz[1]; Robert Oster[1]; Nataliya Ivankova[1]. [1]University of Alabama at Birmingham, Birmingham, AL; [2]University of Tennessee Health Science Center, Memphis, TN. (Control ID #3374944)

BACKGROUND: To meet the health needs of the growing number of rural and older cancer survivors, we explored the views of multiple stakeholders regarding acceptability and potential benefits of a web-based healthy eating and exercise program among cancer survivors.

METHODS: Individual semi-structured interviews were conducted with representatives from stakeholder groups serving cancer survivors to inform the AiM, PLan, and act on LIFestYles (AMPLIFY) intervention: advocacy groups (n=8), organizations (e.g., industry, health system, etc.; n= 11) and supportive partners (n=8). Data were analyzed using inductive thematic analysis with NVivo 12 Pro.

RESULTS: Stakeholders (16 women, 11 men) identified factors that would enhance acceptability of AMPLIFY for cancer survivors and stakeholders. Themes common across stakeholder groups included increased accessibility for disadvantaged populations, data collection and data accessibility, program quality, and social support. Stakeholders believed rural cancer survivors would particularly benefit from increased program accessibility through web-based delivery, noting a need for program materials to match survivors' education level and be culturally diverse. At the same time, stakeholders expressed different views on the acceptability of web-based delivery for older cancer survivors, with the majority endorsing convenience as a factor promoting use among older survivors. All three groups stressed built-in program social support for survivors and accessibility of participant health or outcomes data by advocacy groups, organizations, or participants' physicians as factors increasing acceptability among survivors and stakeholders. Organizations noted the need for a program that was evidence-based and backed by trusted experts and user reviews. Advocacy groups viewed the "off the shelf" quality of the web-based program as an advantage. Both organization and advocacy groups suggested cancer survivor uptake would increase with a program implementation approach that included stakeholder-led physical and virtual resources complementary to the web-based program. Additionally, supportive partners highlighted information reliability, health benefits, goal setting, encouraging text messaging, and being able to exercise in private as factors that would increase AMPLIFY utilization.

CONCLUSIONS: Web-based delivery provides a venue to increase healthy lifestyle program reach for rural and older cancer survivors. Stakeholders serving cancer survivors identified factors that would promote program acceptability and uptake. Exploring the views of multiple stakeholders is useful to inform and enhance dissemination and implementation efforts of such programs among cancer survivors.

STANDARDIZING QUALITY OF VIRTUAL URGENT CARE: AN EXPERIENTIAL ONBOARDING APPROACH USING STANDARDIZED PATIENTS

Daniel Sartori[1]; Viraj Lakdawala[2]; Heather Levitt[1]; Jason Sherwin[4]; Paul Testa[3]; Sondra Zabar[1]. [1]Medicine, NYU Langone Health, Brooklyn, NY; [2]Emergency Medicine, NYU Langone Health, New York, NY; [3]Emergency Medicine, NYU Langone Health, New York, NY; [4]NYU Langone Health, New York, NY. (Control ID #3390572)

BACKGROUND: Virtual Urgent Care (VUC) is a now a common modality for providing real-time assessment and treatment of common medical problems. However, most providers have not had formal telemedicine training or clinical experience. Faculty have little experience with this new modality of healthcare delivery. We created an experiential onboarding program in which standardized patients (SPs) are deployed into a VUC platform to assess and deliver feedback to physicians in an effort to provide individual- level quality assurance and identify program-level areas for improvement.

METHODS: We simulated a synchronous urgent care evaluation of a 25-year-old man with lingering upper respiratory tract symptoms refractory to over-the-counter medications. The SP was trained to strongly request an antibiotic prescription. A mock entry in the electronic medical record, available to providers during the visit, provided demographic, prior medical, pharmacy and allergy information. The encounter was scheduled into a regular 30-minute appointment slot during a routine 8-hour shift. We developed a behaviorally- anchored assessment tool to evaluate core communication, case-specific, and telemedicine-specific skills. Response options comprised 'not done,' 'partly done,' and 'well done.' SPs provided post-encounter verbal feedback to urgent care providers (UCPs), who received a summary report and had an opportunity provide structured feedback regarding the case. A single SP performed 20 / 21 visits.

RESULTS: Twenty-one UCPs, with 2 to 23 years of clinical experience, participated in an announced scheduled visit. UCPs performed 'well done' in Information Gathering (93%) and Relationship Development (99%) domains. All UCPs provided appropriate management plans and did not give antibiotics. In contrast, Education and Counseling skills were less strong (32% 'well done'). Within this domain, few received 'well done' for checking understanding (14%); conveying small bits of information

and summarizing to ensure clarity (9%). Most (71% well done) collaborated with the SP in discussing next steps.

Specific telemedicine skills were infrequently used: only 19% performed a virtual physical exam, 24% utilized the audio/video interface to augment information gathering, 14% optimized technical aspects by assessing sound, video or ensuring a backup plan should video fail.

A subset of UCPs (n=9) provided structured feedback regarding the case. 100% 'somewhat or strongly agreed' that the encounter improved their confidence communicating via the video interface and helped improved telehealth skills.

CONCLUSIONS: This experiential virtual urgent care onboarding program utilizing standardized announced encounters uncovers several areas for improvement within telemedicine-specific and patient education domains. These findings form the basis for dedicated training for virtual urgent care providers to assure quality across the program.

STATE-TO-STATE VARIATION IN MEDICAID COVERAGE OF AND SPENDING ON DIRECT- ACTING ORAL ANTICOAGULANTS

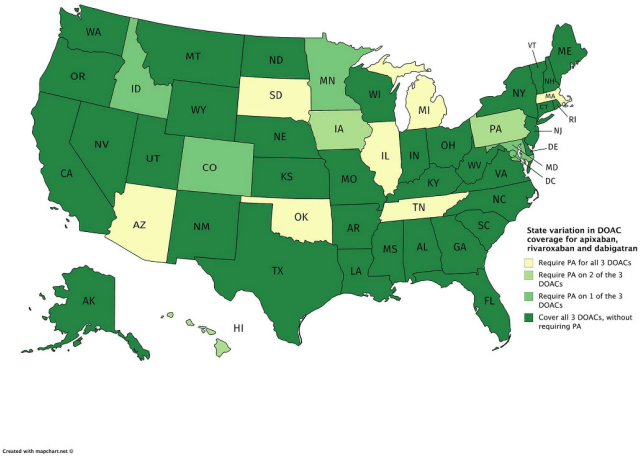
Olufunso Agbalajobi[2]; Shalom Mammen[3]; Utibe R. Essien[1]. [1]Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA; [2]University of Pittsburgh Medical Center, Pittsburgh, PA; [3]University of Pittsburgh, Pittsburgh, PA. (Control ID #3391516)

BACKGROUND: Direct-acting oral anticoagulants (DOACs) have demonstrated greater safety and effectiveness than traditional warfarin, particularly for stroke prevention in patients with atrial fibrillation the most common heart rhythm disorder in the U.S. Prior studies have reported underuse of DOACs in underserved populations (e.g., racial/ethnic minorities and Medicaid enrollees). Yet, little is known about state-to-state variation in Medicaid coverage of DOACs, and whether such variation influences anticoagulation disparities. Thus, we examined contemporary Medicaid coverage of and spending on DOACs.

METHODS: We extracted data from the Medicaid websites of all 50 states in June, 2019, collecting information on coverage of warfarin and DOACs (apixaban, dabigatran, edoxaban, and rivaroxaban). We also identified states that required prior authorization (PA) for DOACs. Additionally, we used Medicaid State Drug Utilization data from all 50 states to assess the total amount reimbursed for each oral anticoagulant from June 2018-June 2019.

RESULTS: As of June 2019, we observed restricted coverage of edoxaban, where 8 states did not cover edoxaban at all and of those that did, 33 required PA. When excluding edoxaban from our assessment, we found that 36 states (72%) did not require PA for any of the other three DOACs. We noted that 7 states required PA on all three DOACs, 3 states required PA on two DOACs, and 4 states required PA on at least one DOAC (Figure). Overall, spending on DOACs was significantly higher than spending on warfarin ($8,646,954), with the highest amount spent on rivaroxaban ($296,568,351), followed by apixaban ($284,049,978), and dabigatran ($20,913,698). States that required PAs did not appear to spend significantly less on DOACs than states without PA.

CONCLUSIONS: Upon review of Medicaid coverage of all 50 states in 2019, we found notable variation in DOAC coverage by state, particularly related to PA requirements. We also found broad variation in Medicaid spending on DOACs by state. Further research on the impact of Medicaid coverage variation on DOAC prescribing and atrial fibrillation-associated outcomes is needed to improve quality and equity of care in this increasingly common condition.



STATIN TREATMENT FOR PRIMARY PREVENTION OF MORTALITY IN PATIENTS AGED >75

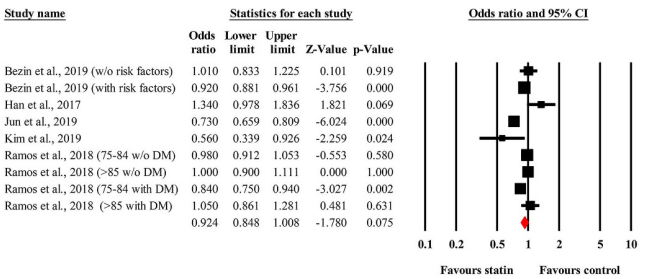
Takayuki Yamada[1]; SACHI TAKAOKA[2]. [1]Internal Medicine, Mount Sinai Beth Israel, New York, NY; [2]generalinternal medicine, Awa Regional Medical Centor, Tateyama, Japan. (Control ID #3373835)

BACKGROUND: The use of statin therapy for secondary prevention has been established in all age groups. However, the role of statin therapy for primary prevention in the elderly remains controversial. The aim of this study is to investigate whether statin for primary prevention is associated with decreased all-cause death in individuals aged > 75 years.

METHODS: We performed a systematic search of PubMed, EMBASE, and the Cochrane Library from inception to December 2019 for studies that assessed the association between statin and mortality in patients aged 75 or older. The primary outcome was all-cause mortality. Odds ratios (ORs) with corresponding 95% confidence interval (CI) were synthesized.

RESULTS: Five studies met the inclusion criteria, for a total of 103,344 patients. During the follow-up period of 4.7-6.0 years, statin administration was not associated with decreased mortality (pooled OR = 0.92, 95% CI 0.85 to 1.01; I2= 79.7 %) (Figure). Egger's test did not show evidence of publication bias.

CONCLUSIONS: Statin treatment for primary prevention among patients aged 75 or older was not associated with decreased mortality. The heterogeneity was high; further studies with risk stratification are needed.



STICKING POINTS: ASSESSING PREVALENCE, PROVIDER AWARENESS AND NURSE PERCEPTIONS ABOUT FINGERSTICK BLOOD GLUCOSE TESTING IN HOSPITALIZED PATIENTS

Caroline Liu[1]; Samir Kamat[1]; Jared Dashevsky[1]; Alyssa Gontzes[1]; Madeline Floodstrand[1]; Anne Linker[2]. [1]Icahn School of Medicine, New York, NY; [2]Division of Hospital Medicine, Icahn School of Medicine, The Mount Sinai Medical Center, New York, NY. (Control ID #3386782)

BACKGROUND: Fingerstick blood glucose (FSBG) testing in the hospital setting allows real-time insulin adjustment, protecting patients from significant hypo/hyperglycemia. Admitted diabetic patients are often placed on sliding scale insulin with four times per day FSBG testing, regardless of home insulin use.

FSBG test materials cost $9 per use (1), and we estimate that $500,000 is spent annually on FSBG supplies for our inpatient teaching service. In patients who are low risk for inadequate glycemic control, FSBG monitoring may add to nursing workload, cause patient discomfort, and waste resources without improving quality of care. We assessed the opportunity to reduce FSBG testing in low risk diabetic patients on the hospital medicine teaching service (HMTS).

METHODS: Our student-run team conducted a multi-faceted assessment of FSBG practices on the HMTS at an urban academic 1,100-bed tertiary care center. This included a point prevalence study (PPS), a provider awareness study (PAS), and a nurse perceptions survey (NPS). The PPS identified the number of patients receiving FSBG monitoring (per the EMR). The PAS tested provider awareness of FSBG orders. Each provider (intern/resident/attending) was given his/her patient list and was asked to identify (in real time) patients with FSBG orders in the last 24 hours, without looking at the EMR. The NPS was a five-question survey of practice patterns/perceived workload attributed to FSBG testing.

RESULTS: The PPS identified that 55 of 103 patients were receiving FSBG monitoring. 31 providers (100% completion) took the PAS. 3/31 correctly identified all patients with FSBG orders. 1/12 interns, 1/12 residents, and 1/7 attendings correctly identified patients with FSBG orders. 42% of interns overestimated and 42% underestimated the percentage of patients on FSBG. 33% of residents overestimated and 50% underestimated the percentage of patients on FSBG. 70% of attendings underestimated the percentage of patients on FSBG. The mean percentage of patients with FSBG testing correctly identified was 66%.

The NPS was administered to 28 nurses with 100% completion. 67.9% reported needing 4-6 minutes to administer a FSBG test, and 17.9% reported requiring 7-10 minutes. 60.7% estimated that fewer than 50% of patients undergoing FSBG testing are given insulin in response to test results.

CONCLUSIONS: Our student-run study demonstrates that FSBG testing is common, that provider awareness of FSBG monitoring is low, and that nurses require 4-10 minutes per fingerstick. In aggregate, FSBG is costly and little research has targeted it as a potential area for waste reduction. As such, FSBG testing represents a potential quality gap. Our work will inform quality improvement interventions to decrease fingersticks that are not changing care, maximize providers' time and hospital resources and improve patient experience.

STIGMA AND PRIMARY CARE ACCESS FOR PATIENTS ON LONG-TERM OPIOIDS

Pooja Lagisetty[1]; Colin macleod[1]; Jennifer Thomas[1]; Stephanie Slat[1]; Amy Bohnert[2]; Kipling Bohnert[3]. [1]Internal Medicine, University of Michigan, Ann Arbor, MI; [2]Anesthesiology, University of Michigan, Ann Arbor, MI; [3]Psychiatry, University of Michigan, Ann Arbor, MI. (Control ID #3390398)

BACKGROUND: Recent data suggest that many primary care physicians (PCPs) are unwilling to accept and care for a new patient who is on long-term opioid therapy. PCPs' reluctance to care for this group is commonly attributed to increased administrative burdens and fears of legal sanctions. Yet, no study has quantified how stigma may influence clinic decisions in caring for patients on a long-term opioid prescription.

METHODS: We used audit "secret shopper" methodology to call primary care clinics across nine different states with varying opioid overdose rates. Each clinic was called twice using two different scenarios. Both scenarios simulated a patient on long-term opioid therapy seeking to schedule a new patient appointment. They differed in the reason their prescription had been discontinued to examine stigma. Scenario A stated that the previous PCP retired while Scenario B indicated that the prior PCP stopped prescribing without providing a specific reason. We measured whetherhad a provider willing to see and potentially prescribe opioids to the patient. If a clinic was unwilling to see the patient for his/her opioid management, we also attempted to schedule an appointment for non-pain related care (e.g. diabetes management). McNemar's test was used to assess differences between scenarios in proportions of prescription and acceptance potential.

RESULTS: 452 clinics had calls completed for both scenarios. Of these, regarding clinic willingness to potentially prescribe opioids, 193 (43%) clinics indicated that their providers would not prescribe opioids in either scenario, 146 (32%) said their providers would be willing to see the patient and may prescribe in both scenarios, and 113 (25%) reported different responses to the two scenarios. In this latter group, clinics had 1.83 greater odds (OR=1.83 CI[1.23,2.76]) of indicating that someone would possibly prescribe if the caller's reason was that their doctor retired compared to if no reason was provided for the stopped prescription. 8.5% of the total paired calls (n=904) resulted in the representative saying they would not prescribe for the patient or even accept them for diabetes management after initially saying they were accepting new patients.

CONCLUSIONS: Among the same clinics, willingness to potentially prescribe opioids for a patient on opioids seeking a new primary care appointment varied significantly based on reason given for needing a new doctor. Additionally, a sizable contingent of the simulated patient calls resulted in denial of care for non-pain related reasons such as diabetes management for patients taking opioids. Our results indicate that beyond administrative requirements and office policies, stigma around opioids and pain management plays a significant role in clinic decision-making when deciding to provide care for patients on opioids for pain.

STRATEGIES FOR PATIENT, FAMILY, AND CAREGIVER ENGAGEMENT: A SCOPING REVIEW AND EVIDENCE MAP

Wendy L. Bennett[1]; Hanan Aboumatar[2]; Samantha I. Pitts[2]; Jeff Day[1]; Kate Holzhauer[2]; Asar Das[2]; Ritu Sharma[4]; Eric B. Bass[3]. [1]Art as Applied to Medicine, Johns Hopkins School of Medicine, Baltimore, MD; [2]Medicine, Johns Hopkins University, School of Medicine, Baltimore, MD; [3]Medicine, Johns Hopkins University, Baltimore, MD; [4]Johns Hopkins Evidence-based Practice Center, Baltimore, MD. (Control ID #3375836)

BACKGROUND: The widely applied Chronic Care Model emphasizes the need for an "informed, activated patient" and a "prepared, proactive team" to improve patient outcomes. We conducted a scoping review to construct a map of the available evidence on patient and family engagement strategies for people with chronic conditions.

METHODS: We adapted a framework for patient and family-caregiver engagement. Key Informants provided input on the framework for categorizing different types of engagement strategies. We searched PubMed and CINAHL from January 2015 to October 2019 to identify systematic reviews of randomized controlled trials and observational studies of strategies for engaging patients and their families or caregivers in active management of chronic conditions (involving more than just education). We also searched for original research on strategies not covered by reviews. Search will be updated February 2020.

RESULTS: We categorized patient and family engagement strategies into direct patient care, health system, and community/policy level strategies. The search yielded 134 systematic reviews. 126 reviews focused on

direct patient care, 5 on the health system level, and none on the community level. Reviews on direct patient care engagement most commonly focused on self-management support (88) and shared decision-making (34), and many used technology-based modalities including mobile health and electronic health record tools. Most included studies in adults (96), while 14 were in children. Self-management support strategies were most commonly tested as part of multi-component interventions. The most frequently reported clinical outcomes were adherence to medication/self-care plans, and chronic disease control (e.g., hemoglobin A1c and blood pressure). For self-management in adults, 26 reviews reported positive effects, 18 reported potential benefits, and 19 reported unclear benefits. None reported any harms. Most of the 34 shared decision-making reviews described multi-component interventions; seven reported positive effects, ten reported potential benefits, eight reported unclear benefits, and one reported no benefits. Health system-level strategies most commonly involved patients and family caregivers serving on patient and community advisory councils and participating in meetings or project teams. No rigorous evaluations were reported on these systems-level strategies. One original article was identified that described patient engagement at the community level and focused on a neighborhood-clinic partnership.

CONCLUSIONS: Patient and family engagement strategies with the most evidence pertained to self-management support. Use of technology to facilitate patient and family engagement is a promising approach. More research is needed to address a big gap in evidence on patient and family engagement at the health system and community/policy levels.

STREET-INVOLVED YOUTH AND YOUNG ADULT PERSPECTIVES ON HARM REDUCTION

Avik Chatterjee[1,2]; Spencer Dunleavy[3]; Isabel Plakas[2]; Jessie M. Gaeta[4]; Elsie Taveras[5]. [1]Internal Medicine, Boston University School of Medicine, Boston, MA; [2]Boston Health Care for the Homeless Program, Boston, MA; [3]Columbia University Vagelos College of Physicians and Surgeons, New York, NY; [4]Medicine, Boston Health Care for the Homeless Program, Boston, MA; [5]Pediatrics, Massachusetts General Hospital, Boston, MA. (Control ID #3391504)

BACKGROUND: The overdose epidemic has not spared youth and young adults (YYA). Despite the presence of life-saving medications for the treatment of opioid use disorder (OUD), in a large cohort in Massachusetts, only 8% of adolescents who experienced a non-fatal opioid-related overdose (NFOD) received medication for OUD (MOUD) in the following year.

For YYA for whom traditional addiction services are not successful or not preferred, harm reduction approaches are promising. Yet, harm reduction strategies—"reduction of negative consequences related to substance use behaviors"—may need to be tailored to preferences of YYAs.

METHODS: In partnership with a Boston-based non-profit organization that provides outreach to YYA experiencing homelessness, we surveyed YYA ≥ 18 years. We asked about demographics, recent substance use and overdose, and knowledge of and access to health care, mental health, and harm reduction services. Surveys took 7-12 minutes to complete.

RESULTS: Fifty-two of 59 individuals (88%) approached by study staff completed the survey; thirty-three (63%) were aged 18-22 and 19 (37%) were ≥ 23. Thirty-four (65%) were male and 11 (21%) reported female gender; 41 (79%) identified as heterosexual. Twenty-three (44%) identified as Black, thirteen (25%) identified as White, fourteen (27%) identified as Latinx and 37 (71%) identified as homeless or unstably housed.

Marijuana (81%) and alcohol (52%) were the most frequently used substances in the last week. Eight (15%) participants reported opioid use in the past 6 months, of whom 3 (38%) reported a history of non-fatal overdose (NFOD)—additionally, 4 (9%) people who denied recent opioid use also reported a history of NFOD.

Fifteen (29%) reported having heard of harm reduction, but only 2 (4%) could define the term on an open- ended question; nine (17%) reported having accessed harm reduction services, and listed local community health centers, a local safety net hospital, a needle exchange program and youth-oriented programs as places where they accessed these services. Twenty-nine (56%) knew what naloxone was, 18 (35%) knew where to get naloxone, but only 4 (8%) usually carried it with them.

Only twenty-two (42%) reported having access to health care services, and 10 (19%) access to mental health services. Cost (33%), waitlists (25%), and unfriendliness to youth (10%) were the most frequent barriers noted to addiction services.

CONCLUSIONS: In this sample of street-involved YYA with high risk of overdose, participants reported familiarity with and interest in specific harm reduction services and substance use treatment, but also reported important barriers in accessing them. Creation of innovative, low-threshold, youth-tailored harm reduction services is warranted.

STRUCTURED INTER-HOSPITAL TRANSFER HANDOFFS TO PREDICT CARE ESCALATION AND MORTALITY - A PROSPECTIVE STUDY

Jonathan D. Kirsch[2]; Michael Rhodes[3]; Karyn Baum[4]; Michael Usher[1]. [1]Department of Medicine/Division of General Internal Medicine, University of Minnesota Medical School, Minneapolis, MN; [2]Internal Medicine, University of Minnesota, Minneapolis, MN; [3]Department of Medicine, University of Minnesota, Minneapolis, MN; [4]Medicine, University of Minnesota, Minneapolis, MN. (Control ID #3392019)

BACKGROUND: Approximately 1.6 million patients are transferred between hospitals yearly, with a disproportionately high mortality. Despite the risk associated with this transition of care, there is no established best practice in coordinating and triaging transfers from outside facilities. The transfer is a process across several hours to several days where physician communication is incongruent from the actual transition of responsibilities and often relies on incomplete documentation. While errors and miscommunication have been documented, the value of structured communication has not been established in prospective studies.

METHODS: We evaluated a convenience sample of 1000 consecutive prospectively collected inter-hospital transfers with a templated transfer note to a representative tertiary referral center. Each note contained structured elements which were extracted and merged to patient outcomes. The primary outcome was in- hospital mortality, with secondary measures including length of stay, and escalation of care within 24 hours. Finally we evaluated the rate of hand-off error: that patients were reported to be stable, but were transferred to the ICU within 6 hours of arrival. We performed multivariate logistic regression to evaluate individual elements prediction of outcome adjusting for age, race, payer, and comorbidities. C-statistic was used to determine how effective hand-off elements predicted inpatient mortality and early transfer to the ICU.

RESULTS: Information contained in the transfer note provided fair prediction of in-hospital mortality In fact relying on information in the dot phrase and age alone provided good prediction of in-hospital hospital

mortality (AUROC: 0.71) and fair prediction of transfer to the ICU within 24 hours (AUROC 0.66). When adjusting for age, demographics, and charleson comorbidity score, individual transfer elements predicted subsequent mortality including whether the patient would be stable throughout transfer (OR 0.34 p <0.001), whether recommendations were given (OR 0.47 p = 0.016), and whether the reason for transfer was to evaluate for transplant (OR 3.59 p = 0.018). Errors occurred in 6% of cases, where patients were documented to be stable, but required critical care within 6 hours of arrival. This was associated with higher rates of inpatient mortality (OR 2.99 p = 0.003)

CONCLUSIONS: In this prospective, observational study of interhospital transfers, we show that a structured hand-off supported by documentation provides valuable information. Both documentation of predicted stability and feedback for care where shown to be associated with lower risk of death. Additionally, in this context, error rates were rare (6%), but associated with higher adjusted mortality. This study supports a growing body of evidence that structured hand-offs and supporting documentation likely improves care and should be applied to high-risk transitions including interhospital transfers.

SUBCLAVIAN AND AXILLARY VEIN ACCESS VS CEPHALIC VEIN CUT DOWN FOR CARDIAC IMPLANTABLE ELECTRONIC DEVICE LEAD IMPLANTATION: A META- ANALYSIS

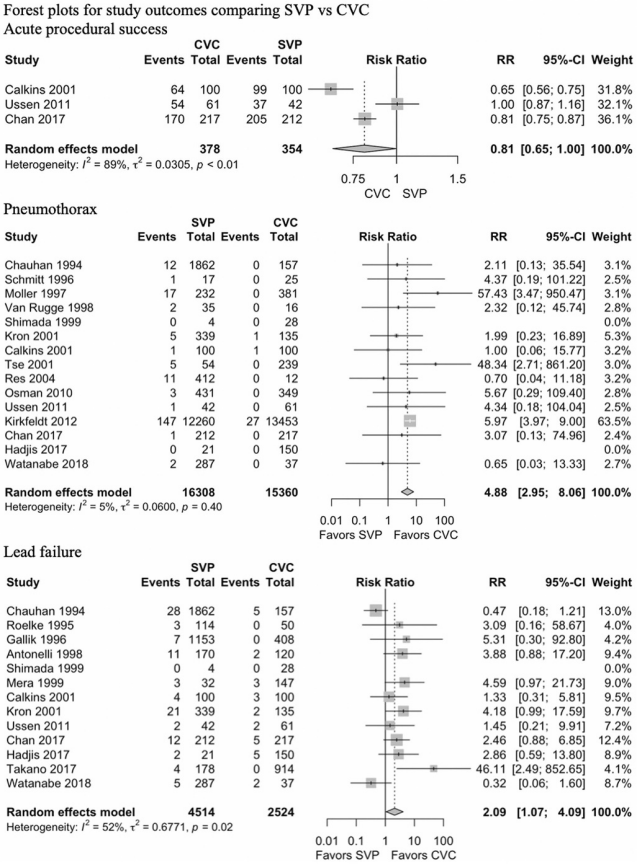
Shannon E. Heffernan[1]; Varunsiri Atti[2]; Mark Mujer[2]; Supratik Rayamajhi[2]. [1]College of Human Medicine, Michigan State University, East Lansing, MI; [2]Internal Medicine, Michigan State University, East Lansing, MI. (Control ID #3346618)

BACKGROUND: Background: Minimally invasive transvenous access is a fundamental step during implantation of cardiac implantable electronic devices (CIEDs). However, the preferred venous access is still subject to ongoing debate and the decision depends on operator experience.

METHODS: Methods: A comprehensive search for studies comparing subclavian vein puncture (SVP) and axillary vein puncture (AVP) vs cephalic vein cutdown (CVC) for CIED implantation was performed in clinicalTrials.gov, PubMed, Cochrane Central Register of Controlled Trials, Google Scholar, Web of Science, EBSCO Services and various scientific conference sessions from inception to July 1st2019. A meta-analysis was performed using random – effects model to calculate risk ratio (RR) and mean difference (MD) with 95% confidence interval (CI).

RESULTS: Results: Twenty-three studies were eligible which included 35,722 patients (SVP= 18,009, AVP= 409 and CVC= 17,304 patients). Compared with CVC, SVP was associated with higher risk of pneumothorax (RR: 4.88, 95%CI: 2.95 – 8.06) and lead failure (RR: 2.09, 95%CI: 1.07 – 4.09) while there was no significant difference in these outcomes when compared with AVP. When compared with AVP, acute procedural success was significantly lower with CVC (RR: 0.80, 95%CI: 0.76 – 0.85). There was no significant difference in other complications such as pocket hematoma/bleeding, device infection and pericardial effusionbetween SVP or AVP when compared with CVC.

CONCLUSIONS: Conclusion: CVC was associated with lower risk of pneumothorax and lead failure compared with SVP. AVP and CVC are both effective approaches for CIED lead implantation and offers the potential to avoid complications usually observed with traditional SVP.



SUBOPTIMAL UTILIZATION OF OSTEOPOROSIS-RELATED SERVICES FOLLOWING HIP FRACTURE IN OLDER ADULTS, 2007-2016

Michelle Shang. Pritzker School of Medicine, University of Chicago, Chicago, IL. (Control ID #3392493)

BACKGROUND: Hip fractures are associated with mortality of 21%-30% in the year following fracture and a 2.5 fold increased risk for incurring a second fracture (3). Previous studies have shown that initiation of pharmacologic intervention following first hip fracture reduces risk of refracture. This retrospective cohort study investigates the treatment patterns following hip fracture and covariate patient characteristics in a nationwide insurance claims database.

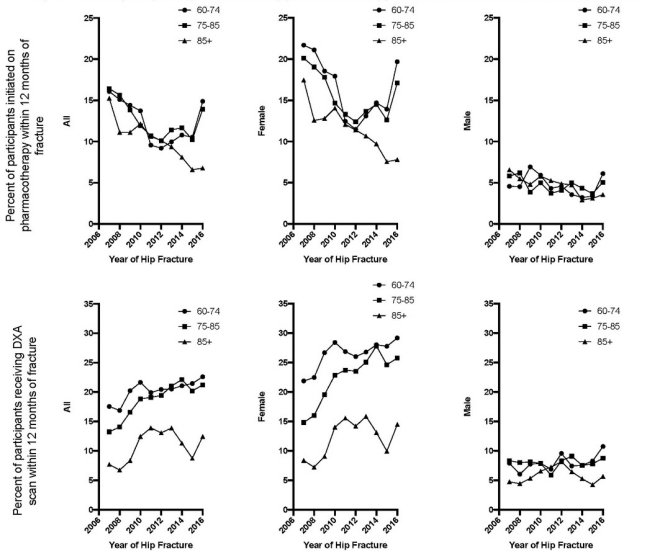
METHODS: PearlDiver is a commercially available database with over 4 billion HIPAA-compliant patient records from the United States. Using ICD-9 and ICD-10 diagnostic codes, we identified a cohort of adults aged 60+ who suffered a hip fracture between 2007 and 2016. We excluded individuals with claims for malignancy, bone pathologies, other fractures, and trauma <12 months before fracture. We identified participants who received a DXA scan or osteoporosis pharmacotherapy by CPT-code or NDC codes. We fitted a multivariate logistic regression to model relative risks of outcomes by sex, age group and year of fracture.

RESULTS: In total, 12,102 (21.5%) of 56,328 total participants utilized at least one osteoporosis-related service (DXA scan or medication) within 12 months following fracture. 3,533 (6.3%) of participants received both recommended services, while 44,226 (78.5%) of participants utilized neither service. Adjusted for sex and age, the chance of medication

initiation decreased 4.6% per year during the study period (RR, 0.954; 95%CI 0.946—0.961; p<0.001) and the chance of DXA scan increased 4.2% per year during in the study period (RR, 1.042; 95% CI, 1.035—1.050). Receipt of a DXA scan following hip fracture was significantly correlated with medication initiation (φ , 0.32; p<0.001).

CONCLUSIONS: We found the overall rate of utilization of any osteoporosis-related services in this cohort to be startlingly low, at 20.4%. Female sex, younger age, and white race predicted for use of osteoporosis medication. Our results emphasize the continued treatment gap for osteoporosis in older adults.

Fig 1. Percentage of participants receiving pharmacotherapy or DXA scan within 12 months of fracture



SUBSTANCE USE DISORDER-RELATED HOSPITALIZATIONS IN A SAFETY-NET HEALTH SYSTEM: TRENDS IN PREVALENCE AND READMISSION

Amber Lindsay[1]; Tyler Winkelman[2]. [1]General Internal Medicine, Hennepin Healthcare, Minneapolis, MN; [2]Internal Medicine, Hennepin County Medical Center, Minneapolis, MN. (Control ID #3391955)

BACKGROUND: Opioid-related hospitalizations increased substantially over the past decade leading to growing efforts to provide services during hospitalization. Hospitalizations related to other substances have received less attention and lags in claims data means most trends do not incorporate data after 2017. Many patients with substance use disorder (SUD) receive care in safety-net health systems, yet the impact of SUD-related hospitalizations in these systems has not been well defined. This study characterizes trends in SUD- related hospitalizations and readmissions in a safety-net health system using standardized admission data over a 12-year period.

METHODS: We conducted a retrospective cohort study of all patients admitted to an urban safety-net hospital between 2008 and 2019. SUD diagnoses were identified based on ICD-9 and 10 codes associated with each admission. We described sociodemographic characteristics of hospitalizations related to SUD compared with those not related to SUD. We examined trends in admissions related to any SUD and stratified analyses by individual and combined SUDs. Finally, we assessed 30-day readmission rates stratified by SUD status. We used STATA MP 15.1 to perform the logistic regressions, controlling for race, age, gender, and year of admission.

RESULTS: Our sample consisted of 206,300 hospitalizations with 60,516 hospitalizations related to SUD. SUD-related hospitalizations were associated with younger age, male gender, and white race/ethnicity. The proportion of hospitalizations associated with any SUD diagnosis increased from 23.1% in 2008 to 34.2% in 2019. Alcohol-related hospitalizations were the most common SUD annually, representing 64.4% of all SUD- related hospitalizations. Among illicit substances, cocaine-related hospitalizations were the most common in 2008 (4.0% of total admissions) while psychostimulants (eg. methamphetamine) were the most common in 2019 (7.6% of total admissions). From 2008 to 2019, psychostimulant-related hospitalizations increased 22- fold (58 to 1,270). Among opioid-related hospitalizations, co-use with psychostimulants increased from 0.3% in 2008 to 35% in 2019. Readmissions were significantly more common among SUD-related hospitalizations (Adjusted odds ratio: 1.12 [95% CI, 1.1-1.2])

CONCLUSIONS: In an urban safety-net hospital, SUD-related admissions steadily increased since 2008 and accounted for one-third of total admissions by 2019. This trend is driven by rising rates of methamphetamine and opioid use combined with steadily high rates of alcohol use. The increasing prevalence of SUD-related admissions has important consequences for safety-net hospitals with regards to resource management and readmission penalties and and further research to expand harm reduction and treatments is needed. EHR data can help health systems adapt to changes in their patient populations as they continue to address the evolving substance crisis

SUBSTANCE USE PATTERNS AND HEALTH PROFILES AMONG US ADULTS WHO USE OPIOIDS, METHAMPHETAMINE OR BOTH, 2015-2018

Riley D. Shearer[1]; Benjamin A. Howell[4]; Gavin Bart[3]; Tyler Winkelman[2]. [1]Medical School, University of Minnesota, Minneapolis, MN; [2]Internal Medicine, Hennepin County Medical Center, Minneapolis, MN; [3]Medicine, Hennepin County Medical Center, Minneapolis, MN; [4]National Clinician Scholars Program, Yale School of Medicine, New Haven, CT. (Control ID #3391566)

BACKGROUND: Methamphetamine use and co-use with opioids has increased substantially, but little is known about the sociodemographic characteristics, substance use patterns, or health profiles of individuals who use methamphetamine. To design effective public health interventions, health care professionals and policymakers need data describing individuals affected by the next wave of the opioid crisis.

METHODS: We used 2015-2018 data from the National Survey on Drug Use and Health and included non- elderly adults aged 18-64 years. We categorized respondents into three groups: opioid use only, methamphetamine use only, or methamphetamine/opioid co-use. Multiple logistic regression models, controlling for sociodemographic factors, were used to compare substance use characteristics and measures of individual health between the three groups.

RESULTS: Between 2015 and 2018 methamphetamine/opioid co-use rose 25% while opioid use alone decreased 23%. People who used methamphetamine were more likely to be unstably housed, low-income, and live in rural areas. Methamphetamine/opioid co-use was associated with an eightfold higher prevalence of injection needle use, a fourfold higher prevalence of HIV/AIDS, and threefold higher prevalence of viral hepatitis compared with opioid use alone. 30% of individuals reporting methamphetamine/opioid co-use had a severe mental illness, twice the prevalence of those using opioids alone.

CONCLUSIONS: Individuals who used methamphetamine (with or without opioids) had more complex substance use and health profiles than individuals who used opioids alone. These findings suggest public health and harm reduction approaches designed to address opioid use may have even greater importance in an era of rising methamphetamine use.

SUGAR ON MY TONGUE: A CASE SERIES OF DKA / HHS HOSPITAL ADMISSIONS AMONGST KNOWN DIABETICS AT A SAFETY-NET HOSPITAL

Anupama M. Kapadia[2]; Meghana Gadgil[1]. [1]Population Health & Internal Medicine, Dell Medical School, Austin, TX; [2]Internal Medicine, Dell Medical School at the University of Texas at Austin, Austin, TX. (Control ID #3387395)

BACKGROUND: Diabetic ketoacidosis (DKA) and hyperosmolar hyperglycemic state (HHS) are serious complications of diabetes mellitus (DM). DKA incidence is rising in the US with 90% of adult cases in known diabetics. This case series illuminate some characteristics of known diabetics admitted with DKA/HHS to inform prevention efforts.

METHODS: Records of all adults admitted in 2018 requiring an insulin drip were pulled from the EMR of our safety-net academic hospital. Four cases per month were selected randomly from this pool. These 48 cases were assessed per inclusion criteria, including laboratory-confirmed DKA or HHS on admission and a DM diagnosis prior to admission. Medical records were then reviewed.

RESULTS: Thirteen out of 48 cases met inclusion criteria. Nine patients were males. Six patients had DM1 and seven patients had DM2. Ages ranged from 24 – 71 with a mean of 46. Per EMR, six patients were non- Hispanic whites, five were Hispanic, and two were black.

Only one patient was uninsured and the remainder had either public or private insurance. Six of thirteen patients were unemployed. Four of 13 patients had unstable housing. Ten of 13 patients had a documented PCP and/or endocrinologist. Primary language was English for 11 patients and Spanish for two. HbA1c ranged from 7.8 – 14 with a mean of 11.2. Eight of the 13 patients had been previously hospitalized for DKA.

12 out of the 13 patients had documented medication nonadherence for a variety of reasons. Seven of 13 patients were seen by a DM educator during the admission. Seven of 13 patients had a documented appointment with PCP or endocrinology prior to discharge. LOS ranged from 1-11 days with a mean of 4.15 days.

CONCLUSIONS: Nearly half of DKA patients in this case series had DM1, which is consistent with the literature. In the US, only 5% of adult diabetics have DM1; DM1 patients represent ~ 59% of DKA cases.

Approximately 45% of US diabetics fail to achieve glycemic targets with high rates of nonadherence. Our data reflects this also, with 92% of cases with medication nonadherence.

Of our cases, ~½ were unemployed, ~ 1/3 had unstable housing, but 92% still had some type of health insurance. The literature suggests DKA patients have higher rates of unstable housing but also that the majority of DM patients with DKA are insured. This suggests that underinsurance may play a role in DKA amongst known diabetics.

Our cases had a male preponderance which is consistent with the literature on DKA admissions.

Our average LOS was 4.15 days, compared with a national average of 3.24 days. Only ~ ½ were seen by a diabetes educator and ~ ½ had follow up scheduled at discharge. These data suggest opportunities for local improvements.

Limitations include the small number of cases and reliance on medical record data. Selection bias was mitigated by a temporally distributed random sampling approach. Further research on DKA/HHS amongst known diabetics will be useful to highlight gaps in local chronic disease care systems.

TAILORED-TO-PLACE MESSAGING WITH THE STEP IT UP MOBILE HEALTH APPLICATION AS A TOOL TO INCREASE PHYSICAL ACTIVITY AND IMPROVE CARDIOVASCULAR HEALTH DISPARITIES AMONG AFRICAN AMERICAN WOMEN

Nithya P. Vijayakumar[1,4]; Sam J. Neally[1]; Kaveri Curlin[1]; Kosuke Tamura[1]; James F. Troendle[1]; Billy S. Collins[1]; Valerie M. Mitchell[1]; Sophie E. Claudel[1]; Joniqua N. Ceasar[1]; Marcus R. Andrews[1]; Yvonne Baumer[1]; Cristhian A. Gutierrez-Huerta[1]; Kathryn G. Tippey[2]; Shayne Giuliano[2]; Regina McCoy[2]; Jessica Zahurak[2]; Tonya Dodge[3]; Tiffany M. Powell-Wiley[1]. [1]National Heart, Lung, and Blood Institute, National Institutes of Health, Bethesda, MD; [2]Connected Health Applications & Interventions (CHAI) Core, The University of North Carolina at Chapel Hill, Chapel Hill, NC; [3]Department of Psychological and Brain Sciences, The George Washington University, Washington, DC, DC; [4]University of Michigan Medical School, Ann Arbor, MI. (Control ID #3372465)

BACKGROUND: Cardiovascular disease (CVD) disparities are attributed in part to the built environment of resource-limited communities. African American (AA) women living in these communities have high CVD prevalence often accompanied by low physical activity (PA).

This study focused on at-risk AA women living in lower socioeconomic status (SES) Washington, DC neighborhoods. We created a mobile health application (app) called Step It Up to determine how app-based coaching tailored to available neighborhood resources (i.e. 'tailored-to-place') can increase PA.

METHODS: This pilot study enrolled a convenience sample of overweight/obese AA women residing in lower SES neighborhoods—DC Wards 5, 7, 8, and Prince George's County—with a goal of 24 participants. Before recruitment, we developed the Step It Up app with UNC CHAI Core using community-based participatory research principles. Participants received the Step It Up app and a Fitbit Charge 2 PA monitor for three weeks. After collecting baseline PA data in week 1, the Step It Up app provided PA self-monitoring tools and sent time- and location-based messages to encourage PA in weeks 2-3. Participants were randomized into one of 3 groups. All groups, including group 1 (control), received timed messages. Groups 2 and 3 (tailored-to-place) also received messages prompted by proximity to PA locations from a database (group 2) or provided by participants themselves (group 3).

Data for analysis excluded minutes with heart rate missing or ≤2SD below the mean, and defined a valid day as ≥10 hours of Fitbit wear. Mean steps/day/week was calculated for each participant and compared between message-type groups using linear mixed models adjusted for age and BMI.

RESULTS: The first 12 participants (n=36 person-weeks) had mean age=57±11 years and body mass index (BMI)=36±6 kg/m2. Groups 1, 2, and 3 (4 participants/group) had 20-21 average valid days of Fitbit wear. At baseline, participants took an average of 7098±2115 steps/day. In week 3 there was an increase of 1993 steps/day compared to week 1. The increase was no greater among tailored-to-place groups (groups 2 and 3) than the control group (Table 1).

CONCLUSIONS: Mobile health apps with remote coaching may contribute to greater PA for at-risk AA women. Preliminary analyses suggest that tailored-to-place messaging may not further enhance this effect. Additional data analysis from the final study sample, including qualitative and survey data, will clarify how tailored-to-place messaging can increase PA and reduce CVD disparities.

TARGETED FAMILY PLANNING SERVICE EXPANSION IN A HIGH RISK POPULATION: A QUALITY IMPROVEMENT INTERVENTION TO INCREASE ACCESS TO FAMILY PLANNING SERVICES FOR PEOPLE WITH SEVERE MENTAL ILLNESS IN AN OUTPATIENT PSYCHIATRIC CLINIC

Subada Soti[1]; Michelle Cleeves[2,1]. [1]University of Colorado School of Medicine, Aurora, CO; [2]GIM, Denver Health and Hospital Authority, Denver, CO. (Control ID #3391340)

BACKGROUND: Patients with severe mental illness (SMI) have higher risks of unintended pregnancies and poor pregnancy outcomes compared to general population, yet are less likely to receive contraception.

Despite having frequent contact with psychiatric services, patients with SMI indicate that a separate family planning (FP) service at their mental health treatment facility would increase their engagement. Thus, our objective was to expand FP services to women and men of childbearing age, who receive out-patient psychiatric care at the Mental Health Center of Denver (MHCD).

METHODS: Denver Health (DH) and MHCD, both safety-net care settings, collaborate to provide a co- located primary care clinic (PCC) within MHCD's largest adult out-patient psychiatric clinic. We leveraged that close working relationship to integrate a monthly half-day FP clinic at the PCC at MHCD. Our services include options counseling and provision of all reversible contraceptive methods as well as referral to DH for permanent sterilization if desired. Expanding these services at a familiar location where clients already receive care reduces many barriers to access for the most vulnerable patients and provides an easy referral resource for psychiatrists, who are not able to address FP needs, yet care for and prescribe teratogenic medication to a high risk population. This service expansion was designed as a quality improvement (QI) project with interventions including collaborating with pharmacy and outreach to MHCD staff to generate patient interest in a walk-in clinic, offering services to MHCD employees to help improve understanding of the FP clinic, reviewing pharmacy work flow to identify patients in need, and expanding outreach to other MHCD service areas, especially their teen and young-adult outreach center.

RESULTS: Using Slicer Dicer Software, we determined that there are 138 women of childbearing age at the PCC at MHCD, only 25 of whom have documented FP usage. Though we cannot access MHCD's data on clients not enrolled at the PCC at MHCD, we can estimate similar, if not worse, uptake in FP services for those patients not engaged in primary care. To date, we have offered 5 half-day FP clinics and seen 9 patients, providing 3 LARCs, and initiating OCPs for 2 patients.

CONCLUSIONS: Reaching patients with SMI and providing preventive services is incredibly challenging, even between institutions with an already close working relationship. Yet, poor prevalence of FP use in patients with SMI highlights the importance of such work. Through rapid implementation of services followed by evaluation and adjustments to our strategy, QI work enables us to continually improve to ideally provide full FP services to as many patients as possible moving forward.

TEACHING HEALTHCARE POLICY TO INTERNAL MEDICINE RESIDENTS DURING MORNING CONFERENCE

Jennifer B. Cowart[1]; Haares Mirzan[1]; J Colt Cowdell[1]; Michael Maniaci[2]; Michele D. Lewis[4]; Jaimie Grega[5]; M Caroline Burton[3]. [1]Internal Medicine, Mayo Clinic Florida, Jacksonville, FL; [2]Internal Medicine, Mayo Clinic in Florida, Jacksonville, FL; [3]Internal Medicine, Mayo Clinic, Rochester, MN; [4]Medicine, Mayo Clinic, Jacksonville, FL; [5]Education - Internal Medicine Residency, Mayo Clinic, Jacksonville, FL. (Control ID #3357576)

BACKGROUND: Physician advocacy and knowledge of healthcare policy are vital elements of medical education and included within the ACGME Core Competency of Systems-Based Practice. However, many GME programs do not incorporate these topics into their trainee education. To address this gap in our program, we introduced a resident curriculum on advocacy and healthcare policy. We administered surveys to determine knowledge and behaviors related to advocacy prior to the course, and to assess for changes following completion of the course.

METHODS: In September 2018, all 47 Internal Medicine residents at a single academic institution were invited to complete an anonymous online survey on belief in the importance of advocacy, knowledge of healthcare policy, and participation in advocacy activities. Response choices ranged from "Strongly disagree" to "Strongly agree" on a 1-to-5 point Likert scale. Residents then underwent a year-long curriculum of monthly lectures during morning conference on the US health insurance system, prescription drug pricing, social determinants of health, and legislative advocacy. After completion of the lectures, residents were re- administered the survey in June 2019.

RESULTS: The pre-survey had 21 respondents (44.7%): 12 PGY-1, 9 PGY-2/3; 12 male, 9 female. The post- survey had 27 respondents (57.4%): 15 PGY-1, 12 PGY-2/3; 9 male, 16 female. Before the course, PGY-2/3s were more likely to be familiar with current healthcare news than PGY-1s [Median±SD; 2.0±0.8 vs 1.0±0.9, p=0.041]. Post-survey results showed increases in describing policy-making [4.0±0.9; p<0.001], knowledge of policy [3.0±0.9; p=0.004], and familiarity with payer sources [4.0±0.9; p<0.001]. Residents continued to agree with the importance of advocacy [4.0±0.9; p=0.149] after the course. There was no change in contacting elected officials (22.2%; p=0.691), participating in advocacy (25.9%; p=0.834), or voting (92.6%; p=0.828). After the course, PGY-2/3s were more likely to report ability to describe policy-making compared to PGY-1s [4.0±0.4 vs 3.0±1.0, p=0.005]. There were no significant differences by gender.

CONCLUSIONS: This study demonstrated the feasibility of administering a healthcare policy curriculum for internal medicine residents during scheduled conferences. Before the course, residents had high levels of belief in the importance of physician advocacy, but low levels of knowledge of healthcare policy and participation in advocacy. After the course, residents showed increased policy knowledge, without increase in advocacy behavior. This suggests that further interventions may be needed to promote resident participation in advocacy. Knowledge improvements occurred across all PGY groups. Future directions for this program include: incorporating non-lecture formats such as flipped classroom and policy article review, increasing the pool of lecturers to improve program sustainability, incorporating resident feedback from the initial year, and implementing a state advocacy leadership day.

TELEMETRY ASSESSMENT OF IN-HOSPITAL ST-ELEVATION MYOCARDIAL INFARCTIONS

Eric G. Mendez, Duc Do, Negeen Shahandeh, Marcella Press. Medicine, UCLA, West Hollywood, CA. (Control ID #3389850)

BACKGROUND: It is estimated that about 10,000 in-hospital ST-segment elevation myocardial infarctions (STEMIs) occur in the United States every year. In most cases, patients are admitted for non-cardiac reasons and develop an acute coronary event during the course of their hospitalization. Due to their unique clinical manifestations, in-hospital STEMIs can often go unrecognized, leading to a delay in treatment and poor patient outcomes. It is imperative for healthcare institutions to implement evidence-based protocols that can improve the management of this clinical entity. The primary obective of this study is to assess the cardiac telemetry of patients diagnosed with in-hospital STEMI and identify any changes prior to the acquisition of the index electrocardiogram (ECG).

METHODS: This is a retrospective review of electronic medical records and telemetry data for adults, 18 years of age and older, who were diagnosed with in-hospital STEMI at UCLA Health hospitals from 2011 through 2012. Patients were identified using the In-hospital STEMI Quality Improvement Project (ISQIP) database by Shahandeh et al. Demographics and index ECG timing were recorded from the ISQIP database. Telemetry rhythm strips with time stamps were acquired through the data compiling tool set created by Do et al. Objective measures were identified by direct review, specifically noting baseline rhythms and electrocardiographic changes at time intervals prior to the index ECG.

RESULTS: A total of four patients were identified from the ISQIP database that had retrievable cardiac telemetry. Rhythm strips were downloaded for the 48-hour interval prior to the acquistion of the 12-lead ECG. After careful review of these strips, 2 of the 4 cases were noted to have telemetry changes well before the in-hospital STEMI was diagnosed. Patient 1 had new ST-segment elevations and depressions 4 hours prior to the index ECG. Patient 2 had new ST-segment elevations and depressions with QRS widening 2.5 hours prior to the index ECG.

CONCLUSIONS: Cardiac monitoring is a critical tool used in hospitals across the United States. In-hospital STEMI is an acute coronary event that is frequently overlooked due to its atypical manifestations. The purpose of this study was to assess whether telemetry could be utilized as an objective measure for this clinical entity. After careful review of the available data, ischemic changes were identified in two cases well before the diagnostic ECG was obtained. These findings indicate a missed opportunity to initiate intervention up to several hours earlier. Although the significance of these results is limited by the small sample size, it is clear that cardiac monitoring can be optimized to help expedite the diagnosis and treatment of in-hospital STEMIs. In addition, quality improvement projects focused on telemetry education for medical staff could also be beneficial.

TEMPERATURE IN UNINFECTED, INFECTED AND BACTEREMIC INPATIENTS

Sidra Speaker[1]; Michael B. Rothberg[2]. [1]Education, Cleveland Clinic Lerner College of Medicine at Case Western Reserve University, Cleveland Heights, OH; [2]Internal Medicine, Cleveland Clinic, Cleveland, OH. (Control ID #3391860)

BACKGROUND: Temperature in the hospital, and its correlation with infection, has not been studied on a large scale. Temperature is known to vary with multiple factors in healthy outpatients, and maximum temperature may provide a more consistent marker for infection than mean or sporadic temperature in inpatients. We used electronic health record (EHR) data to compare temperature distributions for uninfected and infected patients in the inpatient setting.

METHODS: We included EHR data from patients admitted to a Cleveland Clinic hospital in 2017-2018 without active malignancy or immunosuppression. We included one encounter per patient and excluded implausible temperatures. We classified patients as uninfected, infected (but not bacteremic), or bacteremic based on ICD-10 diagnoses. For infected and bacteremic patients, we included only temperatures within ±2 days of the diagnosis.

We used a linear regression to evaluate the association of demographics with maximum temperature in uninfected patients. A second linear regression on temperatures for all patients included infection status as well as demographics and time of day. We calculated maximum temperature interval odds-ratios for each degree rise or fall from the mean temperature.

RESULTS: Of 108,362 patients who met criteria, 698 were excluded due to missing data, leaving 1,698,781 temperatures from 107,673 patients. Overall, 6% were diagnosed with bacteremia and 25% were diagnosed with nonbacteremic infection. Group demographic characteristics were similar: mean age was 63 ± 2 years, 52% were female, 22% Black, and 7% other non-White. Among uninfected inpatients, mean ± SD temperature was 98.06 ± 0.74°F (99% were 97.05-99.07°F) and mean maximum temperature was 98.91 ± 0.71°F (99% were 97.08-100.74°F). Maximum temperature varied slightly by age, sex, race, weight and time of day. Infected and bacteremic patients demonstrated similar demographic and time-of-day effects, but had higher maximum temperatures (0.56°F for infected and 1.93°F for bacteremic patients). There were significant interactions between bacteremia and age and sex. Temperature increases with bacteremia were smaller for older patients (-0.13°F per decade) and women (-0.13°F). At a maximum temperature of 98.0-98.9°F, 2.9% of patients were bacteremic. Interval odds ratios for bacteremia increased at both higher [99-99.9°F (OR: 2.1), 100-100.9°F (OR: 6.5), 101-101.9°F (OR: 12.0), 102-102.9°F (OR: 17.1), ≥103°F (OR: 28.5)] and lower [97-97.9°F (OR: 1.3), 96-96.9°F (OR: 4.4), <96°F (OR: 13.9)] temperatures.

CONCLUSIONS: Mean uninfected inpatient temperature (98.1°F) was lower than generally believed.

Maximum temperatures below 97°F and above 100°F were associated with bacteremia, with more extreme temperatures being most predictive. Temperatures of older patients increased less in response to infection, suggesting that heightened clinical suspicion for bacteremia is appropriate in geriatric patients.

THE ASSOCIATION BETWEEN CARE COORDINATION AND HEALTH CARE UTILIZATION OF ADULT ALABAMA MEDICAID BENEFICIARIES WITH DIABETES

Salmaan Kamal[1]; Caroline Presley[1]; Janet Bronstein[3]; Lucia Juarez[1]; Emily B. Levitan[4]; Andrea Cherrington[2]. [1]Medicine, University of Alabama at Birmingham, Birmingham, AL; [2]Medicine, University of Alabama Birmingham, Birmingham, AL; [3]HCOP, UAB, Birmingham, AL; [4]Epidemiology, University of Alabama at Birmingham, Birmingham, AL. (Control ID #3392170)

BACKGROUND: Diabetes mellitus (DM) is a major cause of morbidity and mortality in the United States. With a prevalence of 9.4%, it is now the seventh-leading cause of death and accounts for greater than $240 billion in health costs annually. Diabetes disproportionately affects low-income populations in Southern states, including Alabama. Care coordination (CC) has been proposed as a way to improve health outcomes and reduce health care utilization (HCU). This study explores the relationship between CC efforts and HCU among adult Medicaid recipients living with DM in Alabama.

METHODS: This was a cohort analysis as part of a larger observational study of adults with diabetes covered by Alabama Medicaid, linking survey data to Medicaid claims data. Receipt of CC was assessed with the question "Has a care coordinator, healthcare outreach worker, or other health care professional from your health plan contacted you to talk about your health, diabetes care or other related issue?." Poisson regression was conducted to test the association of CC and HCU, defined by months with a utilization event (any hospitalization or ambulatory care-sensitive (ACS) hospitalization) in the 6 months after the survey date. Covariates included age, race, ethnicity, gender, education, marital status, rurality, comorbidities, diabetes duration, and insulin use.

RESULTS: A total of 499 participants had complete data with 6 months of continuous enrollment before and after the survey date. Mean age was 53.7 years (SD 9.3) with 19.6% reporting receipt of CC. The sample was mostly female (68.5%), Black (58.5%), with an income less than $10,000 (58.1%), and eligible for Medicaid via disability (91.4%). Compared to those who received CC, those without CC were more likely to be Black (62.1% vs.48.5%; $p<0.05$), rural (36% vs. 33.3%; $p<0.05$), report high levels of social support (63.8% vs. 27.3% High; $p<0.05$), less likely to use insulin (46.9% vs. 55.3%; $p<0.05$), and more likely to have received diabetes education (40.9% vs. 34.8%; $p<0.05$). In unadjusted models, not receiving CC was associated with higher rates of any hospitalization

(IRR 1.4, 95% CI 1.31-1.49) and of ACS hospitalization (IRR 1.51, 95% CI 1.23-1.79). In models adjusting for covariates, not receiving CC was associated with higher rates of any hospitalization (IRR 1.25, 95% CI 1.16-1.35) but not for ACS hospitalizations (IRR 1.1, 95% CI 0.8-1.39).

CONCLUSIONS: In our study of Alabama Medicaid beneficiaries with diabetes, CC was associated with a lower incidence of any hospitalizations over a 6-month period even after adjusting for demographic and clinical variables. Black participants and rural participants were significantly less likely to report CC services, while individuals on insulin and reporting low social support were more likely to receive CC. More studies are needed to examine the causal relationship between CC and HCU, the types of CC that are most effective in reducing hospitalizations, and the cost-effectiveness of these programs.

THE ASSOCIATION BETWEEN CLINICALLY ADMINISTERED OPIOIDS AND DISCHARGE OPIOID PRESCRIPTION WITHIN THE URGENT CARE SETTING: A RETROSPECTIVE COHORT STUDY IN ACADEMIC SAFETY-NET HEALTHCARE INSTITUTION

Susan L. Calcaterra[1]; Yingbo Lou[2]; Lindsey E. Fish[2]; Rachel Everhart[2]; Rebecca Hanratty[3]. [1]Medicine, University of Colorado, Aurora, CO; [2]Department of General Internal Medicine, Denver Health and Hospital and University of Colorado, Denver, CO; [3]General Internal Medicine, Denver Health, Denver, CO. (Control ID #3387943)

BACKGROUND: Emergency departments increasingly utilize nonopioid analgesics to manage acute pain and minimize opioid-related harms. Urgent care centers, commonly staffed by internists and family medicine trained physicians, are rapidly expanding to lower costs, offload busy emergency departments, and provide efficient access to healthcare. Musculoskeletal pain, back pain, headache, and abdominal pain are frequent complaints reported by patients cared for in acute care settings and are commonly treated with oral or intravenous opioids for acute pain control. Little is known about opioid prescribing in urgent care settings. This study assessed the association between in-clinic opioid administration, opioid receipt at discharge, and progression to chronic opioid use among urgent care patients.

METHODS: This was a retrospective cohort study of patients 20 years or older, not on opioid medications, who presented for care to one of two urgent care clinics within a safety-net healthcare system from June 1, 2016 to April 30, 2019. We examined the association between receipt of a clinically administered opioid (CAM-opioid) and opioid receipt at discharge. We also examined the association between receipt of CAM-opioids and progression to chronic opioid use defined as a "90-day or greater supply of non-parenteral opioids with less than a 30-day gap in supply within a 180-day period."

RESULTS: The study sample included 34,978 patients, of which 13.8% (n = 4,842) received CAM-opioids and 86.2% (n = 30,136) did not receive CAM-opioids. After adjusting for age, gender, race/ethnicity, insurance, and pain diagnosis, patients with CAM-opioids were more likely to receive opioids at discharge compared to patients without CAM-opioids (aOR = 12.30, 95% CI 11.44-13.23). Patients with fractures or joint dislocations (aOR = 1.46, 95% CI 1.32 – 1.61) or renal colic (aOR = 8.60, 95% CI 6.89 – 1.74) were more likely to receive an opioid prescription at discharge compared to patients with acute or chronic radicular back pain (ref). Older patients were more likely to receive an opioid prescription at discharge (aOR = 1.01, 95% CI 1.01 – 1.01). Patients with gastroparesis (aOR = 0.62, 95% CI 0.54 – 0.71) or migraines (aOR 0.37, 95% CI 0.30 – 0.45) were less likely to receive an opioid prescription at discharge compared to patients with acute or chronic radicular back pain (ref). Among a selected cohort of patients, CAM-opioids were associated with progression to chronic opioid use (aOR = 2.12, 95% CI 1.66 – 2.71).

CONCLUSIONS: CAM-opioids were strongly associated with opioid receipt at discharge and with progression to chronic opioid use. CAM-opioid receipt during an urgent care encounter could drive availability of prescription opioids for diversion, overdose, physical dependence on opioids, and the development of opioid use disorder. Increased use of nonopioid analgesics in urgent care would likely reduce this association and associated public health harms.

THE ASSOCIATION BETWEEN HOSPITAL DISCHARGE AND OPIOID OVERDOSE IN PATIENTS PRESCRIBED CHRONIC OPIOID THERAPY: A SELF-CONTROLLED CASE SERIES

Jennifer Lyden[1,2]; Stanley Xu[3]; Komal J. Narwaney[3]; Jason M. Glanz[3,4]; Ingrid A. Binswanger[3,2]. [1]General Internal Medicine, Denver Health, Denver, CO; [2]Division of General Internal Medicine, University of Colorado, Aurora, CO; [3]Institute for Health Research, Kaiser Permanente, Colorado, Denver, CO; [4]Epidemiology, University of Colorado School of Public Health, Aurora, CO. (Control ID #3387405)

BACKGROUND: Chronic opioid therapy (COT) is common among hospitalized patients. Research has shown an association between time after hospital discharge and overdose death among individuals with a substance use disorder. Little is known about this relationship in patients on COT. We sought to examine the temporal association between hospital discharge and opioid overdose among patients prescribed COT.

METHODS: We conducted a self-controlled case series (SCCS) using electronic health record data from an integrated health system in Colorado. We identified health plan members who were 18 years and older and prescribed COT between January 1, 2006 and April 30, 2019. COT was defined as three or more opioid prescriptions in a 90-day period. Among these patients, we identified all hospitalizations that occurred during the observation period. Patients discharged to a controlled setting (e.g. skilled nursing facility) were excluded. We defined the risk period as calendar days 0-29 after hospital discharge and the control period as days 30-89 after hospital discharge. Overdose events that occurred during the risk and control periods and came to medical attention were identified using ICD-9 and ICD-10 codes. Conditional Poisson regression was used to estimate the incident rate ratio (IRR) for opioid overdose comparing the risk period to the control period. Stratified analyses were also conducted to assess the IRRs by overdose related hospitalizations and hospitalizations due to all other reasons. Only the first hospital discharge for each individual during the study period was included in this analysis.

RESULTS: We identified 5990 unique patients during the study period who met our enrollment criteria with at least one hospitalization while receiving COT. Twenty overdose cases were identified after qualifying hospitalization and were included in the SCCS analysis. The majority of patients were male (55%), white (85%) and ensured by Medicare (65%). The mean age was 62 years (SD, 7.4) The IRR for opioid overdose was 0.25 (95% CI, 0.08 to 0.81) comparing the risk period to the control period. For individuals with an opioid related hospitalization (N=17), the IRR for overdose event was 0.23 (95% CI, 0.06 to 0.87).

CONCLUSIONS: Among individuals prescribed COT, opioid overdose was uncommon after initial hospital discharge. Among patients who experienced an overdose event, the risk of overdose was significantly lower in the 30-day period after hospital discharge than in the control interval regardless of reason for admission (overdose related hospitalization vs. other). However, our sample size was small and limited to one health system; a larger, multisite study is needed to further investigate this association. Additional research is also needed to identify potential clinical care characteristics that may be protective against opioid overdose among patients prescribed COT.

THE ASSOCIATION BETWEEN PROVIDER COMMUNICATION AND PATIENT OUTCOMES DURING INTER-HOSPITAL TRANSFER

Stephanie Mueller[1]; Evan Shannon[2]; Jeffrey L. Schnipper[3]. [1]Medicine, Brigham and Women, Boston, MA; [2]Division of General Internal Medicine, Brigham and Women's Hospital, Boston, MA; [3]Division of General Medicine, Brigham and Women's Hospital, Boston, MA. (Control ID #3384605)

BACKGROUND: Inter-hospital transfer (IHT) exposes patients to risks of discontinuity of care, including errors in communication. To account for limitations of administrative data, we used medical record review to evaluate the association between provider communication during IHT and clinical outcomes.

METHODS: We performed a retrospective analysis of 347 randomly selected patients from a previously gathered cohort of patients ≥ age 18 transferred to the general medical service of a 793-bed tertiary care hospital from another acute care hospital between January, 2005 and September, 2013. Measures of communication during IHT were abstracted via targeted medical record review using a modified validated abstraction tool, and included: (1) Presence of a patient accept note, i.e., a summary of clinical information documented by the *accepting* clinician at time of patient acceptance for transfer; (2) Availability/quality of a transfer summary as documented by the *transferring* clinician at time of transfer, categorized into unavailable, low quality and high quality, based on inclusion of essential data elements; and (3) Documented reason for transfer, categorized into need for specialized care/procedure, second opinion, patient/family preference, or not documented. Data was abstracted by one of four trained clinicians. Outcome measures were collected administratively and included transfer to the ICU within 48-hours of patient arrival and in- hospital mortality. Covariates for adjustment included patient demographics, comorbidity, illness severity, admit year, and timing of arrival. We used descriptive statistics to determine baseline characteristics and performed multivariate logistic regression to obtain the adjusted effect of measures of communication on the composite clinical outcome of ICU transfer or in-hospital mortality. Secondary analyses evaluated each outcome independently.

RESULTS: We found that 208 (59.9%) of IHT patients had an available accept note prior to arrival and 262 (75.5%) had a high quality transfer summary available on arrival. Reasons for transfer were fairly equally distributed between the measured categories. In adjusted analyses, we found that presence of an accept note was associated with lower adjusted odds of ICU transfer/in-hospital mortality (aOR 0.21; 95% CI 0.07-0.61), largely driven by lower adjusted odds of ICU transfer. Availability/quality of a transfer summary and reason for transfer were not significantly associated with the composite outcome or either individually.

CONCLUSIONS: In this evaluation of IHT patients to general medical services, we found that the majority of IHT patients had a documented accept note, arrived with a high-quality transfer summary, and had documented varied reasons for transfer. We found that the presence of an accept note is associated with lower rates of ICU transfer after adjusting for other patient and transfer factors, suggesting that improved intra-hospital communication during IHT may impact patient outcomes.

THE ASSOCIATION BETWEEN SCHIZOPHRENIA AND ADHERENCE TO MEDICATIONS FOR SECONDARY STROKE PREVENTION

Eshita Kapoor[1]; Kathleen Sheehan[1]; Paul Kurdyak[1]; Jiming Fang[2]; Moira Kapral[1]. [1]Medicine, University of Toronto, Toronto, ON, Canada; [2]Institute for Clinical Evaluative Sciences, Toronto, ON, Canada. (Control ID #3390727)

BACKGROUND: Schizophrenia is associated with mortality after stroke, however the reasons for this are not well-understood. We aimed to determine whether there are differences in one-year adherence to secondary stroke prevention therapies among elderly ischemic stroke survivors with and without schizophrenia.

METHODS: Using the Canadian Institute for Health Information Discharge Abstract Database, we identified all patients aged 65 and over who were hospitalized with stroke between 2004 and 2018 in the province of Ontario, Canada. We then used validated algorithms to identify those with schizophrenia and linked to medication databases to identify prescriptions and to vital statistics to identify deaths. In those who filled a prescription for antihypertensive, lipid-lowering, or anticoagulant (for the sub-group with atrial fibrillation) therapy within 3 months of discharge and were alive at one year, we used Chi-square tests to compare the proportion of people with low adherence (defined as a proportion of days covered < 0.4) in those with and without schizophrenia. We used Cox proportional hazard models to estimate the association between schizophrenia and adherence, adjusting for age, sex, comorbid illness, area of residence, and income quintile.

RESULTS: The study sample consisted of 55842 patients, 574 (1.0%) of whom had schizophrenia. Compared to people without schizophrenia, those with schizophrenia were more likely to have poor adherence to antihypertensive (28.0% vs. 18.8%), lipid-lowering (38.6% vs. 29.8%) and anticoagulant therapy (41.1% vs. 32.0%). Schizophrenia remained a significant predictor of adherence even after adjustment for age, sex, comorbid illness, and area of residence.

CONCLUSIONS: Schizophrenia is associated with low adherence to medications for secondary stroke prevention. Future work should focus on interventions to optimize risk factor management in people with comorbid stroke and schizophrenia, with the goal of reducing post-stroke morbidity and mortality.

THE ASSOCIATION OF A NOVEL MEASURE OF PHARMACY ACCESS WITH INITIATION OF ORAL BREAST CANCER THERAPY

Joan Neuner[3]; Yuhong Zhou[1]; Aaron Winn[2]; Liliana E. Pezzin[1]; Ann Nattinger[3]; Nicole Fergestrom[1]; Kirsten Beyer[1]. [1]Institute for Health and Society, Medical College of Wisconsin, Milwaukee, WI; [2]Pharmacy, Medical College of Wisconsin, Milwaukee, WI; [3]Medicine, Medical College of Wisconsin, Milwaukee, WI. (Control ID #3391570)

BACKGROUND: Initiation of important chronic medications is lower than expected across a number of diseases. A few studies in single metropolitan areas suggest that pharmacy accessibility (or pharmacy "deserts") differs within those areas, but little is known about accessibility across larger regions, and even less is known about impacts of pharmacy access on medication use. Adjuvant oral endocrine therapy for 5-10 years with tamoxifen or aromatase inhibitors reduces all-cause mortality, and inexpensive generic formulations are available. We examined a novel national measure of pharmacy accessibility for its association with initiation of endocrine therapy.

METHODS: We conducted a retrospective cohort study of 30,771 postmenopausal breast cancer patients with newly diagnosed non-metastatic estrogen for estrogen receptor or progesterone receptor positive breast cancer from the 2008-2015 SEER-Medicare cancer registry. We identified and located all retail pharmacies in the US and created a measure of pharmacy access which adjusted for supply and demand using a 2-stage floating catchment area approach. We then classified individuals by residence in a census tract based on approximate quartiles of pharmacy access, and examined the association of commercial (ie nonspecialty) pharmacy access with aromatase inhibitor initiation within 3, 6 and 12 months after diagnosis. On initial analyses, the upper two quartiles appeared similar, so subsequent analyses compared the upper half vs lower pharmacy access groups. We used modified Poisson regression to estimate risk ratios and adjusted for demographics (age, race/ethnicity, census tract level

SES), low income insurance subsidy, clinical characteristics (comorbidities, stage, grade and tumor size) and primary cancer treatments (chemotherapy, radiation and surgery) using inverse probability treatment weights, and did sensitivity analysis using doubly robust models.

RESULTS: The cohort was 88.7% white, 59.9% had Stage 1 and 8.3% HER-2 positive cancer, and 23% received a low-income subsidy, Adjuvant endocrine medications were started in 29.9%, 36.4% and 81.7% of patients () within 3, 6 and 12 months, respectively. Within 3 months of diagnosis, compared with those with lower access, breast cancer patients who had high pharmacy access are more likely to initiate treatment (aRR 1.06; 95%CI 1.01-1.11). Results were consistent at 6 and 12 months, however, they declined over time (at 12 months, aRR=1.01; 95% CI 1.00-1.03). The doubly robust models had similar results.

CONCLUSIONS: In a population-based cohort with established access to medical care, timely initiation of an inexpensive oral anticancer agent was associated with a novel measure of pharmacy accessibility even with careful adjustment for clinical factors and socioeconomic status.

THE ASSOCIATION OF GEOGRAPHIC VERSUS PATIENT REPORTED SOCIAL DETERMINANTS OF HEALTH ON MORTALITY IN CARDIOVASCULAR PATIENTS

Sophia Kostelanetz[1]; Chiara Di Gravio[4]; Jonathan S. Schildcrout[4]; Christianne Roumie[2]; Douglas Conway[2]; Sunil Kripalani[3]. [1]Internal Medicine, Vanderbilt University Medical Center, Nashville, TN; [2]General Internal Medicine and Public Health, Vanderbilt University, Nashville, TN; [3]Medicine, Vanderbilt University Medical Center, Nashville, TN; [4]Biostatistics, Vanderbilt University Medical Center, Nashville, TN. (Control ID #3391550)

BACKGROUND: Social determinants of health (SDH) predict patient outcomes and disproportionately impact the health of disadvantaged populations. SDH are often not considered in care due to the challenge of collecting patient-reported data. Community-level SDH, such as the Brokamp Area Deprivation Index (ADI), are more widely available; however, no research has evaluated the predictive validity of this ADI in adults or its association with patient-reported data. We compared patient-reported SDH to a new Area Deprivation Index (Brokamp ADI) to predict mortality in patients admitted for acute coronary syndrome (ACS) and/or acute exacerbation of heart failure (HF).

METHODS: The Vanderbilt Inpatient Cohort Study (VICS) was a 5-year prospective study that enrolled 3000 adult patients at one academic hospital treated for ACS and/or HF between October 2011 and December 2015. SDH patient-reported data were collected, including income range, education, health insurance, and household size. ADI was calculated using census tract level variables of poverty, median income, high school completion, lack of health insurance, assisted income, and vacant housing. The primary outcome was mortality with up to 5 years follow-up. Covariates included age, gender, race, and primary diagnosis (ACS, HF, or both).

RESULTS: The sample was 59% male, 84% Caucasian, and 93% insured; mean household income was $46,600 (SD $30,100). Census-tract (CT) derived Brokamp ADI components were significantly associated with their corresponding patient-reported (PR) variables, including: (1) CT assisted income and below the poverty limit vs PR below the poverty limit (OR 1.48, 95% CI 1.36, 1.61) and (OR 1.45, 95% CI 1.34, 1.58) respectively, (2) CT vs PR high school completion (OR 1.88, 95% CI 1.66, 2.14), (3) CT vs PR health insurance status (OR 1.51, 95% CI 1.24, 1.85), and (4) CT vs PR median income (OR 2.14, 95% CI 1.97, 2.33). During follow-up, mortality was 11% in the ACS group and 37% in the HF group. In the ACS sample, the composite ADI was associated with increased mortality (HR 1.20, 95% CI 1.06, 1.35); in the HF sample, composite ADI appeared to be associated with mortality, however confidence intervals were wide and overlapped 1 (HR 1.08, 95% CI 0.99, 1.18). When analyzing individual SDH components, individual patient reported variables of poverty (ACS and HF/both subgroups), education (ACS subgroup only), and income (ACS and HF/both subgroups) independently predicted mortality; ADI components of lack of health insurance (ACS subgroup only) and income (ACS subgroup only) were independently predictive of mortality.

CONCLUSIONS: Brokamp ADI variables and corresponding PR are significantly associated on all domains, and the composite Brokamp ADI predicts mortality in hospitalized patients with cardiovascular disease. In the absence of available patient-reported data, hospitals could use the composite Brokamp ADI as a surrogate for patient-reported data to enhance risk prediction models of mortality in cardiovascular disease.

THE CARE CONNECTIONS PROGRAM: A RANDOMIZED TRIAL OF COMMUNITY HEALTH WORKERS TO IMPROVE CARE FOR MEDICALLY AND SOCIALLY COMPLEX PATIENTS

Arleen F. Brown[1,4]; Heidi Behforouz[2]; Ami Shah[2]; Jenebah Lewis[2]; Susan Ettner[1]; Courtney Porter[1,4]; Angelina Majeno[1]; David Y. Huang[1]; Stefanie D. Vassar[1,4]; Savanna Carson[1]; Karen J. Kim[4]; Clemens S. Hong[3]. [1]Division of General Internal Medicine and Health Service Research, UCLA, Los Angeles, CA; [2]Department of Health Services, Los Angeles County, Los Angles, CA; [3]Department of Health Services, Los Angeles County, Los Angeles, CA; [4]Olive View-UCLA Medical Center, Los Angeles, CA. (Control ID #3391800)

BACKGROUND: The Care Connections Program (CCP) embedded community health workers (CHWs) in 8 primary care clinics in the Los Angeles County Department of Health Services (LAC DHS). CHWs guided several patient interventions for clinically and socially complex patients, including medication review, health system navigation, home visits, health coaching, care transitions support, social support, and linkages to appropriate resources. We evaluated the effects of CCP on service use and clinical outcomes and solicited perspectives from patients and CHWs on the impact of program participation.

METHODS: Participant eligibility was based on frequent or avoidable acute care service us (emergency department [ED] visits and hospitalizations), the presence of uncontrolled chronic conditions, and provider referral. Eligible patients were randomized to Intervention (INT) versus Usual Care (UC). Information on patient demographic characteristics, service use 12-month pre- and post-enrollment and chronic condition control (for hypertension, diabetes and hyperlipidemia) were collected from administrative data. Service use (inpatient, emergency department, primary care, and specialty visits) and chronic condition control were analyzed using logistic regression models for any healthcare visits in the 12 months post-enrollment adjusting for service use pre-enrollment, patient demographic and clinical characteristics (age, gender, race/ethnicity, homeless status, comorbid conditions, and where appropriate, baseline chronic condition), and enrollment site. Adjusted percentages were calculated post-estimation.

RESULTS: Between April 2015 and October 2017, 1,291 patients were identified and randomized. Mean age was 59.6 years (SD=12.5), 56% were Latino/Hispanic and 29% African American. 6% were homeless, 76% had hypertension, 61% had diabetes, and 53% hyperlipidemia, with a mean Charlson comorbidity score of 2.23 (SD=2.25) before randomization. At baseline, there were no differences between INT and UC in patient characteristics, chronic conditions, or pre-enrollment utilization. At 12 months, there were no significant regression-adjusted differences between INT and UC in rates of hospital admission (I=27.3% vs UC=25.5%; p=0.64), emergency department visits (I=39.2% vs UC=41.4%; p=0.56), specialist visits (I=78.8% vs UC=76.7%; p=0.48), or chronic condition control. There was a significant increase in primary care visits (I=87.2% vs UC=77.4%; p=0.006).

CONCLUSIONS: In the first year after participation in CCP, CHWs assisted in linking high-utilizer patients to primary care, but the program did not influence acute care visits or specialty outpatient care. Additional research is needed to understand the longer-term impact of CHWs on patient service use and outcomes.

THE EFFECT OF CONTEXT ON MINDSET AND IMPRESSION MANAGEMENT IN RESIDENCY TRAINING AND THE IMPLICATIONS FOR ASSESSMENT AND FEEDBACK

Brandon M. Huffman[2]; Frederic Hafferty[3]; Anjali Bhagra[1]; Emily Leasure[2]; Wil L. Santivasi[2]; Adam P. Sawatsky[1]. [1]General Internal Medicine, Mayo Clinic, Rochester, MN; [2]Internal Medicine, Mayo Clinic, Rochester, MN; [3]Program in Professionalism & Ethics, Mayo Clinic, Rochester, MN. (Control ID #3385927)

BACKGROUND: Feedback is valuable for physician growth; medical education conceptualizes feedback as a bidirectional learning conversation. Within this conceptualization, there is a tension between assessment *for* learning and assessment *of* learning. In this study, we explored residents' experiences with this tension and its perceived impact on the authenticity of their clinical performances.

METHODS: We used a constructivist grounded theory approach, informed by Goffman's theory of impression management and Dweck's theory of mindset. These theoretical lenses guided data collection and analysis. We conducted semi-structured interviews with 15 internal medicine residents (5 PGY-1s, 5 PGY-2s, and 5 PGY-3s). Data collection and analysis were conducted simultaneously and iteratively. We applied open and axial codes, wrote analytic memos, and discussed themes and relations between themes. Using constant comparison between our analysis, theory, and newly-gathered data, we refined our categorization of themes and developed a theoretical model to explain our findings. Theoretical saturation was determined by group consensus.

RESULTS: We identified three concepts regarding assessment and feedback. First, residents identified two mindsets when faced with assessment: 1) becoming better physicians, which we labeled a growth mindset, or 2) achieving a good evaluation from an assessor, which we labeled a fixed mindset. Residents described adopting both mindsets, depending on the context. Second, these mindsets influenced residents' impression management: residents with growth mindsets portrayed weaknesses as opportunities for growth and residents with fixed mindsets portrayed competence and hid weaknesses, not wanting to be judged poorly by their assessor. Third, social and structural context affected mindset and impression management. When residents built relationships with faculty through faculty involvement and investment in their growth, creating trust with that faculty, they adopted a growth mindset. When residents focused on formal assessments, with their perceived permanence and future consequences, they adopted a fixed mindset.

CONCLUSIONS: Context affects residents' mindset and impression management. The formal assessment process in medical education alters the context of feedback; this context may cause residents to adopt fixed mindsets and impede their ability to disclose weaknesses. This may decrease the quality of feedback and hinder resident professional identity formation. Relationship-building, through personal involvement (time) and investment (effort) in individual resident growth, may mitigate the effect of formal assessment and promote a growth mindset. Attention to residency structure around assessment, providing space for relationship-building and creating clarity of the purpose and structure of assessment, can help build formative relationships that support effective learning conversations in graduate medical education.

THE EFFECT OF GEOGRAPHIC COHORTING OF INPATIENT TEACHING TEAMS ON ALL- CAUSE MORTALITY

Andrew J. Klein[1]; Clark A. Veet[1]; Amy D. Lu[2]; Amy J. Kennedy[1]; Etsemaye P. Agonafer[3,4]; Thomas Grau[5]; Scott D. Rothenberger[1,6]; Jennifer Corbelli[1]. [1]Division of General Internal Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA; [2]Department of Medicine, San Francisco VA Health Care System, San Francisco, CA; [3]Division of General Internal Medicine and Health Services Research, UCLA, Los Angeles, CA; [4]National Clinician Scholars Program, UCLA, Los Angelos, CA; [5]VA Pittsburgh Health System, Pittsburgh, PA; [6]Center for Research on Health Care Data Center, University of Pittsburgh School of Medicine, Pittsburgh, PA. (Control ID #3391363)

BACKGROUND: Geographic cohorting is a way of structuring hospital admissions such that patients on a given physician team are admitted to a dedicated hospital unit and, through routine, aims to facilitate interprofessional collaboration, provider-patient communication and timely care. After many years of geographic cohorting at our primary academic site, the University of Pittsburgh Medical Center (UPMC) Internal Medicine Residency program transitioned to geographic cohorting at our academic community hospital. We aimed to evaluate the effect of transitioning to geographic cohorting of inpatient teaching teams on hospital readmissions and mortality at an academic community hospital.

METHODS: We conducted an interrupted time series analysis examining patient outcomes before and after the transition to geographic cohorting on inpatient teaching teams at UPMC Shadyside hospital which occurred in November 2017. The observation period spanned from January 2017 through October 2018, allowing for a two-month run-in period (November-December 2017) at the time of intervention. We included all patients discharged from the inpatient teaching teams during this time. We excluded patients admitted to the ICU and observation admissions. Logistic and linear mixed effects models were constructed to assess the impact of this intervention on patient outcomes and their rates of change. Our primary outcome was six month patient mortality adjusted for pertinent patient characteristics and time-varying covariates. Secondary outcomes included hospital length of stay (LOS) and all-cause 7-day and 30-day readmission rate to a UPMC facility.

RESULTS: During our observation period, the inpatient teaching teams at UPMC Shadyside discharged 1861 unique patients (57% white, 53% female, 62% Medicare-insured, mean age 64) with 1716 patients eligible for inclusion in the final adjusted model, including 888 prior to and 911 after our intervention. Overall, we did not see a significant change in slope for 6 month mortality, LOS, 7-day or 30-day readmission rates after adjusting for age, sex, race, insurance status, and Charlson Comorbidity Index (CCI). While the odds of dying within the next 6 months at the end of our observation period were significantly lower than at the start (OR 0.43, 95% CI 0.24-0.79; $p<0.01$), most of the improvement occurred prior to our intervention.

CONCLUSIONS: Geographic cohorting did not significantly improve or worsen patient 6 month mortality, LOS, 7-day and 30-day readmission of our inpatient teaching teams at UPMC Shadyside Hospital. Additional evaluation is needed to better understand the benefits and costs of geographic cohorting with careful consideration of local institutional factors and engagement of key stakeholders.

THE EFFECT OF OUTPATIENT NOTE TEMPLATES ON NOTE QUALITY: NOTE (NOTATION OPTIMIZATION THROUGH TEMPLATE ENGINEERING) RANDOMIZED CLINICAL TRIAL

Jeremy A. Epstein, Joseph Cofrancesco, Mary Catherine Beach, Helene F. Hedian, Sara Mixter, Hsin-Chieh Yeh, Gail Berkenblit. Medicine, Johns Hopkins University School of Medicine, Baltimore, MD. (Control ID #3386598)

BACKGROUND: Physicians express concern with the current state of clinical documentation, deriding copy-forwarding and excess automatically-imported data. Existing literature on note reform is limited,

describing new note templates and/or note-writing education, with evaluation limited to pre-post analyses. The purpose of this study was to compare the quality of outpatient notes from two different templates using a rigorous methodology of a randomized controlled study design based on a standardized, simulated patient encounter.

METHODS: A new note template was designed that combined the APSO (Assessment, Plan, Subjective, Objective) format with strategies to reduce unnecessary data. This new note format was compared with a standard note template in a non-blinded randomized controlled experiment based on a video of a simulated clinical encounter. A corresponding complete health record was created in the training environment of the electronic medical record. Internal medicine residents were randomized to document the simulated encounter using the standard or new note template. Mimicking clinical conditions, residents completed this exercise in place of scheduled patients in the continuity clinic sessions. Residents evaluated their assigned note templates using a survey. The time to note completion and total note length were recorded. All notes produced were graded by three faculty reviewers using the PDQI-9 instrument, a validated rubric for assessing note quality.

RESULTS: 36 residents participated in the study. 19 were randomized to the standard note template, 17 to the new template. The new template generated notes that were shorter in length (103 vs 285 lines, p<0.001) but took the same amount of time to write (19.8 vs 21.6 min, p=0.654). As assessed by a five-point Likert scale, residents from the new template arm rated their notes as having increased visual appeal (4 vs 3, p=0.05) and less redundancy and clutter (4 vs 3, p=0.006). Overall note template satisfaction was not statistically different between templates.

Faculty reviewers, using a five-point Likert scale, rated the standard note as more up-to-date (4.3 vs 2.7, p=0.001), accurate (3.9 vs 2.6, p=0.003), and useful (4 vs 2.8, p=0.002). The new notes were rated as better organized (4.5 vs 3.3, p<0.001). There was no statistical difference in total quality between the two note templates.

CONCLUSIONS: This randomized controlled study examining the impact of note templates on note quality demonstrates the feasibility of using a simulated clinical encounter to test note templates before introduction into clinical practice. The new note template, in comparison to the standard template, generated shorter length notes that were felt to be more visually appealing and less cluttered by the residents who authored them. However, the faculty reviewers found the new notes to be inferior in several measured elements of quality. Total quality was not different between note templates.

THE EFFECTS OF CONTINUITY OF CARE ON HOSPITALIZATIONS AND EMERGENCY DEPARTMENT VISITS IN PATIENTS WITH OBESITY-ASSOCIATED CHRONIC CONDITION

Satya Surbhi[1]; Ming Chen[1]; Sohul Shuvo[1]; James E. Bailey[2,1]. [1]Center for Health System Improvement, College of Medicine, University of Tennessee Health Science Center, Memphis, TN; [2]Medicine and Preventive Medicine, University of Tennessee Health Science Center, Memphis, TN. (Control ID #3391651)

BACKGROUND: Obesity affects nearly half of U.S. adults and is contributing substantially to an epidemic of obesity-associated chronic conditions (OCC) such as diabetes and hypertension. The OCC epidemic is particularly severe in low-income, medically underserved, predominantly African American areas in the southern U.S. Access to a regular provider has shown to be associated with preventable healthcare utilization. However, little is known regarding the impact of continuity of care for patients with OCC, especially for those living in health professional shortage areas (HPSA) in the South. This study examines whether continuity of care protects patients living with OCC and in the subgroup with type 2 diabetes (OCC+T2D) from emergency department (ED) and hospital utilization. The study also evaluates whether continuity of care is associated with lower health care use for 1) African-Americans vs. Whites/Others and 2) patients residing in HPSA vs. non-HPSA.

METHODS: This study is a retrospective cohort analysis of 2015-2018 data from 5 adult hospitals and >50 outpatient clinics in the Mid-South participating in a regional Diabetes, Wellness, and Prevention, Coalition (DWPC) practice-based research network. Adult patients with obesity and ≥1 diagnosed OCC and the subgroup with diabetes (OCC+T2D) were included. Patients were identified during an index visit defined as the first visit from 1/1/2016-12/31/2017. Outcomes were overall and preventable hospitalizations and ED visits, measured in a 1-year follow-up period. Continuity of care was calculated for each patient at the clinic level. Multivariable negative binomial models were used to assess relationships between continuity of care and overall health care use.

RESULTS: A total of 27,265 patients had OCC and 9,135 had OCC+T2D. Patients in both groups were predominantly female and African-American with an average age of 60 years and mean BMI of 37 kg/m^2. Additionally, majority of the study population resided in HPSA or low-income areas. Multivariable analyses showed that among patients with OCC, higher continuity of care was significantly associated with lower incidence of overall and preventable ED visits (Overall: IRR=0.38[CI: 0.26-0.57]; preventable: IRR=0.52 [CI: 0.37-0.72]) and hospitalizations (Overall: IRR=0.48 [CI: 0.33-0.70]; preventable: IRR=0.80 [CI: 0.46-1.38]). Similar associations were found in the OCC+T2D group. In the unadjusted analysis, continuity of care was significantly associated with lower preventable ED use for patients residing in HPSA compared with those not in HPSA (IRR=0.63 [CI: 0.41-0.95]). However, the association was not significant in the adjusted model.

CONCLUSIONS: This study demonstrates that continuity of care may lower preventable and overall hospitalizations and ED visits particularly for patients residing in HPSA and low-income areas. The study findings highlight the importance of improving continuity of care among medically underserved patients with OCC.

THE EFFECTS OF ENROLLMENT IN MEDICARE ADVANTAGE SPECIAL NEEDS PLANS ON MORTALITY AND UTILIZATION FOR PATIENTS WITH END STAGE RENAL DISEASE

Brian Powers[2,6]; Jiali Yan[1]; Jingsan Zhu[1]; Kristin Linn[3]; Sachin Jain[4]; Jennifer L. Kowalski[5]; Amol S. Navathe[1]. [1]Department of Medical Ethics and Health Policy, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]Department of Medicine, Bringham and Women's Hospital, Boston, MA; [3]Department of Biostatistics, Epidemiology, and Informatics, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [4]CareMore Health Systems, Cerritos, CA; [5]Anthem Public Policy Institue, Washington, D.C., DC; [6]Department of Medicine, Harvard Medical School, Boston, MA. (Control ID #3391101)

BACKGROUND: Medicare Advantage (MA) Special Needs Plans (SNPs) were created as an alternative financing and delivery model to improve care and reduce costs for patients with ESRD, but little is known about their impact. This study examined the association between enrollment in ESRD SNPs and mortality and utilization.

METHODS: We combined data from the United States Renal Data System, a national data system on all individuals with ESRD, with paid claims from CareMore Health, an MA plan that offers ESRD SNPs, to create a linked data with detailed clinical and claims data for FFS and CareMore beneficiaries with ESRD from 2010 to 2017. Using this dataset, we identified beneficiaries who switched from FFS Medicare to ESRD SNPs offered by CareMore Health (SNP Enrollees). We then used coarsened exact matching (CEM) to identify a control group of beneficiaries who were clinically similar to the SNP Enrollees during a baseline period FFS enrollment, but who did not switch into an ESRD SNP (FFS

Controls). We matched patients on granular demographic and clinical variables known to impact mortality and utilization (*e.g.* ESRD duration, dialysis modality, and comorbidities) and utilized data from the USRDS to avoid potential bias from differential coding practices in MA. Our prespecified outcomes were mortality and acute care utilization, and we constructed two separate cohorts for these analyses. The mortality cohort included 441 SNP Enrollees matched to 8,519 FFS Controls and the utilization cohort included 370 SNP Enrollees matched to 6,096 FFS Controls. For the mortality cohort, we modeled mortality over three years of follow-up using weighted Cox regression models. For the utilization cohort, we modeled 12-month utilization rates using linear regression models.

RESULTS: The adjusted average hazard ratio (AHR) for mortality for SNP Enrollees was 0.51 (95% CI 0.40 to 0.66) compared to FFS Controls. SNP Enrollees had 7.88 fewer inpatient (IP) bed days (95% CI -9.42 to -6.34, p<0.001), 0.65 fewer IP admissions (95% CI -0.88 to -0.42, p<0.001), 5.51 fewer skilled nursing facility (SNF) days (95% CI -7.0 to -4.03, p<0.001), and 0.14 fewer SNF admissions (95% CI -0.25 to -0.03, p=0.016). There were no significant differences in dialysis days (p=0.131). These findings were robust to sensitivity analyses that included additional clinical variables (*e.g.* access type, laboratory values) and alternative matching approaches (*e.g.* propensity score matching).

CONCLUSIONS: Enrollment in ESRD SNPs was associated with reduced mortality and lower rates of IP and SNF utilization. To our knowledge, this is the first evaluation of ESRD SNPs since the plans were established in 2003. While this study examined SNPs offered by a single health plan, these findings suggest that SNPs may be an effective alternative financing and delivery model for patients with ESRD.

THE EXPERIENCE OF MALE PHYSICIANS WITH SEXUAL AND GENDER-BASED HARASSMENT: A QUALITATIVE STUDY

Amy H. Farkas[1]; Cecilia Scholcoff[2]; Julie L. Machen[3]; Cynthia Kay[4]; Sarah Nickoloff[5]; Kathlyn Fletcher[6]; Jeffrey Jackson[4]. [1]General Internal Medicine, Medical College of Wiscponsin, Milwaukee, WI; [2]Internal Medicine, Medical College of Wisconsin, Milwaukee, WI; [3]Internal Medicine, Dell Medical School, Austin, TX; [4]Internal Medicine, Zablocki VA Medical Center/Medical College of Wisconsin, Milwaukee, WI; [5]Medicine, Medical College of Wisconsin, Milwauke, WI; [6]Internal Medicine, Medical College of Wisconsin/Milwaukee VAMC, Tbd, AL. (Control ID #3373633)

BACKGROUND: Sexual and gender-based harassment are common in medicine. In literature suggest that men report lower rates of harassment compared to their female collogues with rates ranging from 4.2-65.15%. Additionally, there is data to suggest that the negative effects of harassment are consistent across genders, indicating that harassment is a significant problem for male physicians. These numbers suggest that gender-based and sexual harassment are not uncommon among men in medicine and the variability highlights the need for further investigation. The objective of this study was to better understand the experience men have with sexual and gender-based harassment in medicine.

METHODS: We conducted semi-structured interviews of male physicians, from trainees to attendings, at a tertiary care facility. The interview guide was developed after a review of the literature Participants were recruited via email between April and August of 2019. These interviews were transcribed verbatim and, using an iterative coding approach based in grounded theory, were coded and analyzed for themes.

RESULTS: We conducted a total of 16 interviews. Five major themes were identified: 1) Personal experiences of harassment: "massaging shoulders, putting heads on shoulders, talking about their sex lives, inviting me out to drinks," 2) Witnessed harassment: "talking about women's breasts when they're breastfeeding and how huge they are and wow" 3) Characterization of harassment: "I feel with harassment I would feel threatened," 4) Impact of harassment: "my professional license and career and reputation could potentially be on the line for this kind of interaction," and 5) Strategies for responding to harassment: "try to make it as professional as possible." The men reported experiences with sexual and gender-based harassment but were hesitant to define these encounters as such. They had minimal emotional distress from these encounters but worried about their professional reputation and lacked training for how to respond to these encounters. Many had also witnessed their female colleagues being harassed by both male patients and colleagues but did not respond to or stop the harassment when it originated from a colleague.

CONCLUSIONS: We found that men experience sexual harassment differently from women. Most notably, men report less emotional distress from these encounters and often do not define these events as harassment. However, similar to women, men feel unprepared to respond to episodes of harassment against themselves or others. Whether to deter sexual harassment against themselves, or, more commonly, against a female colleague, men can gain the tools to speak up and be part of the solution to sexual harassment in medicine.

THE HEALTH OF INFORMAL CAREGIVERS IN THE UNITED STATES: DOES BURDEN OF RESPONSIBILITY CORRELATE WITH HEALTH OUTCOMES?

Catherine A. Varnum[1]; Benjamin Ware[1]; Fred W. LaPolla[3]; Colleen C. Gillespie[2]; Katherine Chebly[1]. [1]Internal Medicine - Primary Care, NYU Langone School of Medicine, New York, NY; [2]Medicine/DGIMCI, NYU School of Medicine, New York, NY; [3]Health Sciences Library, NYU Langone Health, New York, NY. (Control ID #3388384)

BACKGROUND: Over 43.5 million American adults identify as informal or unpaid caregivers, and represent an essential part of U.S. healthcare infrastructure for disabled or chronically ill persons. "Caregiver burden" is a well-understood phenomenon, with caregivers at increased risk of social isolation and subsequent mental and physical health consequences. Yet little is known about specific mediators of the burdens of caregiving. This study uses data from the 2018 Health Information National Trends Survey (HINTS) to examine health outcomes of informal caregivers in the US as mediated by intensity of caregiving experiences and level of available social support.

METHODS: This cross-sectional study examines the relationships between intensity of caregiving (low versus high) and health outcomes (diagnoses of anxiety, depression, diabetes or hypertension; measures of self-care, health) in a nationally representative sample. Chi square, t-test, linear and logistic regression analyses compared informal caregivers to the general population, and low versus high intensity caregivers. Multivariate modeling among informal caregivers explored effects of social support on these relationships. (SPSS v.25).

RESULTS: Of 3,504 respondents, 12.3% self-identified as unpaid caregivers. They were more likely to have anxiety/depression diagnoses and poor self-care/health ratings, versus the general population. Among the general population, factors significantly associated with poor self-health rating included being a high-intensity caregiver, low education level, and low income. Having emotional/structural support was associated with better self-rated health and self-care, and lower likelihood of an anxiety/depression diagnosis. Among informal caregivers, structural support was associated with better self-care scores and high-intensity caregiving was associated with poorer self-rated health status.

CONCLUSIONS: Our findings demonstrate an overall difference in health outcomes between informal caregivers and the general population, an effect that appears to be modified by intensity of caregiving and presence of social supports. Given our results, we hope physicians will

consider screening known caregivers for intensity of caregiving and existing social support systems.

THE IMPACT OF AN INTERVENTION TO INCREASE HIV PRE-EXPOSURE PROPHYLAXIS (PREP) UPTAKE AMONG PATIENTS WITH SYPHILIS IN A HOSPITAL-BASED GENERAL INTERNAL MEDICINE (GIM) PRIMARY CARE PRACTICE.

Ryan Bonner[1]; Jessica Stewart[3]; Cassandra Pierre[3]; Jessica Taylor[2]. [1]Internal Medicine, Boston Medical Center, Boston, MA; [2]General Internal Medicine, Boston University/Boston Medical Center, Boston, MA; [3]Infectious Diseases, Boston Medical Cnter, Boston, MA. (Control ID #3390876)

BACKGROUND: HIV pre-exposure prophylaxis (PrEP) with daily tenofovir disoproxil fumarate/emtricitabine reduces HIV incidence in people with sexual and/or injection-related risk. PrEP is recommended by the Centers for Disease Control & Prevention (CDC) and the United States Preventive Services Task Force, but uptake by priority populations and in primary care settings has lagged. Systems interventions show promise in identifying PrEP candidates. Syphilis infection is one objective, potent risk for incident HIV infection; notifying primary care providers (PCPs) that their patient(s) with syphilis may be eligible for PrEP could improve PrEP uptake in this high-risk population. The goal of this study is to evaluate the impact of PCP outreach on PrEP uptake among patients with syphilis in an urban, hospital-based primary care practice.

METHODS: The study took place within the GIM primary care practice at Boston Medical Center (BMC) in Boston, MA. The interdisciplinary Massachusetts Department of Public Health-funded BMC PrEP team developed a hospital-wide registry of patients with positive syphilis tests. A PrEP program manager reviews the registry daily to identify PrEP candidates. On 1/1/2019, a new outreach protocol was implemented. GIM PCPs whose patient(s) appear on the registry receive a form message in the electronic medical record alerting them to potential PrEP eligibility and offering institutional PrEP resources.

We performed a retrospective chart review of all HIV-negative GIM patients with a positive syphilis test in a three-month period before and after the start of the intervention in order to compare the proportion of patients who were 1) offered and 2) prescribed PrEP within one and six months of positive syphilis testing. Duration of time from diagnosis to PrEP prescription, appropriateness of syphilis treatment, and adherence to other STI screening guidelines were also assessed.

RESULTS: Positive syphilis serologies were seen in 43 patients in the pre period and 56 in the post period. The population was 41% female, 67% Black and 3% white; 23% identified as Hispanic. The majority of syphilis results were consistent with untreated late latent disease (48%) or prior treated syphilis (39%). Untreated, infectious syphilis (i.e. primary, secondary, or early latent) represented 5% of positive screens. Patients diagnosed with syphilis in the post-intervention period were more likely to have their syphilis treated correctly (81% vs. 68%). Small increases in PrEP offers (7 vs. 6) and prescriptions (5 vs. 3) within 6 months of positive syphilis testing were also observed. Four of five patients starting PrEP in the post period were Black or Hispanic.

CONCLUSIONS: Overall, a multidisciplinary approach to improve access to PrEP among GIM patients with syphilis was associated with more accurate syphilis treatment. Although the increases in PrEP offers and prescriptions seen were small, this protocol shows promise for reaching populations that have historically been excluded from PrEP care.

THE IMPACT OF ELECTRONIC COMMUNICATION OF MEDICATION DISCONTINUATION TO PHARMACIES (CANCELRX) ON MEDICATION ERRORS: A PILOT STUDY

Samantha I. Pitts[1]; Taylor Woodroof[2]; Danielle Pennock[2]; Yushi Yang[2]; Bridgette Thomas[2]; Allen R. Chen[3]. [1]Medicine, Johns Hopkins University, School of Medicine, Baltimore, MD; [2]Johns Hopkins Medicine, Baltimore, MD; [3]Oncology and Pediatrics, Johns Hopkins University, Baltimore, MD. (Control ID #3392437)

BACKGROUND: Adverse Drug Events (ADE) are frequent in ambulatory care, leading to an estimated 4.5 million patient visits each year. Failure to communicate with pharmacies when medications are discontinued leads to unintended dispensing of medications and ADE. A new functionality in electronic health records (EHRs), CancelRx, allows prescribers to send electronic messages to notify pharmacies when medications are discontinued. The primary objective of this study was to evaluate the impact of CancelRx implementation on medication errors, specifically on prescriptions filled or sold after intended discontinuation.

METHODS: We conducted a pilot pre-post evaluation of CancelRx implementation with 14 prescribers in a single practice at an academic medical center during 3 months prior to and following implementation (January 16, 2018 – April 15, 2018 and January 16, 2019 – April 15, 2019, respectively). We used an EHR database report to identify medications e-prescribed in ambulatory care by pilot prescribers to a health system pharmacy and subsequently discontinued in the EHR. These data were matched to fill and sales data from pharmacy management software to determine if the last filled or sold date followed prescription discontinuation in the EHR. A physician and a pharmacist conducted EHR record review for all prescriptions that appeared to have been dispensed following discontinuation in the EHR to determine if the prescriber intended to discontinue the medication. In addition, in the post-implementation period, we reviewed the EHR of a 40% sample of prescriptions reordered within 120 days to determine if any reorders were the result of unintended medication discontinuation at the pharmacy.

RESULTS: Following CancelRx implementation, fewer medications were filled or sold following intended discontinuation [0.4% (2/474) vs 6.6% (13/197), $p < 0.001$] or sold only [0.0% (0/474) vs 3.0% (6/197), $p = 0.001$], but more medications were reordered in the following 120 days [17.5% (83/474) vs 10.2% (20/197), $p = 0.016$]. Within the sample of records reviewed for medications reordered after CancelRx implementation (n=34), 20.6% (7) may have resulted from unintended discontinuation of the prescription at the pharmacy, when a cancellation message was unintended or was sent following erroneous discontinuation of a prescription in the EHR.

CONCLUSIONS: Implementation of CancelRx reduced the number of medications sold to patients following intended discontinuation but may result in medication errors when medications are discontinued in error in the EHR or when unintentional cancellation messages are sent to pharmacies. Larger studies of CancelRx implementation are needed to confirm these findings and identify best practices for implementation.

THE IMPACT OF FAMILIAL SOCIAL NETWORKS ON BODY MASS INDEX IN ADULTS WITH DIABETES

Joni S. Williams[1,2]; Emma Garacci[2]; Oluwatoyin Olukotun[2]; Olaitan Akinboboye[2]; Leonard E. Egede[1,2]. [1]Medicine, Medical College of Wisconsin, Milwaukee, WI; [2]PCOR, Meidcal College of Wisconsin, Milwaukee, WI. (Control ID #3392427)

BACKGROUND: Diabetes mellitus affects approximately 30.3 million individuals in the U.S., where obesity is a leading risk factor for the development of type 2 diabetes. Evidence suggests social support

improves diabetes outcomes as it promotes disease acceptance and enhances self-management and coping, resulting in less stress, better quality of life, and improved clinical endpoints. When perceived as positive, support from social networks has been instrumental in knowledge sharing and informed decision-making among adults with diabetes, leading to improved glycemic control and self-management and reduced complication rates. However, little is known about the impact of familial social networks on Body Mass Index (BMI) among adults with diabetes. Therefore, the aim of this study was to assess the influence of familial social networks on BMI among a nationally representative sample of adults with diabetes.

METHODS: Data from 385 adults from the Midlife Development in the United States (MIDUS) Survey was analyzed. The outcome was BMI analyzed as a continuous and dichotomized variable (≥30 vs. 30), and the predictor was social network activation, which included family support, family strain, and family affectual solidarity as linear and dichotomized variables. Linear and logistic regression models tested the relationship between familial social network and BMI, controlling for age, education, race, education, marital status, income, insurance, and current employment status.

RESULTS: The mean BMI for the sample was 34.0 ± 8.3. Compared to those with no family support or family affectual solidarity, adults with family support (β=-2.62; 95% CI -4.34, -0.91) and family affectual solidary (β=-2.19; 95% CI -3.82, -0.56) had lower BMI in the linear regression models after adjusting for covariates. There were no significant associations between family strain and BMI in the unadjusted (p=0.284) or fully adjusted models (p=0.546). In obese vs. non-obese adults, those with family support had a 39% lower BMI in the unadjusted model (OR=0.61; 95% CI 0.39, 0.96) compared to those reporting no family support. These significant relationships remained in the fully adjusted model, where those with family support had a 54% lower BMI compared to those with no family support (p=0.002). There were no significant associations between family strain and BMI in obese vs. non-obese adults.

CONCLUSIONS: In this nationally representative sample of adults with diabetes, family support was associated with lower odds of obesity. These findings suggest the need for incorporating familial network members in clinical diabetes management to provide support and facilitate improved weight management and also suggest family support as a target for research interventions focused on understanding the role of social networks in self-management among adults with diabetes.

THE IMPACT OF HOSPITALIST EXPERIENCE ON PATIENT LENGTH OF STAY AND COSTS OF CARE

Matthew A. Pappas, Phuc H. Le, Michael B. Rothberg. Center for Value-based Care Research, Cleveland Clinic Foundation, Cleveland, OH. (Control ID #3386677)

BACKGROUND: The hospitalist model of care is associated with decreased length of hospital stay and lower expenditures compared with inpatient care provided by general internists. Whether hospitalist experience is associated with length of stay or costs is important for the field of Hospital Medicine and the health system more broadly. We set out to investigate whether hospitalists improve at reducing costs or length-of-stay as they gain experience.

METHODS: We created a retrospective cohort consisting of inpatient stays under the care of hospitalists in our health system between 1/1/2008 and 6/30/2016 among patients 18 years of age or greater.

We analyzed these data in multiple ways. First, we limited the dataset to hospitalizations during which the patient was cared for by only one physician and used multilevel negative binomial regression, with hospitalizations clustered by physician and with physician experience, physician age, Medicare Severity- Diagnosis Related Group (MS-DRG), and hospital as hospitalization-level covariates. This analysis included 16,398 hospitalizations and 114 physicians. Second, we included patients cared for by multiple hospitalists and calculated a weighted average experience of the physicians over the hospitalization. We tested whether the weighted experience of the physicians involved in each hospitalization predicted length of stay using a multilevel negative binomial regression. This analysis included 27,711 hospitalizations and 115 physicians. Third, we calculated a rolling average length of stay for each provider, with length of stay attributed to the discharging physician. If hospitalists improve at reducing length of stay as they gain experience, rolling average length of stay should decline as physicians gain experience. We tested that hypothesis using fixed- and random-effects models. This analysis included 16,535 observations among 114 physicians.

We repeated these approaches with endpoints of total costs and direct costs of the hospitalization.

RESULTS: Physician experience was associated with higher patient length of stay or no difference, depending on analytic technique. In our first analysis, each additional year of physician experience was associated with a 0.007 day increase in length of stay (p=0.012). When using the weighted experience of all hospitalists involved during the hospitalization, there was no detectable relationship between experience and length of stay (p>0.2). In our within-hospitalist analyses, each year of experience was associated with a 0.020 day increase in length of stay (p<0.001). No analytic method suggested decreasing length of stay with experience. Results were similar for costs: either no detectable change or increased costs, depending on analytic technique.

CONCLUSIONS: Patient length of stay is unlikely to decrease with hospitalist experience, and may increase. For hospital medicine to remain sustainable as a profession, hospitalists may need to contribute in ways other than reducing patient length of stay.

THE IMPACT OF INTERNET SEARCH ON PATIENT SELF-DIAGNOSIS AND TRIAGE

David M. Levine[1]; Ateev Mehrotra[2]. [1]General Internal Medicine and Primary Care, Brigham and Women's Hospital, Boston, MA; [2]Health Care Policy, Harvard Medical School, Boston, MA. (Control ID #3391328)

BACKGROUND: Many Americans use the Internet to search for health information including why they are ill and where they should get care. The value of using search engines is controversial. Search may direct users to inaccurate information and/or increase anxiety (cyberchondria). We assessed the impact of Internet search on a lay person's ability to triage and self-diagnose.

METHODS: Building on prior work, we created 48 case vignettes (<60 words; <6th grade reading level) that included a chief complaint and additional details. The vignettes were in 4 triage categories (emergent, within 1-day, within 1-week, self-care) and included both common (e.g., viral illness) and severe (e.g., heart attack) conditions. Participants were a national sample of lay people who use the Internet. For each vignette, they reported three outcomes: self-triage (emergent, 1-day, 1-week, self-care), top 3 diagnoses, and nervousness/anxiety regarding the case. Participants were then asked to use the Internet in any way they felt useful to research the vignette. After search, they again reported these outcomes and perceived difficulty in finding useful information. Diagnoses were manually reviewed and considered correct if any of the 3 listed diagnoses was correct. To validate the diagnosis and triage assigned, the vignettes were shown to 18 PCPs. We performed multivariable modeling to identify patient factors associated with correct triage and diagnosis.

RESULTS: The PCPs reported the correct triage and diagnosis in 91.2% (95% CI, 89.2-93.2) and 95.7% (95% CI, 94.3-97.0) of vignettes, respectively. 5000 internet searchers (51% female, 76% white, 23% without

college, 52% zero chronic diseases, 72% good/very good health, mean of 2 physician visits in last 6 months) completed a vignette. Mean search time was 12.1 minutes (95% CI, 10.7-13.5). There was no difference in triage accuracy before and after search (74.5% vs 74.1%; difference, -0.4 [95% CI, -1.4-0.6]). Highest rates of correct triage were for emergent (87.0%) and same-day cases (81.3%). There was an increase in diagnostic accuracy before and after search: 49.8% vs 54.0%, difference, 4.2 [95% CI, 3.1-5.3]), with the greatest increase in lower acuity vignettes. Nervousness/anxiety did not change after search but did increase as the case's triage became more emergent (2.6/5, self-care; 3.9/5, emergent). Only 15% of participants changed their diagnosis after search: 10% from incorrect to correct, 5% from correct to incorrect. Factors associated with an increased likelihood of correct diagnosis included female gender (aOR, 1.52 [95% CI, 1.35-1.69]), non-White race/ethnicities (for example Black aOR, 1.74 [95% CI, 1.24-2.44]), and any lower health status (for example poor aOR, 1.94 [95% CI, 1.26-2.98]).

CONCLUSIONS: Among a nationally-representative sample of online Americans, Internet search had no impact on triage or anxiety but improved diagnosis modestly, with large differences among demographic groups.

THE IMPACT OF PATIENT CONTEXTUAL DATA ON PATIENT-PHYSICIAN COMMUNICATION AND PATIENT ACTIVATION: RESULTS FROM A RANDOMIZED CONTROL TRIAL

Jeana Holt[1]; Rachel Cusatis[2]; Aaron Winn[3]; onur asan[4]; Joni S. Williams[5]; Kathryn E. Flynn[5]; Melek Somai[5]; Bradley H. Crotty[6]. [1]Family and Community Medicine, Medical College of Wisconsin, Milwaukee, WI; [2]CIBMTR, Medical College of Wisconsin, Milwaukee, WI; [3]School of Pharmacy, Medical College of Wisconsin, Milwaukee, WI; [4]school of systems and enterprises, stevens institute of technology, Hoboken, NJ; [5]Medicine, Medical College of Wisconsin, Milwaukee, WI; [6]Collaborative for Healthcare Delivery Science, Medical College of Wisconsin, Milwaukee, WI. (Control ID #3391643)

BACKGROUND: Patient's life circumstances, goals, and preferences for strongly influence their engagement in health and healthcare. Within confines of the primary care visit, clinicians often have difficulty addressing these factors. Digital health tools may be one way to assist patients in identifying and reporting goals, supports, risks, and care preferences for point-of-care (POC) discussions. However, research is limited regarding whether patient contextual data (PCD) gathered using a digital health tool for POC use affects patient-physician communication or patient activation.

METHODS: A two-arm (EHR-integrated PCD Tool and Usual Care), non-blinded, randomized control trial was conducted from May to October 2019 at two urban, academically affiliated primary care clinics. The PCD Tool, integrated into the EHR, collects, summarizes, and presents information about patients' identified health values, needs, goals, supports, risks, and preferences with their health care team. The outcomes were the post-visit Communication Assessment Tool (CAT) score and the Patient Activation Measure (PAM) score. Outcomes were analyzed using intention-to-treat and an instrumental variable approach to estimate the treatment-on-the-treated.

RESULTS: 301 patients were enrolled, randomized with stratification by race to study arms. Most participants were female, > 65, retired, with at least a college degree, and a household income ≥$50,000. There were no significant differences in pre-/post-visit change in PAM scores by arm (p=.079). Some aspects of communication were different between arms, specifically "being treated with respect" (13.76; 95%CI=2.27, 25.25; p=0.02) and that the "provider showed care and concern" (16.39; 95%CI=4.27, 28.52; p<0.01). However, the overall change in the CAT score was not significant (9.32; 95%CI=-1.05, 19.69; p=0.08). The treatment-on-the-treated results demonstrate no change in overall CAT score, but show large effects of specific items: "being treated with respect" (49.80; 95%CI=0.80, 98.79; p=0.05), "showed interest in my ideas" (55.73; 95%CI=4.83, 106.62; p=0.03), "showed care and concern" (59.65; 95%CI=9.69, 109.61; p=0.02) and "spent about the right amount of time with me" (49.82; 95%CI=0.77, 98.86; p=0.05) for participants in the PCD Tool arm.

CONCLUSIONS: The goal of this trial was to understand if the use of a PCD tool designed to enhance the capture and sharing of PCD influenced patient-provider communication and patient activation for primary care patients. We found that the inclusion of PCD improved some aspects of patient-provider communication, but had little effect on patient activation.

THE IMPACT OF THE EHR AND CLERICAL WORK ON BURNOUT IN A LARGE ACADEMIC HOSPITAL SYSTEM

Lauren Peccoralo[1]; Carly Kaplan[1]; Jonathan Ripp[2]. [1]Medicine, Icahn School of Medicine at Mount Sinai, NY, NY; [2]Department of Medicine, Icahn School of Medicine at Mount Sinai, New York, NY. (Control ID #3389644)

BACKGROUND: The advent of the Electronic Health Record (EHR) has transformed the physician workday and disrupted work-life balance through the addition of significant clerical burden related to increased documentation time, order entry, billing, and inbox management, much of which has been associated with burnout. To understand the relationship between burnout, EHR time outside the workday, and clerical task time, we conducted a faculty survey across all departments within the Mount Sinai Health System (MSHS). We hypothesized that time spent on the EHR or clerical work would be associated with greater burnout.

METHODS: We administered a web-based anonymous cross-sectional survey to all faculty at MSHS from 11/2018 through 2/2019. The survey was comprised of validated instruments, including the Mayo Well-Being Index (WBI), Maslach Burnout Inventory (MBI) 2 item scale, and PHQ-2 depression screen, as well as demographics, professional characteristics, and measures of clerical and EHR burden. Data analysis involved dichotomization of Likert scale variables, t-test and chi-square bivariate analyses, and multivariate logistic regressions.

RESULTS: Of 4156 faculty members in the MSHS, 1781 (43%) participated in the survey and we analyzed a subgroup of faculty with clinical responsibilities: 1346 (76% of sample). 35% of clinical faculty were burned out on the WBI, and 30% on the MBI-2. Demographic and professional factors significantly associated with burnout on both scales included being female, lower faculty level, younger age, longer work hours, screening positive for depression, and feeling work does not leave enough time for personal life. Feeling that the practice unloads clerical burden, and that work is meaningful is associated with significantly lower burnout risk. Burnout was also associated with agreement that EHR adds to frustration (37.7% vs. 22.0% burned out on MBI), spending >1 hour on EHR outside the workday (38.3% vs. 28.4%) and >1 hour of clerical work per day (42.5% vs. 26.0%). Results were similar with WBI. In multivariate analysis with the following variables: gender, level, full time employment status, age, work hours per week, clinical time, depression and practice unloading of clerical work, we found that spending >1 hour per day on EHR outside the workday (MBI OR=1.71, p=0.001; WBI OR=1.53, p=0.01) and spending >1 hour on clerical work per day (MBI OR=1.65, p=0.003; WBI OR=1.60, p=0.01) were each significantly and independently associated with burnout on each scale.

CONCLUSIONS: Our findings suggest that spending time on the EHR after work hours and excessive time on clerical tasks may put clinical faculty at greater burnout risk independent of clinical hours worked. The study was limited by its cross-sectional nature and single healthcare system. These results suggest the need for interventions targeting both

drivers within the workplace and the electronic and clerical work that follows physicians home to build a healthier and more clinically effective provider population.

THE INFLUENCE OF NEOLIBERALISM AND THE CONSUMERIZATION OF MEDICINE ON POTENTIALLY INAPPROPRIATE HIGH-INTENSITY LIFE SUSTAINING TREATMENTS NEAR THE END OF LIFE

Elizabeth W. Dzeng[1]; J R. Curtis[2]; Thea Matthews[3]; Jason N. Batten[4]; Sarah Rosenwohl-Mack[1]; Christine Ritchie[5]; Daniel Dohan[3]. [1]Medicine, UCSF, Timonium, MD; [2]Medicine, University of Washington, Seattle, WA; [3]Health Policy, UCSF, San Francisco, CA; [4]School of Medicine, Stanford University, Mountain View, CA; [5]Massachusetts General Hospital, Boston, MA. (Control ID #3375108)

BACKGROUND: Potentially inappropriate high-intensity life-sustaining treatments (LST) near the end of life such as mechanical ventilation and resuscitation have the potential to create ethical challenges where treatments can cause harm and suffering with little chance of benefit. Interventions to reduce inappropriate high-intensity LST have met with limited success, raising the possibility that the social context within which clinical decisions are made may play a role in the persistence of potentially inappropriate high-intensity care. One such contextual factor is neoliberalism, characterized by free-market capitalism, which encourages a culture of consumerization and unlimited choice. The objective of this study is to understand the broader macro-sociological factors that influence institutional culture and individual behavior that impact potentially inappropriate high-intensity care.

METHODS: We conducted 55 semi-structured in-depth interviews with clinicians and administrators at two hospitals in California rated by the Dartmouth Atlas rated as high-intensity and low-intensity for intensity of end-of-life care, as well as eight interviews with clinicians and administrators at a low-intensity public hospital in Washington. Transcripts were analyzed using thematic analysis.

RESULTS: Interviews reveal different practice patterns and behaviors in response to ethical challenges around potentially inappropriate high-intensity LST, which reflect different support structures that mitigate the influences of neoliberalism at an institutional level. Stronger systems-level support structures at the low- intensity hospitals appear to support clinicians in making decisions in a patient's best interest that modulate the intensity of end-of-life care. In contrast, the high-intensity hospital reflects a culture of consumerism, which encourages clinical momentum towards high-intensity LST. This is characterized by a prioritization of an unreflective reverence to patient autonomy; extreme deference towards consumerization; clinician powerlessness to act ethically; a focus on metrics and in particular, patient satisfaction; and the coopting of ethics committees into a regulatory body.

CONCLUSIONS: These results suggest that neoliberal ideologies and the consumerization of medicine shape organizational culture and clinical practice in ways that might modulate the intensity of end-of-life care. Understanding how macro-sociological phenomena influence clinical practices and behaviors have the potential to inform the development of systems-level interventions to mitigate potentially inappropriate high-intensity end-of-life care.

THE MAJORITY OF PATIENTS WITHOUT AN ADVANCE DIRECTIVE AT A SAFETY-NET HOSPITAL PREFER A DIFFERENT SURROGATE DECISION MAKER THAN THE DEFAULT UNDER STATE LAW

Natalia Smirnova, Ashima Lal, Maura George. Medicine, Emory University, Atlanta, GA. (Control ID #3350493)

BACKGROUND: Previous studies show that only one third of Americans have filled out an advance directive. Advance care planning is associated with higher quality of end-of-life care, including more in-hospital death and less hospice utilization. Despite these advantages, gaps in end-of-life care planning persist, particularly in underserved patient populations. We designed a study to assess advance care planning at a large county safety-net hospital.

METHODS: We surveyed 100 patients in primary care clinics at Grady Memorial Hospital, a large county hospital in Atlanta, Georgia. We asked patients if they had filled out an advance directive, then asked them whom they would want to make medical decisions if they were unable to speak for themselves. We also assessed rates of advance care planning completion in the Grady medical intensive care unit by reviewing 69 charts.

RESULTS: 7% (7/100) of primary care clinic patients had filled out an advance directive, and 1.4% (1/69) of intensive care unit patients had an advance directive on file. Of the primary care patients without an advance directive, 58% (54/93) would choose a different surrogate decision maker than their legal next of kin under Georgia law.

CONCLUSIONS: In our safety-net hospital, patients are unlikely to have an advance directive, both in primary care clinics and in the intensive care unit. Rates of advance care completion at our institution are significantly lower than published rates for similar populations. Unexpectedly, the majority of those without an advance directive would choose a different surrogate decision maker than the default under Georgia law. Very few patients had heard of an advance directive, which suggests that they had not been offered to fill one out previously. Several clinic patients expressed interest in filling out an advance directive after completing the survey. Though this study did not have the resources to assist patients completing advance directives during the survey, interested patients were referred to the Grady advance care planning clinic. This study shows that there is a significant unmet need in advance care planning in our underserved patient population.

THE NEED FOR BREVITY DURING SHARED DECISION MAKING FOR CANCER SCREENING: CAN WE COMPROMISE?

Tanner Caverly[2,1]; Sarah E. Skurla[1]; Claire H. Robinson[3]; Brian Zikmund-Fisher[5]; Rodney A. Hayward[4]. [1]Center of Clinical Management and Research, Department of Veterans Affairs, Ann Arbor, MI; [2]Learning Health Sciences and Internal Medicine, University of Michign School of Medicine, Ann Arbor, MI; [3]Health Services Research & Development, VA Ann Arbor Health Care System, Ann Arbor, MI; [4]Internal Medicine, U. Michigan, Ann Arbor, MI; [5]Health Behavior & Health Education, University of Michigan, Ann Arbor, MI. (Control ID #3391067)

BACKGROUND: Detailed shared decision making (SDM) about cancer screening is difficult. Patients need to be better informed but have limited facetime with PCPs. Every minute spent discussing cancer screening is a minute *not* spent on other important issues. Decision-making outside of routine visits isn't always feasible.

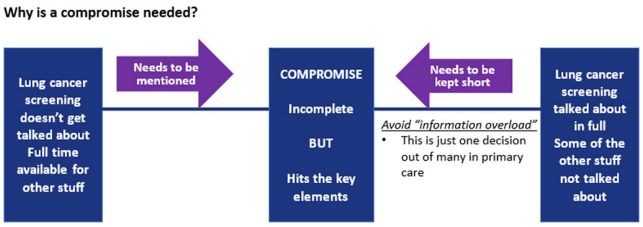
A more feasible approach to SDM may thus require a compromise: SDM that is incomplete but hits key elements (Figure 1). However, little is known about how patients feel about a compromise. Using deliberative focus groups, this study assessed patient perspectives on a compromise solution (brief, targeted SDM) where the PCP focuses on 3 key elements: 1) make a highly personalized recommendation; 2) briefly present qualitative information on the key tradeoffs for an individual; and 3) convey full support for decisional autonomy and desires for more information.

METHODS: We recruited a stratified random sample of Veterans from one academic-affiliated VA health system who were eligible for lung cancer screening, oversampling women and minority patients, to a 6-hour deliberative forum. First, experts informed participants about cancer screening basics and factors that influence heterogeneity in an individual's

net benefit, including their preferences. Then, facilitator-led small groups elicited patient feedback and questions on the Brief SDM compromise proposal.

RESULTS: 36 Veteran heavy smokers participated (50% male, 83% white, 47-79 years old). At final debriefing, all 5 small groups reached consensus that the brief SDM approach was acceptable. There was strong consensus on the importance of patients being final deciders and providing them with more information on request. There was disagreement about the exact language clinicians should use during brief SDM. Surprisingly, despite pushback from expert presenters, patients broadly agreed that clinicians should *not* mention the potential of false positive results leading to downstream invasive procedures, because this information was felt to be 1) inappropriately "scary" and 2) patients could refuse biopsy at a later date.

CONCLUSIONS: Patients recognized the need for brevity during patient-clinician cancer screening discussions and gave a rich rationale for why a brief, targeted SDM approach is acceptable. Obtaining the input of more nationally representative samples of patients is needed. Still, these findings suggest that feasible alternatives to detailed SDM may be useful and acceptable for routine cancer screening discussions. Tools that help clinicians quickly personalize a screening recommendation during a clinic visit are urgently needed.



THE PATIENT, PROVIDER, AND SYSTEM-LEVEL FACTORS THAT CONTRIBUTE TO THE QUALITY OF PATIENT EDUCATION PRIOR TO DISCHARGE: A DIRECT OBSERVATION STUDY

Shreya P. Trivedi[1]; Sara Corderman[2]; Gavi Barnhard[1]; Elyse Berlinberg[1]; Roshan Poudel[1]; Mark D. Schwartz[3]; Leora I. Horwitz[4]; Antoinette Schoenthaler[4]. [1]Internal Medicine, NYU, New York, NY; [2]N/A, SUNY Downstate College of Medicine, Brooklyn, NY; [3]Population Health, NYU School of Medicine, New York, NY; [4]Population Health, NYU School of Medicine, New York, NY. (Control ID #3392456)

BACKGROUND: The transition of care from hospital to home is a vulnerable time. Prior studies indicate that the amount of discharge education and anticipatory guidance that patients may receive vary widely. Suboptimal understanding of the care plan can lead to post-hospitalization morbidity and readmissions. Our aim was to identify the multiple patient-, provider-, and hospital system-level factors that contribute to the quality of discharge education a patient receives prior to discharge. Direct observation on the day of discharge can help inform contributors to inequities in the patient's discharge education experience.

METHODS: Purposeful sampling was used to select patients designated for discharge by noon. On the day of discharge, a trained medical student sat at the bedside of a single patient from 6am until time of discharge, and documented all communication between the patient and the healthcare team. Field notes were analyzed by three independent reviewers using a constant comparison method to identify the patient-, provider- and system-level themes that played a factor into the quality of patient education received in the discharge observations.

RESULTS: We conducted over 150 hours of observation of 30 patients' discharge days across two academic hospitals. On the patient level, we found that patients with previous hospitalizations and thus, familiarity with the hospital discharge process engaged in more question-asking and in turn, received more in-depth education to prepare them for the next care setting. This "hospital literacy" was even more paramount when patients had a previous suboptimal care transition experience, and emerged as a consistent theme of self-advocacy, more so than one's race, perceived health literacy, or the presence of a caregiver. At the provider level, healthcare teams that were focused on pending tests or outstanding consult recommendations provided less comprehensive discharge education since conversations centered on the logistics of that pending factor. The system level factors contributing to less discharge education included patient discharge to a subacute rehabilitation center or discharge over a weekend.

CONCLUSIONS: Understanding the multi-level factors that contribute to the quality of patient discharge education can alert the healthcare team to patients at risk of suboptimal care transitions. Ensuring that our patients exit the hospital with an equitable quality of information, ready to manage their health in the next care setting, will require interventions at every level.

THE PREVALENCE, COSTS, AND HARMS OF LOW-VALUE CANCER SCREENING AMONG OLDER AMERICANS WITH DEMENTIA

John N. Mafi[1]; Cheryl Damberg[3]; Joseph Ladapo[1]; Mei Leng[1]; Kenneth Langa[2]; A. Mark Fendrick[2]; Catherine Sarkisian[1]. [1]Medicine, David Geffen School of Medicine at UCLA, Los Angeles, CA; [2]University of Michigan, Ann Arbor, MI; [3]RAND Corporation, Santa Monica, CA. (Control ID #3389532)

BACKGROUND: Preventive cancer screening offers limited benefit to older adults with dementia and can cause harm. Prior work has established the frequency of cancer screening in dementia patients as recent as 2008. We sought to determine recent U.S. prevalence, costs, and harms of cancer screening delivered to older Americans with dementia.

METHODS: We used data from the Health and Retirement Study (HRS), a nationally representative longitudinal study of the health and economic changes of aging in community-dwelling and institutionalized older Americans. The HRS uses validated cognitive tests to identify patients with cognitive impairment consistent with dementia. We used validated HRS questionnaires that ask participants and/or their proxies whether they underwent colon cancer screening in the past 4 years, and breast, cervical, or prostate cancer screening in the past 2 years. To ensure the test occurred while the patient had dementia, we accounted for the 2- or 4-year lag in the survey questions by including patients aged ≥65 who had dementia for at least 4 years and received colon cancer screening and those who had dementia for at least 2 years and received breast, cervical, or prostate cancer screening in 2016. We used Medicare fee rates to estimate the average amount spent on testing. We used U.S. Preventive Services Taskforce systematic estimates to quantify harms: each year, approximately 0.12% of patients undergoing screening colonoscopies experience major intestinal bleeding/colonic perforation, 0.64% of women undergoing breast cancer screening experience unnecessary breast biopsies, 0.38% of women undergoing cervical cancer screening experience moderate-severe bleeding/pain/discharge from biopsies, and 0.65% of men undergoing prostate cancer screening experience incontinence/impotence from prostate surgeries.

RESULTS: We identified 501 patients in 2016 who had dementia for at least 4 years, representing approximately 1.9 million older Americans; mean age 82.7 years, 69.6% female, 56.4% white, 22.9% black, 18.3% Hispanic, and 2.4% other race/ethnicity. We estimated 520,139 patients (27.5%) who underwent colon cancer

screening, 523,280 women (31.9% of women) who underwent breast cancer screening, 317,521 women (19.5% of women) who underwent cervical cancer screening, and 442,907 men (49.9% of men) who underwent prostate cancer screening—totaling $357 million in spending. These tests led to an estimated 624 patients with major intestinal bleeding/colonic perforations, 3,348 women with unnecessary breast biopsies, 1,206 women with moderate-severe complications from cervical cancer screening, and 2,878 men with urinary incontinence/impotence from prostate cancer screening.

CONCLUSIONS: Older Americans with dementia frequently undergo cancer screening tests with questionable benefit, leading to high costs and substantial harm. Reducing low-value cancer screening has the potential to lower U.S. health care spending and improve patient-oriented outcomes in this vulnerable population.

THE RELATIONSHIP BETWEEN FRAILTY AND PERFORMANCE STATUS IN PATIENTS WITH CIRRHOSIS AWAITING LIVER TRANSPLANTATION

Chelsea Xu[2]; Frederick Yao[1]; Yara Mohamad[1]; Randi Wong[1]; Dorothea S. Kent[1]; Srilakshmi Seetharaman[1]; Yanin Srisengfa[1]; Jennifer C. Lai[1]. [1]Division of Gastroenterology and Hepatology, UCSF, San Francisco, CA; [2]Department of Medicine, UCSF, San Francisco, CA. (Control ID #3390881)

BACKGROUND: Frailty—a multi-dimensional construct that encapsulates physical function, performance status, and nutritional status—has emerged as a critical determinant of mortality in patients with cirrhosis. Currently, the UNOS registry only includes the Karnofsky Performance Status (KPS) scale, which captures only one single component of frailty. We aimed to evaluate the relationship between frailty and KPS.

METHODS: We analyzed data from adults with cirrhosis listed for liver transplantation (LT) without hepatocellular carcinoma at a single center from 2/2014-6/2019 with outpatient assessments of frailty [using the Liver Frailty Index (LFI)] and performance status (using KPS) within 30 days of listing. "Frail" was defined using the previously established LFI cutoff of ≥4.5. Correlation between LFI and KPS was evaluated using Spearman's correlation test. Uni- and sequential multivariable analyses assessed associations between LFI and KPS with waitlist mortality (= death/delisting for sickness) using competing risk models (with LT as the competing risk).

RESULTS: Included were 247 patients with cirrhosis: median MELDNa was 17. Median (IQR) LFI was 3.9 (3.4-4.5); median KPS was 80 (70-90). The correlation between LFI and KPS was -0.32 (p<0.001). Among 61 (25%) patients who were categorized as frail, median (IQR) KPS was 80 (60-90); 45% were modestly impaired (KPS 50-70) and 3% were severely impaired (KPS 10-40). At a median of 8 months follow-up, 25 (10%) patients died/were delisted. In univariable analysis, LFI (sHR 1.09, per 0.1 unit, 95% CI 1.03-1.14) was associated with waitlist mortality while KPS was not (sHR 0.92, per 10 units, 95% CI 0.70-1.22), which remained true in multivariable analysis (Table).

CONCLUSIONS: Among patients with cirrhosis, there was only modest correlation between frailty and performance status. While frailty was predictive of waitlist mortality in our outpatient cohort of LT candidates with a median MELDNa of 17, KPS was not. Our data provide evidence that KPS does not fully capture "frailty" in outpatients with cirrhosis and suggest that frailty, as measured by the Liver Frailty Index, may be more appropriate to capture mortality risk than performance status alone and advocate for its incorporation into the UNOS registry.

Table. Univariable and sequential multivariable competing risk models evaluating the association between LFI and KPS on waitlist mortality.

	Sub-hazard ratio (95% CI) p-value					
Factor	**Univariable**	**Sequential multivariable regression**				
LFI, per 0.1 unit	1.09 (1.03-1.14) p=0.001	1.09 (1.04-1.14) p=0.001	1.08 (1.03-1.13) p=0.001	1.07 (1.02-1.12) p=0.003	1.07 (1.02-1.11) p=0.01	1.07 (1.01-1.11) p=0.01
KPS, per 10 units	0.92 (0.70-1.22) p=0.57	1.02 (0.79-1.31) p=0.90	1.02 (0.79-1.31) p=0.90	1.00 (0.78-1.27) p=0.98	1.00 (0.78-1.29) p=0.99	1.00 (0.78-1.29) p=0.99
MELDNa, per 1 unit	1.04 (0.98-1.10)		1.03 (0.97-1.09)	1.04 (0.97-1.10)	1.03 (0.97-1.10)	1.03 (0.96-1.10)
Age, per year	1.07 (0.99-1.15)			1.06 (0.98-1.14)	1.06 (0.98-1.14)	1.06 (0.98-1.14)
Ascites	2.21 (1.02-4.80)				1.75 (0.81-3.79)	1.73 (0.79-3.79)
Albumin, per g/dL	0.60 (0.30-1.20)					0.68 (0.35-1.33)

THE RELATIONSHIP BETWEEN INDUSTRY PAYMENTS AND ADOPTION OF NEW BREAST CANCER SCREENING TECHNOLOGY

Kunal C. Potnis[1]; Cary Gross[2,3]; Ilana B. Richman[2,3]. [1]Yale School of Medicine, New Haven, CT; [2]Section of General Internal Medicine, Yale School of Medicine, New Haven, CT; [3]COPPER Center, Yale School of Medicine, New Haven, CT. (Control ID #3376766)

BACKGROUND: Citing insufficient evidence, the U.S. Preventive Services Task Force has not recommended for or against the use of digital breast tomosynthesis (DBT) for breast cancer screening. Nevertheless, DBT use has increased substantially in recent years. During this time, DBT manufacturers made significant marketing investments to promote DBT. We evaluated the relationship between radiologists' receipt of industry payments and adoption of DBT.

METHODS: We used Open Payments data from the Centers for Medicare and Medicaid Services (CMS) to identify DBT product-specific general industry payments from 2014-2016. We then linked Open Payments data to radiologists' claims for mammography services in the subsequent year using the Medicare Provider Utilization and Payment file, which includes claims from providers who have rendered services to at least 10 Medicare beneficiaries. We also identified groups of radiologists based on shared practice address. We used logistic regression to measure the association at the provider level between receipt of an industry payment and DBT adoption, defined as any use of screening DBT during a calendar year. We also evaluated whether radiologists who did not personally receive a payment but practiced in a group with someone who did receive a payment were more likely to adopt DBT. Multivariable models were adjusted for providers' sex, state, 2D mammogram volume, and group practice size, with standard errors clustered by group. We expressed results as percentages using marginal effects.

RESULTS: Our sample included 13,083 radiologists who billed for screening mammograms in 2015, 12,837 in 2016, and 12,683 in 2017. From 2015 to 2017, the percent of individual radiologists who received payment in the previous year ranged from 1.0% to 1.6%. During this time, 9.3% to 10.3% of radiologist groups included a radiologist who received payment in the previous year. In 2015, 63% of radiologists who received payment in the previous year used DBT compared to 36% of those who did not receive payment (P < .001). In 2016, DBT use was 75% vs. 52% (P < .001) and, in 2017, 83% vs. 66% (P < .001). In 2015, among radiologists who did not personally receive payment in the previous year but were in a group with someone who did, 47% used DBT at least once compared to 37% of radiologists in a group where no one received payment (P < .005). These figures were 59% vs. 54% (P = 0.13) in 2016 and 77% vs. 68% (P < .002) in 2017.

CONCLUSIONS: We observed a consistent association between receipt of industry payment in the previous year and DBT adoption among radiologists. Although the number of radiologists who personally received payment was small, our results suggest that industry payments may have a

ripple effect within group practices, thus touching a substantially larger number of physicians. As group practice arrangements become more common and complex, considering the role of conflict of interest in groups may deserve greater attention.

THE RELATIONSHIP BETWEEN PATIENT HETEROGENEITY, ANTIBIOTIC TIMING, AND THE OUTCOMES OF PATIENTS WITH SEVERE BACTERIAL INFECTION

Michael Usher[1]; Roshan Tourani[2]; Michael Rhodes[3]; Ben Webber[1]; Christopher Tignanelli[4]; Gyorgy Simon[2]. [1]Department of Medicine/Division of General Internal Medicine, University of Minnesota Medical School, Minneapolis, MN; [2]Institute for Health Informatics, University of Minnesota, Minneapolis, MN; [3]Department of Medicine, University of Minnesota, Minneapolis, MN; [4]Critical Care/Acute Care Surgery, University of Minnesota, Minneapolis, MN. (Control ID #3392074)

BACKGROUND: Sepsis, severe sepsis, and septic shock remain important contributors to hospital utilization, morbidity and mortality in the United States. Timely interventions including blood cultures, intravenous crystalloid infusions, and antibiotics make up the 3-hour sepsis bundle which represents current standard of practice, and the target of hospital quality reporting. Many aspects of sepsis care are still under discussion including best diagnostic criteria, optimal timing of treatment, and management of heterogeneity.

METHODS: We performed a retrospective observational analysis of patients with severe bacterial illness admitted to a 6 hospital network from 2011 to 2017. The primary outcome in this study was a composite of inpatient mortality or length of stay more than 10 days, stratifying by different definitions of sepsis: 2+ SIRS criteria, 2+ SOFA score, both, or neither. We then investigated the ability to predict antibiotic latency, defined as the time from presentation to administration using patient factors prior to treatment including demographics, vitals, labs, and orders collected prior to 1, 3, and 6 hours of presentation. Finally to disentangle the impact of treatment timing from patient factors we compared a cohort that received antibiotics before time "t" against a propensity score matched control that did not across all time points between 15 minutes and 24 hours.

RESULTS: We identified 21,425 patients admitted with severe bacterial infection, of which 29.4% had no sign of sepsis, 35% were SIRS positive, 8% were SOFA positive, and 27.3% were both SIRS and SOFA positive. In all groups antibiotic latency followed a J curve relationship with higher mortality and length of stay within the first hour and after the fourth hour. Patients were observed to have higher acuity when receiving antibiotics within the first hour, and greater complexity when receiving antibiotics late. Patient factors were able to predict with good accuracy whether antibiotics were administered within 1 hour (AUC 0.72), within 3 hours (AUC 0.74), and within 6 hours (AUC 0.76). Earlier antibiotics administration was associated with improved outcomes against matched controls for all time points later than 2.5 hours for all groups including patients who lacked any diagnostic criteria of sepsis.

CONCLUSIONS: Timing of antibiotics for patients admitted with infection is a predictable function of severity of illness and complexity. Earlier antibiotic timing was associated with improved outcomes independent of risk or diagnosis of sepsis, and easier to observe in lower risk patients. Based on these data, future efforts to improve outcomes include education of at-risk individuals to present earlier to the hospital. Additionally, decision support tools should focus on patients who benefit specifically from timely treatment and not merely identifying sepsis or absolute risk. Finally, risk adjusted latency of care is likely a better measure of quality than a 1 hour or 3 hour sepsis bundle adherence.

THE RISING COST OF HEALTHCARE AMONG INDIVIDUALS WITH INTELLECTUAL DISABILITY

Jack Chen[1]; Caren Steinway[1]; Colleen Brensinger[2]; Qing Liu[2]; Sophia Jan[1]. [1]Pediatrics, Cohen Children's Medical Center of Northwell Health, New Hyde Park, NY; [2]Penn Medicine, Philadelphia, PA. (Control ID #3389738)

BACKGROUND: It is estimated that there are 7 to 8 million individuals in the US with intellectual disability (IDD). As those with IDD age they are more likely to experience chronic health conditions requiring care that would lead to increasing health care services such as durable medical equipment, adult day care, and residential care. However analyzing these costs over time can at times be difficult with varying regulations in coding between states.

METHODS: The goal of the study was to evaluate methodology used to analyze Medicaid claims data and review the cost per capita of services for individuals with IDD for 5 states (New York, Ohio, Pennsylvania, California, and Florida) between 2009 and 2012. We conducted a retrospective cohort study on Medicaid Analytic eXtract (MAX) data requested from the Centers for Medicare and Medicaid Services (CMS) for CA, FL, NY, OH, and PA for the years 2009 to 2012. Eligible individuals were 18-64 years old, dually eligible for Medicare and Medicaid benefits, were continuously enrolled in Medicaid (defined as 10 of 12 months) in each year of enrollment, and have an ICD-9 diagnostic code for intellectual disability. Analysis was focused on the total cost per capita for durable medical equipment (DME), residential care, and adult day care.

RESULTS: Over the 4 year study period, DME cost steadily decreased for all states except Ohio, where it saw an increase of over 200% from 2009 to 2012. While New York outspends the other states by over 100 million dollars per capita on residential care, all 5 states' cost have been steady over the 4 years. Similarly, New York greatly outspends the other 4 states in total adult day care cost. Total cost over the 4 years have held with the exception of Ohio, whose total expenditures on adult day care has risen close to 40% from 2009 to 2012. The top 5 drivers of DME expenditures for those individuals with IDD for all 5 states were the following: 1) personal care items; 2) formula; 3) home modifications; 4) environment modification; and 5) wheelchair component-accessory. Drivers of residential care and adult day care costs were harder to ascertain due to variance in billing codes across states.

CONCLUSIONS: Results of our analysis show the rising costs of healthcare and how it can vary between states. However, even with the limited scope of this study it was still difficult identifying these expenditures. Future studies should evaluate the methodology as this information can be useful in informing future spending policies.

THE ROLE OF CLINICAL DECISION SUPPORT ALERTS ON CLOSTRIDIOIDES DIFFICILE TESTING AND INFECTION RATES: A SYSTEMATIC REVIEW

Aaron N. Dunn[2,1]; Nathan Radakovich[2,1]; Jessica Ancker[3]; Curtis J. Donskey[4]; Abhishek Deshpande[1,2]. [1]Medicine, Cleveland Clinic, Cleveland, OH; [2]Cleveland Clinic Lerner College of Medicine at Case Western Reserve University, Cleveland, OH; [3]Healthcare Policy & Research, Weill Cornell Medical College, New York, NY; [4]Cleveland VAMC, Cleveland, OH. (Control ID #3391708)

BACKGROUND: *Clostridioides difficile* infections (CDI) affect over 450,000 people each year in the United States. The optimal strategy for diagnosis, however, remains unclear and inappropriate CDI testing accounts for approximately 15% of all CDI testing leading to overdiagnosis and unnecessary treatments and costs. Several studies have investigated

the utility of electronic decision support alerts in diagnostic stewardship for CDI. Nonetheless, it is unclear if alerts are effective in positively impacting process metrics (e.g., inappropriate CDI testing) or patient-centered outcomes (e.g., CDI rates). The aim of this systematic review was to determine the effect of alerts related to CDI diagnostic stewardship on CDI testing volume and CDI rates among hospitalized adult patients and to determine whether or not there are any adverse effects of these interventions.

METHODS: We queried Ovid MEDLINE and 5 other databases for original studies evaluating the association between clinical decision support alerts for CDI diagnosis and CDI testing volume and/or CDI rate. Two investigators independently extracted the relevant data. Primary outcomes included the total number of *C. difficile* diagnostic tests ordered, the number of clinically indicated tests ordered, and CDI rate before and after the intervention. Secondary outcomes were potential adverse consequences of alert interventions (e.g., rate of CDI-related complications) and alert override rates.

RESULTS: Of 2047 studies identified in the search, 11 observational studies met inclusion criteria. Studies varied significantly in alert triggers and in outcomes of interest. Six of the 11 included studies reported a significant decrease in CDI testing volume, 6 of 6 studies evaluating appropriateness of CDI testing found a significant reduction in the proportion of inappropriate testing, and 4 of 7 studies measuring CDI rate demonstrated a significant decrease in the CDI rate in the post- vs pre-intervention periods. There were limited data reporting adverse outcomes. One study found an increase in CDI testing after implementation of a clinical support tool. Of the included studies, only one reported on adverse clinical outcomes, finding a non-significant increase in CDI-related complications post-intervention. Furthermore, only one study reported alert override rate, identifying that physicians generally ignored approximately one-fourth of electronic alerts, with higher rates among physicians receiving multiple alerts in a single episode and among interns and residents.

CONCLUSIONS: The use of electronic alerts for diagnostic stewardship for *C. difficile* was associated with reductions in CDI testing, the proportion of inappropriate CDI testing, and rates of CDI in most studies.

However, broader concerns related to alerts remain understudied including unintended adverse consequences and alert fatigue. Despite the advantageous effects of electronic alerts described in these studies, there is limited reporting on unintended adverse consequences.

THE ROLE OF CONFIDENCE IN HOME CARE WORKERS' CONTRIBUTION TO HEART FAILURE PATIENTS' SELF-CARE: TESTING A STRUCTURAL EQUATION MODEL

Madeline R. Sterling[3]; Claudio Barbaranelli[1]; Barbara Riegel[2]; Michael Stawnychy[2]; Joanna Bryan[3]; Jacklyn Cho[3]; Ercole Vellone[4]. [1]Sapienza University of Rome, Rome, Italy; [2]School of Nursing, University of Pennsylvania, Philadelphia, PA; [3]Weill Cornell Medicine, New York, NY; [4]University of Rome Tor Vergata, Rome, Italy. (Control ID #3385672)

BACKGROUND: Home healthcare workers (HCWs) frequently care for adults with heart failure (HF). Prior qualitative studies have found that HCWs promote HF patients' self-care, but are poorly prepared to do so and lack confidence. Also, the manner in which mutuality (i.e., the positive quality of the relationship) between HCWs and HF patients contributes to HCWs' care is unknown. Here we investigated these issues quantitatively. Guided by the Situation-specific Theory of Caregiver Contribution to HF self-care, we hypothesized that HCW preparedness and mutuality influenced HCW contribution to patients' self-care maintenance (i.e., behaviors to maintain HF stability) and management (i.e., response to HF symptoms), with HCWs' confidence mediating the relationship.

METHODS: We conducted a cross-sectional survey of English-speaking HCWs employed by 23 home care agencies who cared for a HF patient in the last year in New York, NY. HCWs completed a sociodemographic questionnaire, the Caregiver Preparedness Scale (CPS), the Mutuality Scale (MS), and the Caregiver Contribution to Self-Care of HF Index (CC-SCHFI), which assesses caregiver contribution to self-care maintenance, management, and caregiver confidence. We tested our hypotheses with structural equation modeling (SEM). Mediation analysis was done to test indirect effects.

RESULTS: The 317 HCWs had a median age of 50, 94% were women, 44% were Non-Hispanic Black, 79% had ≥ high school education, 71% were foreign-born, and all spoke English. The HCW had a median of 8.5 years of caregiving experience. Overall, HCWs felt prepared for HF caregiving (CPS mean 3.86 [SD: 0.93])) and had moderately positive relationships with patients (MS mean 3.87 [SD: 0.76]). 63% contributed adequately to self-care maintenance, 22% to self-care management, and 44% felt confident with HF caregiving. The tested model fit the data well (CFI=.98; RMSEA=.04) and showed the following significant relationships: mutuality and preparedness covaried (r=.47); preparedness influenced HCW confidence (b=.79); mutuality influenced HCW contribution to self-care maintenance (b=.25); HCWs confidence influenced their contributions to self-care maintenance (b=.22) and management (b=.52). HCWs' contribution to self-care maintenance influenced their contribution to self-care management (b=.47). Analysis of the indirect effects showed that HCW confidence fully mediated the relationship between preparedness and contributions to self-care maintenance (effect=.17) and management (effect=.41).

CONCLUSIONS: While HCWs' preparedness heavily influenced their contribution to HF self-care, HCWs' confidence, mediated this relationship. Thus, confidence, a modifiable factor, plays a key role in HCWs' contribution to HF self-care. As this workforce increasingly cares for HF patients, the mechanisms underpinning the relationships among HCWs' preparedness, mutuality, confidence, and self-care warrant further study.

THE ROLE OF EHEALTH LITERACY IN THE DIGITAL DIVIDE AMONG HOSPITALIZED PATIENTS

Hanna Vollbrecht[1]; Vineet M. Arora[2]; Sebastian Otero[2]; David Meltzer[2]; Valerie G. Press[3]. [1]Pritzker School of Medicine, Chicago, IL; [2]General Internal Medicine, University of Chicago, Chicago, IL; [3]Medicine and Pediatrics, University of Chicago, Chicago, IL. (Control ID #3368774)

BACKGROUND: Hospitalized patients may benefit from technological interventions to assist with chronic disease care and self-management during transitions of care, a time of heightened vulnerability. However, although technology access is common, an increasing concern is a "digital capability" divide that could interfere with the benefits of these technology-based transition of care interventions. Prior studies have not specifically evaluated the digital capability divide among hospitalized patients. Therefore, we evaluated associations between digital capability, technology access/use, and health literacy among adult inpatients.

METHODS: Hospitalized adult patients on the general medicine service were enrolled in a sub-study of an ongoing quality-of-care study. eHealth literacy, a measure of digital capability that encompasses patient's ability to access and use technology specifically for health-related reasons, was assessed using the validated eHEALS tool. Enrolled participants also completed a technology survey that asked about technology access and use, with questions primarily drawn from benchmarked Pew Research Center survey items. Health literacy was assessed using the three-item Brief Health Literacy Screen. Descriptive statistics, bivariate Chi- squared analyses and multivariate logistic regression analyses (adjusted for age, gender, race, HL) were performed.

RESULTS: Among 105 participants, the mean age was 52.6 (SD: 17.4), the majority were African American (79%), half were female (49%) and

half had at-most a high school education (45%). One-third had low HL (30%) and one-third (31%) had low eHL (mean eHEALS score: 27.8 [SD:7.6]). The Spearman correlation coefficient between HL and eHL assessments was -0.056 (p=0.6). In bivariate analyses with respect to specific technology access and use, low eHL scores were associated with less desktop computer (p<0.01), laptop computer (p<0.01), tablet computer (p<0.01), and smartphone (p<0.01) ownership, but not cellphone ownership (p=0.4). Low eHL scores were also associated with less use of the internet generally (p<0.01), for looking up health information (p<0.01), and for posting health information online (p<0.01), but not with respect to downloading an app for health-related reasons (p=0.9). Results remained unchanged with multivariate analyses except that laptop ownership was not associated with low eHealth.

CONCLUSIONS: Lower eHL was associated with less ownership and use of technology. Interestingly, there were similar levels of cellphone ownership across eHL levels, suggesting this may be the best device to utilize when implementing technology interventions. A traditional HL assessment tool did not correlate with eHL indicating that different capability domains may be assessed by these tools. With the explosion of technology-based interventions, eHL may need to be assessed and addressed to realize their full potential and obtain optimal outcomes.

THE ROLE OF RESIDENTIAL SEGREGATION IN CARDIOVASCULAR DISPARITIES AMONG VETERAN HEALTH ADMINISTRATION USERS

Michelle S. Wong[1]; W. N. Steers[1,2]; Katherine J. Hoggatt[3,4]; Boback Ziaeian[1,2]; Donna L. Washington[1,2]. [1]VA HSR&D Center for the Study of Healthcare Innovation, Implementation & Policy (CSHIIP), VA Greater Los Angeles Healthcare system, Los Angeles, CA; [2]University of California, Los Angeles Geffen School of Medicine, Los Angeles, CA; [3]San Francisco VA Health Care System, San Francisco, CA; [4]University of California, San Francisco, Los Angeles, CA. (Control ID #3390517)

BACKGROUND: Research on residential segregation has focused on its influence on the health of racial/ethnic concordant individuals. For example, studies suggest that non-Hispanic (nH-)Black residential segregation is related to worse cardiovascular health for nH-Black residents.

We know less about how residential segregation relates to cardiovascular disease (CVD) risk among other racial/ethnic minority groups. Within a national sample of Veteran Health Administration (VHA) users, we characterized racial/ethnic disparities in CVD risk and examined whether residential segregation modified these disparities.

METHODS: We linked electronic health record data from a 2017 national cohort of VHA-users (n=5,985,046) to 2013-2017 U.S. Census data to compare CVD risk between nH-Blacks, nH-American Indian/Alaskan Natives (AI/AN), nH-Asians, and nH-Native Hawaiian/Other Pacific Islanders (NH/OPI) vs. nH-Whites. We measured CVD risk with a 5-item index (count) of diagnosed overweight/obesity, diabetes, hyperlipidemia, hypertension, and tobacco use; and residential segregation with nH-Black and Hispanic isolation indices. We used Poisson regression to model CVD risk scores, and post-estimation to express disparities as differences in mean CVD risk scores between each racial/ethnic minority group and nH-Whites. To examine effect modification, we included race/ethnicity-residential segregation product terms. Models also included age, sex, socioeconomic status, rurality and geographic region.

RESULTS: Mean nH-Black isolation index varied across racial/ethnic groups, ranging from 0.15 (AI/ANs) to 0.41 (nH-Blacks); mean Hispanic isolation index ranged from 0.19 (nH-Whites) to 0.52 (Hispanics). Relative to nH-Whites, covariate-adjusted CVD risk scores were greater for AI/ANs (difference=0.07, 95% confidence interval [CI]:0.01-0.14), nH-Blacks (difference=0.22, 95%CI:0.20-0.23), Hispanics (difference=0.06, 95%CI:0.02-0.10), and NH/OPIs (difference=0.16, 95%CI:0.14-0.18); and were lower for Asians (difference=-0.06, 95%CI:-0.11- -0.002).

Living in neighborhoods with greater nH-Black residential segregation increased the magnitude of advantages among Asians (p=0.005), and attenuated Hispanic disparities (p=0.014). In neighborhoods with greater Hispanic residential segregation, the magnitude of Hispanic (p<0.001) and NH/OPI (p=0.011) CVD risk disparities increased and Asian CVD risk advantages decreased (p<0.001).

CONCLUSIONS: Black and Hispanic residential segregation was associated with CVD risk in other racial/ethnic groups. NH-Black residential segregation was not related to CVD risk factors in nH-Black VHA-users but was related to advantages for Asians and Hispanics. Hispanic segregation was related to greater CVD risk in both Hispanics and NH/OPIs. Efforts to reduce cardiovascular health disparities should be tailored to different racial/ethnic groups and may include focusing on those living in segregated communities.

THE ROLE OF SMART PHONES IN HEALTH CARE DECISIONS AND DISCUSSIONS; DOES PATIENT PERCEPTION OF HEALTHCARE QUALITY MATTER?

Christine Schindler[1]; Margot Hedlin[1]; Megan Hosein[1]; Kevin Yip[1]; Fred LaPolla[2]; Colleen Gillespie[1]. [1]Medicine, NYU, New York, NY; [2]NYU, New York, NY. (Control ID #3391652)

BACKGROUND: With the rapid growth of the internet, patients are able to access a wealth of healthcare information outside of the traditional doctor patient relationship that may be unreliable. Understanding the role of the patient-physician relationship on how this information is used in the clinical encounter is essential to provide effective care to patients in the smartphone era.

METHODS: Data from the 2018 Health Information National Trends Survey (HINTS 5, cycle 2) were analyzed (N=3504). The primary analysis examined the effect of the patient perceived quality of the patient-physician relationship on the use of smartphones/internet data in medical discussions and decisions. A secondary analysis looked at further variables including where respondents initially sought health information and their trust of sources on cancer related health information on the same outcomes (the use of smartphones in medical decisions and discussions). Descriptive statistics and multivariable logistic regression were conducted. Patient demographics including age and SES status were controlled for in the predictive model.

RESULTS: A minority of survey respondents use smartphones for healthcare decisions (31.1%) and discussions with their healthcare provider (28.4%). Most respondents use the internet as a first source of health information (55.1%); only 9.6% went to their healthcare provider first. Generally, there was no association between respondents' perception of how their healthcare provider communicated with them and their use of smartphones to help make healthcare decisions. Perceived quality of communication with their healthcare provider was significantly associated with how respondents first access health information in most categories assessed. Within these categories, those who went to their provider first had a higher perceived quality of healthcare provider interaction.

With regard to where people first go for information, those who went to the internet first were the most likely to use their smartphones for healthcare decisions (48% for internet vs 24.5% for doctor vs 31.4% for other, p<0.000) and in discussions with their healthcare provider (41.8% for internet first vs 33.8% for doctor first vs 28.9% for other, p<0.000).

In the final logistic model, respondents who felt that their healthcare provider always spent enough time had decreased odds of using a smartphone for healthcare decisions or in discussion with their health care provider even when accounting for all other demographic variables in the model.

CONCLUSIONS: This study found that most survey respondents in a nationally representative sample are not using smartphones in medical

decisions or discussions. In addition, the perceived quality of a healthcare provider largely does not influence smartphone use in medical decisions and discussions. However, the use of the internet for health information may influence these patterns of behavior.

THE SECRET INGREDIENT: HOW DO OSCE CASES ACTIVATE LEARNERS AROUND TRANSGENDER HEALTH?

Richard E. Greene, Tiffany E. Cook, Colleen Gillespie. Medicine, NYU Grossman School of Medicine, New York, NY. (Control ID #3389635)

BACKGROUND: Transgender and gender non-conforming (TGNB) patients face great challenges when seeking care. Providing gender affirming care requires biomedical knowledge and cultural humility that may be unfamiliar to health care providers. This can create uncertainty, stigma and bias from healthcare providers that can lead to significant health inequities. Little is known about the best way to activate health professional learners to overcome this discomfort and become activated to care for transgender patients. We sought to examine the characteristics of OSCE cases with transgender-identified standardized patients (SP) that activate learners to provide intentional gender-affirming care.

METHODS: A qualitative approach using modified grounded theory was used to elucidate the activating aspects of OSCE cases featuring TGNB standardized patients. TGNB specific OSCE cases ran over 3 years. A purposive sample of current and former Primary Care residents (N=18) at an academic residency in a major urban center participated in focus groups to identify the benefits and challenges of OSCE cases with TGNB patients.

RESULTS: 18 total residents participated in the focus groups. Transcription generated130 pages. During coding, 22 individual codes were developed and grouped by similar themes into 15 "supercodes". Supercodes were sorted by theme into 4 groups: (1) Overall experience with OSCEs as an educational tool, (2) prior experience with TGNB people, (3) Experience specific to the trans-OSCE case, and (4) Power dynamics, learner discomfort, motivation, and metacognition.

CONCLUSIONS: Residents believe their role is important. They differentiate the need to know psychosocial skills (using pronouns and preferred names) from biomedical knowledge (hormone therapy, etc.). Practical application of skills occurs mainly in the context of applying appropriate psychosocial skills to their experience on inpatient services. Residents described rarely seeing TGNB patients in the outpatient setting, and therefore having less experience with biomedical aspects of TGNB care.

Learners reported discomfort with participating in OSCEs but felt they were a valuable learning tool in general. Regarding the specific TGNB cases, residents reported additional discomfort and fear of being perceived as culturally inappropriate by the SP or faculty member. This fear may lead to learner fragility, which may have the effect of driving the resident to learn more or to shut down the learner and reject the material's importance to their practice.

Residents reported a range of believing that gender-affirming care is not something they consider part of their standard practice to aspiring to actively pursue gender-affirming care as a career. The activation outcomes as a result of the OSCE case increased with exposure to multiple cases. More research is needed to identify long-term educational strategies to activate learners.

THE UTILIZATION AND COSTS OF USPSTF GRADE D SERVICES IN MEDICARE, 2007-2016

Carlos Irwin Oronce[1,2]; A. M. Fendrick[6]; Joseph Ladapo[4]; Catherine Sarkisian[5]; John N. Mafi[3]. [1]Medicine, Greater Los Angeles VA Healthcare System, Los Angeles, CA; [2]UCLA National Clinician Scholars Program, Los Angeles, CA; [3]Division of General Internal Medicine and Health Services Research, David Geffen School of Medicine at UCLA, Los Angeles, CA; [4]Medicine, David Geffen School of Medicine at UCLA, Los Angeles, CA; [5]Medicine, UCLA and Greater Los Angeles VA, Los Angeles, CA; [6]University of Michigan, Ann Arbor, MI. (Control ID #3391263)

BACKGROUND: Low-value care (LVC), or patient care that offers no net benefit in specific clinical scenarios, leads to unnecessary spending and patient harm in certain circumstances. The U.S. Preventive Services Task Force (USPSTF) Grade D Recommendations exemplify LVC, given the high certainty that the expected clinical benefits of these services do not exceed the expected harms. We estimate the utilization and costs of ten USPSTF Grade D Services among U.S. Medicare beneficiaries.

METHODS: We conducted a repeated cross-sectional analysis of 2007 to 2016 data from the National Ambulatory Medical Care Survey (NAMCS), a nationally representative survey of U.S. ambulatory visits. NAMCS uses a multistage probability sampling design and data are abstracted directly from medical records. Eligible visits included beneficiaries aged >18 years who listed Medicare as their primary payer. We selected ten USPSTF grade D services based on feasibility of case identification using diagnosis codes and recorded symptoms. These included: (1) cervical cancer screening in women >65 years old, (2) prostate cancer screening in men >75 years old, (3) colonoscopy screening in adults >85 years old, (4) vitamin D screening, (5) cardiovascular disease screening in low risk adults, (6) COPD screening in asymptomatic adults, (7) screening for asymptomatic bacteriuria, (8) vitamin D supplementation for primary prevention of fractures in postmenopausal women, (9) hormone therapy for primary prevention of chronic conditions in postmenopausal women, (10) vitamin E or beta-carotene supplements for primary prevention of cardiovascular disease/cancer. We determined the annual volume of these services based on years available for each measure and then multiplied by per unit costs using Medicare payment rates.

RESULTS: We identified 95,578 unweighted visits, representing approximately 2.4 billion U.S. Medicare visits during the study period. Over 30 million low-value services were provided to Medicare beneficiaries each year, and direct costs ranged from $649,604,514 to $862,159,707 annually. The three most frequently used services were (1) screening for asymptomatic bacteriuria, (2) vitamin D supplementation, and (3) vitamin D deficiency screening, comprising 83% of the measured services and 46% of LVC spending. Three services (1) screening for asymptomatic bacteriuria, (2) cervical cancer screening in women >65 years old, and (3) colonoscopies in adults >85 years old comprised 53% of LVC spending.

CONCLUSIONS: Medicare beneficiaries frequently received Grade D services, costing nearly $1 billion in U.S. health care spending each year. The negative clinical impact and total costs of these low-value services are likely larger as these findings do not capture all D-rated services, as well as the cascade of downstream health care utilization after their use. Reducing Grade D services could offer an opportunity to improve patient-centered outcomes while safely reducing U.S. health care spending.

THIS IS HARD WORK; USING A TEMPLATE FOR GOALS OF CARE CONVERSATIONS AT COMMUNITY HEALTH CENTERS

Annette A. Georgia[1]; Deborah Swiderski[2]; Elizabeth H. Chuang[3]; Anna Flattau[4]; Allison Stark[5]. [1]Department of Social and Family Medicine, Montefiore, New York, NY; [2]Medicine, Montefiore Medical Center, Bronx, NY; [3]Family and Social Medicine, Montefiore Medical Center/Albert Einstein College of Medicine, Bronx, NY; [4]Family and Social Medicine, Montefiore Medical Center, Bronx, NY; [5]Geriatrics and Palliative Medicine, Montefiore Medical Center, Bronx, NY. (Control ID #3384541)

BACKGROUND: Patients with late stage chronic illness and their care teams can benefit from goals-of-care conversations. However, primary care teams often miss the opportunity for conversations, delay them until the very end of life, and/or limit them in scope. Researchers at Ariadne Labs developed a best-practice approach to these conversations, The Serious Illness Conversation Guide (SICG). Several trials demonstrated its effectiveness in well-resourced settings. We sought to determine if training for and use of the SICG would be acceptable and feasible in the low-resourced, high demand primary care environment of community health centers (CHCs) serving a diverse, low income population.

METHODS: 15 Family Medicine physicians at 2 academic CHCs in the Bronx were trained in the use of the SICG. Training took place in the fall of 2018 and consisted of 2 one-hour sessions with didactic and role play components. Eleven physicians completed conversations with 39 unique patients over a 5 month period following training. Each physician was interviewed about their experience using the SICG using a semi- structured interview guide. Interviews were audiotaped and transcribed. Using grounded theory, a coding structure was developed and applied to all transcripts by two investigators (AG, DS). An inductive thematic analysis strategy was used by three investigators to examine the coded data (AG, DS, EC).

RESULTS: Two major themes and several sub-themes emerged from the review of our transcripts: 1) "This is hard work." Subthemes included the juxtaposition of the benefit of a deepened bond with patients from enhanced clinically and socially relevant information, with concerns regarding time constraints and emotional drain on the physician, erosion of patient trust especially when discussing prognosis with patients from diverse backgrounds, management of often complex family dynamics, and patient characteristics that impeded completion of the SIC (e.g. untreated mental illness, cognitive decline, and pressing acute concerns in the context of time-limited visits in oversubscribed clinics). 2) "Adaptation." Participants felt that the SICG tool, while helpful, often needed to be modified during actual use. Many felt that sustaining this process would require adaptation by the system to overcome the barriers of time and emotional drain on the physician.

CONCLUSIONS: These findings shed light on the acceptability and feasibility of the SICG in the CHC setting. While participants enthusiastically embraced the use of the SICG and felt it had a beneficial impact on patient care, there remain barriers to its sustained use. Further work should examine what adaptations are needed to overcome these barriers so that this important intervention can become part of routine practice for the patients served by CHCs.

TIME FOR CLINIC: A MULTI-CENTER ASSESSMENT OF FOURTH YEAR PRIMARY CARE EXPOSURE AND AMBULATORY PREPAREDNESS AMONG INTERNAL MEDICINE INTERNS

Julia B. Nath[1]; Julie Oyler[1]; Amber-Nicole Bird[2]; Maryann K. Overland[3]; Lesley E. King[3]; Christopher Wong[3]; Amy Shaheen[4]; Amber Pincavage[1]. [1]Internal Medicine, University of Chicago, Chicago, IL; [2]General Internal Medicine, University of Pennsylvania, Philadelphia, PA; [3]General Internal Medicine, University of Washington, Seattle, WA; [4]Internal Medicine, UNC, Chapel Hill, NC. (Control ID #3345964)

BACKGROUND: Fourth year medical school training for students applying to internal medicine (IM) residency programs traditionally emphasize inpatient experiences. Only 13% of U.S. medical schools require dedicated IM ambulatory training.[1] Interns arriving for IM residency consistently report low levels of preparedness for ambulatory experiences.[2] We therefore sought to assess fourth year primary care exposure among IM interns and its relationship to self-assessed preparedness for their primary care clinic.

METHODS: The authors created an anonymous sixteen item survey that queried intern demographics, medical school primary care exposure (both IM and multi-specialty), and self-assessed preparedness for ambulatory medicine during residency. In June - August 2019 four geographically diverse IM residency programs (University of Chicago, University of North Carolina, University of Pennsylvania and University of Washington) administered the survey to 161 interns.

RESULTS: A total of 138 interns (86%) responded to the survey. The median last exposure to clinical primary care training was 13 months prior to the start of residency (interquartile range [IQR] 7-18 months). During the fourth year of medical school, the median amount of ambulatory IM experience was zero days (IQR: 0 – 20 days) and 2.5 days for any primary care (IQR: 0 – 26.5 days). Interns who rated themselves as prepared ($\geq$ 3 on 5-point Likert scale) for primary care clinic responsibilities had an average of 4.6 fewer months between their last primary care exposure and the start of internship than those who rated themselves as unprepared (10.7 vs. 15.3 months; 95% CI: 2 – 7 fewer months; $p<0.01$). "Prepared" interns also reported an average of 14.6 more total primary care days (22.3 vs. 7.7 days; 95% CI 8 – 21; $p<0.01$) and 6.5 more IM clinic days (13.7 vs 7.2 days; 95% CI 1.7 – 11; $p<0.01$) during fourth year compared to their "unprepared" counterparts.

CONCLUSIONS: The majority of incoming IM interns had little exposure to primary care during the fourth year of medical school. At the start of residency, IM interns who felt more prepared for their primary care clinic reported more recent and more numerous primary care experiences. Including more primary care experiences as part of fourth-year training could improve preparedness of medical students who are applying to internal medicine residency. Additionally, enhancing initial levels of intern ambulatory supervision or increasing intern ambulatory training experiences may be helpful.

TIME TO ANTIBIOTICS IN SEPSIS: DEFINING TIME-ZERO AMONG PATIENTS WITH MAJOR ORGAN DYSFUNCTION

Katie Raffel[1]; Priya A. Prasad[2]; Armond Esmaili[3]; Kathleen D. Liu[1]; Sachin J. Shah[4]; Kirsten Kangelaris[4]. [1]Internal Medicine, University of California San Francisco, San Francisco, CA; [2]Division of General Internal Medicine, Department of Epidemiology and Biostatistics, UCSF, San Francisco, CA; [3]Medicine, UCSF, San Francisco, CA; [4]Division of Hospital Medicine, Department of Medicine, University of California, San Francisco, San Francisco, CA. (Control ID #3391823)

BACKGROUND: The 2016 Surviving Sepsis Campaign guidelines recommending antibiotic administration within 1-hour of emergency department (ED) presentation have been criticized for their role in overdiagnosis and treatment. More recently clinician experts have called for antibiotic timeliness guidelines that reflect risk of death from acute physiologic derangements, based on the principle that risk of death in sepsis increases after development of major organ dysfunction (MOD). However, the association between time to antibiotics (TTA) from onset of MOD and mortality has not been tested. We evaluated the association between TTA from development of first MOD on mortality in sepsis.

METHODS: We performed a retrospective cohort study at an academic medical center extracting data from the electronic health record (EHR) on adults presenting to the ED between 6/2012 and 12/2018 who met validated Sepsis-III EHR criteria. Time-stamped measurement of MOD within the first 48 hours [defined as 1) lactate $\geq$4, 2) GCS $\leq$12, 3) shock requiring vasopressor or 4) O_2saturation/$FiO_2\leq$300], antibiotic administration and inpatient mortality were collected.

Multivariable logistic regression was used to evaluate the association between time from MOD to antibiotics (before MOD [<0hrs], 0-1hr after MOD, 1-3hrs after MOD and >3hrs after MOD) and in-hospital mortality, adjusting for demographics, comorbidities, severity of illness, and time to MOD (Table).

RESULTS: There were 7,122 patients presenting to the ED with confirmed sepsis and MOD. Median time from ED presentation to MOD identification was 1.5hrs (IQR 0.3 – 6.31), and from ED presentation to antibiotics administration was 2.5hrs. Overall mortality was 17.1% (1221/7122).

In multivariable analysis, when compared with patients receiving antibiotics preceding MOD (<0 hour), patients receiving antibiotics 0-1hr (OR 1.36, 1.08-1.72, p=0.009), 1-3hr (OR 1.53, 1.21-1.92, p<0.001) and >3hr (OR 1.54, 1.22-1.96, p<0.001) after MOD had a stepwise increase in odds of death (Table).

CONCLUSIONS: These results confirm a known mortality benefit to early antibiotics among patients presenting with major organ dysfunction. However, this study newly demonstrates a more pronounced mortality benefit from antibiotics preceding MOD. This benefit compels health systems to maintain current 1-hour TTA target for all patients presenting with sepsis until we are better able to predict development of MOD. Stratifying TTA targets by severity of illness, as defined by acute MOD, could unintentionally increase the mortality of patients with delayed major organ dysfunction.

Table 1: Multivariable* analysis of the association between time to antibiotics from major organ dysfunction on mortality in sepsis

Time from MOD to Antibiotic Categories	Sepsis with MOD Percentage (N= 7,122)	Mortality Odds Ratio (CI)	P-value
<0 hours	39.6 (2,819)	1.0 (ref)	--
0-1 hours	20.3 (1,445)	1.36 (1.08-1.72)	0.009
1-3 hours	21.4 (1,526)	1.53 (1.21-1.92)	<0.001
>3 hours	18.7 (1,332)	1.54 (1.22-1.96)	<0.001

*Multivariable logistic regression adjusted for the following variables: Antibiotic opportunity time (time from ED presentation until development of Major Organ Dysfunction), Illness severity (Sequential Organ Failure Assessment score at the time of sepsis diagnosis, Triage Systemic inflammatory Response Criteria), Demographic characteristics (age, gender, race/ethnicity, limited English proficiency), Elixhauser comorbidity score, admission year, pre-admission location (home, SNF, etc.)

TIME TO BRING IT HOME? ASSESSING POTENTIAL MEDICARE COST SAVINGS ASSOCIATED WITH GREATER HOME DIALYSIS USAGE

Mandar Bodas[1]; Rachael Zuckerman[2]; Steve Sheingold[2]; Jesse Roach[3]; Andre Chappel[2]. [1]Office of Health Policy, Office of Assistant Secretary for Planning and Evaluation, U.S. Department of Health and Human Services, Washington, DC; [2]Office of the Assistant Secretary for Planning and Evaluation, Department of Health and Human Services, Washington, DC; [3]Centers for Medicaid and Medicare, Baltimore, MD. (Control ID #3389716)

BACKGROUND: Nearly 37 million Americans have kidney disease, the ninth-leading cause of death in the United States. Less than 1% of Medicare beneficiaries have ESRD, but this condition accounts for 7% of Medicare's annual budget. ESRD patients are generally treated by dialysis, which is both costly and burdensome for patients. Evidence indicates that home dialysis may be cheaper to provide and better suited to the lifestyles of certain patients. Prior studies comparing home and facility dialysis generally had relatively small sample sizes derived from single healthcare settings. We address this important gap in the literature and produce evidence that can be generalized at the national level

Our objective was to compare spending on Medicare beneficiaries with end stage renal disease (ESRD) that use home dialysis to spending on beneficiaries that use facility dialysis in a comprehensive, nationally-representative administrative claims data set.

METHODS: We used data from Medicare Enrollment Database (EDB) and Master Beneficiary Summary File (MBSF). Using multivariate Generalized Linear Models (GLM) and controlling for demographic characteristics along with comorbidities, we evaluated total per beneficiary per month (PBPM) spending on beneficiaries receiving home and facility dialysis. Since ESRD is a qualifying condition for Medicare coverage for those younger than 65 years, we performed the analysis separately within two sub-groups of Medicare beneficiaries – those who were 66 years or older and those who were 65 years and younger. We used propensity score matching (PSM) methods for our multivariate analysis.

Starting with all Medicare beneficiaries with ESRD enrolled in Parts A and B in the year 2016 (N=314,704), we excluded beneficiaries that commenced dialysis for the first time in 2016, had high number of comorbidities and/or had outlier average costs (more than 5 times the mean PBPM). After applying these exclusions, the total sample size was 247,422. The sample size for our PSM analysis was 74,089.

RESULTS: Overall, 11% of beneficiaries with ESRD were home dialysis users. In both age subgroups, higher proportion facility dialysis users were female, non-Hispanic Black, Hispanic and eligible for Medicaid. In multivariate analysis, we found that the use of home dialysis was associated with significantly lower cost among Medicare ESRD beneficiaries that are 66 years or older (approximately $162 PBPM, or $1,945 per beneficiary annually). However, we did not find statistically significant difference in PBPM costs among Medicare beneficiaries that are 65 years or younger.

CONCLUSIONS: One of the goals under the Advancing American Kidney Health initiative is to have 80 percent of new ESRD patients in 2025 receive dialysis in the home or receive a kidney transplant. We find evidence of lower total Medicare spending on beneficiaries, age 66 years or older, who chose to use home dialysis versus those that use facility dialysis.

TIME TO REIMBURSEMENT FOR HEALTH CARE FACILITIES UNDER THE GHANA NATIONAL HEALTH INSURANCE SCHEME, 2016-2017

June-Ho Kim[1,2]; Griffith A. Bell[2]; Hannah Ratcliffe[2]; Isaac Morrison[3]; John Koku Awoonor-Williams[4]; Stuart R. Lipsitz[1,2]; Asaf Bitton[1,2]; Dan Schwarz[2]; Lisa R. Hirschhorn[5,2]. [1]Division of General Internal Medicine and Primary Care, Brigham and Women's Hospital, Boston, MA; [2]Ariadne Labs, Boston, MA; [3]Ghana Medical Association, Accra, Ghana; [4]Ghana Health Service, Accra, Ghana; [5]Northwestern University Feinberg School of Medicine, Chicago, IL. (Control ID #3392247)

BACKGROUND: Longer reimbursement times of health insurance claims from payers to providers may adversely affect primary health care service delivery readiness and quality, such as provider retention and facility investment in infrastructure and supplies. In Ghana, the 2003 National Health Insurance Scheme (NHIS) was a major step towards universal health coverage. The national standard is ninety days for reimbursement, however, there are few current reports of reimbursement times and factors associated with delays. We describe national times to reimbursement for health care facilities in Ghana and facility-level factors associated with longer reimbursement times.

METHODS: We analyzed a health care facility and household survey conducted in Ghana from 2016-2017 by the Performance Monitoring and Accountability 2020 (PMA2020) program. Data collectors surveyed a nationally representative sample of health facilities on care delivery and facility management, including financing and typical times to reimbursement for claims submitted to the NHIS. We described the range of time to reimbursement and facility-level predictors. In a secondary analysis, we also explored association of time to reimbursement with frequency of late staff payment and retention (number of staff who left the facility in the past 6 months) and patient-reported experiential quality assessed through the linked household survey.

RESULTS: We surveyed 131 health care facilities in 2016 and 135 facilities in 2017 reported claims reimbursement times. The median time

to reimbursement for all facilities in both years was 8 months. Nine facilities (6.87%) reported reimbursement times 1 month or less in 2016 while only two facilities (1.48%) reported 1 month or less in 2017. Factors associated with more rapid reimbursement included greater numbers of beds, having an electronic medical record and using DHIMS2 to track their data. Facilities with annual budgets and those that had been externally audited in the past year also had lower median times to reimbursement. Other facility-level characteristics were not associated with differences in time to reimbursement. There was no relationship for time to reimbursement with frequency of late staff payment and staff retention rates or patient-reported experience measures.

CONCLUSIONS: The median time of eight months from claims submission to reimbursement, is longer than the NHIS goal of a 90-day turnaround. There were various facility-level infrastructure and management factors associated with lower times to reimbursement, but, in our sample, longer reimbursement times were not associated with differences in staff retention or patient experience. Improvements in infrastructure and aspects of facility management at Ghanaian health care facilities may improve claims processing and times to reimbursement. Further research is needed to study the downstream effects on providers and service delivery, which could enhance the country's goal of high-quality health care and universal health coverage.

TITLE COST-CONSCIOUS PRESCRIBING IN DIABETES CARE: AN NHANES ANALYSIS

Alexandra M. Mapp[3]; LeRoi S. Hicks[4]; Jennifer N. Goldstein[1,2]. [1]Medicine, Christiana Care Health System, Newark, DE; [2]The Value Institute, Christiana Care, Newark, DE; [3]Value Institute, Christiana Care Hospital, Newark, DE; [4]Department of Medicine, Christiana Care Health System, Newark, DE. (Control ID #3389453)

BACKGROUND: The price of analog insulin has increased dramatically, making it unaffordable for many patients with diabetes. By contrast, human synthetic insulins are available at a fraction of the cost. The National Academy of Medicine has recommend that providers incorporate financial factors into care management strategies, a strategy referred to as *social risk-informed care*. Although qualitative studies have demonstrated that some clinicians consider the cost of insulin among their patients with financial risk factors, this has not been examined on a national scale.

METHODS: Retrospective cross-sectional analysis of 4 cycles of the National Health and Nutrition Examination Survey (NHANES) to examine use of human versus analog insulin based on self- reported financial constraints, defined as the presence of one or more of the following patient characteristics: food insecurity, poverty, lack of access to prescription drug coverage, low educational attainment, and history of being uninsured in the prior 12 months. Secondary outcomes included the association between use of human versus analog insulin on diabetic complications (uncontrolled Hemoglobin A1c (HbA1c), proteinuria, diabetic retinopathy and overnight hospitalization) stratified by the presence or absence of financial constraints.

RESULTS: Of 22,263 eligible respondents, 698 (3.1%) reported use of insulin and the type of insulin used, representing 485,228 patients nationally. Nearly ¼ respondents, 23.2% (n=195), reported use of human insulin and 72.5% (n=503) of respondents reported at least 1 financial risk factor. Overall, we found that patients with financial risk factors were significantly more likely to use human insulin compared to patients without any financial risk factors (88.5% vs 76.7% p=0.014). Although financial risk was independently associated with an increased odds of adverse diabetes outcomes (AOR 2.37 95% CI 1.16-4.84), the use of human synthetic insulin did not appear to contribute to this risk on multivariate analysis (AOR 0.91 95%CI 0.47-1.75).

CONCLUSIONS: Our study provides evidence that patients with financial risk factors may be more likely to use human synthetic insulins compared to insulin analogs which suggests that providers may be engaging in in social risk-informed care for patients. Although financial risk factors appear to be associated with worse diabetes outcomes, use of human synthetic insulin does not and should be considered as a low-cost alternative to analog insulin among patients with financial risk factors.

TOBACCO SMOKING-INDUCED LEUKOCYTOSIS

Caleb J. Smith[1]; Lindsey Kluck[2]; Gordon Ruan[1]; Aneel Ashrani[2]; C. Christopher Hook[2]; Ariela Marshall[2]; Rajiv K. Pruthi[2]; Mithun V. Shah[2]; Alexandra Wolanskyj-Spinner[2]; Naseema Gangat[2]; Ronald S. Go[2]. [1]Department of Internal Medicine, Mayo Clinic, Rochester, MN; [2]Division of Hematology, Mayo Clinic, Rochester, MN. (Control ID #3390831)

BACKGROUND: Tobacco smoking is a recognized cause of leukocytosis but little is known about the degree of leukocytosis nor the impact of smoking cessation. We aimed to characterize tobacco smoking- induced leukocytosis and describe the longitudinal impact of smoking cessation on white blood cell (WBC) count.

METHODS: Medical records of patients undergoing evaluation by hematologists for persistent leukocytosis which included BCR-ABL testing (polymerase chain reaction and fluorescent *in situ* hybridization) between January 1st, 2014 and December 31st, 2018 were studied. Patients in whom leukocytosis was determined to be secondary to tobacco use after exclusion of other causes were identified. Age, sex, body mass index (BMI), carboxyhemoglobin level, and complete blood cell count (CBC) were collected. Tobacco use was characterized as packs per day (PPD) and pack-years.

RESULTS: Forty patients with a median age of 49.5 years (range: 28-75) were determined to have smoking- induced leukocytosis. 24 patients were female and the mean BMI was 31.5kg/m^2. On average patients smoked 0.9 PPD for a median of 34 pack-years (range: 3-59). Mean CBC values included: WBC count 13.3x10^9/L (range: 9.8 to 20.9x10^9/L), hemoglobin 15.0g/dL, platelet count 298x10^9/L, neutrophil count 8.8 x10^9/L, lymphocyte count 3.2x10^9/L, monocyte count 0.87x10^9/L, eosinophil count 0.34x10^9/L, basophil count 0.09x10^9/L. 39 patients had absolute neutrophilia (98%), 21 lymphocytosis (53%), 20 monocytosis (50%), 19 basophilia (48%), 12 erythrocytosis (30%), 9 eosinophilia (23%), and 8 thrombocytosis (20%). Carboxyhemoglobin was elevated in all patients who were tested (n=6). Eleven patients either quit (n=9) or reduced (n=2) tobacco use. When compared to initial WBC count, reduction in tobacco smoking led to a significant decrease in WBC count (12.8x 10^9/L vs 10.8x10^9/L, p<0.01). On average, leukocytosis improved five months following reduction in tobacco use (range: 1-11 months). None of the patients who continued to smoke had resolution of their leukocytosis.

CONCLUSIONS: Tobacco-induced leukocytosis was characterized by a mild elevation in WBC and was most commonly associated with neutrophilia, lymphocytosis, and/or monocytosis. Cessation of smoking led to improvement in leukocytosis. Tobacco history should be elicited from all patients presenting with leukocytosis to limit unnecessary diagnostic testing, and counselling regarding smoking cessation should be offered.

TRACKING ABNORMAL MAMMOGRAM RESULTS AND BARRIERS TO FOLLOW-UP: PRIMARY CARE PHYSICIANS' PERSPECTIVES

Sarah J. Flynn[1]; Celia P. Kaplan[1]; Steven Gregorich[1]; Jennifer Livaudais Toman[1]; Karla Kerlikowske[1]; Nancy Burke[2]; Leah S. Karliner[1]. [1]Medicine, University of California San Francisco, San Francisco, CA; [2]University of California Merced, Merced, CA. (Control ID #3390860)

BACKGROUND: Lack of timely follow-up of abnormal mammogram results can lead to delays in breast cancer diagnoses. Ensuring follow-up is usually a task for ordering providers - largely primary care physicians (PCPs). Tracking systems are important aids in assuring timely follow-up. We investigated the variability in tracking systems for abnormal mammogram results among PCP practices and examined how this variability related to perceived barriers to achieving follow-up.

METHODS: We surveyed General Internal Medicine and Family Medicine PCPs practicing in San Francisco. Practice models included academic, public safety net, staff model HMO, and private. Survey questions investigated formal tracking system utilization (none, outside of electronic medical record [EMR], EMR with registry, EMR with registry and alerts) and perceived barriers to follow-up. We combined and averaged barrier scores to create a measure of follow-up barrier burden based on score distribution (range 0-3): low (0-0.9), moderate (1-1.6), high (1.7-3). We investigated associations between tracking system type, practice model, and follow-up barrier burden.

RESULTS: Of 588 eligible respondents, 300 (51%) completed the survey. Almost half (47%) reported having no formal tracking system. Type of tracking system varied across practice models ($p<0.001$): academic PCPs were least likely to report having a formal tracking system (15/79; 19% with any tracking system) and staff model HMO PCPs were most likely to report tracking in the EMR with a registry and alerts (38/45; 84%). Follow-up barrier burden also varied across practice models ($p<0.001$): 82% of academic and 80% of public safety net PCPs experienced moderate or high burden compared to 36% of staff model HMO and 60% of private practice PCPs. Tracking system type was associated with follow-up barrier burden ($p=0.004$). Of 86 PCPs experiencing high follow-up barrier burden, most either had no formal tracking system (52%) or tracked outside the EMR (19%). Of 93 PCPs experiencing low follow-up barrier burden, 52% tracked within the EMR with a registry. Follow-up barrier burden was not associated with the proportion of patients served by the practices from race-ethnic minorities ($p=0.85$), with limited English proficiency ($p=0.44$), or with Medicaid insurance ($p=0.92$).

CONCLUSIONS: Utilization of tracking systems for abnormal mammogram results varied across practice models. Higher follow-up barrier burden was associated with inadequate tracking systems. This was most prevalent in academic and public safety net settings. Follow-up barrier burden was not associated with patient characteristics, but rather with system issues related to tracking. To reduce burden that may lead to delayed follow-up and poor quality of care, primary care practices should address systems-level factors by maximizing EMR capabilities to track abnormal mammogram results.

TRACKING CHRONIC OPIOID PRESCRIBING METRICS FOR QUALITY IMPROVEMENT – WHAT HAPPENS TO PATIENTS WHO FALL OFF THE LIST?

Sonali Rodrigues, Marilyn Katz, Rebecca Andrews. Internal Medicine, University of Connecticut School of Medicine, Hartford, CT. (Control ID #3388253)

BACKGROUND: In the past fifteen years, there has been a reported 370% increase in opioid overdose deaths in the United States. In light of this epidemic, there has been movement to address the safe prescribing of long term opioid therapy (LTOT) as issues of "doctor-shopping" and limited evidence of impact on pain/function have been revealed. While this movement has contributed to a decrease in the number of new opioid prescriptions, providers are faced with the question of how to treat patients who have been on LTOT for years. In evaluating the outcomes of this population, recent studies have noted that patients on LTOT demonstrate a higher mortality rate, as well as a higher rate of overdose-related deaths when the opioid prescription had been discontinued.

In line with national and state guidelines, UConn Health recently implemented a policy for patients receiving LTOT as defined as 3 months or longer. The data regarding this patient population was evaluated to assess UConn providers' compliance to this policy. Over time, the number of patients identified as receiving LTOT from UConn prescribers has decreased. The goal of this study is to evaluate the reason why patients discontinued their prescription at UConn since the policy was introduced, as these patients may represent a group at high risk of opioid misuse or overdose.

METHODS: As part of an ongoing quality improvement project, data on patients receiving chronic opioids (at least 3 prescriptions during a 12-week period) from UConn Health prescribers have been reviewed on a quarterly basis. We compared data sets from one data pull to the next to determine which patients had "fallen off" the list, with a total of 322 patients. Patients on suboxone or methadone for opioid use disorder were excluded from the study. For each patient, pain type, active opioid prescriptions, date of prescription discontinuation or last fill date, date of last appointment with the responsible prescriber, and reason for discontinuation were documented based on information from the patient chart and the Connecticut prescription monitoring database program.

RESULTS: Data is still in review. Initial analysis reveals very few patients have discontinued their opioid prescriptions. The most common reasons for no longer being on the list fall into the following categories: "patient seeing pain management," "receiving prescription from outside provider," "opioids restarted," "lost to follow-up," or "left practice". Patients who left the practice often did so due to provider-initiated discontinuation of their prescription. The least frequent reason for discontinuation has been "resolution of pain".

CONCLUSIONS: As providers have become more aware of the harm of initiating opioid prescriptions, there remains a question of how to manage patients already on LTOT. Our study demonstrates that most of these patients have not transitioned to being opioid free, indicating a need for further research on the outcomes of chronic pain patients.

TRACKING PATIENT PERCEPTIONS OF INTERPROFESSIONAL TEAMWORK IN TWO RESIDENT TRAINING PRACTICES

Esther YI[2]; Lauren Block[1]; Danielle Miller[3]; Daniel J. Coletti[1,2]. [1]Medicine, Northwell Health, Great Neck, NY; [2]The Donald and Barbara Zucker School of Medicine at Hofstra Northwell, Hempstead, NY; [3]Medicine, Northwell Health, New York, NY. (Control ID #3391450)

BACKGROUND: Internal medicine residency programs are incorporating interprofessional (IP) training experiences into ambulatory curricula, but the IP competencies most appreciated by patients served by training practices have yet to be fully elucidated. The objective of this report was to compare patient satisfaction and perception of teamwork in patients seen by an innovative IP team with patients seen in a general resident continuity practice. We also sought to assess changes in patient satisfaction in these two practices over two time periods.

METHODS: Participants were patients in a hospital-affiliated ambulatory clinic that houses both a traditional Internal Medicine (IM) resident practice and a novel IP training program for residents, medical students, and trainees in physician assistant, pharmacy, and psychology programs. Patients are randomly assigned to one of the two practices. A convenience sample was asked to complete a questionnaire comprised of the PIVOT (Patients' Insight and Views of Teamwork), 14 additional items assessing perceptions of quality and access to care, and open-ended iquestions to obtain impressions of the clinic and teamwork. Surveys were offered in English and Spanish. Data was collected during two 8-week periods in summer 2017 and summer 2019. A two-by-two factorial design analyzed group differences at the two time points. We also conducted content analysis of open-ended items.

RESULTS: We obtained surveys from 131 patients treated by the IP practice and 114 patients in the traditional resident practice (38% male, 62% female, mean age = 54.44(15.32)). Satisfaction was high overall, with a small but nonsignificant increase in mean PIVOT scores from 2017 (M=4.23(0.6)) to 2019 (M=4.32(0.53), F(1,241)=1.67, p=0.2). Mean scores in the IP clinic (M=4.3(0.59)) and the traditional clinic (M=4.25(0.55)) were comparable (F(1,241)=0.54, p=0.46). Item analysis suggested that patients in the IP clinic felt better informed about delays (F(1,185)=5.81, p=.02). Patients seen by the IP team more frequently included specific names of team members in their comments. Patients in both clinics highlighted improved communication as one of the main advantages of teamwork within the patient care team.

CONCLUSIONS: Patient satisfaction was generally high in the IP and traditional resident clinics at both time points, with some indications that interprofessional care may lend itself to better coordination of care and attentiveness to patients' needs. Moreover, responses to open ended items suggest that patients recognize the importance of teamwork in enhancing communication. Mentioning specific names of team members may also be an indication that patients in the IP practice felt more connected to their providers. Additional data collection is required over time to further assess the effectiveness of interprofessional care and patients' perceptions of teamwork.

TRACKS IN INTERNAL MEDICINE RESIDENCY TRAINING PROGRAMS: CUSTOMIZING RESIDENCY EDUCATION

Eliana Hempel[1]; Jennifer Cooper[1]; Elizabeth Zimmerman[2]; Jed Gonzalo[2]. [1]Medicine, Penn State Health, Hershey, PA; [2]Medicine, Penn State College of Medicine, Hershey, PA. (Control ID #3391094)

BACKGROUND: Opportunities for specialized training in Internal Medicine Residency Programs (IMRPs) first emerged in the 1970s in the form of Primary Care Tracks (PCTs). With increasing health system complexity, further specialized tracks within IMRPs, such as hospitalist tracks and clinician-educator tracks, have also been developed. Despite the expansion of these opportunities, there is a paucity of data on their prevalence. We explored the prevalence and track types currently offered in IMRPs to better define the current state of residency training.

METHODS: To identify the prevalence and types of tracks within ACGME-accredited IMRPs, we reviewed program-reported data from program websites and the AMA's Fellowship and Residency Electronic Interactive Database Access System (FREIDA™). We utilized each program's ACGME code to access their website and FREIDA report. We developed a review tool to classify the tracks reported on both resources. Frequencies of track types were then tabulated.

RESULTS: To date, 298 of 539 IMRPs have been reviewed. Results reveal a great variety of track offerings with the most prevalent tracks being PCTs, research, global health, and hospitalist tracks. All tracks are listed in Table 1. With the exception of research tracks, tracks were more frequently reported on FREIDA than on program websites. Additional analyses are underway.

CONCLUSIONS: At least one track was present in 37% of IMRPs. Early data suggests that programs with only one track are most likely to feature PCTs. The discrepancies between FREIDA and program websites may pose challenges for residency applicants. Our results are limited by the information presented in these resources, which may be outdated or inaccurate. However, medical educators and students have few other resources with which to review currently available residency tracks. Our data confirms that IMRPs continue to customize residency training by offering a variety of specialized training tracks.

TRAINING RESIDENT-PHYSICIANS TO IDENTIFY AND ADDRESS HEALTH AND HEALTHCARE DISPARITIES: A MEGA THINKING AND PLANNING STRATEGY

Yorlenis Rodriguez, Dona Rose, Vida Farhangi, Karen Hamad, Wilhelmine Wiese-Rometsch. Internal Medicine Residency Program, Florida State University-Sarasota Memorial Hospital, Sarasota, FL. (Control ID #3391739)

BACKGROUND: The Accreditation Council for Graduate Medical Education (ACGME) expects physicians trained to identify and address disparities in health and healthcare. The Florida State University (FSU) Internal Medicine Residency Program at Sarasota Memorial Health Care System (SMHCS) used Kaufman's Mega Thinking and Planning (MTP) principles in its design to improve health and health care outcomes for the community of Sarasota.

METHODS: Mega planning posits that all organizations add value to society. Macro planning identifies intra- and extra-mural stakeholders to provide inputs with measurable objectives. Micro planning operationalizes staff inputs congruent with organizational performance metrics. MTP requires alignment of vision at the mega, macro and micro levels. This ideal, but measurable vision, guides planning elements including societal impact, processes, inputs, integration and performance-based outcomes.

ACGME, FSU, and SMH visions anchored MTP resulting in a collaboration between FSU, SMHCS and community partners (Macro) to build an internal medicine resident-based primary care clinic (Micro) using patient-centered medical home (PCMH) model. The Clinic serves an impoverished adult population with complex healthcare needs contributing to high rates of hospitalizations and utilization of emergency services. On- site services include pharmacists, dietitians, financial benefits coordinator, medical-legal aid.

RESULTS: Clinic services commenced July 2017 with inaugural PGY1 residents. Results are presented through June 2019: 3,754 established patients with 8,258 patient encounters; 2,518 uninsured patients screened and 57% qualified for assistance; 3,245 laboratory medicine assays. PCMH metrics: influenza immunization 48%; pneumococcal vaccination 13%; colorectal cancer screening 60%; breast cancer screening 83%; HbA1c poor control (>9%) 60%; and medical attention for diabetic nephropathy 93%. Macro performance included SMHCS inpatient and Emergency Department services referred over 300 patients; SMHCS Community Specialty Center provided free specialty care for 938 patients; and Good Samaritan Pharmacy funded over $1M for prescriptions. Improved health is evidenced by established clinic patients (pre-post through June 2019) increased hospitalization (access), but reduced readmission patterns (improved follow-up). Generalizable resident-driven scholarship involving QI initiative themes include congestive heart failure; pre-DM2 intensive primary care; primary care prevention and advanced directive planning.

CONCLUSIONS: Critical to MTP success is consensus building framework with avenue to ideal vison through performance criteria at Micro and Macro levels. This process drives an ethical and practical strategy to ensure added value to society. Practice patterns learned during residency training are predictive of future practice. Our clinic provides residents a longitudinal 39-weeks experience immersed in this abstract's story.

TRANSFORMATIVE LEARNING IN GRADUATE MEDICAL EDUCATION – A SCOPING REVIEW

Benjamin Vipler[1,2]; Jennifer McCall-Hosenfeld[2]; Paul Haidet[2]. [1]General Internal medicine, Penn State Health, Lancaster, PA; [2]Medicine, Penn State College of Medicine, Hershey, PA. (Control ID #3391785)

BACKGROUND: Transformative learning (TL) is an educational theory centered on perspective transformation, and has recently emerged as a promising technique in health professions education (HPE).[1-4] TL may be particularly salient for addressing social determinants of health (SDH). While direct patient experiences with the medically underserved may benefit learners, a change in worldview – as espoused by TL – may be necessary to produce optimal practice behaviors. Unfortunately, ways to employ TL in graduate medical education (GME) may not be obvious, and its penetration in this realm is currently unclear. We undertook this study to better understand the literature on TL within GME, with particular attention to learning SDH.

METHODS: Systematic comprehensive searches were executed in the MEDLINE database for articles that met predefined inclusion and exclusion criteria. Articles were included if they discussed TL in the post-graduate training setting (defined as post-receipt of the terminal degree but before unsupervised practice). Search criteria used Boolean operators to include various synonyms for TL and GME. References to other manuscripts on TL cited by included papers were evaluated for inclusion. A qualitative thematic analysis was performed with an initial focus on TL venues, outcomes, educational intent, learner perspective, and motivation. Through inductive coding, additional emerging themes and subcategories relevant to TL within GME were included, revealing SDH as a key theme.

RESULTS: We initially identified 69 citations. Through title, abstract, and full manuscript review, we narrowed our final set of citations to 12 manuscripts (figure 2).[5-16] The GME populations included a wide range of medical and surgical specialties,[5-7,10-16] psychology fellowship trainees[8] and Mexican social servants.[9] Four overarching themes were identified: 1) "Care of the medically underserved," 2) "Mentorship, role-modeling, and coaching," 3) "Inspiration from the larger organizational level," and 4) "Improvement in patient care." Seven manuscripts (58%) referenced TL in relation to the medically underserved.[6,7,9,10,13,15,16] Specific venues included international health electives (IHEs),[6] incarcerated patients or returning citizens,[7] community-based social service organizations,[15] and rural clinical training experiences.[9,10] The patient-doctor relationship,[6] resource limitations,[6,15] and team dynamics[9,10] were all integral to transformation. These transformations often drove commitment to future action.[6]

CONCLUSIONS: Transformative learning is a relatively new educational theory whose value is increasingly recognized in the HPE literature. The majority of currently published literature on TL within GME relates to care of the underserved, highlighting its connection to learning SDH. TL has potential to inspire future action among trainees. TL is an important tool for medical educators to create experiences that will have a lasting impact on their trainees and the patients and populations they serve.

TRANSGENDER CARE: RETENTION RATE OF TRANSGENDER PATIENTS AT AN LGBTQ CENTER OF EXCELLENCE

Kavitha Periyalwar. GIM, Denver Health, Denver, CO. (Control ID #3387489)

BACKGROUND: Transgender patients have low rates of access to health services due a wide range of issues including violence, legal barriers, stigma and discrimination (3). Estimating the prevalence of transgenderism has proven to be difficult with various studies coming up with a rate of approximately 0.6% (1, 2). For reference, the worldwide prevalence of HIV is 0.6-0.9% (9). By limiting access to care, transgender patients often lack basic preventative care, mental health support, as well as hormonal management leading some to self-medicate with unregulated and unlicensed hormonal preparations frequently bought over the internet (6).

Transgender patients are often living in the margins of society and face many restrictions even when attempting to access medical care. By creating an LGBTQ Center of Excellence, which is committed to providing excellent and affirming care for LFBTQ communities, we strive to remove some of these barriers for our most vulnerable patients. So how are we doing?

METHODS: EMR Epic application, Slicer Dicer, was used to identify all transgender patients (as identified in patient demographics) who were seen at Denver Health Medical Center by a primary care provider (defined as internal medicine or family medicine) in the last year (10/23/2018-12/20/2019). This data was then extracted to Microsoft Excel and manipulated using pivot tables to determine the number of times each patient returned for a follow up visit. This process was then repeated looking at all patients seen at Denver Health Medical Center during the same time frame and by the same group of providers, for comparison purposes.

RESULTS: A total of 947 patients were found to identify as transgender and sought care in the office setting from a primary care provider at Denver Health Medical Center between 10/23/2018 and 12/20/2019. Of these patients, 639 (67.5%) returned for one or more follow up visits. For comparison, 125 435 total patients presented for an office visit to a primary care provider at Denver Health Medical Center during the same time frame. Of these patients, 89 069 (71%) returned for one or more follow up visits.

CONCLUSIONS: Studies have already showed that a delay in accessing care leads to poorer outcomes amongst transgender patients (8). Therefore reducing barriers to care is paramount when treating this vulnerable population. Primary care physicians, in particular, play a key role in the care of transgender patients. This study shows that creating a center of excellence whose mission is to reduce barriers improves access to care for this population and brings their rate follow up to near equal to overall follow up rates.

TREATMENT OUTCOMES AND MORTALITY AMONG HOMELESS ADULTS IN AN OUTPATIENT-BASED ADDICTION TREATMENT PROGRAM, 2008-2018

Danielle R. Fine[1]; Elizabeth Lewis[2]; Sanju Nembang[2]; Jessie Gaeta[2]; Travis P. Baggett[1,2]. [1]Division of General Internal Medicine, Massachusetts General Hospital, Boston, MA; [2]Boston Health Care for the Homeless Program, Boston, MA. (Control ID #3377428)

BACKGROUND: People experiencing homelessness have been disproportionately impacted by the opioid crisis, with drug overdose death rates 20 times higher than the general population. There is very limited evidence examining the outcomes of Outpatient-Based Addiction Treatment (OBAT) programs designed specifically for homeless people. The objective of this study is to evaluate addiction treatment outcomes and risk factors for mortality in homeless-experienced patients with opioid use disorder (OUD).

METHODS: We conducted a retrospective cohort study of all adults (≥ 18 years) who had at least one OBAT encounter at Boston Health Care for the Homeless Program (BHCHP) between January 1, 2008 and December 31, 2017. The primary outcome was all-cause mortality, defined as any death that occurred by December 31, 2018 and identified by linking participants to the Massachusetts Registry of Vital Records and Statistics. Secondary treatment-related outcomes were retention in addiction care (defined by the presence of a urinary toxicology screen), buprenorphine adherence (defined by a positive buprenorphine toxicology result), and opioid abstinence (defined by a negative opioid toxicology result), all abstracted from the BHCHP medical record and measured on a monthly basis. We used descriptive statistics to assess these treatment-related outcomes at 1, 3, 6, and 12 months, and we used multivariable cox regression to identify baseline and time-varying characteristics associated with all-cause mortality.

RESULTS: We identified 1,238 patients with at least one OBAT encounter during the study period. The majority were male (74.0%) and nearly half were white (48.6%) with a mean age of 42.5 years. A total of 738 (59.6%) patients were retained in continuous addiction care at 1 month, 358 (28.9%) at 3 months, 219 (17.7%) at 6 months, and 135 (10.9%) at 12 months. The median number of months of buprenorphine adherence was 3 (IQR 1, 16) and the median number of months of opioid abstinence was 0 (IQR 0, 6). Overall, 157 (12.7%) patients died, yielding an all-cause mortality rate of 30.3 deaths per 1,000 person-years. Among those with cause of death information available (n=63), 50.8% died from a drug overdose. Older age predicted a higher mortality risk (aHR=1.43 per 10-year increment, 95% CI=1.23, 1.67; p<0.0001), while retention in addiction care conferred a lower mortality risk (aHR=0.46, 95% CI=0.29, 0.73; p=0.0008).

CONCLUSIONS: This cohort of homeless-experienced adults seeking OUD care had a high mortality rate, with over half of all deaths being attributable to drug overdose. There were significant drop-offs in retention in addiction care, particularly within the first 3 months of OBAT engagement. Although complete opioid abstinence was uncommon, retention in care was associated with decreased risk of mortality. Interventions to improve retention in addiction care within the homeless community will be important to mitigate mortality risk in this vulnerable population.

TRENDS IN NONCARDIOVASCULAR COMORBIDITIES AMONG PATIENTS WITH ACUTE MYOCARDIAL INFARCTION

CATHERINE L. TENG[1]; Pengyang Li[2]. [1]Yale New Haven Health, Greenwich Hospital, Greenwich, CT; [2]St. Vincent Hospital, Worcester, MA. (Control ID #3351833)

BACKGROUND: Updated knowledge of the full spectrum of comorbidities among patients with myocardial infarction(MI) in the United States remains limited. Specifically, there is limited data regarding noncardiovascular comorbidities in myocardial infarction, and if any, their prevalence varies tremendously between studies (Table 1). It was also suggested that some of those noncardiovascular comorbidities, like renal dysfunction and anemia, are associated with poor prognosis.

METHODS: Using the latest National Inpatient Sample database (NIS), we identified 127,730 patients admitted to hospital in 2016 with a principle diagnosis of MI. Comorbidities were identified by using ICD-10 in all the secondary diagnoses. We compared the cardiovascular comorbidities from NIS with the comorbidities revealed from previously published literature.

RESULTS: Among 127,730 of 129,305 patients carry a diagnosis of MI. The most common comorbidities remain conventional cardiovascular disease, including known coronary artery disease (61.61%), hyperlipidemia (58.62%), hypertension (53.97%), smoking (46.9%), type 2 diabetes mellitus (27.45%) and atrial fibrillation (19.7%).

The proportion of noncardiovascular comorbidities are significantly higher than previously supposed. As a matter of fact, little data was found discussing the non-cardiovascular comorbidities among patients with MI (Table 1). The common noncardiovascular comorbidities are the following: chronic renal disease (39.68%), anemia(24.53%), acute renal injury(19.12%), chronic obstructive pulmonary disease(13.2%), anxiety(9.94%) and depression(8.59%).

CONCLUSIONS: We conclude that in current era, myocardial infarction is a condition that is associated with an increasing burden of noncardiovascular comorbidities, which has not been systematically studied before. There is a need for future research on those noncardiovascular comorbidities in an effort to optimize the outcome of acute myocardial infarction.

TABLE 1. MYOCARDIAL INFARCTION AND THE PREVALENCE OF COMORBIDITIES (%)

TRUSTING COMMUNITY PARTNERSHIPS: A DESCRIPTIVE ANALYSIS OF PRE-CLERKSHIP CLINICAL EXPERIENCES

Erin Deery[2]; Caridad Hernandez[1]; Christine A. Kauffman[3]; Analia Castiglioni[1]. [1]Internal Medicine, University of Central Florida College of Medicine, Orlando, FL; [2]univeristy of Central Florida College of Medicine, Orlando, FL; [3]Medical Education, University of Central Florida College of Medicine, Orlando, FL. (Control ID #3392476)

BACKGROUND: Pre-clerkship clinical experiences are a vital component of undergraduate medical education. Engagement in an authentic clinical setting promotes students' deeper learning and professional identity formation. The University of Central Florida College of Medicine (UCF COM) offers a longitudinal clinical experience, Community of Practice (COP), along the first two years, partnering with volunteer community physicians. The objective of this study was to perform a descriptive analysis of COP to better understand the pre-clerkship clinical environment, patient population, and level of student involvement.

METHODS: During COP sessions, M1 and M2 students complete a Patient Encounter Log (PEL) capturing information regarding session location (inpatient vs outpatient), number of patients seen, patient demographics and chief complaint, level of student involvement and activities performed (i.e. history, exam, oral presentation, etc.). Through a retrospective, descriptive study, data from PELs from the academic years 2015-2016 through 2018-2019, were abstracted and deidentified prior to analyses. Descriptive statistical analyses of the responses recorded in the PELs were performed using SPSS software.

RESULTS: There were a total of 15,952 patients logged. COP-1 sessions took place most often in an Outpatient Setting (77.2%) and in an Acute Care Setting (56.2%) across COP-2. The patient population had a 50/50 distribution of female and male patients. About half of the patients seen in COP-1 were adults (ages of 18-64 years), with 19% being pediatric and 30.5% geriatric populations. Patients seen by COP-2 students were more evenly distributed (35.9% adult, 30% pediatric and 33.9% geriatric). For

both COP programs, cardiovascular, abdominal and musculoskeletal chief complaints were most prevalent, whereas Genitourinary and Gynecological complaints were seen least often. Student Involvement is outlined in Table 1.

CONCLUSIONS: UCFCOM COP program engages students with a diverse patient population in a variety of clinical settings. Student participation and clinical skills performed increased from COP-1 to COP-2 suggesting a rise in student involvement and clinical competence over time. There was a notable increase in the performance of clinical skills independently from COP-1 to COP-2. This study provides insight into community partnership models of pre-clerkship clinical education.

U.S. NONPROFIT HOSPITALS' COMMUNITY HEALTH NEEDS ASSESSMENTS AND IMPLEMENTATION STRATEGIES IN THE ERA OF THE AFFORDABLE CARE ACT

Leo Lopez[2,1]; Cary Gross[3]; Meera Dhodapkar[2,1]. [1]Internal Medicine, Yale University School of Medicine, New Haven, CT; [2]National Clinician Scholars Program, Yale University School of Medicine, New Haven, CT; [3]General Internal Medicine, Yale School of Medicine, New Haven, CT. (Control ID #3391914)

BACKGROUND: The Affordable Care Act codified new requirements as a condition for nonprofit hospitals maintaining their tax-exemption, including the conduct and internet-based dissemination of a triennial community health needs assessment (CHNA), and the adoption of a related implementation strategy (IS). Prior work suggests that only 11% of hospitals had conducted a CHNA before the rules went into effect. We determined hospitals' compliance with conducting a CHNA, adopting an IS, and making the documents publicly available. We then assessed the quality of publicly available CHNAs and ISs using explicit criteria based on IRS reporting guidelines.

METHODS: We performed a observational study of U.S. nonprofit hospitals. Using specific search terms on the Propublica Nonprofit Project Database, we identified a stratified random sample of 500 general and specialty nonprofit hospitals. We obtained the IRS form 990 Schedule H for each hospital to assess self- reported adherence to the CHNA and IS requirements. We then accessed hospital websites to obtain CHNAs and ISs using an explicit, standardized search of hospital websites. We then evaluated the quality of the available CHNAs and ISs by generating a score using the CDC State Plan Index (SPI) likert scale. This scale codifies the level of detail provided in these reports across multiple domains, ranging from 0 (not addressed) to 5=high quality/highly detailed. Quality was evaluated by trained abstractors, with random sample of reports undergoing dual review to ensure reliability.

RESULTS: Of the 500 U.S. hospitals in our sample, 99% (n=495) reported on their IRS 990 form that they had conducted a CHNA, and 98.4% (n=492) reported that they had made it available online. We were able to locate 87% (n=430) of these CHNAs online. Similarly, 98% (n=490) reported that they adopted an IS, and 80% (n=353) could be located online. The preliminary quality of both the CHNAs and ISs was variable. The average score was 3.26/5 for CHNAs (n=349). The proportion of CHNAs with a rating of solid or high quality varied: description of the community served (82% of CHNAs), description of methods (78%) to the process for obtaining input from the community (40%) or prioritizing health needs (33%) or evaluating impact (46%). Finally, 41.3% of IS strategies were evaluated as solid or high quality.

CONCLUSIONS: Although nearly all nonprofit hospitals were reportedly in compliance with the CHNA and IS requirements under the ACA, a minority of hospitals did not make these documents publicly available. Our preliminary assessment of CHNA quality found that many hospitals are neglecting crucial evaluation components in their effort to assess community health. Federal policy-makers have an opportunity to increase transparency and accountability amongst nonprofit hospitals by enforcing current IRS code.

UNANNOUNCED STANDARDIZED PATIENTS AS A MEASURE OF LONGITUDINAL CLINICAL SKILL DEVELOPMENT

Lisa Altshuler, Jeffrey Wilhite, Amanda Mari, Sarah Chaudhary, Khemraj Hardowar, Harriet Fisher, Kathleen Hanley, Adina Kalet, Colleen Gillespie, Sondra R. Zabar. Division of General Internal Medicine, New York University School of Medicine, New York, NY. (Control ID #3391789)

BACKGROUND: Unannounced Standardized Patients (USPs) provide opportunity to measure residents' clinical skills in actual practice. USPs, or secret shoppers, are trained to ensure accurate case portrayal across encounters, making them optimal for tracking changes in skills longitudinally. At present, little is known about how residents handle USP visits with repeat cases. This study examines variation in resident communication and global domain scores when visited by the same USP case at two separate time points during residency training.

METHODS: Primary care residents (n=46) were assessed twice by one of six standardized cases (asthma, fatigue, Hepatitis B concern, back pain, shoulder pain, or well visit) during the course of their residency, typically during their first and third training year. Upon visit completion, residents were rated using a behaviorally-anchored checklist. Communication domains assessed included info gathering (4 items), relationship development (5 items), and patient education (4 items). Other domains included patient activation (4 items) and satisfaction (4 items). Responses were scored as not done, partly done, or well done. Summary scores (mean % well done) were calculated by domain. All cases were combined to create composite scores, due to small sample sizes per case. First and second visit domain scores were compared using a t-test. Finally, we grouped high performers (80% or higher on communication scores during their first visit) because this measure demonstrated competency.

RESULTS: With cases combined, there were no significant differences based on time of assessment and changes in score between first and second visit were small. 14/46 (30%) learners who performed well on composite overall communication scores (80% or higher) during their first visit outperformed poorer communicators in patient satisfaction (93% vs 61%, P<.001) and activation (48% vs 18%, P<.001). In subsequent visits, these high performers performed at a similar level to their fellow residents, with no significant differences noted. Further, when looking at individual trajectories, individual learner scores in the communication domain increased between visits for 21 learners (46%), decreased for 19 (41%), and stayed same for 7 (15%).

CONCLUSIONS: Results suggest that a learning curve occurs between assessments during the first year in residency and subsequent assessments. This could be due to an increased capacity to engage with a patient occurring training progression, or due to a better understanding of addressing common chief complaints presented with our USP cases. Understanding causes of individual-level score decreases will enable tailoring of educational interventions suitable for specific learner trajectories, as will a deeper dive into the impact of the clinical microsystem on performance. We predict a more nuanced understanding of these mediating factors through our plan of increasing our repeat visit sample size.

UNCONTROLLED BLOOD PRESSURE AND RESISTANT HYPERTENSION IN ELDERLY CHRONIC KIDNEY DISEASE PATIENTS

Lipika Samal[2,3]; Edward Wu[2]; Skye Aaron[2]; Gearoid McMahon[1,3]; David W. Bates[2,3]; Sushrut Waikar[4,5]. [1]Division of Nephrology, Brigham and Women's Hospital, Boston, MA; [2]Division of General Internal Medicine, Brigham and Women's Hospital, Boston, MA; [3]Harvard Medical School, Boston, MA; [4]Division of Medicine, Boston Medical Center, Boston, MA; [5]Boston University School of Medicine, Section of Nephrology, Boston, MA. (Control ID #3391416)

BACKGROUND: A subgroup analysis from the SPRINT trial limited to patients ≥80 years old showed improved cardiovascular outcomes and no difference in injurious falls for patients in the intensive treatment arm (who achieved a mean systolic blood pressure of 123.9 mmHg). Management of hypertension in elderly CKD patients is complex. JNC8 recommends a target of 150/90 mmHg for adults aged ≥60, but also recommends a target of 140/90 mmHg for CKD patients, irrespective of age. We examined primary care data on systolic blood pressure (SBP) and number of anti-hypertensive (anti-HTN) medications in CKD patients ≥80 years old, as compared to younger CKD patients.

METHODS: Patients who had a primary care visit at one of our 15 primary care clinics between 4/1/2018-4/1/2019 were eligible. We included adults with stage 3-4 CKD in the preceding two years, defined as two estimated glomerular filtration rates (eGFR) between 15–59 mL/min/1.73 m^2 separated by at least 90 days. We divided CKD patients into three age groups 40-64, 65-79, and ≥80 years old, in order to compare mean SBP and mean number of anti-HTN medications across these groups. We also determined how many patients had resistant hypertension in each age group (SBP ≥140 mmHg despite being on ≥3 anti-HTN medications).

RESULTS: Of 105,849 primary care patients, 8,013 had stage 3-4 CKD. The CKD patients were 59% female, 12% African American, and 6% Hispanic or Latino. The mean SBP was higher for CKD patients ≥80 years old compared to patients aged 65-79 (132.1 mmHg vs. 129.9 mmHg, p <0.0001) and compared to patients aged 40-64 (132.1 mmHg vs. 128.1 mmHg; p < 0.0001). The mean number of anti-HTN medications was higher for CKD patients ≥80 years old compared to patients aged 40-64 (2.16 vs. 1.90, p <0.0001), but not compared to patients aged 65-79 (2.16 vs. 2.12). Uncontrolled SBP (≥140 mmHg) and resistant hypertension increased across stage of CKD and age group (Table 1).

CONCLUSIONS: In this cohort of patients with stage 3-4 CKD, mean SBP is highest for patients ≥80 years old, despite similarly aggressive management as that of patients 65-79 years old. Further research is needed to determine how increasing the number of anti-HTN medications in CKD patients ≥80 years old would affect cardiovascular outcomes, acute kidney injury, renal failure, and falls.

UNDERSTANDING BARRIERS AND SOLUTIONS TO OBTAINING AND UTILIZING AN X-WAIVER AMONG VETERANS AFFAIRS PRIMARY CARE PROVIDERS

Juliana Macri[1]; Sarah Leyde[3]; Tessa Rife[2]; Shalini Patel[1]. [1]UCSF Department of Medicine, San Francisco VA Health Care System, San Bruno, CA; [2]Dept of Pharmacy, San Francisco VA Health Care System, San Francisco, CA; [3]UCSF Department of Medicine, Zuckerberg San Francisco General Hospital, San Francisco, CA. (Control ID #3390551)

BACKGROUND: Opioid use disorder (OUD) and chronic pain are common, often co-occurring, conditions that are highly prevalent among Veterans. Within the San Francisco Veterans Affairs Healthcare System (SFVAHCS), only 33.0% of Veterans with OUD are prescribed pharmacotherapy treatment and over 1,000 have risk factors for developing OUD (e.g., prescribed chronic opioids). Buprenorphine, an evidence-based and highly effective treatment for both OUD and pain, can be prescribed by primary care providers (PCPs) with additional training and an X-waiver from the DEA. Of the 87 SFVAHCS PCPs, 17 (19.5%) are waivered; however, only 7 (8.0%) have prescribed buprenorphine within the past 6 months. We sought to understand barriers to obtaining an X-waiver, and identify interventions to increase buprenorphine prescribing from primary care.

METHODS: We created and distributed an online survey to all SFVAHCS PCPs (n=87) who work in geriatric, infectious disease, tele-primary care, and rural and urban primary care settings. Non-waivered providers were surveyed to evaluate interest in becoming waivered and barriers to obtaining a waiver. Waivered providers were surveyed to evaluate barriers to prescribing buprenorphine and solutions to increase prescribing.

RESULTS: Of the 40 survey responders (46.0% response rate), 25 (62.5%) were not waivered and 15 (37.5%) were waivered. Some non-waivered providers expressed interest in obtaining an X-waiver (mean 3.60 on a 5-point Likert scale, where 5=very interested). The most frequently reported barriers to becoming waivered were: 1) lack of time to complete training (n=17); 2) limited access to training (n=9); and 3) lack of incentive to become waivered (n=8). Among waivered providers, the most commonly reported barriers to prescribing were: 1) lack of knowledge and/or experience (n=9); 2) lack of clinic support/infrastructure (n=8); and 3) lack of time to counsel patients during visits (n=6). Interventions that waivered providers were interested in included: 1) a "buprenorphine mentor" to call as needed (mean 4.57 on a 5-point Likert scale, where 5=very interested); 2) educational materials (mean 4.14); 3) a 1-hour refresher course (mean 4.00); and 4) data identifying potential candidates for buprenorphine (mean 4.00).

CONCLUSIONS: Based on our survey of SFVAHCS PCPs, there are simple, actionable strategies that may increase the proportion of Veterans who have access to evidence-based treatment for OUD and chronic pain. Providing time, training resources, and employee incentives could increase the number of waivered PCPs. Once waivered, PCPs need further support to ensure confidence and skills in routine prescribing of buprenorphine. Strategies include mentorship, provider educational materials, and establishing clinic infrastructure to reduce the administrative burden of prescribing buprenorphine.

UNDERSTANDING CLINICIAN ATTITUDES TOWARD SCREENING FOR SOCIAL DETERMINANTS OF HEALTH IN A PRIMARY CARE SAFETY-NET CLINIC

Lisa Altshuler[1]; Harriet Fisher[1]; Amanda Mari[1]; Jeffrey Wilhite[1]; Khemraj Hardowar[1]; Mark D. Schwartz[1,2]; Isaac Holmes[1,3]; Reina Smith[3]; Andrew Wallach[1]; Richard E. Greene[1]; Anne Dembitzer[1]; Kathleen Hanley[1]; Colleen Gillespie[1]; Sondra R. Zabar[1]. [1]Division of General Internal Medicine, New York University School of Medicine, New York, NY; [2]Population Health, NYU School of Medicine, New York, NY; [3]Ambulatory Care, NYC Health + Hospitals/Bellevue, New York, NY. (Control ID #3391718)

BACKGROUND: Social determinants of health (SDoH) play a significant role in health outcomes, but little is known about care teams' attitudes about addressing SDoH. Our safety-net clinic has begun to implement SDoH screening and referral systems, but efforts to increase clinical responses to SDoH necessitates an understanding of how providers and clinical teams see their roles in responding to particular SDoH concerns.

METHODS: An annual survey was administered (anonymously) to clinical care teams in an urban safety-net clinic from 2017-2019, asking about ten SDoH conditions (mental health, health insurance, food, housing, transportation, finances, employment, child care, education and legal Aid). For each, respondents rated with a 4-point Likert-scale whether they agreed that health systems should address it (not at all, a little, somewhat, a great deal). They also indicated their agreement (using strongly disagree, somewhat disagree, somewhat agree, strongly agree) with two statements 1) resources are available for SDoH and 2) I can make appropriate referrals.

RESULTS: 232 surveys were collected (103 residents, 125 faculty and staff (F/S), 5 unknown) over three years. Of note, mental health (84%) and health insurance (79%) were seen as very important for health systems to address, with other SDoH items seen as very important by fewer respondents. They reported little confidence that the health system had adequate resources (51%) and were unsure how to connect patients with services (39%).

When these results were broken out by year, we found the following: In 2017 (n=77), approximately 35% of respondents thought the issues of employment, childcare, legal aid, and adult education should be addressed "a little," but in 2018 (n=81) and 2019 (n=74) respondents found the health system should be more responsible, with over 35% of respondents stating that these four issues should be addressed "somewhat" by health systems. In addition, half of respondents in 2019 felt that financial problems should be addressed "a great deal," up from 31% in 2017. Across all years, food, housing, mental health, and health insurance were seen as SDoH that should be addressed "a great deal". It is of note that respondents across all years reported limited understanding of referral methods and options available to their patients.

CONCLUSIONS: Many of the SDoH conditions were seen by respondents as outside the purview of health systems. However, over the three years, more members increased the number of SDoH conditions that should be addressed a "great deal." Responses also indicated that many of the team members do not feel prepared to deal with "unmet social needs". Additional examination of clinic SDoH coding, referral rates, resources, and team member perspectives will deepen our understanding of how we can cultivate a culture that enables team members to respond to SDoH in a way that is sensitive to their needs and patient needs.

UNIVERSAL SCREENING FOR SOCIAL DETERMINANTS OF HEALTH AND UNMET SOCIAL NEEDS DURING WELL VISITS AT THE INTERNAL MEDICINE-PEDIATRICS PRIMARY CARE GROUP PRACTICE

Jori Sheade[1]; Rebecca Chohlas-Wood[1]; Anna Volerman[2]; Ella Bradford[3]. [1]Internal Medicine and Pediatrics, University of Chicago, Chicago, IL; [2]Medicine & Pediatrics, University of Chicago, Chicago, IL; [3]University of Chicago, Chicago, IL. (Control ID #3376383)

BACKGROUND: Children raised in poverty commonly face unmet basic needs, such as food insecurity and unstable housing, and are at higher likelihood of exposure to violence. As a result of these unmet social needs, they are more likely to experience poorer health than children from more advantageous background. The link between social determinants of health and well-being is not limited to children. The American Academy of Pediatrics recommends universal screening for social determinants of health at all well-child checks, however there was no standardized system for screening children or adults at the University of Chicago Primary Care Group Medicine-Pediatrics clinic, which serves primarily low-income families on Chicago's South Side. We aimed to design and implement a protocol for universal screening of social determinants of health at every well child visit, then expand to include adult physicals.

METHODS: The validated WE CARE and IHELLP social determinants of health screening tools were modified to create a specific survey for our clinic, in collaboration between physicians and the clinic social worker. Based on identified community needs, our screening tool focused on housing insecurity, food insecurity, difficulty paying for utilities, difficulty with transportation to medical appointments, need for childcare, and exposure to domestic or community violence. We ensured all modifications maintained appropriate language for families with low health literacy. The medical assistants distributed the survey during the rooming process for every well-child check in our clinic, and now expanded to all adult physicals. Practitioners reviewed the questionnaire during the visit. If any the questions screened positive, shared a standardized resource with a list of community services that addressed the specific need.

RESULTS: In our initial sample of 93 screened families, 19% of our screeners were positive in one or more category. Of the positives, 44% were positive in two or more categories. The most common needs raised were affordable childcare (9.6%, n=9) and paying for utilities (8.6%, n=8). Five percent of our population screened positive for food insecurity and two percent positive for housing insecurity. Nearly all families that screened positive in one or more area were interested in receiving resources to address their needs.

CONCLUSIONS: Physicians have the capability to impact the link between unmet basic needs and health. We implemented a screening process for social determinants of health within an academic medicine-pediatrics clinic using a team-based care model and found a high rate of positive social determinants of health. By identifying unmet basic needs and linking families with appropriate community services, we can intervene and help support better health in the South Side of Chicago, impacting both short and long-term health. We are currently in the process of surveying families that screened positive to determine the effectiveness of our intervention and areas for improvement.

UNMET MEDICAL CARE NEEDS AMONG CALIFORNIA ADULTS DISPLACED DUE TO HOUSING COST

Katherine L. Chen[1,2]; Lauren E. Wisk[1]; Teryl K. Nuckols[2]; Joann G. Elmore[1]; Neil Steers[1,4]; Frederick J. Zimmerman[3]. [1]Internal Medicine, UCLA, Los Angeles, CA; [2]Internal Medicine, Cedars-Sinai Medical Center, Los Angeles, CA; [3]UCLA Fielding School of Pubic Health, Los Angeles, CA; [4]Veterans Affairs Greater Los Angeles Healthcare System, Los Angeles, CA. (Control ID #3390587)

BACKGROUND: Over 30% of all Americans and 40% of Californians face displacement from their communities as they struggle with burdensome housing costs, defined by the U.S. Department of Housing & Urban Development as housing expenses above 30% of household income. Displacement has the potential to exacerbate neighborhood segregation and health disparities. Previous studies linked the burden of housing cost to delays in seeking and receiving medical care, but little is known about health care access after displacement occurs. The objective of this study was to evaluate the health consequences of displacement in the context of housing cost.

METHODS: We performed a secondary analysis of all adult respondents in the California Health Interview Survey (CHIS) from 2011-2017 (n=146,417). The CHIS sample design excluded institutionalized or homeless individuals and anyone without a phone. All measures were self-reported. The primary independent variable was move history in the past 5 years, coded in 3 categories: moved due to housing cost, moved for other reasons, and did not move. The two outcome variables were recent unmet medication need and other recent unmet health care needs. We used logistic regression to model the association between move history and the odds of each unmet-need outcome, adjusting for sex, age, race/ethnicity, income, employment, education, family composition, and neighborhood

type as potential confounders. Analyses were stratified by income and by general health to assess moderation.

RESULTS: In our sample, 51% were female with a mean age of 46 years; 36% had incomes below 200% of the federal poverty level, and 5% had moved in the past 5 years due to housing cost. Unmet medication need was reported by 11% of total sample, and other unmet health care needs were reported by 14%. Compared to those who did not move, people who moved due to housing cost had increased odds of both unmet medication need (OR 1.54 [95% CI: 1.31-1.81]) and other unmet health care needs (OR 1.45 [95% CI: 1.23-1.69]). Moves for other reasons were associated with smaller increases in odds of both outcomes (OR 1.17 [95% CI: 1.07-1.28] and OR 1.20 [95% CI: 1.10-1.30], respectively). In stratified analyses, those with lower income and worse general health had higher prevalence of unmet needs but smaller effect sizes for the associations between move status and unmet needs.

CONCLUSIONS: Our results indicate that moves due to housing cost are associated with increased risk of unmet medical needs. To our knowledge, this was the first study to examine displacement using the California Health Interview Survey, which provided a large, diverse sample focused on a state at the center of debates on affordable housing and displacement. These findings highlight the potential for housing policy to promote health equity. Future interventions are merited to ensure care continuity during residential moves in the short term and to prevent displacement in the long term.

UNSHELTERED STATUS AMONG HOMELESS-EXPERIENCED VETERANS IS ASSOCIATED WITH SOCIAL VULNERABILITY, ADDICTION, OVERDOSE AND PAIN: RESULTS OF A NATIONAL SURVEY

Stefan Kertesz[1]; Aerin DeRussy[2]; Young-il Kim[3]; Adam Gordon[4]; Audrey Jones[5]; April E. Hoge[6]; Allyson Varley[7]; Kevin R. Riggs[7]; Sally K. Holmes[6]; David Pollio[8]; Lillian Gelberg[9]; Sonya Gabrielian[10]; Erika Austin[11]; John Blosnich[12]; Ann E. Montgomery[13]. [1]Medicine, Birmingham VA Medical Center & U. Alabama Birmingham, Homewood, AL; [2]Research, Birmingham VA Medical Center, Birmingham, AL; [3]Medicine, University of Alabama at Birmingham, Birmingham, AL; [4]University of Pittsburgh and VA Pittsburgh Healthcare System, Pittsburgh, PA; [5]IDEAS Center, VA Salt Lake City Health Care System, Salt Lake City, UT; [6]Research, Birmingham VA Medical Center, Birmingham, AL; [7]Division of Preventive Medicine, University of Alabama at Birmingham, Birmingham, AL; [8]University of Alabama at Birmingham, Birmingham, AL; [9]Department of Family Medicine, UCLA, Los Angeles, CA; [10]VA Greater Los Angeles Health Care System and David Geffen School of Medicine at UCLA, Los Angeles, CA; [11]Biostatistics, UAB, Birmingham, AL; [12]Pittsburgh VA Medical Center, Pittsburgh, PA; [13]Birmingham VAMC, U.S. Department of Veterans Affairs, Birmingham, AL. (Control ID #3390581)

BACKGROUND: Homelessness varies from sleeping in places not meant for habitation (e.g., outdoors) to shelters, to another's home. Unsheltered status draws attention because it is visible, and it may vary by regional factors. Even after a residence is found, a history of having been unsheltered may connote unique vulnerability, but this has not been surveyed. Analyzing a national survey of Homeless-Experienced Veterans (HEVs), we hypothesized that unsheltered experience would be most common in the West and that it would be associated with greater health and social vulnerability.

METHODS: We surveyed 5766 HEVs from 26 VA Medical centers across 4 US census regions: West (n=9 VAMCs, n=2545 HEV), South (n=10, n=2154), Northeast (n=3, n=443) and Midwest (n=4, n=624). "Unsheltered" experience was based on endorsing ≥ 7 nights unsheltered (i.e. outside) in the 6 months before survey. Surveys queried: (a) sociodemographics; (b) social support (endorsing ≥ 4 out of 6 forms of support rated as "good"), marital status, difficulty affording basic necessities, income >$1000, and employment; (c) health conditions included a count of medical conditions, severe chronic pain, psychiatric symptoms on the Colorado Symptoms Index, alcohol and drug problems on a validated screener, and alcohol/drug overdose requiring emergency care. Analyses compared HEVs with and without unsheltered experience.

RESULTS: The percentage with ≥7 unsheltered nights was higher in the South (10%) and West (10%) than Midwest (5%) and Northeast (5%) (p<.001). Age, race and gender did not differ substantially by shelter status. Unsheltered HEVs were more likely to have been chronically homeless in the past 3 years (61% vs 12%); to have income ≤$1000/month (54% vs 38%); to be unemployed (27% vs 16%); to report problems paying for necessities (72% vs 51%). They were less likely to have good social support (56% vs 75%). They had greater prevalence of self-reported overdose, drug and alcohol problems and pain. This study's response rate (40%) was modestly lower than that reported for VA's patient experience survey in its 2012 Patient Centered Medical Home Evaluation (47%).

CONCLUSIONS: While unsheltered homeless experience was not common in this sample, 1 in 10 HEVs in the South and West reported 7 or more nights without shelter in the last 6 months. Unsheltered experience was associated with social and health vulnerabilities. For individuals coming out of homelessness, unsheltered experience signals a likely need for intensified services focused on addiction, overdose risk, and establishing economic and social resources.

Characteristic (*p<.05; ** p<.001)	Unsheltered ≥ 7 nights	Sheltered
Overdose in prior 3 years*	9%	6%
Alcohol problem**	39%	27%
Drug problem**	27%	12%
Severe chronic pain, %**	50%	36%
Psychiatric symptoms (0-24)(sd)**	10.2 (±7.2)	6.6 (±6.3)
Medical conditions (0-8) (sd) (NS)	2.0 (±1.6)	1.9 (±1.5)

USE AND PERCEPTIONS OF ONLINE DOCTOR RATINGS AMONG OLDER US ADULTS

Jeffrey T. Kullgren[1,3]; Preeti Malani[2,3]; Matthias Kirch[3]; Dianne Singer[3]; Erica Solway[3]; David Hanauer[3]. [1]VA Center for Clinical Management Research and Department of Internal Medicine, Ann Arbor VA Healthcare System and University of Michigan, Ann Arbor, MI; [2]Internal Medicine, University of Michigan, Ann Arbor, MI; [3]University of Michigan Institute for Healthcare Policy and Innovation, Ann Arbor, MI. (Control ID #3391645)

BACKGROUND: Online ratings are widely available for many consumer products, and are increasingly available for doctors. Such information could be particularly helpful to older adults, who generally see more doctors than younger individuals and thus have more opportunities to make decisions about which doctors they will visit. Yet, little is known about how older adults use and perceive online doctor ratings.

METHODS: In May 2019, 2,256 Ipsos KnowledgePanel participants 50 to 80 years of age completed an online survey as part of the National Poll on Healthy Aging (completion rate 76%). Participants were asked whether they had ever used online doctor ratings. If so, participants were asked when, and how, they had used such ratings. All participants were asked to rate the importance of online ratings and other factors when choosing a doctor. Sample weights were used to generate nationally representative estimates of use and perceptions of online doctor ratings. Weighted multivariable logistic regression was used to measure associations between participants' age, gender, race/ethnicity, income, education, health status, and region and their use and perceptions of online doctor ratings.

RESULTS: Among older adults, 43% had ever reviewed online doctor ratings (14% more than once in the past year, 19% once in the past year, and 10% more than one year ago). Only 7% of respondents had ever posted an online rating of a doctor. Among those who reviewed ratings more than once in the past year, 67% had chosen a doctor due to good ratings and 57% reported not choosing a doctor due to poor ratings. Female gender [odds ratio (OR) 1.62], having a college degree (OR 1.98), annual household income > $100,000 (OR 1.78), and having a chronic condition (OR 1.34) were all associated with ever using online doctor ratings. In choosing a doctor, 20% of participants thought that online doctor ratings were very important. A similar percentage of respondents (23%) felt word of mouth recommendations from family or friends were very important, but more felt time to get an appointment (61%), a doctor's years of experience (42%), and a recommendation from another doctor (40%) were very important. Non-white individuals were more likely to perceive online ratings as being very important (OR 1.62) when choosing a doctor.

CONCLUSIONS: More than 4 in 10 older US adults have used online doctor ratings. Women and individuals with more education, higher incomes, or a chronic condition are more likely than others to have ever used this information. When selecting a doctor, older adults are just as likely to perceive online ratings as being very important as a word of mouth recommendation, though other factors are more commonly seen as very important. As more people of all ages seek online ratings when choosing a doctor, clinicians, patients, and policymakers should be aware of the benefits, and potential risks, of using rating sites for these important decisions.

USE OF CHART-STIMULATED RECALL TO EXAMINE UNCERTAINTY IN MEDICAL DECISION-MAKING AMONG SENIOR INTERNAL MEDICINE RESIDENTS

Marina Mutter[1,2]; Jillian Kyle[1,3]; Emmanuelle B. Yecies[1,3]; Deborah DiNardo[1,3]. [1]University of Pittsburgh School of Medicine, Pittsburgh, PA; [2]University of Pittsburgh Medical Center, Pittsburgh, PA; [3]VA Pittsburgh Healthcare System, Pittsburgh, PA. (Control ID #3391201)

BACKGROUND: Errors in medical decision making are common and have been linked to adverse events and patient harm, particularly when uncertainty exists. Prior studies have explored resident uncertainty, often through critical incident technique, but were limited by use of written format, use of hypothetical cases, or by hindsight and/or recall bias. Chart-stimulated recall (CSR, an educational and research method that pairs review of a patient chart with an oral interview) has potential for use in this setting, both to explore uncertainty in real-time, and to promote reflection as a means of improving decision-making. In this study, we utilized chart-stimulated recall-based interviews to qualitatively examine uncertainty in medical decision-making among senior internal medicine (IM) residents. We also sought to evaluate the utility of CSR as an educational tool to promote reflection about uncertainty in decision-making.

METHODS: We invited senior IM residents rotating on inpatient night float at the University of Pittsburgh Medical Center from February to September 2019 to participate. Each participant completed one, 20-minute CSR session based on a self-selected case from the prior evening's shift in which there was uncertainty in medical decision-making. Interviews explored the nature of, approach to, and communication about uncertainty, and were audio-recorded, de-identified and transcribed verbatim. A codebook was then developed and refined. Two coders independently applied the codes to interview transcripts and interviews were subsequently analyzed for themes. Residents also completed a feedback survey about the educational value of the reflective exercise.

RESULTS: Between February and September 2019, 41 out of 45 (91%) eligible residents participated in the study. The most frequently cited sources of uncertainty were 1) patient history, 2) medication-related, 3) presence of a severe/life-threatening condition and 4) need for a consultant overnight. The most frequently cited approaches to uncertainty were 1) review/obtain further history, 2) use of physical exam and 3) use of consultants. The majority of residents reported communicating their uncertainty to patients/families and at sign-out to daytime providers. Residents felt comfortable discussing their uncertainty (87% agree/strongly agree) and felt that the opportunity to think aloud during the exercise was valuable (60% agree/strongly agree).

CONCLUSIONS: Our study demonstrated a novel approach to the exploration of uncertainty in medical decision-making, with the use of CSR. The common use of history, physical exam and consultants as approaches to uncertainty reinforces the need for continued quality education in these areas to improve patient care. Finally, communication of uncertainty to patients and other providers is common and suggests the need to optimize that communication in order to strengthen patient-provider and provider-provider relationships.

USE OF TWO-STEP ALGORITHM TO REDUCE UNNECESSARY TESTING FOR CLOSTRIDIOIDES DIFFICILE INFECTION AT A COMMUNITY BASED HOSPITAL.

Janis Atkinson[1]; Randa Sharag Eldin[1]; Mohamed Ibrahim[2]; Gauri Pethe[1]; Mariam Charkviani[1]. [1]internal medicine, Amita Health St Francis Hospital, Evanston, IL; [2]internal medicine, Aurora/Advocate St Luke Hospital, Milwaukee, WI. (Control ID #3349286)

BACKGROUND: Diagnosis of Clostridioides difficile infection (CDI) is challenging due to non-specificity of symptoms, the lack of reliable tests to distinguish CDI from non-CDI related symptoms and the high prevalence of colonization in the general population. According to the most recent CDC report on antibiotic resistance. There were 223,900 documented cases of C difficile in hospitalized patients in 2017. 12,800 estimated deaths were reported in 2017 as well. Our project aims to optimize pre-test probability and reduce the number of unnecessary tests for CDI.

METHODS: This is an intervention study that aims to reduce the rate of unnecessary CDI tests at Saint Francis Hospital. A multidisciplinary team was formed to redesign the process of CDI diagnosis. A lab ticket was created to ensure that certain conditions are met before the sample is sent to the lab. The ticket was then hardwired to the electronic health record (EHR) as part of the CDI diagnosis orderset, that aimed to improve the pre-test probability. Once the sample is deemed appropriate; a 2-step approach was implemented. Glutamate Dehydrogenase and toxin enzyme-linked immunosorbent assay (EIA) were performed as part of the first step. If both tests are positive then the diagnosis of CDI is confirmed. If both are negative then the diagnosis is excluded. A positive GDH with negative toxin EIA will trigger PCR testing to confirm or exclude the diagnosis. Initial tests were then moved on-site in order to expedite the test results. All positive tests were sent to the national database in order to calculate the Standardized infection ratio.

RESULTS: In the first quarter of 2018, a total of 155 patients were tested for CDI out of 1,965 patients admitted. In the first quarter of 2019, after implementing our protocol, 120 patients were tested for CDI out of 1,998 (p=0.021). 29 out of the 155 patients were positive for CDI in the first quarter of 2018 and 17 out of 120 were tested positive for CDI in the first quarter of 2019 (p=0.075). Therefore, our protocol decreased the number of unnecessary tested cases for CDI without significantly decreasing the number of positive tests.

The standardized infection ratio also decreased from 0.90 to 0.70. After moving the initial set of tests on-site, average turn-around time improved by 87%. This translated to an estimated drug cost savings per quarter of $16,500.00.

CONCLUSIONS: This study suggests that implementing a 2 step approach to CDI diagnosis results in significant reduction in unnecessary treatment and improves antibiotics use in the hospital.

USE OF UNANNOUNCED STANDARDIZED PATIENTS AND AUDIT/FEEDBACK TO IMPROVE PHYSICIAN RESPONSE TO SOCIAL DETERMINANTS OF HEALTH

Sondra R. Zabar, Jeffrey Wilhite, Kathleen Hanley, Lisa Altshuler, Harriet Fisher, Adina Kalet, Khemraj Hardowar, Amanda Mari, Barbara Porter, Andrew Wallach, Colleen Gillespie. Division of General Internal Medicine, New York University School of Medicine, New York, NY. (Control ID #3391637)

BACKGROUND: While much is known about the importance of addressing Social Determinants of Health (SDoH), less is known about how physicians elicit, respond to, and act upon their patients' SDoH information. We report on the results of a study that 1) sent Unannounced Standardized Patients (USPs) with programmed SDoH into clinics to assess whether providers uncovered, explored and acted upon the SDoH, 2) provided audit/feedback reports with educational components to clinical teams, and 3) tracked the impact of that intervention on provider response to SDoH.

METHODS: Highly trained USPs (secret shoppers) portrayed six scenarios (fatigue, asthma, Hepatitis B concern, shoulder pain, back pain, well-visit), each with specific housing (overcrowding, late rent, and mold) and social isolation (shyness, recent break up, and anxiety) concerns that they shared if asked broadly about. USPs assessed team and provider SDoH practices (eliciting, acknowledging/exploring, and providing resources and/or referrals). 383 USP visits were made to residents in 5 primary care teams in 2 urban, safety- net clinics. 123 visits were fielded during baseline period (Feb 2017-Jan 2018); 185 visits during intervention period (Jan 2018–Mar 2019) throughout which quarterly audit/feedback reports of the teams' response to the USPs' SDoH and targeted education on SDoH were distributed; and 75 follow-up phase visits were fielded (Apr-Dec 2019). Analyses compared rates of eliciting and responding to SDoH across the 3 periods (chi- square, z-scores). One team, by design, did not receive the intervention and serves as a comparison group.

RESULTS: Among the intervention teams, the rate of eliciting the housing SDoH increased from 46% at baseline to 59% during the intervention period (p=.045) and also increased, but not significantly, for the social issue (40% to 52%, p=.077). There was a significant increase from baseline to intervention in providing resources/referrals for housing (from 7% to 24%, p=.001) and for social isolation (from 13% to 24%, p=.042) (mostly resources, very few referrals were made). The comparison team's rates followed a different pattern: eliciting the housing issue and the social isolation issue decreased from baseline to the intervention period (housing: 61% to 45%; social isolation: 39% to 33% of visits) and the rate of providing resources/referrals stayed steady at 13% for both. In the cases where SDoH were most clinically relevant, baseline rates of identifying the SDoH were high (>70%) but rates of acting on the SDoH increased significantly from baseline to intervention. Increases seen in the intervention period were not sustained in the follow-up period.

CONCLUSIONS: Giving providers SDoH data along with targeted education was associated with increased but unsustained rates of eliciting and responding to housing and social issues. The USP methodology was an effective means of presenting controlled SDoH and providing audit/feedback data. Ongoing education and feedback may be needed.

USING 24-HR DIETARY RECALL TO VALIDATE AND OPTIMIZE DAILY SODIUM INTAKE ESTIMATES MADE BY DASH-Q

Jenna Hobeika[1]; Kimberly A. Muellers[2]; Jenny J. Lin[1]. [1]Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; [2]General Internal Medicine, Icahn School of Medicine at Mount Sinai, New York, NY. (Control ID #3391639)

BACKGROUND: Hypertension is a leading risk factor for cardiovascular and cerebrovascular injury and mortality worldwide. Salt intake reduction has been shown to effectively lower blood pressure. However, evaluating patients' dietary habits is challenging and time intensive. The current gold standard using 24-hour dietary recall is an arduous 20-60 min process that requires trained personnel and multiple administrations. The DASH-Q, a subscale of the Hypertensive Self-Care Activity Level Effect (H-SCALE), is a self-reported dietary assessment consisting of 12 items that describe the number of days per week certain diet criteria are followed. Although previous studies have demonstrated a relationship in the expected direction between DASH-Q score and systolic blood pressure, limited data currently exist evaluating the ability of the DASH-Q score to identify diets that exceed the daily 1500mg of sodium recommended by the American Heart Association. This study aims to assess the accuracy of and to optimize the DASH-Q score to identify dietary salt intake greater than 1500mg/day by comparing it to the 24-hour dietary recall method.

METHODS: Subjects were prostate cancer survivors with hypertension recruited from the New York City area. Data from participants' 24-hour dietary recall was inputted into a computerized software program (Nutritionist Pro) to estimate daily salt intake. DASH-Q assessments completed by each participant were scored from 0-84 with higher scores representing healthier diets. Using scoring guidelines recommended by the H-SCALE committee, DASH-Q scores less than 57 were labeled "unhealthy" and the rest were labeled "healthy." Sensitivity and specificity for an "unhealthy" DASH-Q score to identify daily sodium intake greater than 1500mg were calculated. Furthermore, we assessed the performance of the DASH-Q at each possible cutoff score using the receiver-operating characteristic (ROC) analysis. The optimal threshold value was determined using Youden's J Index (sensitivity + specificity - 1).

RESULTS: A total of 68 dietary recalls and DASH-Qs were analyzed. Average daily sodium intake in this population was 1975mg. Using the recommended cutoff of <57, the sensitivity and specificity of the DASH-Q score to correctly identify patients with daily sodium intake greater than 1500mg were 29.3% and 96% respectively. Applying Younden's J Index to our ROC analysis found that a DASH-Q cutoff of <66 was associated with 78% sensitivity and 66% specificity.

CONCLUSIONS: For this population, current DASH-Q guidelines do a poor job of accurately identifying patients with a high-salt diet. A cutoff score of <66 should be used to more accurately identify patients with high-salt diets.

USING ARTIFICIAL INTELLIGENCE TO INFORM A DIFFERENTIAL DIAGNOSIS FOR SKIN COMPLAINTS

Yuan Liu[1]; Yun Liu[1]; Peggy Bui[1,2]. [1]Google Research, Palo Alto, CA; [2]Division of Hospital Medicine, UCSF, San Francisco, CA. (Control ID #3381914)

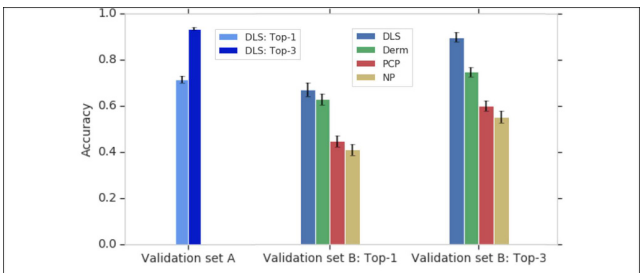
BACKGROUND: An estimated 1.9 billion people have a skin condition and, due to a shortage of dermatologists, many are seen by generalists instead. In the U.S., up to 37% of patients seen in clinic have at least one skin complaint and more than half are seen by non-dermatologists. However, studies show a significant gap in the accuracy of skin condition diagnoses, with the accuracy of non-dermatologists between 24% and

70%, compared to 77-96% for dermatologists. This can lead to suboptimal referrals, delays in care, and errors in diagnosis and treatment.

METHODS: Using de-identified cases (images, history) referred to a teledermatology practice from 17 clinical sites, we developed an artificial intelligence (AI) model based on a deep learning system (DLS) to evaluate the most common skin conditions seen in primary care. The first 14,021 cases were used for development and the last 3,756 cases for validation. A rotating panel of three board-certified dermatologists reviewed each case to determine the reference standard used to evaluate the DLS' accuracy. Additional clinicians who did not participate in formulating the reference standard were also tested against the reference standard.

RESULTS: On the validation set A, the DLS achieved 0.71 and 0.93 top-1 and top-3 accuracies respectively, indicating the fraction of cases where the DLS's top diagnosis and top 3 diagnoses contains the correct diagnosis. 18 clinicians evaluated a stratified random subset of the validation set (n=963 cases) for comparison. On this subset (Validation set B), the DLS achieved a 0.67 top-1 accuracy, non-inferior to board- certified dermatologists (Derms, 0.63, p<0.001), and higher than board-certified internal medicine or family medicine primary care providers (PCPs, 0.45) and independently-practicing nurse practitioners (NPs, 0.41). The top-3 accuracy showed a similar trend: 0.90 DLS, 0.75 Derms, 0.60 PCPs, and 0.55 NPs.

CONCLUSIONS: The DLS distinguishes between 26 of the most common skin conditions (representing roughly 80% of the volume of skin cases seen in clinic) with an accuracy on-par with U.S. board-certified dermatologists. This study highlights the potential of AI to augment the ability of general practitioners to accurately diagnose skin conditions by suggesting differential diagnoses that may not have been considered. Future work will be needed to prospectively assess the clinical impact of using this tool in actual clinical workflows.



The DLS's leading (top-1) differential diagnosis is substantially higher than PCPs and NPs, and on par with dermatologists. This accuracy increases substantially when we look at the DLS's top-3 accuracy, suggesting that in the majority of cases the DLS's ranked list of diagnoses contains the correct ground truth answer for the case.

USING A SIMULATED NIGHT-ONCALL TO ASSESS NEAR-GRADUATE READINESS-FOR-INTERNSHIP

Kinga Eliasz[1]; Tavinder Ark[2]; Ruth Crowe[1]; Maureen Francis[3]; Joey Nicholson[1]; Sondra R. Zabar[1]; Thomas Riles[1]; Adina Kalet[2]. [1]New York University Grossman School of Medicine, New York, NY; [2]Medical College of Wisconsin, Milwaukee, WI; [3]Texas Tech University Health Sciences Center El Paso, Paul L. Foster School of Medicine, El Paso, TX. (Control ID #3390376)

BACKGROUND: To measure readiness for transition-to-residency of near-graduating medical students, we designed an end-of-medical school simulation and describe results across two medical schools.

METHODS: Night-onCall (NOC) is an immersive educational experience that provides near-graduating medical students with the opportunity to play the role of an intern as they complete a series of authentic clinical activities during a simulated "night on call" while assessed by multiple standardized raters from different perspectives. Most NOC activities are rated on a scale of "not done", "partially done", or "well done". Activities that are fundamental to the NOC experience include standardized patient (SP) encounters with a standardized nurse (SN) present, an oral case presentation to a standardized attending (SA), an evidence-based medicine (EBM) activity where students are required to form a clinical question for one of the cases and search the literature to answer it, and a handoff of the cases to a standardized intern (SI). The patient cases common across the 2 versions of NOC include a post-operative oliguria (Ol) case, an urgent case with patient presenting with a headache with hypertension (Hyp), and an informed consent (IC) case with a family member present at the bedside.

RESULTS: 346 students across two institutions participated in NOC – Institution-A includes 3 cohorts and Institution-B includes 1 cohort. Results are presented as the mean % of items well done (WD) ± standard deviation. Learners demonstrated strong communication skills from the SP perspective across the patient cases: Ol 76% ± 22, Hyp 83% ± 19, IC 76% ± 23. In the 2 cases where learners also interacted with a SN, communication and relationship building performance was also strong: Ol 74% ± 32, Hyp 80% ± 25. However, learners struggled to know how to engage the SN during patient encounters: Ol 51% ± 22, Hyp 63% ± 25, and faced challenges with the physical exam: Ol 43% ± 20, Hyp 42% ± 18. In the EBM activity, reporting on % competent items, students were able to find high-quality evidence (91% ± 25) and use appropriate resources (96% ± 13), however effective search strategies and forming the clinical question were poor (33% ± 34 and 50% ± 39). Students also struggled with the quality of their handover to the SI (47% ± 36).

CONCLUSIONS: Graduating medical students demonstrated strong NOC communication performance, probably reflecting a strong curricular focus on communication skills. Lower mean scores and great performance variability in activities such as physical exam, involving the SN, parts of EBM, and handover are areas needing support in the transition-to-residency. Student may struggle when having to "put it all together", integrating many skills under time pressure. A single end-of-training immersive simulation can provide learners with a meaningful assessment focused on readiness-for-internship and educators an opportunity to make curricular changes based on actual student readiness data.

USING DATA FROM PRESCRIPTION DRUG MONITORING PROGRAMS TO IDENTIFY PATIENTS' RISK OF BECOMING LONG-TERM OPIOID USERS: A COHORT STUDY

Stephen G. Henry[1,2]; Eryn Murphy[2]; Iraklis E. Tseregounis[2]; Aaron B. Shev[3]; Andrew J. Crawford[3]; Garen J. Wintemute[3,4]; Susan Stewart[5]. [1]Internal Medicine, University of California Davis, Sacramento, CA; [2]Center for Healthcare Policy and Research, University of California, Davis, Sacramento, CA; [3]Violence Prevention Research Program, University of California, Davis, Sacramento, CA; [4]Emergency Medicine, University of California, Davis, Sacramento, CA; [5]Public Health Sciences, University of California, Davis, Davis, CA. (Control ID #3391391)

BACKGROUND: Patients who are prescribed opioids and take them continuously for ≥90 days tend to remain on opioids for years and are susceptible to opioid-related harms. Strategies that help clinicians identify new prescription opioid users likely to become long-term users may help reduce inappropriate incident long-term prescription opioid use.

METHODS: We conducted a cohort study to examine whether data contained in prescription drug monitoring programs (PDMPs; statewide databases that record all outpatient controlled substance prescriptions and that clinicians can check in real time) could predict incident long-term prescription opioid use. Data were 2008-2018 prescription data from California's PDMP. Our cohort comprised all patients with an incident opioid analgesic prescription during 2010-2017 and no opioid prescriptions in the prior 2 years. The outcome was incident long-term opioid use, defined as having ≥3 opioid prescriptions comprising an episode of opioid use lasting >90 days after the date of a patient's incident opioid

prescription ("day 0"). Patients prescribed ≥500 mg morphine equivalents per day on day 0 were excluded. We constructed 3 logistic regression models: day 0 (using PDMP data available through day 0), day 30 (using data through day 29), and day 60 (using PDMP data through day 59). Independent variables were age, sex, number of pills per opioid prescription, opioid prescriptions per opioid prescriber, having >1 unique opioid prescriber, using >1 pharmacy, opioid formulation (pill, liquid, other), any long-acting opioid prescription, any active benzodiazepine prescription, any other active controlled substance prescription, any prescription from prescribers in the top 5th percentile of statewide opioid prescribers, and (for day 30 and day 60 models) change in total pills prescribed on day 30 or 60 versus day 0. Models accounted for year and area-level characteristics (rural vs urban and socioeconomic status) using census data based on patent ZIP code. Model fit was evaluated by area under the receiver operating characteristic curve (AUC).

RESULTS: Our cohort included 30.5 million (~3.8 million per year) previously opioid naïve patients with an incident opioid prescription; 1.9 million (6.2%) became long-term opioid users. AUC for the day 0, day 30, and day 60 models were 0.81, 0.88, and 0.94, respectively. Odds ratios for all variables were statistically significant; variables with large odds ratios included active benzodiazepine prescription, >1 unique opioid prescriber, any long-acting opioids, and any "other" (vs pill or liquid) opioid formulation.

CONCLUSIONS: Patients' risk of becoming long-term opioid users after an incident opioid prescription can be accurately predicted with data contained in PDMPs. Risk prediction algorithms based on PDMP data could help clinicians identify patients likely to become long-term opioid users, and so are a promising strategy for reducing inappropriate incident long-term opioid use.

USING ELECTRONIC HEALTH RECORD DATA TO IDENTIFY PHYSICIAN PHENOTYPES WITH DIFFERENTIAL RESPONSES TO A NUDGE FOR INFLUENZA VACCINATION

Sujatha Changolkar[1]; Jeffrey Rewley[1,2]; Mohan Balachandran[1]; Charles Rareshide[1]; Christopher K. Snider[1]; Susan C. Day[1]; Mitesh S. Patel[1,2]. [1]University of Pennsylvania, Philadelphia, PA; [2]Crescenz Veterans Affairs Medical Center, Philadelphia, PA. (Control ID #3358644)

BACKGROUND: Less than 40% of adults in the United States receive the influenza vaccination annually. An active choice nudge in the electronic health record (EHR) significantly increased flu vaccination rates at Penn Medicine primary care clinics by 9.5-percentage points. While the overall impact was positive, the nudge may not have been effective for some physicians. The objective of this study was to use EHR data to identify physician phenotypes and assess differential responses to the nudge.

METHODS: During the 2016-2017 flu season, 3 primary care practices at Penn Medicine implemented a BestPractice Advisory that prompted medical assistants to ask patients about flu vaccination and template the order for physicians to review during the visit. Latent class analysis was used to identify physician phenotypes based on 9 demographic, training, and practice pattern variables. A difference-in-differences approach was used to compare changes in influenza vaccination rates. Physicians from the 3 intervention and 7 control sites who saw patients throughout the 2015-16 (pre-intervention) and 2016-17 (intervention) flu seasons were included. Patients were eligible if they visited their primary care physician for a new or return visit and were due for vaccination. Data was obtained from the EHR and publicly available sources.

For each physician latent class, a generalized linear model with logit link was fit to the binary outcome of influenza vaccination at the patient visit level. These models adjusted for patient demographics, comorbidity and insurance, had practice site and month fixed effects, included interaction terms for year and group, and were clustered by physician. The adjusted differences in vaccination rates and 95% confidence intervals were generated via the bootstrapping procedure, resampling patients 1000 times. Resampling of patients was conducted by physicians to maintain clustering at the physician level.

RESULTS: The sample comprised 56 physicians and 45,410 patient visits. The model segmented physicians into classes that had higher (N=41) and lower (N=15) clinical workloads. Physicians in the higher clinical workload class had a mean (SD) of 819 (429) encounters, 12 (5) appointments per day, and 4 (1) days per week in clinic. The lower clinical workload class had a mean (SD) of 344 (129) encounters, 8 (3) appointments per day, and 3 (1) days per week in clinic. Among higher clinical workload physicians, the nudge was associated with a significant increase in influenza vaccination (adjusted difference-in-difference in percentage points, 7.9; 95% CI, 0.4-9.0; P=.01). The lower clinical workload class was not associated with a significant difference (adjusted difference-in-difference in percentage points, -1.0; 95% CI, -5.3-5.8; P=.90). **CONCLUSIONS:** This is one of the first studies to identify physician phenotypes with differential responses to an EHR intervention for flu vaccination. Findings reveal new opportunities for targeted implementation of EHR nudges to combat alert fatigue.

USING EXPERIMENTAL DATA FROM MOVING TO OPPORTUNITY TO INVESTIGATE THE LONG-TERM IMPACT OF NEIGHBORHOODS ON HOSPITAL ADMISSIONS FOR SPECIFIC CLINICAL CONDITIONS

Craig E. Pollack[1,3]; Amanda L. Blackford[2]; Debbie Bozzi[3]; Bradley Herring[3]. [1]Medicine, Johns Hopkins University School of Medicine, Baltimore, MD; [2]Biostatistics and Bioinformatics, Johns Hopkins University, Baltimore, MD; [3]Health Policy and Management, Johns Hopkins School of Public Health, Baltimore, MD. (Control ID #3387544)

BACKGROUND: Federal policymakers are currently considering modifications to housing programs designed to reduce neighborhood poverty exposure. Evaluating the association between housing and neighborhood environments with subsequent healthcare use has been challenging due to non-random decisions families make about where to live and lack of data on long-term outcomes. Recent research linked the Moving To Opportunity (MTO) experiment's participants with up to 20 subsequent years of administrative data for hospital utilization and found that children randomized to receive a housing voucher —which enabled moves out of high poverty neighborhoods—had sustained reductions in hospital use. In follow-on analyses, we investigated whether the observed long-term impact of voucher receipt on hospital use was for specific clinical conditions.

METHODS: The MTO experiment randomized families living in public housing within high-poverty neighborhoods in Baltimore, Boston, Chicago, Los Angeles, or New York during 1994-1998 to three study groups: (1) experimental housing voucher to be used in a low poverty (<10% poverty) neighborhood, (2) traditional housing voucher without restrictions, and (3) control group. We linked MTO participants to all- payer hospital discharge data (from 1995-2015) and Medicaid data (from 1999-2014) and identified hospitalizations for asthma, other respiratory conditions, injuries, mental health, diabetes, obesity, and hypertension. Differences in the rates of annual, condition-specific hospitalizations were estimated between study groups with an Intention-To-Treat framework and negative binomial, longitudinal models.

RESULTS: Among those randomized as adults, 4,142 (90.0%) were linked to claims data, giving a median of 13.4 years of follow-up time (up to 21 years after randomization, N=56,462 person-years); 98% were female with a median initial age of 32. Among those randomized as children, 9,170 (81.2%) were linked to claims data (N=127,300 person-

years); 50% were female with a median initial age of 8. For adults at randomization, we did not observe significant differences between study groups for the number of hospitalizations for any of the seven conditions. For children at randomization, those in the two voucher groups had lower admissions rates for mental health disorders (Incidence Risk Ratio 0.70, 95% Confidence Interval [CI] 0.51, 0.95) and asthma (IRR 0.64, 95% CI 0.41, 1.00) compared to the control group; results did not reach statistical significance for other conditions. A 10-percentage point increase in neighborhood poverty for children was associated with a 34% increase (95% CI 1.01, 1.78) in hospital admissions for mental health disorders over the long-term follow-up.

CONCLUSIONS: Housing policies that reduce neighborhood poverty exposure may lead to long-term savings for hospitalizations related to asthma and mental health among children as they become young adults and thus help offset the costs of the housing subsidies.

USING FOCUS GROUPS OF CAREGIVERS OF INDIVIDUALS WITH IDD TO IDENTIFY TARGETS FOR LTC PLANNING INTERVENTIONS

Vanessa Chicas[2,1]; Caren Steinway[1]; Matthew Schwartz[1]; Jack Chen[1]; Charmaine S. Wright[3]; Michelle Cornacchia[5]; Thomas Davis[5]; John Berens[6]; Ilka Riddle[4]; Sophia Jan[1]. [1]Pediatrics, Cohen Children's Medical Center of Northwell Health, New Hyde Park, NY; [2]General Pediatrics, Northwell Health, Roosevelt, NY; [3]Christiana Care Health System, Newark, DE; [4]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [5]Geisinger Medical Center, Danville, PA; [6]Baylor College of Medicine, Houston, TX. (Control ID #3389713)

BACKGROUND: Individuals with intellectual/developmental disabilities (IDD) are expected to outlive their caregivers. Although many caregivers of individuals with IDD worry about their relative's future, few develop solid long-term care (LTC) plans. The goal of this project was to identify targets for LTC planning interventions for caregivers of individuals with IDD. As a result, we plan to build a LTC planning website intervention in order to help families plan the lifespan for individuals with IDD. We conducted focus groups with caregivers of individuals with IDD in order to receive suggestions for a LTC planning tool in the form of a website.

METHODS: Between April 2018 and October 2019, focus groups were conducted across five states with caregivers of individuals with IDD. Participants completed a survey that included demographic questions, Waisman Activities of Daily Living Scale (W-ADL), and Scales of Independent Behavior-Revised, Problem Behavior Scale (SIB-R). Caregivers were shown two LTC planning websites. Caregivers then participated in focus groups where they were asked about perceived barriers and facilitators of LTC planning and suggestions for tools to promote LTC planning among families like theirs. Focus group recordings were transcribed verbatim and coded using the constant comparative method to identify major themes.

RESULTS: Forty-nine caregivers participated in focus groups (mean age, 55.9). Individuals with IDD ranged from 7-40 years old (mean, 22.7); 83% had $\geq$ 1 problem behavior. The mean W-ADL score was 1.1, meaning that most individuals with IDD need assistance with activities of daily living. Focus groups revealed multiple facilitators and barriers to planning, which are especially prominent when services are lost during transition to adulthood. Suggestions for online tool characteristics included: a resource database; accurate LTC planning information; and a timeline to help with knowing when to plan for certain things. Additionally, participants suggested an interactive planning tool. They had more specific website suggestions for accessibility, finances, housing, insurance, and resources in order to help them plan for the rest of their relative's life in the case that they outlive their parents.

CONCLUSIONS: Interventions for LTC planning may improve quality of life, independence, and personal choice of adults with IDD and their caregivers. Information gathered will be used to develop an online planning tool to aid as an intervention to the planning process.

USING POSITIVE DEVIANCE IN MEDICAL EDUCATION TO EMPOWER LEARNING

Robert G. Badgett, Elisha J. Brumfield, Ali S. Jahansooz. Internal Medicine, KUSM-W, Wichita, KS. (Control ID #3390165)

BACKGROUND: Positive deviance (PD), a form of workforce empowerment that is consistent with complexity science (CS) leadership, has been used successfully in clinical care but not applied to medical education. We introduced PD into a low-stakes setting, improving residents' tactics to speed the handling outpatient test results, in order to: 1) improve the clinical process, and 2) expose trainees to PD.

METHODS: Each resident attended a PD seminar of 7 to 8 residents. The agenda PD items (CS category) were: goal setting (community building), collect each resident's tactics (information gathering), identify deviants and determine unique tactics (information sensemaking), develop best practice (information using). At each step of the seminar, residents' opinions were collected with a RedCap survey. Prior to the seminar, forest plots determined our overall proportion of results handled within 2 days (timely rate, TR), the TR of each resident, and the heterogeneity (I2) of the group. The forest plots were anonymized and emailed before the seminar to each resident with their own result identified.

RESULTS: Our baseline TR was 52% (range 0% to 97%; I2 = 85%) with a mean of 7.4 days. Residents' predicted mean was 8 days. The residents voted for a TR goal of 2 days. In each seminar, after collecting and showing each member's tactics without attribution, 72% and 58% of residents voted to encourage the deviants and all participants, respectively, to identify themselves. After the seminar, 83% of residents either agreed or strongly agreed with "Overall, this component of our curriculum compares favorably to other components" ($p = 0.96$ for comparison of this same question to other components in our last year-end curriculum survey). Regarding the leading of PD seminars, our informal impression is: 1) the RedCap survey with real-time group feedback, once optimized, helped guide the seminar, and 2) at least 3 sessions were needed before teachers new to PD were able to guide discussions of best tactics. The impact of the seminars on the TR is being measured.

CONCLUSIONS: In this initial use of PD to empower learning on a mundane task, the residents' received the experience similarly to established components of our curriculum. The finding that 72% of residents encouraged identifying positive deviants suggests that about a quarter of residents were uncomfortable with this introduction to PD. Measurement of the impact on clinical workflow is pending.

USING TEXT MESSAGES TO CONNECT NEWLY ENROLLED MEDICAID BENEFICIARIES TO PRIMARY CARE: A RANDOMIZED CONTROLLED TRIAL

David M. Levine[1]; Pragya Kakani[2]; Ateev Mehrotra[2]. [1]General Internal Medicine and Primary Care, Brigham and Women's Hospital, Boston, MA; [2]Health Care Policy, Harvard Medical School, Boston, MA. (Control ID #3391405)

BACKGROUND: Navigating the health system and accessing primary care is often difficult for newly insured Medicaid beneficiaries. Having a primary care provider may be critical for receipt of preventive services, identification of chronic illness, and deterring unnecessary emergency

department use. Automated tailored text messages have successfully helped patients navigate the health system but have never been tested as a means of helping patients visit primary care for the first time.

METHODS: We studied newly enrolled beneficiaries of a large California Medicaid plan. All enrollees were randomly allocated to automated text messages and traditional new member communication (intervention) versus traditional new member communication alone (control). The automated text messages were delivered during a 16-week program by a company specializing in text messaging systems. The system delivered information via text and was able to respond to participant free-text responses using natural language processing. All outcome data were obtained from the health plan's administrative data or the text message company. Our primary outcome was completion of one or more primary care visits within 120-days.

Secondary outcomes included completion of the initial health assessment by primary care (a requirement of all California Medicaid plans); diagnosis of a chronic disease; and utilization within 120-days and within 1 year. We present an intention to treat analysis, and due to low uptake, we also obtained adjusted differences and p-values through an instrumental variable analysis (not shown, as it did not change any findings).

RESULTS: 8432 beneficiaries (4201 texting group; 4231 control group) were randomized; mean age was 37 years and 24% were White. In the texting group, 31% engaged with text messages. In the texting vs control group after 120 days, there were no differences in having a primary care visit (44.9% vs 45.2%; difference, -0.27%; p=0.802) or emergency department use (16.2% vs 16.0%; difference, 0.23%; p=0.771). After 1 year, there were no differences in diagnosis of a chronic disease (29.0% vs 27.8%; difference, 1.2%; p=0.213) or appropriate preventive care (for example, diabetes screening: 14.1% vs 13.4%; difference, 0.69%; p=0.357). Emergency department use (32.7% vs 30.2%; difference, 2.5%; p=0.014) was greater in the texting group.

CONCLUSIONS: Newly enrolled Medicaid beneficiaries who received automated text messages were not more likely to receive primary care, receive preventive services, or a diagnosis of chronic disease. However, the intervention arm was more likely to use the emergency department. To our knowledge, this is the first randomized controlled trial to analyze whether text messages help newly enrolled patients obtain primary care. Automated text messages as a means of helping newly enrolled Medicaid beneficiaries navigate the health care system and obtain primary care were ineffective.

USING THE SUMMARY OF DIABETES SELF CARE ACTIVITIES MEASURE TO EVALUATE SATURATED FAT INTAKE IN PATIENTS WITH TYPE 2 DIABETES

Charlotte Ezratty[1]; Jenna Hobeika[1]; Kimberly A. Muellers[4]; Mita Goel[3]; Yael Harris[5]; Jenny J. Lin[2]. [1]Student, Icahn School of Medicine at Mount Sinai, New York, NY; [2]Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; [3]Northwestern, Chicago, IL; [4]General Internal Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; [5]Medicine, Zucker School of Medicine at Hoftsra Northwell, Great Neck, NY. (Control ID #3391414)

BACKGROUND: The American Diabetes Association (ADA) provides nutritional recommendations as part of diabetes management and specifically recommends less than 10% calories from saturated fat, since saturated fat raises blood cholesterol levels and thus increases risk for cardiovascular disease. The 24-hour diet recall is the gold standard for determining dietary intake; however, it is cumbersome and time-consuming to administer and is not used in usual clinical practice. While shorter diet assessments are available, it is not clear if they accurately reflect dietary intake. We undertook this study to assess how the Summary of Diabetes Self Care Activities Measure (SDSCA) performs in capturing saturated fat intake in patients with type 2 diabetes.

METHODS: We are currently enrolling breast cancer survivors with type 2 diabetes for a prospective study and a research assistant administered both the 24-hour diet recall and SDSCA. Dietary recall was recorded into Nutritionist Pro, a computerized software program that estimates daily saturated fat intake and calculates percent calories from saturated fat. Participants whose saturated fat intake was >10% of total calories were considered nonadherent to diet recommendations. The SDSCA asks participants "On how many of the last seven days did you eat high fat foods such as rec meat or full-fat dairy products?" We computed the sensitivity and specificity of this question for identifying participants who were nonadherent based on 24- hour dietary recall.

RESULTS: To date, a total of 40 patients have completed the 24-hour diet recall and SDSCA. Mean percent calories consumed from saturated fat was 11.2% (ranging from 4% to 37%). Patients who reported a high fat diet for ≥4 days consumed on average 15.4% of their calories from saturated fat. Sensitivity and specificity of the SDSCA to identify these patients' adherence to the ADA guidelines were 25% and 85%, respectively. When lowering the cutoff to ≥3 days of reported high fat diet, sensitivity and specificity were 45% and 80%, respectively. Sensitivity and specificity were both 55% when further lowering the cutoff to ≥2 days of reported high fat diet.

CONCLUSIONS: In this population, the SDSCA does not accurately identify patients' adherence to ADA guidelines regarding recommended intake of saturated fat. There is a need to develop more sensitive, clinically-useful short survey questions to capture patients' dietary intake.

US WOMEN'S KNOWLEDGE THAT BREASTFEEDING REDUCES BREAST CANCER RISK

Adrienne Hoyt-Austin[1]; Melanie S. Dove[3]; Laura R. Kair[1]; Renata Abrahao[4]; E. Bimla Schwarz[2]. [1]Pediatrics, University of California, Davis, Sacramento, CA; [2]Division of General Medicine, University of California, Davis, Sacramento, CA; [3]Department of Public Health Sciences, University of California, Davis, Davis, CA; [4]Center for Healthcare Policy and Research & Center for Oncology Hematology Outcomes Research and Training, Division of Hematology and Oncology, University of California, Davis, Sacramento, CA. (Control ID #3389603)

BACKGROUND: As breast cancer affects one of every eight women in the United States, modifiable risk factors are of great importance to public health. In the 1960's, studies demonstrated that mothers who breastfed their infants were less likely to develop breast cancer. Since then, multiple studies have confirmed that breastfeeding reduces maternal risk of breast cancer mortality. However, relatively few US women breastfeed their infants as recommended by the US Centers for Disease Control and Prevention.

METHODS: To estimate awareness of the relationship between breastfeeding and breast cancer risk, we analyzed population-representative data collected by the National Survey for Family Growth 2015-2017 from a sample of 5554 women aged 15-49. We used multivariable logistic regression to examine the effects of age, parity, breastfeeding history, race, ethnicity, prior mammogram, family and personal history of breast cancer, tobacco and alcohol use on women's awareness of this modifiable risk factor.

RESULTS: Only 38.4% of US women were aware that breastfeeding reduces risk of breast cancer. Nulliparous women (29% vs 46%, p<.0001; adjusted OR=0.46, 95% CI=0.38-0.55) and women older than 45 (38% vs 43%, p=.0018, adjusted OR 0.54, 95% CI=0.37-0.79) were less likely to know that breastfeeding reduces risk of breast cancer. In addition, women who had personal history of breast cancer were less likely to say that breastfeeding prevents breast cancer (23% vs 39%, p=.04, adjusted OR=0.24, 95% CI=0.06-0.96). Awareness of this modifiable risk factor did not vary by race, ethnicity, family history of breast cancer, alcohol use,

or smoking status. Additional subset analysis of parous women demonstrated that parous women who had never breastfed were less likely than those who had breastfed to be aware that breastfeeding reduces risk of breast cancer (30% vs 57%, p<0.001, adjusted OR=0.35, 95% CI=0.26-0.46).

CONCLUSIONS: Almost two-thirds of US women remain unaware that breastfeeding reduces risk for breast cancer. When providing preconception counseling and lactation support, it is of vital importance that women are educated regarding the dose-dependent breast cancer risk reduction that breastfeeding provides.

UTILITY OF AN ELECTRONIC HEALTH RECORD REPORT TO IDENTIFY PATIENTS WITH DELAYS IN TESTING FOR POORLY CONTROLLED DIABETES

Jessica L. Schwartz[1]; Daisy Duan[2]; Jamie Briddell[3]; Meera Mohan[4]; Nisa Maruthur[1]; Samantha I. Pitts[1]. [1]Medicine, Johns Hopkins University School of Medicine, Baltimore, MD; [2]Division of Endocrinology, Diabetes & Metabolism, Johns Hopkins University School of Medicine, Baltimore, MD; [3]Nursing, Johns Hopkins University, Baltimore, MD; [4]Nursing, Rush University, Chicago, IL. (Control ID #3390790)

BACKGROUND: Patients with poorly controlled diabetes require frequent hemoglobin A1c (HbA1c) monitoring to inform treatment decisions, with American Diabetes Association (ADA) guidelines recommending testing every 3-6 months. Electronic tools, including reports that extract data from the electronic health record (EHR), are often used to identify patients who are overdue for testing. However, incomplete electronic data may limit the accuracy of EHR reports to identify testing delays. We evaluated whether an EHR report can appropriately identify patients with poorly controlled diabetes who are overdue for HbA1c testing and assessed contributing factors to confirmed delays.

METHODS: We developed an EHR report to identify patients >18 years old with a HbA1c >9% between October 1, 2017 and March 30, 2018 ordered by a primary care provider (PCP) affiliated with a single academic medical center using a shared EHR. Then, we conducted a retrospective chart review of 200 randomly sampled patients who appeared to have a delay in testing based on the report, i.e. no repeat HbA1c within 6 months of the original test. The primary outcome was the proportion of patients who were misclassified as having a delay when a repeat HbA1c was documented in the EHR within the 6-month follow-up period. We further reviewed records with confirmed delays among the first 100 randomly sampled charts to describe potential contributors to delays.

RESULTS: We identified 1923 patients with 2955 HbA1c results >9% ordered by 173 PCPs during the study period. Approximately 35% of patients (n=685; 52% male, 45% African American, median age 55) had a suspected delay in testing. Among the charts reviewed to date (n=120), a repeat HbA1c within 6-months was identified in 12% (n=14, 95% CI: 7-20%), primarily in scanned outside records (13/14). Interestingly, an additional 9% of patients (n=11, 95% CI: 5-16%) were not expected to continue care after the initial HbA1c (e.g., moved out of state). Among the 90 patient records further reviewed for contributing factors to delays, only 44 had documented discussions about repeat testing for hyperglycemia, with the majority (n=35, 80%, 95% CI: 65-90%) focused on self-monitoring. Additionally, 63% of patients (n=57, 95% CI: 52-73%) missed or cancelled an appointment without rescheduling during the 6-month follow-up window.

CONCLUSIONS: A meaningful number of patients were misclassified by an EHR report as having delays in testing for poorly controlled diabetes when they either had timely testing or were not expected to continue care. Clinical decision support tools using this report, therefore, would not accurately identify the target population for intervention. Improving documentation of outside lab results would lead to more accurate EHR reports. Both patient and provider behaviors appear to influence timeliness of HbA1c testing. Additional studies on contributing factors to delays in care will help to identify possible interventions.

UTILIZATION OF TRANSITIONAL CARE MANAGEMENT FOLLOW-UP VISITS ON 30-DAY READMISSION

Kevin Coppa[1]; Sara Abrahams[2]; Eun Ji Kim[2]; Jamie Hirsch[1]. [1]Department of Information Services, Northwell Health, Englewood, NJ; [2]General Internal Medicine, Northwell Hofstra School of Medicine, Lake Success, NY. (Control ID #3391724)

BACKGROUND: The US spends one-sixth of its total expenditures on medical care, and multiple hospitalizations account for a quarter of all Medicare expenditures. Post-discharge follow-up visits have been associated with reduction in 30-day readmission and the Centers for Medicare and Medicaid Services incentivized post-discharge follow-ups by reimbursing providers who had follow-up contact with discharged patients within 48 hours and a follow-up visit within 2 weeks with higher relative value units through transitional care management (TCM). The TCM visits are designed to improve the transition to home or rehab facility after a hospitalization and have been associated with decreased readmission rates. Using data from a large health system, we examined the patient characteristics associated with TCM visit usage and their 30-day readmissions.

METHODS: This analysis includes ambulatory appointments within 14 days of discharge from one of 13 hospitals in an Integrated Delivery Network from January 12, 2018 to January 12, 2020. We included follow- up appointments in the Medicine, Cardiology, or Neurology division because other specialties rarely utilized TCM visits. The primary outcome was readmission within 30-days post-discharge. We used the chi-squared test for categorical variables and Kruskal-Wallis for continuous variables to examine characteristic associated with a TCM versus non-TCM visits. We ran both an unadjusted and adjusted logistic regression model to determine the odds ratios for association between TCM utilization and 30-day readmission.

RESULTS: Of the 48,483 visits, 6,404 (13.2%) were TCM visits and 42,079 (86.8%) were non TCM visits within 14 days of discharge. Patients with TCM visits had lower 30-day readmissions (10.7%, n=684) compared to those who had non-TCM follow-up (14.6%, n=6,149) (p-value<0.001). A higher percentage of non-Hispanic Whites used TCM visits compared to racial/ethnic minorities and patients admitted to the Medicine service had a higher usage compared to non-Medicine services (p-value<0.001). In adjusted multivariable logistic regression, TCM visits were associated with decreased odds of 30-day readmission compared to normal follow-up visit (OR=0.65 [0.60-0.71], p-value<0.001) adjusting for covariates.

CONCLUSIONS: Our study contributes to the evidence that TCM follow-up visits decrease the odds of 30- day readmission compared to non-TCM visits and further identifies patient characteristics associated with the TCM visit utilization. Expanding TCM visits to include more racial/ethnic minority populations may help to decrease risk of 30-day readmission among these groups. Health system level strategies to target non-TCM utilizers will be critical in reducing overall 30-day readmission.

VARIATION IN SUBSTANCE USE SCREENING OUTCOMES WITH COMMONLY USED SCREENING STRATEGIES IN PRIMARY CARE: FINDINGS FROM A MULTI-SITE IMPLEMENTATION STUDY

Jennifer McNeely[1,2]; Angeline Adam[1]; Leah Hamilton[1]; Joseph Kannry[3]; Richard N. Rosenthal[5]; Sarah E. Wakeman[4]; Timothy WIlens[6]; Sarah Farkas[7]; Aimee Wahle[8]; Seth Pitts[8]; Carmen Rosa[9]; John Rotrosen[7]. Innovation, NYU Grossman School of Medicine, New York, NY; [3]Medicine, Division of General Internal Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; [4]Medicine, Massachusetts General Hospital, Charlestown, MA; [5]Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY; [6]Psychiatry, Massachusetts General Hospital, Boston, MA; [7]Psychiatry, NYU Grossman School of Medicine, New York, NY; [8]The Emmes Corporation, Rockville, MD; [9]Center for the Clinical Trials Network, National Institute on Drug Abuse, Bethesda, MD. (Control ID #3390567)

BACKGROUND: Screening for alcohol use in adult primary care patients has been guideline-recommended for decades, but has proven challenging to implement. A new draft recommendation from the US Preventive Services Task Force on screening for drug use is expected to increase both the interest in screening and the challenges to integrating it into practice. Primary care clinics seeking to implement screening for substance use struggle to choose the approach that is best suited to their resources, workflows, and patient populations. To inform these decisions, we conducted a multi-site study in the NIDA Clinical Trials Network to inform the implementation and feasibility of electronic health record (EHR)-integrated screening.

METHODS: In two urban academic health systems, researchers worked with stakeholders from six clinics to define and then implement their optimal screening approach. The implementation process, guided by the Knowledge-to-Action framework, involved qualitative interviews, development and usability testing of EHR- integrated screening and decision support tools, then introduction of screening and monitoring of implementation outcomes. All clinics used single-item screening questions for alcohol/drugs followed by the AUDIT-C/DAST-10 for patients screening positive. Clinics chose between screening at routine vs. annual visits; and staff-administered vs. electronic self-administered screening. Results were recorded in the EHR, and data was extracted quarterly to describe implementation outcomes, including screening rate and detected prevalence of unhealthy (moderate-high risk) use among those screened. Findings are from the first year after implementation at each clinic.

RESULTS: Across all clinics, of the 93,114 patients with primary care visits, 72% were screened for alcohol and 71% were screened for drugs. Screening at routine encounters, in comparison to annual visits, achieved higher screening rates for alcohol (90-95% vs. 24-72%) and drugs (90-94% vs 25-70%). Clinics using staff- administered screening, in comparison to patient self-administered screening, had lower rates of detection of unhealthy alcohol use (1.6% vs. 14.7-36.6%). Detection of unhealthy drug use was low at all clinics, ranging from 0.5-1.0%.

CONCLUSIONS: EHR-integrated screening was feasible to implement in all six clinics, though one had consistently lower screening rates (24-25%) than the others. Screening at routine primary care visits with a self-administered approach offered the most opportunities for identifying unhealthy alcohol use. Detection of drug use was low regardless of screening approach. Although limited by differences among clinics and their patient populations, this study provides insight into outcomes that may be expected with commonly used screening strategies in primary care.

VARIATIONS IN THE QUALITY AND COST OF CARE AMONG PHYSICIANS

Zirui Song[1,2]; Sneha Kannan[2]; Robert Gambrel[3]; Muthiah Vaduganathan[4]; Matthew Resnick[5,3]. [1]Department of Health Care Policy, Harvard Medical School, Boston, MA; [2]Department of Medicine, Massachusetts General Hospital, Boston, MA; [3]Embold Health, Nashville, TN; [4]Division of Cardiovascular Medicine, Brigham and Women's Hospital, Boston, MA; [5]Departments of Urology and Health Policy, Vanderbilt University Medical Center, Nashville, TN. (Control ID #3392287)

BACKGROUND: While efforts to improve the value of care have a national scope, most health care decisions remain local. Patients and families choose among providers close to home. Employers and payers contract with local providers for their insurance plans. While literature on variations in quality and cost between regions has been vastly influential, between-region variations are not necessarily actionable for patients, payers, or providers. To date, data are lacking on physician-level variations in quality and cost within regions.

METHODS: Using 2012-2018 claims from multiple insurers, we examined physician-level variation in quality and cost across 10 key clinical domains within 5 major markets in the U.S. The domains comprised: CAD care by cardiologists, diabetes care by endocrinologists, GI care by gastroenterologists, COPD care by pulmonologists, prenatal care and delivery by obstetricians, joint replacement care by orthopedists, low back care by orthopedists or neurosurgeons, preventive care by PCPs, acute disease management by PCPs, and chronic disease management by PCPs. We measured physician performance within defined clinical scenarios posed by clinical guidelines. In statistical analyses, differences in performance between physicians within specialty were adjusted for patient health and socioeconomic status.

RESULTS: Within each region, physicians varied in quality and cost of care across the 10 clinical domains. For example, among patients with chronic CAD, the top performing quintile of cardiologists had, on average, 64.7% of their patients on a statin (high value). By comparison, 59.1% of such patients were on a statin among cardiologists in quintile 2, 54.0% in quintile 3, 49.1% in quintile 4, and 39.2% in quintile 5. Variation in stress testing among patients with stable coronary artery disease (lower value) varied from 8.3 per 100 patients per year in quintile 1 to 31.6 per 100 patients in quintiles 5. CAD-related spending ranged from $2,775 per patient per year in quintile 1 to $8,059 in quintile 5. Adjusted differences between quintile 1 and other quintiles were all significant at $p<0.001$. Other specialists and PCPs demonstrated analogous variations. The correlation between quality and cost at the physician level varied across clinical domains, though was generally weak across these clinical domains.

CONCLUSIONS: Consistent and substantial physician-level variations in quality and cost of care were observed across 10 clinical domains within 5 major U.S. markets. Our results suggest that practice pattern variations within specific, common clinical scenarios among similar specialists are large. These differences within regions are not likely due to between-region differences, but differential coding and selection within-region remain plausible. Understanding physician-level variations in quality and costs may help patients, employers, and payers become more effective consumers and purchasers of health care, as well as help physicians compete on quality at the local level.

VA'S PRIMARY CARE INTENSIVE MANAGEMENT (PIM) PATIENTS' TOP CITED BARRIERS AND FACILITATORS TO ENGAGEMENT

Alicia Bergman[1]; Susan E. Stockdale[2]; Tana Luger[1]; Marian L. Katz[3]; Donna M. Zulman[4]; Evelyn T. Chang[5]. [1]Center for the Study of Healthcare Innovation, Implementation & Policy, VA Greater Los Angeles, North Hills, CA; [2]HSR&D Center of Excellence, Greater Los Angeles VA Healthcare System, Sepulveda, CA; [3]Research, Veterans Health Administration, North Hills, CA; [4]Internal Medicine, Stanford University and VA Palo Alto, Stanford, CA; [5]General Internal Medicine, VA- Greater Los Angeles, Los Angeles, CA. (Control ID #3392277)

BACKGROUND: Patient engagement among complex high-need patients in intensive primary care programs can be challenging, as many patients experience medical, social, and behavioral barriers to active participation in their care. The Veterans Health Administration (VA) has

implemented and tested intensive primary care programs called PACT Intensive Management (PIM). Our goal was to qualitatively investigate the barriers and facilitators these patients encountered in becoming engaged in their care and the PIM program.

METHODS: Semi-structured interviews were conducted with 51 patients who had at least four encounters with the PIM team regarding their experiences with and reflections on PIM. Interviews were recorded, professionally transcribed, coded in ATLAS.ti, and analyzed to identify patients' self-reported barriers and facilitators to engagement, both prior to and during their enrollment with PIM.

RESULTS: The top barriers to patient engagement most frequently cited by patients were 1) delay or lack of follow-up from providers; 2) changes or turnover in providers/staff; 3) transportation difficulties; and 4) uncontrolled pain. Patients discussed instances of waiting to hear back on the status of test results, but one patient recounted how with the PIM team it was the opposite: "[They] make sure that nothing gets dropped or overlooked.". Provider and staff changes/turnover caused difficulties for some patients because they did not know who to talk to ("I've got to totally get someone else new to help [me]". Getting to appointments presented difficulties for others, due reasons such as an inability to drive, having limited access to a car, or not being able to climb the VA bus steps. Some patients discussed how their uncontrolled pain impeded their ability to take their blood pressure or make it to exercise classes or "back camp". Other barriers included housing difficulties, financial insecurity (e.g., not being able to afford more healthy food), difficulty navigating around the VA Medical Center, and long wait times for appointments. The most frequently mentioned facilitator to engagement was provider availability/quick response time. For instance, one patient said, "I think I'm doing a little better actually because I can go see them at any time if I need to and I don't have to try and schedule an appointment." Other facilitators were providers demonstrating caring and concern, providers following up or holding patients accountable, home visits, personalized care delivery, providers facilitating access to specialty care, and providers having extra patience and not rushing.

CONCLUSIONS: Patients in PIM identified numerous personal, provider, and system-level factors that impeded or facilitated their engagement with their healthcare, with the PIM program, or with the VA. Increased awareness of barriers and facilitators to patient engagement among high-risk patients may inform intervention design for intensive primary care programs and other services for high-need patients.

VERY LOW-CALORIE MEALS FOR INTENSIVE WEIGHT LOSS PREFERRED BY MEDICALLY UNDERSERVED PATIENTS WITH OBESITY-ASSOCIATED CHRONIC CONDITIONS AND PERCEIVED BARRIERS TO EATING HEALTHY

Michelle Duncan[1]; Satya Surbhi[2]; Kirstie Finch[3]; Sierra M. Gaffney[4]; Cardella L. Leak[2]; Patti Smith[2]; James E. Bailey[5,3]. [1]College of Medicine, University of Tennessee Health Science Center, Memphis, TN; [2]Center for Health System Improvement, Medicine, University of Tennessee Health Science Center, Memphis, TN; [3]Internal Medicine, University of Tennessee Health Science Center College of Medicine, Lebanon, TN; [4]College of Medicine, University of Tennessee Health Science Center, Memphis, TN; [5]Medicine and Preventive Medicine, University of Tennessee Health Science Center, Memphis, TN. (Control ID #3392165)

BACKGROUND: The prevalence of obesity and obesity-associated conditions, such as diabetes and hypertension, has increased globally in the past decade. Unfortunately, people who are of lower socioeconomic status and those who are uninsured have disproportionally high diabetic complications and morbidity. Lifestyle changes, like intensive changes to diet, can be employed to reverse the effects of obesity. Intensive low-calorie diets that induce weight loss have been able to achieve remission of obesity-related chronic conditions. In this study, we examined patients' interest in a plant-based healthy eating program and the barriers to healthy eating among the medically underserved in Memphis, Tennessee.

METHODS: Patients with obesity and at least one obesity-associated chronic condition were identified using a regional Diabetes, Prevention, and Wellness Coalition registry. Patients were recruited by phone. Four focus groups and concurrent surveys were conducted with patients of a Federally Qualified Health Center in Memphis, Tennessee. Interview questions addressed what patients perceived as barriers to eating healthy, and what specific low-calorie foods and meals they would be willing to prepare and eat for breakfast, lunch, and dinner. Focus Groups were audio-recorded and transcribed using dragon dictation software. Qualitative analysis was done using NVivo 12 software to identify common themes of conversation.

RESULTS: 17 patients participated, with an average age of 49.3. 76% of patients indicated they would be very interested in a plant-based eating program. Specific meals that patients chose frequently incorporated foods that were already familiar to them. Meals were rated from 1-5, with 1 being their favorite meal and 5 being their least favorite meal. The most popular meals for breakfast, lunch, and dinner respectively were spinach, tomato, and onion omelet (avg. rating 2.2), Chicken, black eyed peas, and greens (avg. rating 2.1), and Baked chicken with green beans and carrots (avg. rating 2.2). Many participants indicated they currently do not eat fruits or vegetables frequently but would be interested in switching to a plant-based diet if it would help cure a potential obesity-associated chronic condition. 54% of patients said the cost of fruits and vegetables was a major barrier to eating healthy. Focus groups confirmed this sentiment, as well as patients indicating they had a lack of knowledge of healthy foods which lessens the variety of healthy foods that they eat.

CONCLUSIONS: This study suggests patients with obesity in medically underserved areas are interested in a plant based healthy eating program. The incorporation of foods that are already familiar to the patient is more likely to be implemented into the very-low calorie diets of the medically underserved. Cost of fruits and vegetables is the barrier most concerning to patients, which could be ameliorated through clinic and community-based healthy eating and weight loss programs.

VETERANS' CARE NEEDS AFTER EMERGENCY DEPARTMENT VISITS FOR AMBULATORY CARE SENSITIVE CONDITIONS

Kristina M. Cordasco[1,2]; Anita H. Yuan[1]; Kymberly Aoki[1]; David Ganz[3,2]. [1]Center for the Study of Healthcare Innovation, Implementation and Policy (CSHIIP), Veterans Health Administration (VA), Los Angeles, CA; [2]Medicine, University of California, Los Angeles, Los Angeles, CA; [3]GRECC, VA Greater Los Angeles Healthcare System, Los Angeles, CA. (Control ID #3391197)

BACKGROUND: Poor coordination across care transitions for patients with chronic ambulatory care sensitive conditions (ACSCs) leads to adverse clinical outcomes, inefficient care, and less favorable patient experiences. Prior work has shown that Veterans are at high risk for post-emergency department (ED) adverse outcomes; more knowledge is needed regarding Veterans' care needs after "treat-and-release" ED visits for ACSCs in order to plan interventions that mitigate those adverse outcomes. To better understand follow-up care needs among ACSC treat-and-release ED visits at VA Greater Los Angeles (GLA), we assessed the prevalence and types of ED provider recommendations for specific follow-up care.

METHODS: We identified treat-and-release GLA ED visits, from 10/1/2017 to 6/30/2018, with an ACSC diagnosis of asthma, chronic obstructive pulmonary disease (COPD), heart failure (HF), diabetes, or hypertension. For 250 randomly-selected visits, a trained nurse abstractor, using

a structured abstraction tool, reviewed Veterans' ED medical records to assess for ED provider recommendations for specific follow-up care needs. Further, because miscommunications around medications changes are a common etiology for adverse events across transitions in care, we also assessed for ED provider changes to Veterans' home medications.

RESULTS: Among the 250 encounters, 36% were for hypertension, 30% COPD, 18% diabetes, 16% asthma, and 7% HF; 6% of the visits involved two ACSC conditions. In 44% of visits, a new medication was prescribed. Medication dose or frequency was changed in 10% of visits and, in 3%, a medication was stopped. The ED provider made at least one specific follow-up care recommendation in 68% of visits, including symptom checks (41% of all visits), medication adjustments (22%), blood pressure measurements (14%), medical or surgical specialty care appointments (8%), laboratory test or result follow-up (5%), specialized testing (e.g., cardiac or pulmonary tests, 2%), radiology test or result follow-up (3%), social work services (e.g., housing, 1%), mental health care (1%), nutrition counseling (1%) and weight measurement (<1%). Forty percent of visits specified one follow-up care need, 23% specified two needs, and 4% specified three or more needs. By condition, care needs were specified in 71% of HF, 70% of COPD, 68% of hypertension, 66% of diabetes, and 60% of asthma visits.

CONCLUSIONS: Most Veterans with treat-and-release ED visits for ACSCs have primary care, specialty care, and/or social work follow-up care needs. Some have multiple needs. Veterans with complex or multiple care needs, and/or diminished capacity for obtaining needed care, may need care coordination assistance following ED visits. Future work should identify which Veterans need such assistance, and investigate mechanisms for effectively providing it, in order to optimize Veteran post-ED outcomes and experiences.

VIDEO-BASED EDUCATION: THE GLOBAL REACH OF NEJM VIDEOS IN CLINICAL MEDICINE

Michael Healy[1,2]; Carl Gustaf Stefan Axelsson[1]; Jeffrey Eddowes[2]; Karen Buckley[2]; Michelle Hache[2]; Matthew O'Rourke[2]; Roy Phitayakorn[1,2]. [1]Department of Surgery, Massachusetts General Hospital, Harvard Medical School, Boston, MA; [2]NEJM Group, Waltham, MA. (Control ID #3372826)

BACKGROUND: The use of video-based education in medical education is rapidly increasing, although it is unclear which learner groups are watching these videos and how they are being used. The New England Journal of Medicine's (NEJM) Videos in Clinical Medicine is one example of a series of videos that are available for learners to access. The objective of this pilot study was to understand the utilization of these videos.

METHODS: We analyzed data from 50,469 unique learners (including attending physicians, residents, students, and other learners) who viewed a NEJM Video in Clinical Medicine between July 2015 and November 2019. Learners were grouped by learner type and country where the video was viewed, videos were grouped into broad specialty categories, and two-sample Wilcoxon rank-sum tests were performed.

RESULTS: Of the four learner types, most of the 50,469 learners were attending physicians (n=30,397, 60.23%). In total, these learners represented over 190 countries/territories, with the highest percentage from the U.S. (n=19,378, 38.40%). The breakdown of these countries/territories by region was: North America (n=20,421, 40.46%), Latin America and Caribbean (n=8,990, 17.81%), Western Europe (n=8,328, 16.50%), East Asia and Pacific (n=5,483, 10.86%), South Asia (n=2,630, 5.21%), Middle East and North Africa (n=2,426, 4.81%), Eastern Europe and Central Asia (n=1,076, 2.13%), Eastern and Southern Africa (n=800, 1.59%), and West and Central Africa (n=314, 0.62%), with 1 learner's country/territory not listed.

The 50,469 learners combined to view 80 videos 204,372 times. The most-viewed video was the Clinical Examination of the Shoulder (views=11,389) and the least-viewed video was the Tympanocentesis in Children with Acute Otitis Media (views=338). Categorizing the 80 videos included 27 videos in the anesthesia/surgical specialty category (views=78,654); 39 videos in the bedside/ambulatory procedures category (views=94,209); and 14 videos in the medical specialty category (views=31,509). There was a statistically significant difference between the viewing of anesthesia/surgical videos ($p<0.0001$), bedside/ambulatory procedure videos ($p<0.0001$), and medical specialty videos ($p<0.0001$), where non-U.S. learners had a larger sum of ranks for the number of video views than U.S. leaners in each video category.

Additionally, there was a statistically significant difference between the viewing of anesthesia/surgical videos ($p<0.0001$), bedside/ambulatory procedure videos ($p<0.0001$), and medical specialty videos ($p=0.0115$), where attending physician learners had a larger sum of ranks for the number of video views than non- attending physician learners in each video category.

CONCLUSIONS: This preliminary study indicates that the viewing of clinically relevant videos by video category does differ by learner location and learner group. Future work could qualitatively explore how to better meet each learner group's goals and needs in order to offer personalized medical education curricula.

WEIGHING THE OPTIONS: DESPITE THE TIME BURDEN, GENERAL INTERNISTS OPT FOR LIFESTYLE COUNSELING WITHOUT MEDICATIONS FOR OBESITY

Douglas Lambert[1]; Najia Dar[1]; Herman Kane[1]; Kieran Feeley[1]; Eun Ji Kim[2]; Joseph Conigliaro[3]; Jamie Kane[1]. [1]Internal Medicine, Northwell Health System, Great Neck, NY; [2]General Internal Medicine, Northwell Hofstra School of Medicine, Lake Success, NY; [3]Internal Medicine, Zucker School of Medicine, New Hyde Park, NY. (Control ID #3391885)

BACKGROUND: Obesity medicine practice includes lifestyle counseling and prescribing weight loss medications, as recommended by multiple society guidelines. Weight loss medications are recommended in addition to lifestyle changes for appropriate patients with a body mass index (BMI) > 30, or > 27 with obesity-related complications. Many barriers to obesity medicine practice have been identified by general internists, including the perceived time burden, and unease with weight loss medications. To inform the development of an obesity medicine curriculum for general internists within our health system, we conducted a survey of affiliated internists to examine current obesity medicine practice patterns, barriers to treatment, and desired resources.

METHODS: Between July and October 2018, a twelve-question survey was emailed to general internists within affiliated internal medicine practices. Survey questions asked about knowledge and comfort in obesity medicine, practice patterns, resources used, barriers faced, and resources desired to support practice.

RESULTS: 45 physicians completed the survey. Practice settings were 29% clinical researcher, 22% academic affiliate, and 42% private practice. 22% identified as very knowledgeable, and 76% as somewhat knowledgeable about obesity medicine. 16% identified as very comfortable, 73% as somewhat comfortable, and 11% as somewhat uncomfortable practicing obesity medicine. Lack of time was the most frequently cited barrier to practice (60%). 42% of respondents used weight loss medications, while 98% engaged in lifestyle counseling. Bariatric surgery (84%) and nutrition (88%) were the most common referrals. Those not prescribing medications cited adverse effects (81%) and clinician preference for alternatives (65%) as the most common reasons. Among those prescribing medications, off-label metformin was most commonly prescribed (63%), followed by phentermine/topiramate (58%) or GLP-1 agonists (58%).

CONCLUSIONS: Knowledge and comfort with obesity medicine practice are suboptimal among general internists within our health system. While counseling was the most common practice method, physicians cited time as a barrier, which may limit efficacy. Bariatric surgery referrals were very common; however, most physicians desired greater obesity medicine expertise availability. Only 42% of physicians prescribed weight loss medications, most commonly off-label metformin, likely due to its long track record of safety in spite of relatively modest weight loss efficacy. Our findings suggest internists are out of step with obesity medicine guidelines; and low medication usage is apparently influenced by concerns over medication safety and side effects. General internists within our health system would benefit from additional training in weight loss medication prescribing, and greater obesity medicine specialist availability.

WHAT DO HOMELESS EXPERIENCED VETERANS WANT US TO KNOW WHEN WE SURVEY THEM ABOUT THEIR CARE? ANALYSIS OF COMMENTS FROM THE PCQ-HOST STUDY.

Allyson Varley[2,1]; April E. Hoge[2]; Audrey Jones[3]; Ann E. Montgomery[4]; John Blosnich[5]; Sonya Gabrielian[6]; David Pollio[2]; Kevin R. Riggs[1]; Lillian Gelberg[6]; Adam Gordon[7]; Stefan Kertesz[8]. [1]Division of Preventive Medicine, University of Alabama at Birmingham, Birmingham, AL; [2]Health Services Research & Development, Birmingham VA Medical Center, Birmingham, AL; [3]IDEAS Center, VA Salt Lake City Health Care System, Salt Lake City, UT; [4]Birmingham VAMC, U.S. Department of Veterans Affairs, Birmingham, AL; [5]Center for Health Equity Research and Promotion (CHERP), VA Pittsburgh, Pittsburgh, PA; [6]VA Greater Los Angeles, Los Angeles, CA; [7]VA Salt Lake City, Salt Lake City, UT; [8]Medicine, Birmingham VA Medical Center & U. Alabama Birmingham, Homewood, AL. (Control ID #3390442)

BACKGROUND: Patients experiencing homelessness face major challenges and report poor experiences with health care systems. Developing better services and conducting robust research requires learning the right questions to ask these patients. The Primary Care Quality and Homeless Service Tailoring (PCQ-HoST) Study sought to compare experiences of homeless-experienced veterans (HEVs) receiving primary care (PC) in the VA from either mainstream or Homeless Patient Aligned Care Teams (H-PACT) through a mail-based survey. We explore unprompted comments written in the margins to understand topics where surveys may fall short.

METHODS: The sample included HEVs who used VA PC and completed a survey by mail. Survey items were close-ended, derived from validated instruments and explored domains of PC satisfaction and health. We copied HEVs' unprompted written comments verbatim into NVIVO. We enumerated comment frequency by domain and used a content analysis approach to group comments into themes.

RESULTS: A total 657/5337 (12%) respondents offered 1935 comments. The most frequently commented domains are summarized in Table 1. In the *Primary Care* domain when asked to describe their experience with PC providers, HEVs noted the specific provider they were referencing. When asked about current use of *Drugs and Alcohol*, HEVs declared being in recovery or not using substances at all and clarified specific substances they had used. When asked about their *Social Environment*, HEVs added unexpected social supports, including dogs, God and their health care providers. On standard employment and education *Sociodemographics* items, HEVs noted reasons for not working (like disability) and specific degrees earned. In the *Quality of Life and Pain* domain, HEVs detailed pain sources and that pain exceeded the provided Likert scale (e.g., "plus 4").

CONCLUSIONS: One in eight HEVs added unprompted written comments to a validated mailed patient experience survey, suggesting surveys missed important patient concerns. Among them, HEVs wanted to specify which clinician they referenced when delivering feedback on their PC experience. Standard questions about drug and alcohol use failed to ask about recovery, and these respondents wanted us to know. The present study suggests HEVs participate in health systems research, and want to assure researchers understand the reasons behind their responses. In short, to increase the patient centeredness of surveys for people experiencing homelessness, the "*not applicable"* response option is not enough. Open-ended text could help improve future surveys.

DOMAIN (# OF COMMENTS)	EXAMPLE
Primary care (422)	*Love Dr. [name] & Staff!!!*
Drugs and alcohol (254)	*"Been sober for 9 months in A.A"*
Social environment (204)	*"God" (re: social support)*
	"Can always improve, but tough to set, get, and keep appointments" (re: social activities)
Homelessness (155)	*"Close to 8 years"*
Demographics (130)	*"Plumber trade school"*
Quality of Life & Pain (93)	*"Due to surgery on left arm"*

WHAT HAPPENS WHEN A PATIENT VOLUNTEERS A FINANCIAL INSECURITY ISSUE? PRIMARY CARE TEAM RESPONSES TO SOCIAL DETERMINANTS OF HEALTH RELATED TO FINANCIAL CONCERNS

Sondra R. Zabar, Jeffrey Wilhite, Kathleen Hanley, Lisa Altshuler, Harriet Fisher, Adina Kalet, Khemraj Hardowar, Amanda Mari, Barbara Porter, Andrew Wallach, Colleen Gillespie. Division of General Internal Medicine, New York University School of Medicine, New York, NY. (Control ID #3391676)

BACKGROUND: While much is known about the importance of addressing Social Determinants of Health, less is known about how members of the care team respond to patient-volunteered SDoH - especially when the determinant is related to financial insecurity. With increasing calls for universal screening for SDoH - what do teams do when a patient shares a financial concern? We report on the use of Unannounced Standardized Patients (USP) to assess how primary care teams respond to volunteered information about financial insecurity and whether an audit/feedback intervention (with targeted education included) improved that response.

METHODS: Highly trained USPs (secret shoppers) portrayed six common scenarios (fatigue, asthma, Hepatitis B concern, shoulder pain, back pain, well visit). USPs volunteered a financial concern (fear of losing job, challenges with financially supporting parent, trouble meeting rent) to the medical assistant (MA) and then again to their provider and assessed the response of both the MA (did they acknowledge and/ or forward the information to the provider?) and the provider (did they acknowledge/ explore and/or provide resources/referrals?). A total of 383 USP visits were delivered to 5 care teams in 2 safety-net clinics. Providers were medicine residents. 123 visits were fielded during the baseline period (Feb 2017-Jan 2018); 185 visits during the intervention period (Jan 2018–Mar 2019) throughout which quarterly audit/feedback reports of the teams' response to the USPs' SDoH and targeted education on SDoH were distributed. 75 follow-up phase visits were fielded (Apr-Dec 2019). Analyses compared rates of MA and provider response to the volunteered financial insecurity issue across the 3 periods (chi-square, z-scores).

RESULTS: The baseline rate of responding in some way to the volunteered information was high for both the MA (86% acknowledged) and the providers (100% responded). These overall rates of response did

not change substantially or significantly across the three time periods (MA: Intervention period = 87%, Follow- Up period=90%; Provider: Intervention period=98%; Follow-Up period=98%). Rates of acting upon the volunteered information also remained quite consistent across the time periods: from 29 to 35% of MA forwarded the information to the provider across the 3 time periods and from 22 to 28% of providers in each intervention period gave the patient resources or a referral (mostly resources).

CONCLUSIONS: Our findings highlight the importance of patients directly telling team members about a financial concern. Future research should explore whether screening tools are effective in instigating a response. Audit/feedback reports with targeted educational components did not appear to influence the teams' response unlike what we found for housing and social concerns that had to be elicited. Whether this is due to differences in volunteered vs. elicited SDoH or to the nature of the SDoH (financial vs housing/social) warrants further investigation.

WHAT IS THE RELATIONSHIP BETWEEN HOSPITAL STAFF ENGAGEMENT AND MORTALITY?

Robert G. Badgett[1]; Leon Jonker[2]; Sudha Xirasagar[3]. [1]Internal Medicine, KU School of Medicine-Wichita, Wichita, KS; [2]Research & Development Department, North Cumbria Integrated Care NHS Foundation Trust, Carlisle, Cumbria, United Kingdom; [3]Department of Health Services Policy and Management, University of South Carolina, Columbia, SC. (Control ID #3391998)

BACKGROUND: Health care workforce research has focused on burnout and its consequences. We extend this work, hypothesizing that workforce well-being, specifically engagement, may promote organizational performance.

METHODS: We measured workforce engagement with three questions from the National Health Services's (NHS) Staff Surveys that mapped to the three factors of the validated UWES-9 survey: vigor, absorption, and dedication. We studied organizational performance using the standardized summary Hospital-level Mortality Indicator (SHMI), available for all English hospital Trusts from 2012 to 2018. In analysis 1, SHMI was the dependent variable. Engagement was the key independent variable, studied in the years preceding, concurrent, and following the SHMI year. In analysis 2, to account for potential reciprocal associations between SHMI with engagement, we used widely accepted cross-lagged regression. Lagged regression enabled accounting for the effects of unmeasured Trust-level variables on SHMI by adjusting for prior values of SHMI, the lag duration determined from analysis 1. Lastly, heterogeneity of engagement across Trusts was assessed using 2017 data.

RESULTS: The number of participating Trusts and average number of staff responses per Trust each year ranged between 141 and 398 in 2012, to 130 and 2423 in 2018. Mean staff response rate across Trusts was 45% (range: 43.5% to 46.6%). Pooling data for all years, Trust SHMI ranged from 0.9996 to 1.0044, and engagement, 3.83 to 3.94, with no significant changes in either measure across the years. Detailed analysis of 2017 data showed high heterogeneity across Trusts ($I^2 > 85\%$) for all three factors of engagement.

In analysis 1, using pooled data for 2013 through 2017, current SHMI was significantly and negatively predicted by current engagement (ß =-0.05; p = 0.041), and further, predicted engagement in the ensuing year. However prior year engagement did not predict SHMI. Based on the observed reciprocal associations, analysis 2 with lagged regression showed that 1) engagement predicted concurrent year SHMI after adjusting for prior year SHMI (ß =-0.04; p = 0.040) and 2) SHMI predicted concurrent year engagement after adjusting for prior year engagement (ß =-0.07; p = 0.001).

CONCLUSIONS: Our finding, using current NHS human resource data, that higher levels of current workforce engagement predicts lower current mortality rates confirms previously documented findings in other industries of the immediacy of the association between engagement and performance. However, our finding of a reciprocal association is new, suggesting that good performance increases engagement and vice versa.

Despite significant associations, the small effect sizes suggest the need to capture other relevant workforce states, such as 'thriving' which adds continuous learning and improvement to engagement, that are not currently monitored by NHS. The heterogeneity in rates of workforce engagement suggests opportunities to foster mutual learning across Trusts.

WHEN TO ADAPT WITH PROTON PUMP INHIBITORS (PPIS): IMPLEMENTATION OF PPIS IN HIGH RISK PATIENTS

Isabella Bergagnini[1]; Caleb Wutawunashe[1]; Rebecca Mazurkiewicz[2]; Elena Ivanina[3]. [1]Medicine, Lenox Hill Hospital, New York, NY; [2]Medicine, Lenox Hill Hospital, New York, NY; [3]Gastroenterology, Lenox Hill Hospital, Brooklyn, NY. (Control ID #3390821)

BACKGROUND: The use of Dual Anti-Platelet Therapy (DAPT) following acute coronary syndrome (ACS) and percutaneous coronary intervention (PCI) increases the risk of gastrointestinal bleeding (GIB) twofold in high risk patients. The use of proton pump inhibitors (PPIs) have been shown to decrease this unwanted complication in the ACCF/ACG/AHA 2010 Expert Consensus Document on the Concomitant Use of Proton Pump Inhibitors and Thienopyridines. Nonetheless, inadequate and at times inappropriate use of PPIs has been reported with one study reporting a rate of up to 56.4%, increasing the risk for adverse outcomes including GIB. We hypothesized that adherence to the 2010 Consensus in PPI use in this high-risk population is an issue ultimately increasing the risk for unwanted sequelae.

METHODS: Adult patients discharged on DAPT (aspirin plus clopidogrel, prasugrel or ticagrelor) from the regional medical floors, medical and cardiac intensive care and telemetry units between 1/1/2018-5/31/2018 at our community hospital were included in the analysis. Those under the surgery service or with a diagnosis of gastroesophageal reflux disease (GERD), H. pylori infection, gastric or duodenal ulcer, and gastritis prior to admission were excluded. Medical records were reviewed for reason for admission and for instruction to continue, initiate or discontinue a PPI upon discharge. Appropriateness of use of a PPI was determined by the presence of additional risk factors for GIB such as concurrent NSAID, anti-coagulation or chronic steroid use, history of GIB and/or advanced age (defined as age ≥75).

RESULTS: Two-hundred forty-eight patients met our inclusion criteria for this study. Of these patients, fifty- two (21%) were discharged on a PPI, the majority of which (55.8%, 29/52) were inappropriately prescribed. On the other hand, one-hundred ninety-six (79%) patients were not discharged on a PPI with the majority (88.8%) of these cases appropriately not prescribed these agents. Interestingly, only 24% (23/95) of patients of advanced age were placed on a PPI. More importantly, 14.3% (3/21) of patients who were inappropriately not discharged on a PPI were later readmitted for GIB.

CONCLUSIONS: Our hospital has demonstrated some adherence to the 2010 Consensus guidelines; however significant room for improvement remains as far as implementation of PPIs in high risk patients. An alarming 76% of the total patients analyzed were also not placed on a PPI in a highly susceptible group, specifically those of advanced age, demonstrating a greater need to focus on these vulnerable individuals. A hesitancy to prescribe may lie therein with the adverse effects associated with PPI use including but not limited to bone loss, pneumonia and C. difficile. We plan to provide proper education to help us ascertain our goals and ultimately improve these numbers and decrease the incidence of this preventable unwanted sequelae associated with lack of use of gastroprotective agents.

WHEN URGENCY IS NOT URGENT: THE USE OF INTRAVENOUS ANTIHYPERTENSIVE THERAPY FOR ASYMPTOMATIC SEVERE HYPERTENSION ON THE MEDICINE WARDS

Patrick J. Kramer[1]; Paul Shaniuk[2]. [1]Internal Medicine, Case Western Reserve University/University Hospitals Cleveland Medical Center, Cleveland, OH; [2]Internal Medicine, Louis Stokes Cleveland VA Medical Center, Lyndhurst, OH. (Control ID #3390000)

BACKGROUND: The acute treatment of asymptomatic severe hypertension (i.e. hypertensive urgency) has been increasingly identified as both unnecessary and potentially harmful to patients, particularly those that are hospitalized. Intravenous (IV) antihypertensive agents have been shown to have unpredictable effects on blood pressure, including rapid reductions in pressures that can unintentionally precipitate end-organ damage. Additionally, there is the potential for high cost burden and increased utilization of cardiac monitoring when these parenteral agents are administered.

METHODS: In this retrospective chart review, we analyzed all instances of the administration of either IV hydralazine or labetalol over a consecutive 12-month period on the medical wards at a single institution. Initial blood pressures, indications for administration, times of administration, adverse events, the need for transfer or admission to a cardiac monitoring unit, and changes to homegoing blood pressure regimens were analyzed.

RESULTS: 59 unique patients received 111 total doses of either IV hydralazine (75) or IV labetalol (36) on the wards from July 1, 2017 through June 30, 2018. 76 (69.4%) doses were given in the setting of asymptomatic hypertension including 11 (9.9%) given to patients who did not meet criteria for hypertensive urgency with systolic blood pressure (SBP) < 180 and diastolic blood pressure (DBP) < 120.

Within the severe asymptomatic hypertension group, 56 (73.6%) doses were given overnight (7PM - 7AM). There were 27 (40.5%) adverse events of a decrease of either SBP or DBP by > 25% over the next 6 hours. There were 19 transfers or direct admissions (50.0% of the group) to the cardiac monitoring unit. A one day stay in the cardiac monitoring unit was 43% more expensive than a bed on the general medicine floor for the average patient during this year. Changes to homegoing blood pressures medications were made in 31 (81.6%) of patients with severe asymptomatic hypertension.

CONCLUSIONS: The use of IV antihypertensive therapy for severe hypertension in hospitalized patients was often not indicated and was associated with high incidence of adverse events. It also increased utilization of intensive cardiac monitoring and led to increased costs of care. The majority of doses were given overnight.

WHERE ARE THE PATIENTS? HOW FIRST YEAR MEDICAL STUDENTS PERCEIVE PROFESSIONALISM.

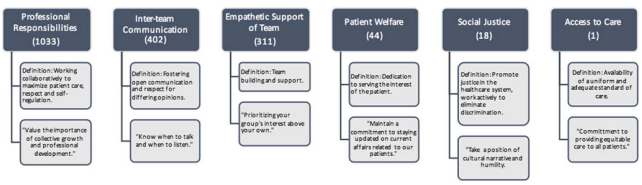
Jacklyn Lee, James D. Harrison, Stephanie Rennke. Medicine, Division of Hospital Medicine, University of California San Francisco, San Francisco, CA. (Control ID #3391229)

BACKGROUND: Medical professionalism is not often explicitly taught to medical students, especially as it relates to roles and responsibilities in today's collaborative medical environment. Our objective was to explore first year medical students' perspectives of medical professionalism following a workshop on professional identity.

METHODS: All first year medical students enrolled at a university-based medical school from 2017-2019 were assigned to small groups containing 5-6 peers and one faculty facilitator. Students participated in a two-part workshop series. The first session focused on defining medical professionalism, followed by a second session where students created their own professionalism charter summarizing their values related to professional relationships, code of conduct, role expectations and ground rules. We analyzed each charter using content analysis, specifically a theory-driven and data-driven approach. We first attributed value statements to principles contained within the American Board of Internal Medicine Physician's Charter which outlines fundamental principles and professional responsibilities of medical professionalism and then also created new coding topics that arose.

RESULTS: In the three-year study period, a total of 465 students and 77 small groups created 77 professionalism charters. We identified 2083 distinct principles within all charters. "Professional Responsibility" (n=1033) was the most commonly reported value statement and highlighted collaboration and mutual respect within the team. "Inter-Team Communication" (n=402) included values such as fostering open dialogue and respecting differences in opinion, while "Empathetic Support of Team" (n=311) referenced team building values. Summaries of select statements and representative quotes are shown in Figure 1. Statements related to the provider-patient interaction such as "Patient Welfare", "Social Justice", and "Access to Care" were not as commonly ranked by students.

CONCLUSIONS: Students did not focus on patient-related values and responsibilities when constructing charters about medical professionalism. This could suggest that early medical students may not be as primed to view their role as a patient care provider within the clinical system, or that they do not consider the provider-patient interaction as an aspect of medical professionalism at this early stage of their career. It will be vital that content around patient welfare, social justice and access to care be incorporated into future curricula.



WHICH STRATEGIES IMPROVE PHYSICIANS' EXPERIENCE WITH HEALTH INFORMATION TECHNOLOGY?

Rebekah Gardner[1,2]; Brittany Mandeville[2,3]; Jacqueline Haskell[2]; Emily Cooper[4]. [1]Department of Medicine, Brown University, Providence, RI; [2]Healthcentric Advisors, Providence, RI; [3]Brown University School of Public Health, Providence, RI; [4]Healthcentric Advisors, Providence, RI. (Control ID #3381088)

BACKGROUND: While electronic health records (EHRs) have improved billing efficiency and note legibility, they may also disrupt clinical workflows, affect patient interactions, and contribute to physician burnout. This study aimed to identify effective strategies, as reported by physicians, to mitigate these EHR shortcomings.

METHODS: The Rhode Island Department of Health administers a health information technology (HIT) survey biennially to all physicians in active practice statewide. The 2019 survey asked physicians about strategies implemented personally or by their practice to improve their experience working with HIT. Physicians who selected at least one strategy were then asked if each implemented strategy was "actually useful." Survey questions were derived from prior research and developed in collaboration with a statewide healthcare stakeholder group. We piloted new questions for clarity and relevance and refined them based on physician feedback.

RESULTS: The 2019 survey was administered to 4,266 physicians, with a response rate of 43%. Office- based physicians most commonly reported

that their practices had implemented voice-recognition dictation software (48%), printers in the clinical area (43%), and staff support with EHR tasks (36%) to improve their HIT experience. The changes identified as "actually useful" by the highest proportion of office-based respondents were staff support with EHR tasks, scheduled time blocks to complete desk work, and staff support with documentation. Among hospital-based physicians, the most commonly implemented strategy was also voice-recognition dictation software (68%), followed by badge/fingerprint login (51%). The change identified as "actually useful" by the highest proportion of hospital-based respondents was touchscreen functionality.

Office- and hospital-based physicians identified self-care (e.g., exercise, meditation) as the most commonly implemented personal change (48% and 47%, respectively). 26% of office-based and 15% of hospital-based physicians reported reducing clinical hours or working part-time to improve their experience working with HIT. The changes identified as "actually useful" by the highest proportion of office-based physicians were self-care, customizing the EHR, and writing more concise notes; the highest proportion of hospital-based physicians identified talking with colleagues to learn tips and tricks, customizing the EHR, and writing more concise notes as "actually useful" strategies.

CONCLUSIONS: Most physicians reported that both they personally and their practices had implemented strategies to improve their experience working with HIT. Physicians found some strategies more helpful than others, many which differed between office- and hospital-based physicians. From a workforce and access perspective, prioritizing strategies that physicians find "actually useful" is critical, as many physicians in both settings reported reducing clinical hours to improve their experience.

WHO PAYS FOR RISING INSULIN PRICES? EVIDENCE FROM A NATIONAL COMMERCIALLY INSURED POPULATION

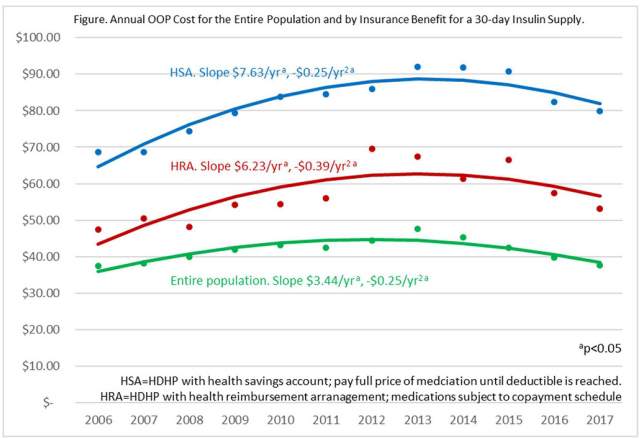
Amir Meiri[1]; Dennis Ross-Degnan[2]; James F. Wharam[3]. [1]Dept of Population Medicine, Harvard Medical School/Harvard Pilgrim Health Care Institute, Boston, MA; [2]Population Medicine, Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, MA; [3]Population Medicine, Harvard Medical School and Harvard Pilgrim Healthcare, Boston, MA. (Control ID #3373664)

BACKGROUND: High out-of-pocket (OOP) costs contribute to delays in or termination of care. Patients with health savings account high-deductible health plans (HSA-HDHP) are uniquely exposed to high OOP medication costs until reaching their deductible. Extensive media attention suggests that insulin OOP costs are rising dramatically. No studies have assessed trends in insulin OOP payments among the commercially insured population to evaluate which groups are paying for these higher insulin costs. We hypothesized that OOP insulin costs among commercially insured members would increase during 2006-2017, with HSA- HDHP members having the highest cost-sharing and largest increases compared to non-HSA plan members. We aimed to identify trends in OOP prices and costs for insulin stratified by insurance benefit design.

METHODS: We conducted time-series claims-based analysis of a large commercially insured population of 612,071 diabetes patients during 2006-2017. We calculated inflation-adjusted annual median price and mean OOP cost per 30-day insulin fill stratified by insurance benefit and mean proportion of insulin prices paid by patients. We modeled these trends using first-order autoregressive segmented regression.

RESULTS: The median price for a 30-day insulin fill rose from $143 to $394 from 2006 to 2017. Patients' mean OOP cost per 30-day fill was $36 in 2006, peaked at $45 in 2012, then declined to $38 by 2017. Patients paid a decreasing proportion of the insulin price, from approximately 24% to 10% between 2006 and 2017. Among HSA-HDHP, OOP costs per 30-day insulin fill increased from $65 in 2006 to a peak of $89 in 2013 and then decreased to $82 by 2017.

CONCLUSIONS: Despite impressions created by news media, rising insulin prices have not translated into increased OOP costs among most commercially insured patients from 2006-2017. HSA-HDHP members had higher OOP costs, but these began declining in 2014. Insurers are absorbing the rising costs of insulin and maybe managing these rising prices by increasing premiums for all, implying a need for robust policies to address rising drug prices. While federal and state legislatures are beginning to address rising insulin costs through transparency and price capping policies additional research is needed to understand these policies' impacts.



WHY ARE THERE EMOJIS?: CLINICIAN EXPERIENCES WITH PAGER-REPLACEMENT MESSAGING APP

Joy L. Lee[1]; Areeba Y. Kara[2]; Bethany Radecki[2]; Monica Huffman[4]; Michael Weiner[3]. [1]General Internal Medicine, Indiana University School of Medicine, Indianapolis, IN; [2]Department of Inpatient Medicine, IU Health Physicians, Indianapolis, IN; [3]Department of Medicine, Indiana University, Indianapolis, IN; [4]Regenstrief Institute, Inc, Indianapolis, IN. (Control ID #3384054)

BACKGROUND: Hospitals are increasingly replacing clinicians' pagers with secure, smartphone-based alternatives that accommodate more detailed bidirectional text and an expanded array of functions. In the process, clinical team communication is becoming increasingly digital and text-based. These changes have potentially large consequences for team workflow and relationships, as well as patient safety. This project seeks to assess clinician experiences with the implementation of a new pager-replacement app.

METHODS: We conducted two focus groups and seven semi-structured interviews with hospitalists and nurses at a Midwestern academic medical center. Moderators and interviewers asked participants to describe their workflow and decision-making for using the traditional pager and the new communication app, the perceived effects of the communication app, and user experiences with team communication.

RESULTS: Fifteen physicians, 6 advanced practice providers, and 7 registered nurses participated in the study. The new pager app changed the participants' communication workflow. By making two-way communication possible, the new pager app now also requires additional decision making that traditional pagers did not, especially for the conveying of non-urgent information. Participants liked the app's ease of contacting other team members, but disliked their own increased accessibility by others. Physicians, in particular, felt burdened by the volume of messages they received from nurses. The clinicians lacked consensus and shared

understandings regarding the app's purpose, and when and how to use it. For example, many physicians expressed finding the photo-taking function of the app to be a useful and convenient for consultations, while some nurses expressed a reluctance to use the feature because they did not know it to be HIPAA-compliant and had concerns about protecting patients' privacy. The lack of shared understanding and expectations led to frustrations, missed opportunities, and differing patterns of use.

CONCLUSIONS: The introduction of a pager-replacing smartphone app not only changed how clinicians communicate, but also how they make decisions about when and how to communicate with team members. However, in the absence of shared expectations and understandings for how pagers are to be replaced, professional tensions and workflow confusion can arise, with possible negative consequences for patient care. As hospitals adapt and change how clinical teams communicate, thoughtful guidance and planning are required to ensure that novel communication technologies facilitate effective and safe delivery of care.

WHY DOES PREECLAMPSIA RECUR? EXPLORING THE ROLE OF MODIFIABLE CARDIOVASCULAR RISK FACTORS

S. M. Ogunwole[1]; Xiaobin Wang[2]; Xiumei Hong[2]; Janice L. Henderson[3]; Wendy L. Bennett[4]. [1]Department of Medicine, Johns Hopkins University School of Medicine, San Antonio, TX; [2]Population, Family and Reproductive Health, Johns Hopkins School of Public Health, Baltimore, MD; [3]Gyn/Ob, JHU, Baltimore, MD; [4]Medicine, Johns Hopkins School of Medicine, Baltimore, MD. (Control ID #3391159)

BACKGROUND: Women with recurrent preeclampsia represent a group at uniquely high risk for maternal and perinatal morbidity, as well as, future adverse cardiovascular, renal, and metabolic outcomes throughout their life course. While it is well recognized that a history of preeclampsia in a prior pregnancy is the strongest risk factor for recurrent preeclampsia, some women with a history of preeclampsia do not go on to develop recurrent preeclampsia in subsequent pregnancies. Identifying risk factor differences between women with and without recurrent preeclampsia may lead to the delivery of targeted primary care-based interventions in the interpregnancy period that can reduce risks in future pregnancies as well as long-term health. The aim of this study is to examine the association of modifiable risk factors (obesity, hypertension) with recurrent preeclampsia. We hypothesized that women with recurrent preeclampsia develop these risk factors between pregnancy at higher rates than women without recurrent preeclampsia; and that these risk factors increase the risk of recurrent preeclampsia.

METHODS: This is a secondary data analysis of maternal participants from the Boston Birth Cohort, a birth cohort of over 8500 predominantly low-income, pregnant women and infants from racial/ethnic minority groups, with oversampling of preterm birth/low birth weight infants. For this analysis we included 619 women who had an index and subsequent pregnancy captured. The main outcome was recurrent preeclampsia (diagnosed by clinical criteria and defined as having preeclampsia in both index and subsequent pregnancies). The exposures of interest were chronic hypertension or obesity diagnosed before subsequent pregnancy. We used a $\chi 2$ test to evaluate the baseline characters of study participants with respect to their preeclampsia status at subsequent pregnancy. We then used logistic regression to assess the crude and adjusted association between 1) chronic hypertension 2) obesity and recurrent preeclampsia.

RESULTS: Of 619 women in the sample, the majority (82%) were normotensive in both their index and subsequent pregnancies. The incidence of preeclampsia was 13% (n=78) in the index pregnancy, and among these women, 42% (n=33) experienced recurrent preeclampsia. Compared to women without recurrent preeclampsia, those with recurrent preeclampsia were more likely to have a history of low birth weight or preterm birth infant in the index pregnancy; and any (new or persistent) diagnosis of chronic hypertension and obesity prior to subsequent pregnancy. The odds of recurrent preeclampsia associated with a new chronic hypertension (vs. no hypertension), was 7.6 (95% CI 2.2-26. The odds of recurrent preeclampsia associated with new diagnosis of obesity (vs. no obesity) was 3.5 (95%CI .93,12.0)

CONCLUSIONS: Modifiable risk factors of obesity and hypertension are strongly associated with recurrent preeclampsia. Primary care providers need to assess preeclampsia history as part of risk stratification.

WOMEN'S EXPERIENCES, PREFERENCES AND REACTIONS TO RECEIVING INFORMATION ABOUT PERSONAL BREAST DENSITY BY STATES' DENSE BREAST NOTIFICATION LEGISLATION STATUS AND WOMEN'S RACE/ETHNICITY

Nancy R. Kressin[1]; Tracy A. Battaglia[1]; Jolie B. Wormwood[2]; Priscilla J. Slanetz[3]; Cristina Brinkerhoff[1]; Christine Gunn[1]. [1]Medicine/Section of General Internal Medicine, Boston University School of Medicine, Boston, MA; [2]Psychology, University of New Hampshire, Durham, NH; [3]Medicine/Radiology Body Imaging, Boston University School of Medicine, Boston, MA. (Control ID #3384249)

BACKGROUND: State dense breast notification (DBN) legislation requires informing women about breast density (BD) with mammogram results. Yet little is known about how women receive or react to information about their personal BD, whether race/ethnicity has any differential impact, or how experiences align with women's preferences for receiving BD information.

METHODS: We assessed how women received, and prefer to receive, personal BD information, and reactions to such information, in a national, weekly, bilingual random digit dial telephone survey targeting a representative sample of the U.S. population. Women (N=1088) in all states aged 40-76 reporting receipt of a mammogram in <2 years, with no history of breast cancer, and who had heard the term 'breast density', were eligible. Bivariate analyses examined how outcomes varied by state DBN status and women's race/ethnicity.

RESULTS: Overall, 56% of women (N=601) reported receiving information about personal BD; women in DBN states (59%) and White women (58%) were significantly more likely to report receiving such information than women in non-DBN states (48%) and Black women (50%), respectively. Among those reporting receipt of personal BD information, most (93%) had received it by talking with their provider; 49% had also learned from a letter/notice from the provider and 20% had also learned from a website/portal. Compared to women in non-DBN states, women in DBN states were significantly more likely to have received a letter with their personal BD (52% vs. 41%) and were significantly less likely to have learned of personal BD through discussion with their provider (92% vs. 98%). White women were significantly less likely (14%) to have learned their personal BD via a website/portal compared to Black (24%) or Hispanic (27%) women. When all women were asked how they would like to learn about BD, only 13% preferred a letter/notice, 7% preferred a website/portal, and 80% preferred to learn from their provider, with no differences by state DBN status or race/ethnicity.

Of the women who had received information on personal BD, 87% felt somewhat/very informed, 14% said that knowing their BD made them feel somewhat/very anxious, and 10% felt somewhat/very confused. Black women were more likely to report feeling informed (92%) vs. White women (85%). Women in DBN states were more likely to report heightened anxiety (15%) than women in non-DBN states (7%), as were Black (18%) and Hispanic (19%) women compared to White women (10%).

CONCLUSIONS: Findings suggest that BD legislation has somewhat achieved its intended effects of notifying women about BD through written notifications, though most women preferred to receive this information directly from their provider. Differential experiences and preferences by women's

race/ethnicity suggest that efforts to educate women about BD should identify, consider, and address the differing means by which women in various groups learn, and prefer to learn, about their BD.

WOMEN'S EXPERIENCES WITH PROVIDERS REGARDING BREAST DENSITY BY STATES' DENSE BREAST NOTIFICATION LEGISLATION STATUS AND WOMEN'S RACE/ETHNICITY

Nancy R. Kressin[1]; Christine Gunn[1]; Jolie B. Wormwood[2]; Priscilla J. Slanetz[3]; Cristina Brinkerhoff[1]; Tracy A. Battaglia[1]. [1]Medicine/General Internal Medicine, Boston University School of Medicine, Boston, MA; [2]Psychology, University of New Hampshire, Durham, NH; [3]Medicine/Radiology Body Imaging, Boston University School of Medicine, Boston, MA. (Control ID #3384181)

BACKGROUND: State dense breast notification (DBN) legislation requires informing women about breast density (BD) with mammogram results, to encourage women to discuss personal breast cancer (BC) risk and supplemental screening with physicians. Little is known about how such information has affected women's interactions with their providers or their plans for future BC screening, or whether women's race/ethnicity has any differential influence.

METHODS: We assessed various aspects of women's BD discussions with providers in a national, weekly, bilingual random digit dial telephone survey targeting a representative sample of the U.S. population. Women in all states aged 40-76 reporting receipt of a mammogram in <2 years, with no history of BC, who had heard the term 'breast density' were eligible to participate. Bivariate analyses assessed women's experiences discussing BD with providers, by women's DBN state status and race/ethnicity; multivariate analyses controlled for BC risk where appropriate.

RESULTS: 351 women (32% of 1088 respondents) had discussed breast density with their provider after their last mammogram, with significantly more Hispanic women (41%) and women in DBN states (35%) having had such a discussion compared to White women (29%) and women in non-DBN states (25%), respectively. When last discussing BD with a provider, women reported that most providers (90%) asked about BC risk and discussed the mammogram results (94%); 68% of providers elicited the woman's worries and concerns; 60% discussed other screening options; 63% discussed future BC risk; and 64% completely answered the woman's questions. Providers were significantly more likely to ask about BC risk (96%) and discuss mammogram results (96%) with Black women than with Hispanic women (87% and 87%).

After learning their personal BD, most women (60%) decided not to change the frequency of future mammograms, though 9% of women decided to decrease frequency and 17% decided to have them more frequently. Overall, 26% of women decided to have additional screening tests for BC after discussing BD with the provider, though this was significantly higher in DBN states (29%) than non-DBN states (14%). This difference was still significant after controlling for women's self-reported BD, family history of BC, and prior breast biopsy.

CONCLUSIONS: Only one third of respondents discussed BD with their providers, and there were few differences in the content of the discussions by state DBN legislation status. However, more women in DBN states decided to have additional screening tests for BC after discussing BD with providers. The differences in experiences and plans by women's race/ethnicity suggest that some women of color are more likely to discuss BD with providers, that such women's providers are more likely to assess BC risk, and that such women more often plan to have supplemental screening, although the reasons for these differences remain unknown.

WORK EFFORT AND THE PHYSICIAN GENDER PAY GAP: EVIDENCE FROM PRIMARY CARE

Ishani Ganguli[3]; Bethany Sheridan[4]; Joshua Gray[5]; Michael E. Chernew[1]; Meredith Rosenthal[2]; Hannah Neprash[6]. [1]Department of Health Care Policy, Harvard Medical School, Boston, MA; [2]Harvard TH Chan School of Public Health, Boston, MA; [3]Brigham and Women's Hospital, Division of General Internal Medicine and Primary Care, Boston, MA; [4]Athena Health, Watertown, MA; [5]Unaffiliated, Boston, MA; [6]Health Policy & Management, University of Minnesota School of Public Health, Minneapolis, MN. (Control ID #3391377)

BACKGROUND: Female physicians are a growing share of the workforce and may achieve better patient outcomes, yet they are paid less than their male counterparts. This persistent wage gap is often attributed in part to women having lower work effort, but evidence-to-date is largely limited by self-report and lack of detail on clinical revenue and known gender differences in practice style. We used a novel database to understand revenue differences by physician gender in primary care.

METHODS: Using a national sample of all-payer claims and electronic health record (EHR) data from athenahealth, we conducted a cross-sectional analysis of 16.3 million office visits in 2017 by primary care physicians (PCPs; internal medicine, family practice, or general practice specialty). Our primary predictor was physician gender and our primary outcomes were visit count, visit revenue, and observed visit length (using EHR time stamps). We estimated multivariate regression models at the annual, day, and visit level adjusting for physician characteristics (age, credential, specialty, clinic sessions per week), patient characteristics (age, gender, race/ethnicity, marital status, chronic condition count, payer, new-to-physician (defined as no prior visit with that PCP since 2011)), and practice fixed effects. We then stratified results by physician age and patient gender and performed subgroup analyses of visits for patients with 2 or more medical conditions and of specific types (same-day, problem-based vs preventive, established vs new patient) and complexity levels (defined by billing code).

RESULTS: Compared to male PCPs in the same practices, female PCPs were younger and worked the same number of sessions per week. Patients seen by female PCPs were more likely to be below age 65, female, non-white, and covered by Medicaid or commercial insurance. In 2017, female PCPs earned 10.7% ($38,577) less visit revenue than male PCPs in the same practices and conducted 10.6% (323.9) fewer visits over 2.6% (5.4) fewer clinic days, yet spent 3.6% (1,470.2 minutes) more observed visit time in the year. Per visit, female PCPs earned equal revenue but documented 5.5% (0.2) more diagnoses, placed 11.6% (0.5) more orders, and spent 15.2% (2.8 minutes) longer with each patient. These results were consistent in subgroup analyses by patient gender and health status and by visit type and complexity. Over the year, the gender revenue gap was largest among older physicians (aged 65+ years vs 25-44 or 45-64) while the difference in observed time was largest among the youngest physicians (25-44). All differences were statistically significant at $p<0.001$.

CONCLUSIONS: Female PCPs earned 11% less visit revenue than male PCPs in the same practice due to conducting fewer visits yet spent 4% more time in direct patient care per year. To the extent that more time per visit is associated with better outcomes, as prior work suggests, policymakers and practice leaders should find ways to value physician work beyond productivity.

"I'M THE DISEASE": EXPLANATORY MODEL OF OPIOID ADDICTION AMONG PATIENTS WITH OPIOID USE DISORDER IN SUSTAINED REMISSION.

Jarratt Pytell[1]; Michael Sklar[4]; Joseph A. Carrese[2]; Darius Rastegar[3]; Geetanjali Chander[3]. [1]Division of General Internal Medicine / Division of Addiction Medicine, Johns Hopkins Universtiy, Baltimore, MD; [2]Department of Medicine, Johns Hopkins University, Baltimore, MD; [3]Medicine, Johns Hopkins University, Baltimore, MD; [4]Addiction Treatment Services, Johns Hopkins University, Baltimore, MD. (Control ID #3343070)

BACKGROUND: The chronic disease model of opioid use disorder (OUD) is increasingly accepted among clinicians who care for patients with OUD. However, how patients with OUD in sustained remission perceive their OUD is not known. The purpose of this study was to describe patients' explanatory model of OUD among those with OUD in sustained remission.

METHODS: We recruited patients with OUD receiving opioid agonist therapy who remain illicit opioid free for at least 5 years to participate in a qualitative study involving individual semi-structured interviews. Clinicians identified potential participants who could provide an informed perspective. We used maximized variation sampling to recruit a demographically diverse sample and to ensure variability in medications (buprenorphine vs methadone) and clinical setting (opioid treatment program vs office-based treatment). Using an existing framework, the interview guide was developed to elicit various dimensions of participants' explanatory model of OUD including etiology, symptoms, pathophysiology, course, and treatment (Kleinman). Two investigators independently analyzed the transcripts and iteratively reviewed and discussed results to inform subsequent interviews. We used constant comparative analysis with inductive and deductive coding to identify themes.

RESULTS: We interviewed 14 participants. Median time since last illicit opioid use was 13 years (IQR 10 – 15). Two broad categories of participants' explanatory model emerged based on where participants perceived their addiction originated. First, an internal explanatory model where participants felt OUD is inherent to their being and originates in their genes or family traits. This resulted in feelings of being predestined to develop an addiction. Therefore, ongoing treatment and complete abstinence from substances is required to maintain recovery. Second, an external explanatory model where participants felt OUD flowed from trauma or social norms and addiction was potentially preventable. Treatment can be time-limited and focused on the underlying cause of addiction. The occasional use of other substances (including alcohol) is permissible.

CONCLUSIONS: Participants with OUD in sustained remission had two different approaches to understanding their OUD; an internal and external explanatory model of OUD. These perceptions influenced how participants view ongoing treatment and acceptability of substance use. In clinical practice, a patient's explanatory model could differ with clinicians' explanatory model or the chronic disease model of OUD. Therefore, regular inquiry about a patient's explanatory model of OUD may be important to providing optimal patient-centered care.

"SICK AND TIRED OF BEING SICK AND TIRED": EXPLORING FACILITATORS AND DETERRENTS FOR MOUD TREATMENT INITIATION AMONG OPIOID USERS EXPERIENCING HOMELESSNESS

Natalie Swartz[3]; Travis P. Baggett[4,2]; Avik Chatterjee[1,2]. [1]Internal Medicine, Boston University School of Medicine, Boston, MA; [2]Boston Health Care for the Homeless Program, Boston, MA; [3]Health and Society, Harvard College, Cambridge, MA; [4]General Medicine Division, Massachusetts General Hospital, Boston, MA. (Control ID #3391946)

BACKGROUND: People experiencing homelessness are 30 times more likely to die from opioid overdose than people who are housed. While medications for opioid use disorder (MOUD) reduce fatal overdose risk, uptake of MOUD in this vulnerable population is low, even after a non-fatal overdose.

METHODS: We recruited adults experiencing homelessness and with history of opioid overdose from a drop-in center in Boston, MA. We conducted semi-structured interviews exploring views on MOUD uptake, including after overdose events. We used Borkan's immersion/crystallization method and NVivo12 analysis software to identify themes.

RESULTS: Interviews were completed with 29 individuals. Sixteen had accessed prescribed MOUD and 13 had not. Mean age was 38.4 years, and 48% (14/29) reported female gender. Fifty-nine percent (17/29) reported White race and 24% (7/29) reported Latino ethnicity.

Participants commonly reported that "after someone overdoses, nobody really cares about the resources there are. They care about getting more [opioids] because usually they're sick at that point because of the [overdose reversal drug] Narcan." Less prominently, some participants stated that overdoses immediately increased their MOUD interest because they saw overdosing as "rock bottom" or feared dying. More consistently than citing overdose events, participants described that motivation for seeking MOUD came from feeling "sick and tired of being sick and tired" from the cumulative costs of opioid dependence. Participants in both groups identified several benefits of MOUD, primarily to reduce use and "to take care [of] your priorities." Participants also described Medicaid making MOUD affordable. Positive experiences with health and treatment professionals and advice from peers and family also facilitated treatment.

For treatment deterrents, participants worried MOUD amounts to "just substituting one drug for another" but with more red tape and delay than using street opioids. Participants identified deterrents in methadone's regulatory requirements ("it's liquid handcuffs.") and in the temptation to sell prescribed buprenorphine. Homelessness intensified access challenges. For example, participants faced stigma from health professionals in "the way that they talk to people, how long you're going to wait." Staying in a high-use "environment" in or near shelters was a barrier: "I would walk out of the shelter and there would be a line of about 30 people going down the street in various stages of loading up." Some reported incarceration forcing discontinuation of MOUDs ("it was cold turkey, and it was the worst"). In the non-treatment group, several participants had not sought MOUD because they did not think they used heroin often enough.

CONCLUSIONS: While overdose events present an opportunity to link some patients into treatment, a broad array of tailored interventions at other times are necessary to facilitate treatment initiation and continuation for this vulnerable population.

"THAT'S THE WHOLE ART OF DOING PRIMARY CARE:" PHYSICIAN PERSPECTIVES ON PRESCRIBING PRACTICES FOR OLDER PATIENTS WITH POLYPHARMACY

Daniel Moussa[2]; Michael B. Rothberg[3]; Elizabeth Pfoh[4]; Anita D. Misra-Hebert[3]; Kathryn A. Martinez[1]. [1]Center for Value-Based Care Research, Cleveland Clinic, Cleveland, OH; [2]Lerner College of Medicine, Cleveland Clinic, Cleveland, OH; [3]Internal Medicine, Cleveland Clinic, Cleveland, OH; [4]Medicine, Cleveland Clinic, Cleveland, OH. (Control ID #3391395)

BACKGROUND: Over the last decade, the prevalence of polypharmacy in older adults (i.e. taking too many medications) has nearly doubled, increasing the risk of adverse events in this population. To better design care for older patients, it's important to understand how physicians make decisions about prescribing and deprescribing medications for patients who take a lot of them. This qualitative study describes physician perspectives on polypharmacy, prescribing and deprescribing for older patients.

METHODS: We recruited primary care physicians practicing in the Cleveland Clinic Heath System to participate in semi-structured interviews about polypharmacy. The interview guide was developed based on literature review and expert opinion. Questions focused on two goals: (1) understanding the physician's approach to prescribing and de-prescribing medications for older adults, including use of guidelines such as Beer's Criteria, and (2) describing their definition of polypharmacy, its contributors, and how it can be mitigated or reduced. Interviews began in September 2019 and continued until January 2020, when thematic

saturation was reached. Interviews were 30 minutes long, audio recorded and transcribed verbatim. Transcripts were coded and analyzed using a grounded theory approach to identify themes.

RESULTS: Ten physicians participated in interviews and we identified four major themes: (1) Physicians had difficulty defining polypharmacy in terms of a specific total number of medications because it varied by patient. Rather than a numeric definition, some physicians saw polypharmacy as a process: "Polypharmacy, from my perspective, is the inevitable creep of adding medications to someone's regimen as they present with new or evolving health issues." (2) Physicians found it difficult to deprescribe medications for medically complex patients who were seen by multiple physicians, including specialists. One said "Do I feel comfortable overriding this physician who is supposedly an expert in the field?" (3) Physicians identified the electronic health record (EHR) both as a driver of new prescribing and as a potential tool to facilitate deprescribing. Physicians felt informed by EHR best practice alerts about which patients would benefit from new drugs (e.g. statins). The EHR also helped physicians identify patients with polypharmacy, assuming the medication list was accurate. (4) Physicians noted that time constraints during clinical visits hamper their ability to deprescribe medications: "Polypharmacy is just something we don't pay enough attention to because we have many things on our plate. It is like the plate spinners in the circus, you've already got plates in both hands and on both feet and then someone throws you another plate."

CONCLUSIONS: Efforts to support the autonomy of primary care physicians in managing polypharmacy for medically complex patients are needed. Focusing on the role of the EHR in both driving and preventing polypharmacy may be an effective starting point.

"WHAT'S THE DIFFERENCE OF ONE MORE PILL?" PATIENT PERSPECTIVES ON RISKS AND BENEFITS OF CONTINUING AND TAPERING CHRONIC OPIOID THERAPY

Hector R. Perez[1]; Melanie Prinz[1]; Michele Buonora[2]; Joanna L. Starrels[3]. [1]Division of General Internal Medicine, Albert Einstein College of Medicine, Bronx, NY; [2]Internal Medicine, Montefiore Medical Center, Bronx, NY; [3]General Internal Medicine, Albert Einstein College of Medicine & Montefiore Medical Center, Bronx, NY. (Control ID #3391438)

BACKGROUND: Tapering can be considered in patients for whom benefits of continuing chronic opioid therapy (COT) are low compared to risks. However, engaging patients in a taper can be difficult and requires patient buy-in. Understanding how a variety of COT patients perceive risks and benefits may be critical to understanding how to promote patient buy-in for a taper. Therefore, we sought to evaluate perspectives on risks and benefits of COT in two samples of patients who did and did not experience an opioid taper, respectively.

METHODS: We conducted telephone interviews with patients who did and did not experience opioid tapers in a large urban health system in the Bronx, NY. Patients were eligible if they were 18 years of age or older and on a stable dose of COT before experiencing an intentional reduction between 2016-17 of at least 30%. Opioid tapers were confirmed using manual chart review. Exclusion criteria included history of malignancy. Participants were presented with a sample patient on COT with low benefit of continuing COT compared to risks; she was on high dose opioid therapy, experienced persistent pain after several opioid dose increases, and had a recent family history of opioid overdose. Participants were asked what they would tell the patient to do, as if giving advice to a friend. Sociodemographics were collected from the electronic medical record. Interview transcripts were coded and analyzed using a thematic analysis approach focusing on risks and benefits of COT use.

RESULTS: Of 101 patients contacted, 20 participated. The average age was 57.6 and 12 were males. Of interviewees, 10 participants had undergone a taper and 10 participants had not. We found participants who had undergone a taper tended to recommend a taper for the sample patient (n=4) because of risk from continuing COT ("try to lower it…it's like taking drugs"). Conversely, participants who had not undergone a taper tended to recommend maintaining the current dose of COT (n=5), also because of risk ("she should stay at three and be happy…because it could be dangerous"). Risks discussed included overdose, tolerance, and dependence and did not differ between the groups. Among the participants in both groups who recommended a dose increase (n=4 in tapered group, n=3 in non-tapered group), most stated that increasing the dose would provide far better benefits—such as pain control—compared to risks, which they felt were minimal ("If she's getting pain and she's not getting relief…the doctor should raise up").

CONCLUSIONS: Patients tended to differ in their recommendations for the sample patient based upon their experiences with tapering. Everyone in the sample was able to identify risks of COT, but a small group incorrectly felt confident that benefits would be better with continued increases in dose. Evaluating and discussing a patient's assessment of benefits, in addition to risks, are critical strategies to promote buy-in among patients resistant to tapering.

"FLESH"-ING OUT THE DIAGNOSIS: APPROACH TO GIANT NECK MASS

Charles Milrod, Helen Lyo, Jason Sherer. Internal Medicine, Boston University Medical Center, Boston, MA. (Control ID #3390433)

LEARNING OBJECTIVE #1: Evaluate the diagnostic utility of fine needle aspiration versus surgical biopsy in giant neck masses.

LEARNING OBJECTIVE #2: Recognize the capacity for neck masses to regrow after excision and importance of surveillance monitoring.

CASE: A 55 year-old gentleman presents for evaluation of recurrent posterior neck mass. Present since 2001, he had 3 excisional surgeries, most recently 2017, and the mass grows back each time. In the past two weeks he developed new ulcerations with clear drainage prompting him to seek help. Physical exam revealed a large posterior neck mass measuring 15 x 15 x 12 cms with significant ulceration. Labs were notable for a leukocytosis of 21.7 K/UL and hemoglobin of 6.0 g/dL. Infectious etiology was ruled out with negative blood cultures, HIV and HTLV tests. CT neck showed large ulcerating soft tissue mass measuring up to 15cm with associated extensive cervical lymphadenopathy. MRI cervical spine showed no bone or spinal cord involvement. Ultrasound-guided biopsy showed atypical squamous cells with keratinization and nesting pattern, however this sample was inadequate for diagnosis. For definitive management he underwent excision of the tumor with radical posterior neck dissection and a latissimus pedicled flap reconstruction. The pathology revealed squamous cell carcinoma.

IMPACT/DISCUSSION: This case illustrates the challenges in diagnosing the etiology of a neck mass. A fine needle aspiration is not always definitive, particularly if the mass is solid. As highlighted in this case, core biopsy or surgical biopsy provide superior tissue diagnosis although it is more invasive and involves a higher level of expertise. We aim to contribute to the literature by highlighting the diagnostic value of surgical biopsy in head and neck masses.

The patient described above had 3 excisional surgeries in another country and lost contact with healthcare providers after immigrating to USA. This dramatic example showcase how a usually manageable disease like squamous cell carcinoma can become uncontrolled in the absence of healthcare access and demonstrates the need for routine follow-up of a condition likely to recur.

CONCLUSION: Clinicians should not shy away from invasive biopsies for diagnostics in neck mass. The invasiveness of the biopsy is correlated to the diagnostic yield, with FNA being of the least diagnostic utility and surgical biopsy being the most definitive. In this case, surgical biopsy established the ultimate diagnosis of squamous cell carcinoma.

Even after appropriate diagnostics and treatment, neck masses can recur. There is an obvious need for routine follow-up and this dramatic case demonstrates how uncontrolled a usually manageable disease like squamous cell carcinoma can become uncontrolled in the absence of healthcare access.

"I WASN'T SURE WE'D MAKE IT": OPIOID WITHDRAWAL IN PREGNANT INCARCERATED

Anna M. Munoa[2,1]; Dayan Colon Sanchez[3,4]; Michelle Gaffaney[5]. [1]Internal Medicine, University of Colorado School of Medicine, Denver, CO; [2]Medicine, Denver Health Medical Center, Denver, CO; [3]Psychiatry, Denver Health Medical Center, Denver, CO; [4]Psychiatry, University of Colorado School of Medicine, Denver, CO; [5]Behavioral Health, Denver Health Medical Center, Denver, CO. (Control ID #3361168)

LEARNING OBJECTIVE #1: Identifying the stigma which lead to barriers in treatment of pregnant opioid dependent women

LEARNING OBJECTIVE #2: Understand the role of the internist in providing opioid agonist treatment in this vulnerable population.

CASE: CY is a young woman whom was prescribed opioids after a shoulder injury with rapid transition to IV heroin at the age 13. At 23 she was arrested and during jail intake was found to be pregnant, about 6 weeks along. Per the protocol of the jail she was admitted to the hospital for management of opioid withdrawal. She was started methadone and discharged back to jail when she was on a stable dose. She was subsequently transferred to multiple different jurisdictions with limited abilities to continue methadone and ultimately bonded out prior to continuation of the medication. 10 days after release from jail she presents to a hospital and was diagnosed with sepsis from endocarditis complicated by acute renal failure and threatened preterm labor. She was hospitalized for one and a half months receiving intravenous antibiotics and was restarted on methadone. A month and a half after discharge from the hospital she delivered a term baby girl. For one year post-partum CY continued to receive methadone, individual and group therapy. She was working part time and living at home with her mother and her daughter.

IMPACT/DISCUSSION: The rate of women using opioids during peripartum is on the rise nationally. National opioid use disorder rates at delivery more than quadrupled during 1999-2014. During pregnancy, chronic untreated opioid addiction is associated with lack of prenatal care and multiple complications for the mother and fetus. The American Society of Addiction Medicine published guidelines in 2015 for treatment of women with opioid use disorder (OUD) during pregnancy with the recommendation that pregnant women with OUD should be treated with opioid agonist treatment (OAT) which includes buprenorphine or methadone. Treatment should also be initiated as soon as possible. However, incarcerated pregnant women are a vulnerable population and have limited access to these services. Recognition of opioid dependence and diagnosis of pregnancy frequently fall upon primary care providers in both the community as well as incarceration. Identification and treatment with OAT is essential to good outcomes for both women and pregnancy.

CONCLUSION: Understanding of the expanding opioid epidemic with increased access to OAT has improved treatment to many individuals. However, it is important to recognize the vulnerability of populations at high risk including pregnant women, incarcerated women, and those experiencing both. Early recognition of OUD and connection to OAT with advocacy for consistent treatment across all areas of medical care is essential for improved health outcomes and communities

"RHEUM" TO IMPROVE: GPA IN DISGUISE

George Mundanchira[1]; Jennifer Verbsky[1]; Joseph Conigliaro[2]. [1]Medicine, Northwell Health, Plainview, NY; [2]Internal Medicine, Zucker School of Medicine, New Hyde Park, NY. (Control ID #3390489)

LEARNING OBJECTIVE #1:

Identify migratory arthritis as an unusual presentation of GPA.

LEARNING OBJECTIVE #2: Recognize the importance of continuity of care in diagnosing a rheumatologic condition presenting with multiple nonspecific symptoms.

CASE: A 78 year old woman with a history of HTN and breast cancer in remission presents to the outpatient clinic for sudden right hand swelling, fatigue, dry mouth and cough. Five weeks prior, the patient had transient swelling, redness, and pain of the right ankle for three days, treated by an outside physician with antibiotics for presumed cellulitis, followed by left calf swelling and redness one week later, for which she was treated by a different physician with antibiotics again for cellulitis. One week later, she developed right ear pain and fevers, treated at urgent care with antibiotic drops for otitis externa, and one week prior to presentation developed intermittent severe shoulder pain with intermittent swelling and pain of other joints, for which an orthopedist ordered an MRI to rule out a rotator cuff tear. Uric acid and lyme titers were negative. Other labs were significant for mild anemia, elevated transaminases, microscopic hematuria, and an elevated urine protein to creatinine ratio. Due to the patient's constellation of symptoms, inflammatory markers were drawn, revealing a CRP of 4.86, with a positive C-ANCA of >1:1280 and a positive proteinase 3 ab of >200. The day after presentation, she was hospitalized for profound lethargy, recurrent fevers to 101F, and lower extremity petechiae. After infectious sources were ruled out, the patient was diagnosed with Granulomatosis with polyangiitis (GPA) based on all above lab findings. Prednisone and PCP prophylaxis were started, and the patient was discharged home with an outpatient kidney biopsy to confirm diagnosis.

IMPACT/DISCUSSION: GPA is a small-vessel vasculitis that typically presents as rhinosinusitis, ear pain, cough, shortness of breath, urinary abnormalities, and neuropathy, as well as constitutional symptoms including fever, fatigue, and anorexia. In GPA, arthritis is often an associated symptom, but there are few cases in the literature of polyarthritis as the initial symptom as it was in this case. Migratory transient arthritis with constitutional symptoms should prompt consideration of a rheumatologic disease.

This patient saw multiple physicians who treated her with antibiotics for presumed infections, which in retrospect were likely due to the rapid development of GPA. The key to diagnosis in this case was in evaluating the various presentations chronologically, and when seen in a continuum, allowed for nonspecific symptoms to become disease-specific manifestations prompting exploration for inflammatory and vasculitis markers, leading to a diagnosis of GPA.

CONCLUSION: GPA should be considered in the differential diagnosis of migratory arthritis with constitutional symptoms. Continuity of care allows for summative evaluation of often nonspecific transient symptoms for possible elusive diagnoses.

A BALANCING ACT: SUPRATHERAPEUTIC INR IN THE SETTING OF MECHANICAL MITRAL VALVE

Leslie M. Ocampo[1]; Rafael Otero[2]; Eddy Valdez[2]; Mais Alnoukari[2]; Ismael Polo[2]; Henry Kwang[2,1]. [1]Internal Medicine, University of Texas, Rio Grande Valley, Harlingen, TX; [2]Valley Baptist Medical Center, Harlingen, TX. (Control ID #3391941)

LEARNING OBJECTIVE #1: Manage patients with supratherapeutic INR with atrial fibrillation and mechanical heart valve

CASE: A 76 year-old male with a history of atrial fibrillation and mitral valve replacement on warfarin presented to the ER with "achy" non-radiating lower abdominal pain associated with nausea for the past several days. The patient did not report fever, diarrhea, constipation or any exacerbating or relieving factors. He had a history of a prior appendectomy but denied any prior GI bleeding. On admission, the patient had rate controlled atrial fibrillation with a heart rate of 106 and blood pressure of 119/100. The patient was in no acute stress, but was found to have mild bleeding of the gums in addition to soft abdominal distention and moderate, generalized tenderness on palpation. Laboratory findings were positive for INR 4.99. Given the diffuse abdominal tenderness, an abdominal CT was ordered which showed severe wall thickening of jejunal bowel loops. The patient was given one 5mg dose of Vitamin K and admitted as inpatient. DVT prophylaxis was not administered during the hospital stay, and the patient underwent laparoscopic surgical resection of a portion of the proximal jejunum which had suffered hemorrhagic ischemia. After the resection, cardiology and oncology recommendations involved reinstituting therapeutic anticoagulation.

IMPACT/DISCUSSION: Supratherapeutic INR in the setting of a mechanical mitral valve can present a challenge in the clinical management of patients with acute gastrointestinal bleeding. Caution must be taken in order to decrease bleeding through Vitamin K reversal, all while maintaining the patient on a therapeutic INR level so as to ensure the adequate anticoagulation indicated in the setting of a mechanical valve. One must carefully weigh the benefits of anticoagulation and the risk of bleeding in these individuals. Given the high risk of thromboembolic events in a patient with a mechanical mitral valve and atrial fibrillation, anticoagulation is a crucial component of the patient's medication regimen. In the event that supratherapeutic INR levels are reached, it's important to establish hemodynamic stability by reversing anticoagulation effect, supplementing the missing coagulation factors, like Vitamin K. However, caution must be taken so as to not cause rapid complete reversal of anticoagulation to subtherapeutic INR levels that could lead to a thromboembolism.

CONCLUSION: The 2014 AHA/ACC guideline for the *Management of Patients With Valvular Heart Disease* recommends a therapeutic INR of 2.5-3.5 in patients with mechanical heart valves who are at an increased risk of thromboembolism from atrial fibrillation. Early detection and addressing the source of the bleed through imaging studies and frequent monitoring of INR is essential in the management of these patients. In the case of this patient, immediate reversal of the anticoagulation potentially saved the patient's life prior to the resection as the hemorrhage was limited to the jejunum.

A CLASSIC CASE OF PERNICIOUS ANEMIA HIDING IN PLAIN SIGHT

Kathryn Leyens[1]; Thomas R. Radomski[2]; Matthew J. Bittner[1]. [1]Internal Medicine, UPMC, Pittsburgh, PA; [2]Division of General Internal Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA. (Control ID #3392136)

LEARNING OBJECTIVE #1:

Identify the presenting signs and symptoms of untreated pernicious anemia (PA)

LEARNING OBJECTIVE #2: Define the diagnosis of pernicious anemia

CASE: This is a 72-year-old female with no known medical history in the setting of no prior medical care who presented to an outside hospital in the setting of syncope. She was found to have a hemoglobin of 5.5 g/dL requiring blood transfusion and increased left intraocular pressure concerning for angle closure glaucoma. Upper endoscopy was performed due to concern for GI bleed which demonstrated mildly erythematous mucosa in the gastric body. She was transferred to our hospital for further ophthalmologic management. In addition to intermittent syncopal episodes, the patient and family also reported altered mental status, bright red blood per rectum for 20+ years, gastric reflux, and tingling/numbness of her hands and feet.

Patient was incidentally noted to have pancytopenia with significant neutropenia (800 cells/mm^3) and elevated MCV (130 fL). She was also noted to have evidence of hemolytic anemia including elevated bilirubin, low haptoglobin, and elevated LDH. Vitamin B12 levels were undetectable. Peripheral blood smear demonstrated megaloblastic anemia. Her exam was significant for atrophic glossitis. She demonstrated dramatic improvement with the repletion of B12 even after three days. Eventually, IFA returned positive. She was discharged home on B12 repletion.

IMPACT/DISCUSSION: This case demonstrates a vast array of both typical and atypical changes seen in untreated pernicious anemia. This autoimmune condition primarily has effects on the hematologic, immunologic, gastric, and neurologic systems of the body which create the underlying pathology that was found in this patient. She had multiple common findings of PA including anemia, glossitis, peripheral tingling/numbness, and changes in mental status. She also presented with two less common findings of PA including pancytopenia and hemolytic anemia. Pancytopenia occurs in the setting of diminished erythropoiesis and myelopoiesis. Both of these hematologic changes improved solely with the administration of parenteral B12. This patient has all four primary diagnostic criteria including low serum B12, megaloblastic anemia, upper endoscopy with erythematous mucosa of gastric body concerning for atrophy, and IFA positivity.

CONCLUSION:

- PA can have a multitude of presenting signs and symptoms including pancytopenia and hemolytic anemia. All of these improved with parenteral administration of B12.
- The diagnosis of PA includes: 1) low serum B12 levels, 2) megaloblastic anemia, 3) PCA or IFA, and 4) gastric atrophy.
- In later stages of PA, IFA is more accurate given that the majority of parietal cells have been destroyed resulting in lower levels of PCA.
- Patients with PA require assessment of thyroid disease and monitoring for iron-deficiency anemia and gastric malignancy.

AMOXICILLIN-CLAVULANATE AS THE CAUSE FOR ACUTE LIVER INJURY IN OLDER ADULTS

Emily Owen. Internal Medicine, University of Wisconsin Hospital and Clinics, Madison, WI. (Control ID #3392114)

LEARNING OBJECTIVE #1: Identify the most common antibiotics to induce acute liver injury.

LEARNING OBJECTIVE #2: Identify the patient populations at greatest risk for Amoxicillin-Clavulanate (AC) drug-induced liver injury (DILI) and their respective outcomes.

CASE: A 79-year-old female with hypertension presented to the ED for generalized pruritus. Ten days prior to presentation she developed generalized pruritus, in addition to nausea and vomiting. She denied recent fevers, chills or weight loss. She drinks one cocktail and one beer nightly. On exam, she appeared jaundiced with no stigmata of end stage liver disease. Her abdomen was non-distended with mild tenderness to palpation of the right upper quadrant. Liver edge was not palpable. Labs were notable for a Total Bilirubin: 26, ALP: 1700, AST: 859, ALT: 582, INR: 0.9. CT scan was negative for pancreatic mass or biliary obstruction. On further history, she reported treatment for a gout flare with prednisone and Amoxicillin- Clavulanate (AC) two weeks ago. She ultimately underwent a liver biopsy that showed mixed cholestatic hepatitis suggestive of a drug reaction. She was started on ursodiol and prednisone. Her lab values normalized two months post hospitalization.

IMPACT/DISCUSSION: In the US, AC is the third most commonly prescribed antibiotic in the outpatient setting and the most likely to cause drug-induced liver injury (DILI). Other antibiotics associated with DILI include erythromycin, nitrofurantoin and sulfamethoxazole/trimethoprim. Interestingly, DILI secondary to amoxicillin is much less common suggesting that clavulanic acid is the primary agent for injury. The incidence of AC DILI has been estimated to be 17 cases per 100,000 compared to erythromycin estimated at <4 cases per 100,000. Risk factors for AC DILI include male sex and older age. With regard to age, one study cited an average age of 60 years versus 48 for other DILI. For the majority of patients with AC DILI, supportive care alone is sufficient for recovery. A prospective study conducted in Spain found that patients with drug-induced hepatocellular jaundice had an 11.7% chance of progressing to death or transplantation. When looking at outcomes for AC DILI specifically, several studies report that women are more likely to develop fulminant liver failure requiring transplant. One study reported that 6.6% of female participants required a liver transplant compared to 0% of male participants. This suggests that although older men are at greater risk for AC DILI, women with AC DILI may be more likely to suffer the most severe adverse outcomes. This case heightened my awareness to the risk of this commonly prescribed antibiotic. Given the possible poor outcomes, AC use in these higher risk populations should be used with caution.

CONCLUSION: AC is a commonly prescribed antibiotic that can cause DILI. AC DILI can lead to severe outcomes including liver failure.

Older men are at highest risk for AC DILI, but women are more likely to experience the most severe adverse outcomes.

CATCH 22: MANAGEMENT OF LIFE-THREATENING VENTRICULAR SEPTAL RUPTURE IN ACUTE MYOCARDIAL INFARCTION.

Chukwudum Ufondu[1]; Mit Patel[1]; Steven Song[2]; Ali Hama Amin[2]. [1]Internal Medicine, Virginia Tech Carilion, Roanoke, VA; [2]Cardiology, Virginia Tech Carilion, Roanoke, VA. (Control ID #3388293)

LEARNING OBJECTIVE #1:

Recognize the clinical presentation of post-myocardial infarction ventricular septal defect.

LEARNING OBJECTIVE #2:

Recognize the dilemma associated with adequate management of post-myocardial infarction ventricular septal defect.

CASE: A 75-year-old man presented to the emergency department with 2 days of flu-like symptoms. Electrocardiogram (ECG) was consistent with inferior ST-elevation myocardial infarction. Transthoracic echocardiogram (TTE) revealed left ventricular ejection fraction of 45%, right ventricle (RV) volume and pressure overload, with a large post-infarction 2 cm muscular ventricular septal defect (VSD) and left to right shunting. He was hypotensive requiring vasopressor support and subsequent venoarterial extracorporeal membrane oxygenation (ECMO). Coronary angiography showed significant multivessel coronary artery disease. He received percutaneous intervention (PCI) to the culprit right coronary artery (RCA), followed by repair of VSD with pericardial patch using infarct exclusion technique. His clinical condition declined 2 weeks postop resulting in multi-organ failure and he was eventually made comfort care.

IMPACT/DISCUSSION: Post-MI VSD can occur within a few days after transmural MI. Conservative treatment is associated with 97% mortality, whereas surgical intervention is associated with 47% mortality in the first 30 days. Studies suggest improved mortality with PCI prior to VSD repair. Early surgical repair can be complicated due to friability of the myocardium. Delaying surgical intervention may facilitate successful repair by allowing friable tissue to organize, strengthen, and become well-differentiated from surrounding healthy tissue.

CONCLUSION: Management of post-myocardial infarction ventricular septal rupture is controversial. Timing and method of repair always bring about great debate. A multidisciplinary cardiac team should be involved in the care for patients with this rare complication of MI.

COMPLICATED LEGIONELLA PNEUMONIA WITH FALSE NEGATIVE URINE ANTIGEN TEST

Hind El Soufi[1]; Andrew Mekaiel[1]; Yahya El Soufi[2]; Farshad Bagheri[3]. [1]Internal Medicine, Jamaica Hospital Medical Center, Jamaica, NY; [2]Lebanese University Faculty of Medical Sciences, Beirut, Lebanon; [3]Director of Infectious diseases, Jamaica Hospital Medical Center, Jamaica, NY. (Control ID #3391529)

LEARNING OBJECTIVE #1: Recognize severe Legionella Pneumonia infection with end organ failure.

LEARNING OBJECTIVE #2: Consider repeating Legionella urine antigen test in highly suspected cases with negative initial results.

CASE: A previously healthy 34-year-old man was brought to the emergency department for fever, chills, diarrhea, nonproductive cough and progressive confusion.

Upon presentation, patient was only oriented to self and vital signs were significant for tachycardia, tachypnea, SaO2 of 93% on room air, and low-grade fever. On physical exam, crackles were heard on the right upper lung field. Lab tests showed mild leukocytosis (WBC 11.7), thrombocytopenia (platelets 101), hyponatremia (Na 126 mEq/L), rhabdomyolysis (CPK of 96,000 U/L), coagulopathy (INR 1.7), transaminitis (ALT 168 U/L, AST 715 U/L), procalcitonin of 4.06 ng/ml and creatinine of 1.2 mg/dl. Chest radiograph and confirmatory CT chest showed consolidation in the right upper lobe. CT head was normal. Urine antigen for Legionella was negative. Patient was admitted to the hospital and started on broad spectrum antibiotics and aggressive IV hydration.

Due to high suspicion for Legionella infection, urine antigen test was repeated and came back positive confirming Legionella pneumonia. Antibiotics were de-escalated to levofloxacin. However, rifampicin was then added for severe sepsis and worsening respiratory status. Repeat chest X-Ray revealed bilateral pulmonary congestion. Follow-up labs were significant for positive troponin of 0.123 ng/ml and CPK of 130,000 U/L. Echocardiogram showed severely reduced LV function (EF ~ 20%) and diffuse hypokinesia. Hospital course was complicated by ventricular tachycardia, subsequent fibrillation and cardiac arrest. Patient was resuscitated, intubated and then transferred to the ICU.

An automatic implantable cardioverter defibrillator was placed; and the patient remained stable afterwards and eventually was discharged to subacute rehabilitation.

IMPACT/DISCUSSION: Legionella grows in water systems and spreads in small droplets. Pneumonia caused by Legionella is clinically and radiographically similar to other forms of pneumonia. Testing options include nucleic acid detection, urine antigen, and culture. False negative urine antigen for Legionella can be suspected in case of diluted sample, testing occurring after 7 days of infection, and infection by Legionella pneumophila non serogroup 1. Therefore, when strongly suspecting Legionella infection, repeat testing should be considered. Severe infection can lead to end-organ failure including rhabdomyolysis, kidney damage, hepatitis and even myocarditis which could be the cause of the acute onset of heart failure in this case.

CONCLUSION: It is important to always have a high index of suspicion for Legionella pneumonia when the clinical tableau is in favor, even if the initial urine antigen is falsely negative.

MYASTHENIA GRAVIS INDUCED BY PEMBROLIZUMAB

Karolina Viquez[1]; Ashley Thompson[2]; Brady Culver[1]; Adam Cole[2]. [1]Department of Internal Medicine, University of Kentucky, Lexington-Fayette, KY; [2]Division of Pulmonary and Critical Care, Uniersity of Kentucky, Lexington, KY. (Control ID #3367963)

LEARNING OBJECTIVE #1: Review the pathophysiology and clinical manifestations of Myasthenia gravis

LEARNING OBJECTIVE #2: Recognize the association of Pembrolizumab with Myasthenia gravis

CASE: 81 yo male with a history of urothelial carcinoma who received the first treatment with pembrolizumab 3 weeks ago, presents with a 1 week history of diffuse myalgias, fatigue, diplopia and shortness of breath.

On admission he was tachycardic and hypoxic. Had mildly elevated lactate and troponin without chest pain or ECG changes, transaminitis and a creatine kinase level of 7860. Infectious workup negative. Computed tomography-pulmonary angiogram (CT PA) showed no embolism and stable pulmonary metastatic disease. Transthoracic echo showed no wall motion abnormalities, EF >55%. On physical exam generalized muscular weakness and a negative inspiratory force (NIF) of 28 cm H2O. The patient developed progressive acute hypoxic and hypercarbic respiratory failure requiring BIPAP therapy. Hematology recommended Methylprednisolone 50mg BID due to concern for checkpoint inhibitor associated myositis. Acetylcholinesterase antibody resulted positive, therefore a course of IVIG 2g/kg for 5 days and Pyridostigmine was recommended, and Methylprednisolone increased to 100mg BID. In spite of this therapy, the his NIF worsened to -15 cm H2O and the decision was to proceed with endotracheal intubation. Given lack of improvement with IVIG, plasmapheresis was initiated and he received a total of 5 sessions. The patient ultimately required a tracheostomy and attempts to liberate him from mechanical ventilation continue

IMPACT/DISCUSSION: MG is an autoimmune disease, with pathogenic antibodies against the AChR on the neuromuscular junction or against muscle-specific tyrosine kinase. Immunosuppressive therapies such as corticosteroids, IVIG, and steroid-sparing agents are requiered for long-term management. Pembrolizumab is an anti-programmed cell death protein-1 (anti-PD-1) monoclonal antibody. PD-1 is a cell surface receptor that prevents T- cell activation, reduces autoimmunity, and promotes self tolerance. Pembrolizumab treatment results in enhanced immune responses to tumor cells and normal host tissues. Several adverse events have been described including myositis and rhabdomyolysis, but few of cases of drug-induced MG have been reported.

Our patient presented with MG after the first cycle of treatment with pembrolizumab and his MG crisis led to respiratory failure requiring endotracheal intubation. The treatment of MG includes high dose steroids, IVIG and plasmapheresis in circumstance of failed first line therapies. Pembrolizumab should be immediately discontinued, and only resumed following careful consideration by a multidisciplinary team

CONCLUSION: MG exacerbation is a life-threatening complication that requires collaborative decision- making with the patient, neurologist, and oncologist to consider permanent discontinuation of the checkpoint inhibitor. A high index of suspicion is crucial for early diagnosis of MG associated with checkpoint inhibitors

NECK MASSAGE FOLLOWED BY PAGET-SCHROETTER SYNDROME TREATED WITH ULTRASOUND-ASSISTED, CATHETER-DIRECTED THROMBOLYSIS IN A MIDDLE-AGED FEMALE

Ahmad Hallak[1]; Muhammad Kashif Amin[1]; Randa Hazam[2]; Yusuf Hallak[4]; M Tarek Naguib[3]. [1]Internal Medicine, Texas Tech University Health Sciences, Amarillo, TX; [2]Internal medicine, Ttuhsc, Amarillo, TX; [3]Internal Medicine, Texas Tech University, Amarillo, TX; [4]Mohammed Bin Rashid University Of Medicine and Health Sciences, Dubai, United Arab Emirates. (Control ID #3391913)

LEARNING OBJECTIVE #1: Vigorous neck massage can aggravate scalenus anterior chronic compression of subclavian vein producing thrombosis.

CASE: A previously healthy 39-year-old female presented a few hours after neck massage with discomfort and swelling in the left arm and shoulder. Venous duplex scan showed thrombosis of the left subclavian, axillary and brachial vein. Numbness and bluish discoloration in the left upper extremity prompted a venogram that showed thrombosis of the left subclavian vein. An ultrasound-assisted catheter-directed thrombolysis was performed with prompt resolution of symptoms. Repeat venogram showed resolution of the thrombus with a significant stenosis in the mid and distal third of the left subclavian vein. Interestingly, the venogram showed complete occlusion of the subclavian vein with arm abduction and elevation, while the vein appeared patent with residual stenosis in the anatomical position. She was diagnosed with Venous Thoracic Outlet Syndrome. MRI showed subclavian vein compression by the scalenus anterior muscle.

IMPACT/DISCUSSION: The Venous Thoracic Outlet Syndrome leading to axillo-subclavian thrombosis, also known as Paget– Schroetter syndrome results from the subclavian vein compression in the anterior-most part of the thoracic outlet region. It comprises 3-5% of all thoracic outlet syndromes, with an incidence of 1:100,000 per year. The subclavian vein is highly vulnerable to injury as it passes by the junction of the first rib and clavicle. Hypertrophied scalenus anterior, subclavius, or abnormal bone morphology (clavicle or first rib) may encroach on the costoclavicular space causing compression. In addition, repetitive forces in this area frequently lead to fixed intrinsic damage from repetitive microtrauma to the intimal layer and inflammation with extrinsic scar tissue formation. As the vein becomes less mobile, it becomes susceptible to stretch, rupture or thrombosis. Once primary thrombosis is recognized, catheter-directed thrombolytic therapy is usually successful if initiated within 10 to 14 days of clot formation. Our patient had fixed venous stenosis, evident on venogram after thrombolysis. Massage may have been sought to relieve scalene area discomfort and likely aggravated pre-existing stenosis thereby inciting the coagulation cascade leading to thrombosis.

Definitive management includes decompression surgery of the thoracic outlet followed by anticoagulation for 3 to 6 months. Severe persistent symptoms may warrant venous reconstruction.

CONCLUSION: Thoracic outlet syndrome can present as subclavian vein thrombosis, especially after neck massage. Catheter- directed thrombolysis is recommended in these patients. Persistent symptoms warrant surgical intervention.

WHEN BLOOD IS NOT AN OPTION

Vishnu Nagalapuram, Prudhvi Regula, Mouna Gunda, Krishna Venkata. Internal Medicine, University of Alabama at Birmingham, Montgomery Internal Medicine Residency Program, Montgomery, AL. (Control ID #3372133)

LEARNING OBJECTIVE #1:

To recognize hemoglobin-based oxygen carriers (HBOC) as important supplemental bridges for hemorrhagic shock in patients who refuse blood products.

LEARNING OBJECTIVE #2:

To describe the logistics of obtaining bovine-HBOC and care of the patient during infusion.

CASE:A 48-year-old Jehovah's Witness was transferred for management of massive pulmonary embolism (PE) following surgery. She received ultrasound-guided catheter-directed thrombolysis and anticoagulation. The next day, she became hypotensive with worsening dyspnea and hemoglobin (Hb) dropped from 10g/dL to 6.6g/dL. CT abdomen and pelvis showed rectus sheath hematoma with hemoperitoneum. Thrombolytic therapy and anticoagulation were stopped and an IVC filter was placed. As she refused blood transfusions, she was started on erythropoietin and iron. Subsequent to a drop in hemoglobin to 3.3g/dL, we procured bovine-HBOC, obtained FDA and local IRB approval, then initiated infusion. After receiving 6 units of HBOC, her Hb rose to 6.8g/dL and BP normalized. We closely monitored for methemoglobinemia. However, without anticoagulation, the PE extended and she developed severe hypotension requiring dobutamine. Despite optimal medical management, she deteriorated and arrested.

IMPACT/DISCUSSION: Treating hemorrhagic shock in patients who refuse blood products is challenging. To prevent ischemic complications, different types of HBOC's are used as a bridge to supplement oxygen delivery until exogenous erythropoietin and iron administration can restore adequate RBC mass. Bovine- HBOC (HBOC-201) is manufactured in the U.S. and approved for use in S. Africa and Russia, but is not FDA approved for clinical use in the U.S. Permissions from the local IRB and FDA (for compassionate use) must be obtained. HBOC could be considered at a Hb of 5-6 g/dL depending on patients' hemodynamics. HBOC doesn't require ABO compatibility and has no storage restrictions. It has a half-life of 20 hrs and 1 unit can increase Hb by approximately 0.63 g/dl. HBOC dosage is determined by measuring both free plasma Hb plus measured intracellular Hb (standard Hb from a CBC). The infusion should be stopped if methemoglobin levels exceed 10%, or cyanosis or dyspnea occur. Important side effects include nausea, vomiting, diarrhea, dysphagia, achalasia, and methemoglobinemia. These may be related to hypertension and vasoconstriction from nitric oxide scavenging properties of free Hb. Although a meta-analysis of HBOCs from various sources showed higher rates of myocardial infarction and death, those results cannot be extrapolated to bovine-HBOC. Several successful treatments with bovine-HBOC have been reported. An expanded access study on bovine-HBOC for treatment of life-threatening anemia was initiated in the U.S. and is expected to be completed by July 2020.

CONCLUSION: Bovine-HBOC in hemorrhagic shock for patients who refuse blood products should be considered on an individual basis when benefits outweigh risks.

WHEN TO RESTART A STATIN IN A PATIENT WITH ASYMPTOMATIC CK ELEVATION AND MYOCARDIAL INFARCTION

andy pham. internal medicine, cpmc, San Francisco, CA. (Control ID #3373342)

LEARNING OBJECTIVE #1:

There is firm evidence to support the use of statins to reduce cardiovascular morbidity and mortality. The major reason for discontinuation of statin therapy is statin-associated muscle symptoms (SAMSs). However, no universally accepted definition of statin toxicity/intolerance exists. The American Heart Association and American College of Cardiology (AHA/ACC) 2018 Guidelines for the Management of Blood Cholesterol recommend a comprehensive approach to patients who experience SAMSs. To truly diagnosis statin toxicity it requires a systematic approach of dechallenge and rechallenge to assess causation, multiple statin challenges to support diagnosis, and elimination of other underlying causes of the described side effects.

CASE: A 49 year old male patient presented with a NSTEMI and a DES was placed. He was started on ticagretol, aspirin, and atorvastatin. One year later, he complained of ongoing myalgia. His CK was elevated (2355 units/L) and his AST was 105 units/L and his ALT 66 units/L. Atorvastatin was discontinued. When the patient returned one year later, liver enzymes had normalized, but CK was still high (1642 units/L) without myalgia present. His total cholesterol at this time was 276 mg/dl with LDL of 181 mg/dl. The patient now described constipation, lethargy, and weight gain. A test of his thyroid function test abnormal: TSH 109 milli-international units/L, Free T4 0.16 milli-international units/L, and positive TPO antibodies. After being put on levothyroxine, his symptoms improved, his CK normalized and the patient tolerated statin challenge well.

IMPACT/DISCUSSION: Up to 72% of all statin adverse events are muscle related. Up to 30% of patients who would benefit from statins discontinue statins due to those side effects. Statin related muscle symptoms can present as myalgia, myopathy, myositis with elevated CK or at its most severe, rhabdomyolysis. There are 7 progressively worse statin-related myotoxicity phenotypes: asymptomatic CK elevation, tolerable and intolerable myalgia, myopathy, severe myopathy, rhabdomyolysis, and autoimmune-mediated necrotizing myositis. From a clinical viewpoint, SAMSs can be divided into 4 groups: (1) rhabdomyolysis characterized by high CK concentrations (>100-fold the upper limit of normal [ULN]), myoglobinuria, and renal impairment; (2) myalgia or mild hyperCKemia (<5× ULN); (3) self-limited toxic statin myopathy (CK levels 10 to 100x ULN); and (4) myositis or immune-mediated necrotizing myopathy with HMG-CoA reductase antibodies and CK levels 10 to100× ULN.

CONCLUSION: Our patient most likely had CK elevation due to hypothyroidism and either mild hyperCKemia or self-limited toxic statin myopathy.

The AHA/ ACC 2018 Guidelines explicitly suggest reassessing after 6-8 weeks when CK elevation occurs after statin use. Premature closure can easily misdiagnose CK elevation due to other causes as statin toxicity. It is important to recognize that statin toxicity and secondary causes of CK elevation like hypothyroidism can appear simultaneously.

A 47-YEAR-OLD MALE DEMONSTRATING DENGUE AND ZIKA IMMUNOLOGIC CROSS- REACTIVITY.

Aleksandra Pivovarova[1]; Maria X. Bueno Rios[2]. [1]Internal Medicine, University of Mississippi Medical Center, Jackson, MS; [2]Infectious Diseases, University of Mississippi Medical Center, Jackson, MS. (Control ID #3343037)

LEARNING OBJECTIVE #1: Recognize cross reactivity among Flavivirus family complicating the serologic diagnosis.

LEARNING OBJECTIVE #2: Utilize nucleic acid amplification tests (NAATs) as a preferred method of diagnosis within 7-day of onset of symptoms.

CASE: A 47-year-old male with unremarkable PMH presented with fever, nausea, headaches and back pain that started 1 week ago. Patient returned from Cuba 10 days ago. Reported Mosquito bites while in Cuba. ROS positive for fever, poor appetite, abdominal pain, back pain, headache, nausea. On physical exam afebrile, BP 107/87,HR 71,RR 20,SpO2 97%, well-developed, well-nourished male with conjunctival injection, petechial rash in bilateral ankles and soft palate. Labs significant for thrombocytopenia, leukopenia, and mildly elevated liver enzymes. Work-up negative for HIV, EBV, HBV, HAV, HCV, RPR. US abdomen unremarkable. Patient was clinically improving after a few days of supportive treatment. Liver enzymes normalized; thrombocytopenia resolved. Serology came back positive for Dengue, Zika and West Nile. From clinical standpoint patient's presentation was more consistent with dengue fever. Patient was discharged home in stable condition.

IMPACT/DISCUSSION: Dengue fever is an infection caused by 4 distinct types of flavivirus, can be asymptomatic or with variety of

symptoms including headaches, myalgia, ocular/retro orbital pain, arthralgia, rash, hemorrhagic manifestations, leukopenia. ZIKAV is a flavivirus closely related to dengue, West Nile, and yellow fever. Zika usually presents with low-grade fever, pruritic maculopapular rash, arthralgia and/or nonpurulent conjunctivitis. ZIKAV and DENV exhibit similar clinical presentation, as well as geographic distribution. Diagnosis is usually made by molecular testing or serologic method. For patients presenting within 7 days from onset of symptoms, RT-PCR of serum and urine for detection of viral nucleic acid should be performed. IgM antibodies develop within the first week of infection. IgM can be used when the viral nucleic acid is no longer detectable, IgM antibodies are detectable for months and even longer after infection. Identifying the specific timing of viral infection can be a challenge. False-positive results due to cross- reactivity of envelope proteins, especially between ZIKAV and DENV have been described. Shared epitopes in the envelope proteins are the cause of the structural similarity and cross-reactivity. Previous bioinformatic analyses have found that the envelope (E) protein of DENV2 and ZIKV share close to 53.9% amino acid sequence.

Hence the decision about the diagnosis has to be made based on clinical presentation.

CONCLUSION: The preferred method for Dengue and Zika diagnosis is NAAT. However, viral nucleic acid may not be detectable after 7 days following infection, and serology is the alternative method for establishing the diagnosis. Structural similarity of proteins in Zika and Dengue predisposes to immunologic cross reactivity, hence, the clinical presentation should assist in diagnosis.

A CASE OF ABDOMINAL COCOON POST RENAL TRANSPLANT

Tu N. Nguyen[1]; Lawrence Ku[2]; Anshu Abhat[3]. [1]Internal Medicine, Cedars-Sinai Medical Center, Los Angeles, CA; [2]Internal Medicine, Harbor UCLA, Torrance, CA; [3]Medicine, Harbor-UCLA Medical Center, Pasadena, CA. (Control ID #3391627)

LEARNING OBJECTIVE #1: Develop differential diagnosis for small bowel obstruction and ascites in a post-transplant patient

LEARNING OBJECTIVE #2: Identify complications from peritoneal dialysis

CASE: A 38-year-old woman with ESRD from lupus nephritis and deceased-donor kidney transplant 6 months ago, chronic Hepatitis B, and prior tuberculosis, presented with 2 months of abdominal pain. She endorsed progressive epigastric pain, bilious emesis after meals, abdominal bloating, intermittent diarrhea, and weight loss of 30 lbs in 6 months, only tolerating a liquid diet. She had been on PD for 11 years prior to transplant. She was treated for pulmonary TB 14 years ago in South Africa for 8 months. Physical exam revealed a distended, tympanic, mildly tender abdomen; no tenderness over the transplant site; normal bowel sounds; and a small, firm peri-umbilical nodule. Abdominal CT showed a large amount of ascites and severe luminal narrowing of the small bowel, consistent with high-grade small bowel obstruction. Differential diagnosis included TB peritonitis, post-transplant lymphoproliferative disorders (PTLD), and EPS. Ascitic fluid showed 1120 WBC with 71% lymphocytes and 29% monocytes, and a SAAG of 0.8, not consistent with PTLD. Sputum and ascites MTB PCR were negative, making TB peritonitis unlikely. Peritoneal biopsy to definitively diagnose EPS and rule out TB peritonitis was deferred given high risk of adhesion and worsening obstruction, as well as concern for inadequate healing. She was started on empiric treatment for EPS with tamoxifen and mycophenolic acid; nutritional optimization with TPN, and a diet of clear liquids.

IMPACT/DISCUSSION: Encapsulating peritoneal sclerosis (EPS) is a rare complication of peritoneal dialysis, with incidence of 0.7 to 13.6 per 1000 patient-years in PD. Although its pathogenesis is uncertain, the "two-hit hypothesis" theorizes that a peritoneal membrane injury from longstanding PD followed by a "second hit" leads to its development. This patient had multiple "second hit" risk factors for EPS, including long duration on PD, renal transplantation, and the use of beta-blockers and calcineurin inhibitors. Other risk factors include severe recurrent peritonitis, PD with high dialysate glucose, ultrafiltration failure, and increased solute transport. Early EPS is nonspecific, presenting with anorexia, nausea, diarrhea, and intermittent abdominal pain. Late EPS has features of ileus, peritoneal adhesions, and intermittent obstruction. EPS is diagnosed by laparotomy demonstrating a thickened, brown peritoneum enclosing the intestinal contents, although rarely done due to risks. EPS is associated with significant morbidity and high mortality of 50% at 2 years.

CONCLUSION: EPS, also known as abdominal cocoon, is a rare complication of PD. EPS is characterized by intraperitoneal inflammation and fibrosis, causing encasement of bowel loops and a clinical syndrome of bowel obstruction. EPS should be considered in patients with a history of PD presenting with symptoms of ileus and bowel obstruction.

A CASE OF ACQUIRED APLASTIC ANEMIA CAUSED BY EOSINOPHILIC FASCIITIS.

Mohammad Khan[1]; Ruhani Desai[2]; Kinanah Yaseen[3]; Alexandra Villa-Forte[1]. [1]Internal Medicine, Cleveland Clinic Foundation, Beachwood, OH; [2]Internal Medicine, Cleveland clinic foundation, Cleveland, OH; [3]internal medicine, Cleveland Clinic, Westlake, OH. (Control ID #3392126)

LEARNING OBJECTIVE #1: Recognize the importance of identifying and treating secondary causes of aplastic anemia.

CASE: A 48-year-old Caucasian man was evaluated for pancytopenia, myalgias and rash. His symptoms began several months prior to his presentation with onset of an erythematous rash localized to his neck. Over time, his rash spread with patchy involvement of his trunk and extremities and took on a more fibrotic, hypopigmented appearance. He also developed symptoms of fatigue, mucosal bleeding, intermittent fevers, and myalgias. Past medical history included a childhood diagnosis of linear scleroderma that did not require treatment. He denied taking new medications and had no history of radiation or toxic exposures. Results of initial testing uncovered new-onset pancytopenia and inflammatory marker elevation. Noteworthy results of workup of his pancytopenia included peripheral smear without blasts or atypical cells and negative testing for nutritional deficiencies and viral infections–including HIV, viral hepatitis, and parvovirus. Serologic testing detected homogenous ANA titer elevation, elevated anti-histone Ab levels, and absence of antibodies to extractable nuclear antigens–including anticentromere and Scl70 antibodies. Skin biopsy results were characteristic of pathology seen in eosinophilic fasciitis (EF), showing dermal sclerosis, subcutaneous septal fibrosis, and fascial degeneration with chronic inflammatory changes.

He was subsequently transferred to our facility for further management. On physical examination, he had multiple areas of hypopigmented, indurated skin with peau d'orange appearance on in his abdomen, neck, and extremities with sparing of his hands and feet. Taken altogether, his exam findings, characteristic rash, and skin biopsy results represented a near textbook presentation of EF and established our diagnosis. Meanwhile, a diagnosis of acquired aplastic anemia (AA) was made after results of a bone marrow biopsy revealed severely hypocellular marrow and negligible hematopoiesis without fibrosis. Treatment included therapy with anti-lymphocyte globulin (ATG) and cyclosporine for his AA and prednisone for his EF.

IMPACT/DISCUSSION: Aplastic anemia (AA) is a rare disease process thought to arise from lymphocytic destruction of hematopoietic cells within the bone marrow. Diagnosis requires both peripheral pancytopenia

and bone marrow biopsy revealing hypocellular marrow without evidence of fibrosis. Though the majority of cases of AA are idiopathic, prompt identification of secondary causes is essential to provide comprehensive treatment. Eosinophilic fasciitis (EF)—a rare connective tissue disease—has been recognized as a cause of acquired AA. Within this case, a thorough investigation of our patient's rash helped establish this rare diagnosis, allowing us to treat not only his AA but also the precipitating underlying condition as well.

CONCLUSION: A thorough evaluation of secondary causes of acquired AA is essential. Eosinophilic fasciitis is a rare cause of acquired AA.

A CASE OF ACQUIRED HEMOLYTIC UREMIC SYNDROME IN A RENAL TRANSPLANT PATIENT

Nicolas Krepostman[1]; Blaine Knox[1]; Anthi Katsouli[2]. [1]Internal Medicine, Loyola University Medical Center, Chicago, IL; [2]Internal Medicine, Hospitalist, Loyola University Medical Center, South Barrington, IL. (Control ID #3390043)

LEARNING OBJECTIVE #1: Recognize the acquired causes of hemolytic uremic syndrome (HUS)

LEARNING OBJECTIVE #2: Distinguish between different HUS variants in renal transplant recipients

CASE: A 59-year-old woman with history of focal segmental glomerulonephritis (FSGS) and renal transplantation on sirolimus presented with three days of cramping abdominal pain, vomiting and watery diarrhea. She was hemodynamically stable on admission and physical exam was notable only for diffuse left- sided tenderness. Initial workup revealed a Hgb of 16, WBC of 13, Plt of 250 and Cr of 0.8. CT abdomen showed edema of the distal colon and rectum. She was started on antibiotics for presumed infectious colitis, however her diarrhea progressed and she developed hematochezia. A repeat CT demonstrated significant progression of her colitis. Labs on day eight of her admission showed a WBC of 21.2, Hgb 9.4, Plt 50, Cr 3.2. Hemolysis labs revealed LDH > 2000 and haptoglobin < 30. Stool PCR was positive for Shiga-toxin producing E. coli and there were schistocytes on peripheral smear. She was diagnosed with HUS and antibiotics were discontinued. She underwent a renal biopsy, which demonstrated active thrombotic microangiopathy. She was treated supportively with the remainder of her hospital course complicated by anemia requiring multiple blood transfusions, as well as renal failure requiring hemodialysis. She was discharged to acute inpatient rehab and two weeks later no longer required dialysis.

IMPACT/DISCUSSION: Our case illustrates a renal transplant patient who developed HUS, defined by a triad of hemolytic anemia, thrombocytopenia and acute renal damage. Previously characterized by typical vs. atypical, more current literature now classifies HUS into hereditary vs. acquired causes. Acquired causes commonly refer to Shiga toxin-producing Escherichia coli (STEC) but can also include autoantibodies to complement factors, which is evaluated through testing a CH50 level. Low CH50 levels (<60) indicate a deficiency in the complement pathway and can be treated with eculizumab, a monoclonal c5 antibody that has been shown to be effective in improving renal outcomes. In renal transplant recipients 0.8% to 14% of patients have been found to develop acquired HUS from calcineurin or MTOR inhibitors. Our patient was taking sirolimus, an MTOR inhibitor, which can lead to a drug-induced thrombotic microangiopathy. She was found to have an elevated CH50 level and was therefore treated supportively for presumed STEC HUS. Given that STEC HUS is widely considered a childhood disease, this case adds to the growing evidence that adults can also be affected.

CONCLUSION: Hemolytic anemia, thrombocytopenia, and acute renal damage should prompt clinicians to consider the diagnosis of HUS, which can be acquired either via infection or complement antibodies. Complement-mediated HUS should be considered in patients taking calcineurin or MTOR inhibitors, with eculizumab being effective therapy in this population.

A CASE OF ACUTE GOUTY ARTHRITIS MIMICKING PROSTHETIC JOINT INFECTION IN A 50-YEAR-OLD WOMAN

Caitlin Bolender[3]; John C. Christensen[1,2]. [1]Department of Medicine, Intermountain Medical Center, Murray, UT; [2]Division of General Internal Medicine, University of Utah, Salt Lake City, UT; [3]Dermatology, University of Utah, Salt Lake City, UT. (Control ID #3385769)

LEARNING OBJECTIVE #1: Recognize that acute gout may present in prosthetic joints

LEARNING OBJECTIVE #2: Acute gouty arthropathy may mimic prosthetic joint infection and surgical intervention is not typically indicated

CASE: A 50 year-old, African-American woman with history of bilateral total knee replacements, heart failure with reduced ejection failure, stage 3 chronic kidney disease, alcohol dependence, and acute myeloid leukemia status post remote bone marrow transplant presented to the emergency department with a 24-hour history of pain and swelling in her left knee as well as subjective fevers. She denied intravenous drug use or recent dental procedures. She denied any history of gout.

Vital signs were remarkable for a temperature of 38.4 C and a heart rate of 123 bpm. Her left knee was warm and tender to palpation, with pain on passive range of motion and an effusion was present. There was no evidence of overlying cellulitis.

Synovial fluid was pink and cloudy with 35,000 WBC/microL, 25,000 RBC/microL, 94% neutrophils, and monosodium urate crystals were present. Gram stain was negative. The fluid was sent for culture. She was given one dose of colchicine. She defervesced and antibiotics were not administered.

Orthopedic surgery was consulted and recommended joint washout with possible liner exchange given the concern for concomitant septic prosthetic joint infection. On hospital day 3, the patient was taken to the operating room. Repeat synovial fluid samples were obtained intraoperatively which showed 3900 WBC/microL, 82,000 RBC/microL, 83% neutrophils and no crystals. Surgical impression was consistent with gouty arthritis. The patient improved and was discharged home on hospital day 5 after receiving a 5-day course of prednisone and having received no antibiotics. Her cultures remained negative.

IMPACT/DISCUSSION: The diagnosis of gouty arthritis in a prosthetic joint is difficult to establish due to the rarity of this condition. To date, there have been only 17 confirmed cases of gout and 13 cases of pseudogout in prosthetic joints. Our patient had no previous history of gout; however, she had several predisposing risk factors including high dose diuretics and a history of alcohol abuse.

Despite a synovial fluid analysis consistent with gout, providers were reluctant to defer surgery due to the suspicion for septic arthritis. Of the 30 reported cases of this condition, unsurprisingly, 59% underwent invasive surgical washout. Of these cases, only 4 patients had concomitant infection. As with our patient, the presenting symptoms of fever, tachycardia, and pain make it challenging to distinguish between gout and active infection. Reliance on aspirated joint fluid analyses are imperative in preventing surgical exploration. As awareness of the diagnosis of crystal arthropathy in those with prosthetic joints grow, subsequent rates of unnecessary invasive intervention may potentially be reduced.

CONCLUSION: By recognizing that acute gout may present in prosthetic joints, providers may help their patients avoid unnecessary surgery

A CASE OF ACUTE VISION LOSS: ORBITAL CELLULITIS VERSUS CAVERNOUS SINUS THROMBOSIS

Catherine Teskin[1]; Shaina Nazare[2]; Emily Bollinger[1]; Joseph M. Deutsch[2]. [1]Internal Medicine, Christiana Care, Wilmington, DE; [2]Internal Medicine, Christiana Care Health System, New Castle, DE. (Control ID #3363561)

LEARNING OBJECTIVE #1: Recognize clinical presentation of cavernous sinus thrombosis.

LEARNING OBJECTIVE #2: Outline treatment of cavernous sinus thrombosis.

CASE: 70 year-old male with past medical history of primary myelofibrosis on Jakafi chemotherapy who presented with acute vision loss of his left eye over two days. The patient recently started chemotherapy with last dose received three weeks prior to presentation. Vital signs were normal with exam findings significant for periorbital edema, tenderness and erythema, limited extraocular movement, proptosis, and complete loss of vision of the left eye. Initial labs were pertinent for elevated white blood cells secondary to primary myelofibrosis, hemoglobin of 6.4 g/dl near baseline, elevated CRP and ESR, and negative blood cultures.

Imaging included non-contrast CT head that revealed preseptal/retrobulbar swelling followed by MRI that revealed findings consistent with orbital cellulitis versus cavernous sinus thrombosis. At this time, broad spectrum antibiotics and heparin were started to treat possible infection and/or thrombosis. Opthalmology did not recommend surgical intervention, but patient was started on IV steroids, per their recommendations. Hematology felt patient's presentation was related to inflammation due to thrombosis, rather than an infectious etiology given patient remained afebrile with negative blood cultures and without obvious abscess on imaging. Antibiotics were discontinued. The patient was transitioned to Lovenox and oral Prednisone taper. Patient's proptosis and extraocular movement improved tremendously throughout his hospital course, but he did not regain vision.

IMPACT/DISCUSSION: Cavernous Sinus Thrombosis (CST) is a potentially life-threatening rare disorder with about five cases per million people reported annually[1]. The cavernous sinus contains vital structures including: internal carotid artery and cranial nerves III, IV, V, and VI, and consequently typically presents with ptosis, ophthalmoplegia, diplopia, and paresthesia around the ocular cavity[2], as well as, fever, headache, and periorbital swelling[3]. Etiology is typically multifactorial with risk factors including prothrombotic conditions such as: malignancy, pregnancy, infection, and head trauma. Prompt diagnosis and treatment is paramount to prevent permanent vision loss. The development of CST in our patient was likely a result of his prothrombotic and immunosuppressive state in the setting of his malignancy and ongoing chemotherapy. Due to the rarity of this condition there were no clinical trials available to guide treatment course. In general, it is recommended to start antimicrobial and antithrombotic therapy. Often, a course of corticosteroids can be given, however their efficacy has not been demonstrated[3].

CONCLUSION: This case reflects the importance of collaboration between multiple specialties to enhance patient care and commit to an accurate diagnosis.

CST should be on the differential for patients with prothrombotic conditions and cranial nerve findings on physical exam.

A CASE OF ADULT-ONSET HENOCH–SCHöNLEIN PURPURA

Catherine Teskin[1]; Nikita Donti[2]; Eric Russell[1]. [1]Internal Medicine, Christiana Care, Wilmington, DE; [2]Internal Medicine, Christiana Care Health Systems, Wilmington, DE. (Control ID #3367356)

LEARNING OBJECTIVE #1: Recognizing the clinical features of Henoch–Schönlein Purpura.

LEARNING OBJECTIVE #2: Outline the treatment of Henoch–Schönlein Purpura.

CASE: 70 year-old male with severe tophaceous gout recently restarted on allopurinol presented with ecchymotic lesions of his extremities with associated arthralgias that developed over 2 weeks. On presentation, the vital signs were normal and significant exam findings were diffuse ecchymotic lesions of all extremities with hemorrhagic plaques of fingers and tense vesicles of feet. Lab work included unremarkable CBC, normal ESR, elevated CRP, elevated CPK, significant acute kidney injury, and urine analysis remarkable for proteinuria and red blood cells. Hospital course was complicated by coffee-ground emesis and hypotension necessitating ICU transfer. Underwent endoscopy revealing esophagitis and portal hypertensive gastropathy. Initial rheumatologic differential included various vasculitis like cocaine or drug induced, and Sweet's Syndrome. Further workup included low C3, elevated IgA, undetectable rheumatoid factor, cryoglobulinemia not present, negative HIV/Hepatitis and vasculitis panel, and negative urine drug screen. Skin biopsy revealed IgA deposits in venules of superficial dermis leading to the diagnosis of HSP. Given the deposition was IgA rather than IgG or IgM without eosinophils, negative vasculitis panel, and evidence of systemic involvement, it was surmised this was less likely drug induced vasculitis. Patient was stabilized and discharged on Prednisone with rheumatology follow-up.

IMPACT/DISCUSSION: IgA vasculitis, formerly called Henoch-Schonlein purpura (HSP), is an immune- mediated vasculitis associated with IgA deposition. Etiology is unknown but a variety of triggers are recognized, including an abnormal inflammatory process deriving from immune reactions to various antigenic stimuli in a genetically prone individual[1]. HSP is more common in the pediatric and Asian population with male predominance. It is characterized by a clinical tetrad: palpable purpura without thrombocytopenia and coagulopathy, arthralgia, abdominal pain, and renal disease. Adults have increased risk for renal involvement and prompt diagnosis can help prevent advanced renal disease. HSP is generally self- limited and managed in the ambulatory setting, unless there's inability to maintain oral intake, GI bleeding, mental status changes, severe pain, or renal insufficiency. Treatment is generally supportive. Evidence suggests steroids hasten resolution of arthritis and abdominal pain but do not prevent recurrence[2].

Treatment of nephritis with immunomodulators is considered with >1g/day proteinuria and/or impaired renal function during an acute episode. ACE inhibitors may be used to treat proteinuria. Renal biopsy is obtained to determine the degree of crescent formation and is the best prognosticator[3].

CONCLUSION: Prompt diagnosis of HSP in adults is paramount to prevent renal impairment. Consider getting renal biopsy to determine severity of renal disease and prognostication.

A CASE OF AL (LIGHT CHAIN) AMYLOIDOSIS WITH MULTISYSTEM INVOLVEMENT

Meghana Singh[1]; Anantha Sriharsha Madgula[1]; Swarup Kumar[2]. [1]Internal Medicine, UConn school of medicine, Hartford, CT; [2]Hematology/Oncology, University of Connecticut, Hartford, CT. (Control ID #3392013)

LEARNING OBJECTIVE #1: Recognize that amyloidosis can be a cause of heart failure and that early diagnosis is key for initiation of effective therapy and reduction of mortality

LEARNING OBJECTIVE #2: Understand that there are therapies for the treatment of AL amyloidosis.

CASE: 61-year-old male with history of diabetes mellitus, hypertension, presented to the hospital with fatigue and dyspnea on exertion,

progressively worsening for a year. He was diagnosed with heart failure and started on diuretic therapy. Echocardiogram showed decreased left ventricular (LV) cavity size, with an ejection fraction of 65%. He continued to have dyspnea and gained 15 pounds since discharge six weeks earlier. On readmission, electrocardiogram (EKG) showed first-degree AV block and new bi-fascicular block. Cardiac catheterization was done showing elevated filling pressures, with no evidence of obstructive coronary disease. He was also noted to have persistent transaminitis, unchanged with heart failure directed therapy. A liver biopsy was then done, with findings consistent with congestive hepatopathy. Due to continued lack of clinical improvement, extensive workup including a cardiac MRI was performed. This was consistent with global cardiac amyloidosis. A follow up cardiac technetium pyrophosphate (PYP) scan was equivocal for TTR amyloidosis. The liver biopsy was then stained with Congo red stain, positive for amyloid deposits. Serum electrophoresis identified the presence of a monoclonal protein as well as an abnormal free light ratio (free kappa 9.2 mg/dl, free lambda 403.7 mg/dl and kappa lambda ratio of 0.02). Bone marrow biopsy also confirmed amyloid involvement and typing was confirmatory for AL type amyloid. He was started on treatment with cyclophosphamide, bortezomib, and dexamethasone (CyBorD).

IMPACT/DISCUSSION: AL amyloidosis is the most common type of systemic amyloidosis and commonly affects the heart, kidneys, liver, or nervous system due to deposition of abnormally folded immunoglobulin light chains in the tissues. Cardiac involvement (70-80%) is the leading cause of mortality. Diagnosis is usually delayed in a large proportion of patients (25%) and can lead to irreversible cardiac damage with survival less than 12 months since diagnosis. The goals of therapy are to support the patient by treatment of end-organ dysfunction as well as eradication of the clone of B cells producing these misfolded immunoglobulin light chains. Multiple myeloma directed treatment such as the CyBorD regimen is effective when initiated early and is eventually followed by autologous hematopoietic stem cell therapy. Novel therapies such as carfilzomib, daratumumab, elotuzumab have also proven to be effective.

CONCLUSION: It is important for clinicians to have a high index of suspicion for amyloidosis in patients presenting with heart failure, especially if there is evidence of involvement of multiple organ systems. Early diagnosis and treatment are crucial to reduce mortality.

A CASE OF ANTI NXP-2 ANTIBODY-ASSOCIATED DERMATOMYOSITIS WITH AN UNPREDICTABLE COURSE

Mahnoor Mir[1]; Justin Haloot[1]; LAKENE RAISSA DJOUFACK DJOUMESSI[2]; Eric Author[1]; Kanapa Kornsawad[3]. [1]Internal Medicine, University of Texas Health Science Center San Antonio, San Antonio, TX; [2]INTERNAL MEDICINE, UTHSCSA, San Antonio, TX; [3]Internal Medicine, University of Texas Health Science Center, San Antonio, TX. (Control ID #3388629)

LEARNING OBJECTIVE #1: Steroid resistant Dermatomyositis

CASE: A 36-year-old Laotian female with a history of hypothyroidism presented with 3 days of worsening symmetrical proximal muscle weakness and anasarca. She was recently seen at another hospital and presented with one day of worsening throat swelling and diffuse anasarca. Over the next 2 months, she developed dysphagia requiring a PEG tube and was discharged with an unclear diagnosis. Physical exam revealed significantly weak muscle strength associated with erythema of the lower back. Laboratory studies were significant for elevated CK, aldolase, and positive anti-NXP-2 antibody(Ab). ANA, Anti-Smith/Anti- DNA, Anti-Jo, AChR antibodies were negative. A muscle biopsy demonstrated non-specific inflammatory changes with lymphocytic infiltrates. MRI findings were consistent with myositis. Diagnosis of Anti-NXP2 Ab Dermatomyositis (DM) was made. Malignancy screening was negative except for abdominal CT with a dermoid cyst. High-dose corticosteroids were started followed by pulse-dose steroids, IV immunoglobulin, and plasma exchange followed by dermoid cyst removal. However, her symptoms persisted with worsening soft tissue swelling, myalgias, and weakness with the development of heliotrope rash and shawl's sign. She was given Rituximab with no response and started on Tofacitinib

IMPACT/DISCUSSION: DM has a prevalence ranging from 0.005 to 0.02% with a 2 to 1 female predominance. The prevalence of anti-NXP-2 Ab among patients with DM varies from 11% to 30%.

Dysphagia, calcinosis, diffuse soft tissue swelling, myalgia, and mild skin involvement are common presenting symptoms, which are consistent with our case aside from the calcinosis. Cancer prevalence in DM varies and many patients develop cancer within 3 years following diagnosis. In a study of colorectal cancer and DM, removal of the tumor lead to a complete resolution of DM in about 54% (14/26). An extensive workup, including a whole-body PET/CT scan, was negative for cancer in our patient and she failed to improve after removal of the dermoid cyst, which was thought to be causing a paraneoplastic syndrome. Although DM has been historically associated with cancer, this association has no proof in a recent meta- analysis. Corticosteroids are the cornerstone of myositis treatment, with up to 60% of patients showing some response, though there is no evidence to support the choice of corticosteroid-sparing agents in the treatment of steroid-resistant DM. In our patient, there was no response despite several modalities of immunosuppressants.

CONCLUSION: Proximal muscle weakness is a very common chief complaint with multiple differentials. Anti-NXP2- Ab DM remains a very rare condition and recognition is important for appropriate workup, diagnosis, and management. More studies are needed to further characterize this subset of DM. Appropriate cancer screening up to 3 years following the diagnosis of DM is paramount.

A CASE OF COPPER DEFICIENCY MYELONEUROPATHY AFTER BARIATRIC SURGERY

Nisa Desai[1]; Rachel H. Kon[2]. [1]Internal Medicine, University of Virginia, Charlottesville, VA; [2]Medicine, University of Virginia School of Medicine, Charlottesville, VA. (Control ID #3346430)

LEARNING OBJECTIVE #1: Recognize micronutrient deficiencies associated with bariatric surgery, which are commonly managed by internists

LEARNING OBJECTIVE #2: Diagnose and manage copper deficiency myeloneuropathy

CASE: 44 year old female with medical history of morbid obesity (pre-op BMI=72 kg/m^2) underwent Roux-en-Y gastric bypass (RYGB). She was started on multivitamin BID, calcium BID, Vitamin D, Iron, and B12 supplementation. Her course was complicated by dumping syndrome, severe dehydration, and poor oral intake requiring hospitalization. Eight months after surgery, she began to develop numbness and weakness on bilateral lower extremities and unsteady gait. On exam, she had intact proprioception, reduced lower extremity strength, decreased sensation from T4 level to ankles to light touch, pinprick and temperature vibration along with diminished lower extremity reflexes. MRI brain and spine, EMG, and lumbar puncture studies were unremarkable. Labs notable for normal B12, normal Vitamin E, Copper level 0.73 (0.75-1.45 mcg/ml), thiamine level 30.0 (70-180 nmol/L), Vitamin B6 level 2.0 (5-50 mcg/L), and Vitamin A level 19.7 (32.5-78.0 mcg/dL). It was ultimately concluded that multiple vitamin deficiencies, notably copper deficiency, were the source of her myeloneuropathic presentation.

IMPACT/DISCUSSION: Bariatric surgery is often complicated by multiple micronutrient deficiencies. Vitamin B12, folic acid, copper and Vitamin E deficiency are particularly associated with myeloneuropathy. Gastric

surgery is the most common cause of copper deficiency, which is otherwise a rare phenomenon. This case highlights how myeloneuropathy is often associated with non-localizing symptoms, which may delay diagnosis and treatment. Typical presentation of copper deficiency myeloneuropathy includes gait disorder, bilateral paresthesias, and sensory ataxia. Treatment is tapered oral copper repletion with periodic assessment of copper levels. Our patient did well after copper repletion, with resolution of her myeloneuropathy symptoms. 10 months post-op BMI is 45 kg/m^2.

Thus, nutritional deficiencies after bariatric surgery represent a long-term clinical problem encountered by internists. Nutritional assessments are recommended every 3-6 months during the first year after bariatric surgery and then annually. For RYGB, CBC, CMP, ferritin, vitamin A, 25-OH vitamin D, thiamine, B12, folate, PTH and prealbumin should be considered. It is important to recognize the subtle signs and symptoms of these nutritional deficiencies and exercise post-surgical monitoring accordingly.

CONCLUSION: 1) When neurologic symptoms develop after bariatric surgery, internists should have a high suspicion for micronutrient deficiencies

2) Copper deficiency myeloneuropathy is a rare disorder that often presents with gait disorder, bilateral paresthesias and sensory ataxia. Symptoms are reversible with appropriate copper supplementation.

A CASE OF CYTOMEGALOVIRUS HEPATITIS IN AN IMMUNOCOMPETENT PATIENT

Mina Tawadrous, Ajay Gade. Internal Medicine, Brookwood Baptist Health, Birmingham, AL. (Control ID #3341700)

LEARNING OBJECTIVE #1: Recognize Cytomegalovirus infection as a possible cause of non-specific prodromal symptoms and unexplained hepatitis in an immunocompetent individual.

LEARNING OBJECTIVE #2: Recognize the diagnostic tools available to facilitate the diagnosis of Cytomegalovirus infection.

CASE: A 64-year-old female with a past medical history of hypertension presented to the hospital with 3 weeks of recurrent fevers, headaches, generalized abdominal pain, and fatigue. Physical exam was only remarkable for a temperature of 101.2 °F. Laboratory tests were remarkable for a white count of 10,200 cells/mm3 cells. WBC differential was significant for increased atypical lymphocytosis of 7.6%. The alkaline phosphatase was 352 U/L, alanine aminotransferase of 572 U/L, and aspartate aminotransferase of 483 U/L, with a total bilirubin of 0.3 mg/dL. Ferritin was elevated at 1100 ng/mL. Hepatitis A, B and C tests, serum ANA, ANCA, anti-smooth, ceruloplasmin and antimitochondrial antibodies were all negative. Blood and urine cultures were also negative. CT of the abdomen and pelvis was remarkable only for sigmoid colonic diverticulosis. Echocardiogram showed normal ejection fraction with no evidence of vegetations or lesions. The patient underwent CT-guided liver biopsy, as well as EGD with biopsies of the antrum and duodenum.

CMV IgM was elevated at >240 with a negative IgG titre. A follow up CMV DNA quantification via polymerase chain reaction (PCR) was elevated at 2188 Units/mL (normal <200). Subsequently, biopsies of the liver, stomach antrum and duodenum were obtained and were positive for CMV staining in both the liver and stomach antrum. The patient eventually made progressive recovery with supportive therapy only.

IMPACT/DISCUSSION: CMV is a highly prevalent double stranded DNA virus that is well documented in the immunocompromised and neonate population with a wide range of clinical manifestations. However, CMV infection in immunocompetent adults is far less understood. Unexplained fever for prolonged periods is often the primary presentation. In addition to mononucleosis-like symptoms, subclinical transaminitis is also a common finding in immunocompetent patients.

The incidence of CMV infections and complications in immunocompetent individuals appear to be higher than previously thought. When CMV is suspected, widely available non-invasive options for diagnosis can be used. Serologic studies using CMV-specific Ig-M is a common non-invasive option for an acute CMV infection. Qualitative and quantitative PCR further aid in enhancing the diagnostic modality. However, tissue biopsy identification of CMV "Owl's Eye" inclusions or positive immunohistochemistry staining on histopathology remains the gold standard. In our patient, CMV inclusion bodies were seen in both the stomach antrum and liver biopsies.

CONCLUSION: This case illustrates the importance of considering CMV in every patient with unexplained hepatitis. Delayed diagnosis may lead to potential adverse outcomes and increased hospitalization costs.

A CASE OF DIAGNOSTIC BIAS IN TREATMENT OF SYMPTOMATIC ANEMIA IN A PATIENT WITH A LONG HISTORY OF SIGNIFICANT ALCOHOL INTAKE.

Daniel D'Alessandro. Internal Medicine, Hackensack University Medical Center, Hasbrouck Heights, NJ. (Control ID #3374500)

LEARNING OBJECTIVE #1: To recognize the importance of the initial history and initial diagnostic studies in the evauation of symptomatic anemia in a patient with a history of significant alcohol consumption.

CASE: A 55 year old female presented to hospital with 1 week history of weakness and dyspnea on exertion. She also noted pallor.

The patient admitted to six to nine glasses of wine per week, predominantly on weekends, since the age of 25. The patient denied hematemesis, dark stools, bright red blood per rectum, or vaginal bleeding.

She was noted to have pallor and sinus tachycardia. The patient was not notably jaundice.

The abdomen was non-distended; there was no hepatosplenomegaly; there was no shifting dullness; there was no caput medusae.

No spider angiomas were seen. The stool guaiac test was negative.

The patient's initial Hemoglobin was 8 with a Hematocrit of 24; White Blood Cell Count was 7 with Normal Differential;

Platelet count was 108. The patient's AST was mildly elevated; ALT was normal; PT/PTT were normal; Total Bilirubin was mildly elevated but Bilirubin was not fractionated. Iron studies were normal.

The patient was transfused with 2 units of packed red blood cells. The patient's tachycardia, weakness, and dyspnea on exertion resolved after transfusion. The patient was discharged with the understanding that she and her primary care physician would arrange prompt consultation with a gastroenterologist for endoscopy and colonoscopy to find source of anemia as an outpatient.

The patient was seen by a gastroenterologist, an endoscopy and colonoscopy were scheduled.

The patient returned to hospital 3 months later before endoscopy and colonoscopy could be arranged, due to symptomatic anemia again with Heart Rate of 120 on presentation. The patient admitted that she continued to drink alcohol, but subsequent laboratory testing revealed an elevated Indirect Bilirubin. Additional history was obtained and the patient reported Alopecia Areata at approximately 20 years of age which resolved with treatment with steroids.

The patient was also noted to have an LDH of 1,700 and a Haptoglobin of less than 8.

IMPACT/DISCUSSION: The initial history in this case was deficient in asking the patient about hematologic causes of anemia and was biased in

focusing on gastrointestinal caused due to the Alcohol history. Taking a more thorough history would have revealed the Alopecia Areata, Also, fractionating the Bilirubin on the initial diagnostic tests would have given us the clue for hemolysis. Prompt, initial Hematologic consultation may have prevented re-admission.

CONCLUSION: It was agreed that the patient had some degree of Hemolysis contributing to her anemia. It is well known that Alcohol consumption can cause hemolysis and that Hemolytic anemia is more common in Alcoholism than the general public. The patient's history of Alopecia Areata further raised a question of Autoimmune Hemolytic anemia. Hematology, subsequently placed the patient on a course of steroids which resulted in resolution of syptoms and lab abnormalities.

A CASE OF DRUG-INDUCED FEVER: BLAME IT ON CARBAMAZEPINE!

Salma Asous, Amtul Mansoor, Lily Yung. Internal Medicine, Northwell Health, Glen Oaks, NY. (Control ID #3392438)

LEARNING OBJECTIVE #1: To identify clinical features of drug-induced fevers.

LEARNING OBJECTIVE #2: To demonstrate the importance of including medications as part of the differential diagnosis for fevers of unknown etiology.

CASE: A 49 year old male with a recent diagnosis of terminal neuralgia presents to the ED for subjective fevers. Patient also complained of a dull posterior headache, dizziness, and blurry vision. He denied neck pain, stiffness, or photophobia. Patient recently had a dosage increase of carbamazepine from 200mg TID to 400mg TID. Patient travels to North Carolina once a month and his last trip was a month ago. Patient did not have any history of allergies or drug hypersensitivity reaction. On exam patient had a fever of 101.6 F and was tachycardic to 110. Neurological exam was normal. Laboratory values were significant for carbamazepine level 12.2 (normal < 12), CRP 5.28, AST 110, ALT 130 without leukocytosis or eosinophilia. Patient's initial infectious work up included CXR, urinalysis, respiratory viral panel, HIV were negative. Blood cultures remained negative throughout the hospital stay. Patient's home medications were continued including carbamazepine but at a lower dosage of 300 mg TID. Patient continued to have fevers as high as 103.8F for the next few days. Further infectious disease workup was performed which included CT chest, quant gold, EBV, CMV, hepatitis B and C were negative. Because the patient traveled to and from North Carolina, tick born illnesses were tested - Erlichia, Anaplasma, Babesia, Lyme and West Nile virus were negative. With no improvement in fevers and thus far infectious workup was negative, it was thought to be drug induced and carbamazepine was stopped. After 48 hours of stopping carbamazepine, patient remained afebrile, asymptomatic and was discharged with neurology follow up.

IMPACT/DISCUSSION: This case describes a case of drug induced fevers secondary to carbamazepine. A drug fever is defined as "fever coinciding with administration of a drug and disappearing after the discontinuation of the drug, with no other cause evident after careful physical exam and laboratory investigation." The treatment of drug-induced fevers is the immediate discontinuation of the offending drug. This patient had fever and elevated liver enzymes as the sole manifestation of adverse drug reaction without the presence of rash or eosinophilia. It is clinically important to recognize drug induced fevers, as failure to recognize leads to extraneous laboratory testing, futile therapies, and prolonged hospitalization.

CONCLUSION: Drug induced fever is a diagnosis of exclusion but is frequently underdiagnosed. Though rare, carbamazepine is a potential culprit. Once drug induced fever is suspected, one should immediately discontinue the offending agent.

A CASE OF E. RHUSIOPATHIAE BACTEREMIA IN AN IMMUNOCOMPROMISED INDIVIDUAL

Rebecca Samuel[1]; Kalyani Kumar[1]; Joseph Swisher[1]; Celeste Newby[2]. [1]Medicine, Tulane, New Orleans, LA; [2]Internal Medicine, Tulane University Hospitals, New Orleans, LA. (Control ID #3390767)

LEARNING OBJECTIVE #1: Understand transmission of E. Rhusiopathiae infection

LEARNING OBJECTIVE #2: Highlight difficulties of diagnosis and treatment of E. Rhusiopathiae

CASE: A 55-year-old homeless man with a history of alcoholic cirrhosis presented after he was found to be febrile with a foul-smelling lower extremity ulcer. Patient denied any history of trauma or recent animal contact. He was febrile to 100.9F and tachycardia. Admission labs were significant for leukocytosis. He was placed on broad spectrum antibiotics for management of sepsis. Blood cultures subsequently grew out erysipelothrix rhusipathiae and treatment was narrowed to IV penicillin. A transesophageal echocardiogram did not reveal any evidence of infective endocarditis.

IMPACT/DISCUSSION: While E. rhusiopathiae is commonly associated with cutaneous infections, only 90 cases of E. rhusiopathiae bacteremia have been reported thus far. E. rhusiopathiae is typically transmitted through contact with animals such as sheep, cattle, chickens, turkeys, dogs, and cats. Most cases occur via scratches or puncture wounds of the skin. As a result of this transmission process, infections in humans are most commonly seen secondary to occupational exposure, notably in farmers. A detailed history was unrevealing for exposures in the patient described here but he may have had contact with common street animals while being homeless.

In addition to having no exposure to known carriers of E.rhusiopathiae, he also had no evidence of infective endocarditis (IE). E. rhusiopathiae rarely causes severe disease but does carry a significant risk for IE. A 2017 retrospective review demonstrated that E.rhusiopathie can cause invasive blood stream infections in the absence of IE however approximately 90% of all reported cases of E.rhusiopathiae bacteremia have been associated with it. As of 2017, only 22 human case reports of bacteremia without IE have been documented.

Given the rarity of the bacteria, diagnosis and treatment can be difficult. E.rhusiopathiae is commonly assumed to be a sample contaminant. Several reports of lab identification error have been documented with this species, including misidentification as streptococcus viridans. For the most accurate diagnosis, it has been recommended that blood cultures be run through Matrix-assisted laser desorption/ionization-time of flight mass spectroscopy (MALDI-TOF MS). E. Rhusiopathiae is notably resistant to vancomycin and there is documentation of both aminoglycoside and sulfonamide resistance. The recommended antibiotic of choice is IV penicillin G at a dose of 12-20 million units per day. A 2017 case report however identified a penicillin resistant strain that was susceptible to ceftriaxone. Thus, susceptibilities are recommended if there is no clinical improvement following penicillin administration.

CONCLUSION: E. rhusiopathiae is often considered a contaminant when identified on bacterial cultures. An general internist should remain aware this pathogen has the ability to cause invasive infections as in this case.

A CASE OF GUILLAIN-BARRé SYNDROME (GBS) FOLLOWING ZOSTER VACCINATION.

Ankita Tripathi, Patricia Dharapak, Violetta Laskova. Medicine, MSBI, New York, NY. (Control ID #3392184)

LEARNING OBJECTIVE #1: Prompt recognition of a potentially fatal adverse effect of Varicella Zoster virus vaccination.

CASE: A 66-year old physically active woman with a history of breast cancer in remission presented with a sudden onset of leg weakness, which spread proximally over two days resulting in 3 falls and a mild associated dysphagia. She denied recent travel or sick contacts. She received Shingrix 9 days prior to symptom onset. Her neurological exam revealed decreased strength in lower extremities (4/5 hip flexion, 4/5 knee extensors/flexors), decreased sensation in the calves and diffuse areflexia of the biceps, triceps, brachioradialis, patellar and ankles. HIV, RPR, and a viral hepatitis panel were non-reactive. Hemoglobin A1c, CK, B12, CK, SPEP, ACE, CRP, and ESR were all within normal limits. A contrast MRI of the complete spine and MRI brain were without acute pathology. Analysis of her CSF revealed cytoalbuminologic dissociation concerning for GBS: protein-53.2 mg/dl, WBCs 1. Therapy with IVIG was initiated but on the second day, the patient's weakness progressed to the upper extremities, her dysphagia worsened and hypophonia developed. She was transferred to the intensive care unit. With completion of 5 days of IVIG, the NIF normalized, dysphagia resolved, mild improvement was seen in hip flexion strength bilaterally and her upper extremity strength remained stable. She was ultimately discharged to an acute rehabilitation facility.

IMPACT/DISCUSSION: GBS is a rare condition in which the immune system attacks the peripheral nerves. The mortality rate approximates 3-5% and is attributable to complications resulting from respiratory muscle paralysis, pulmonary embolism, infections and cardiac arrest. While the etiology of GBS is still unknown, viral infections such as Influenza, Cytomegalovirus and Zika, and bacterial infections such as *C. jejuni* can act as triggers. In 2004, causality was confirmed between the 1976 influenza vaccine and GBS. The association between GBS and other vaccines remains anecdotal due to a paucity of available data.

The adjuvant recombinant zoster vaccine (RZV) was first marketed in October 2017 for the prevention of herpes zoster in individuals aged ≥50 years. A pooled analysis of two large randomized trials in 2019 did not show an increased risk of developing a new potential immune-mediated disease (pIMD) or exacerbation of an underlying pIMD in RZV recipients aged ≥50. Our patient's GBS onset developed 9 days after vaccine administration. To our knowledge, there is only one other reported case of Zoster vaccination associated GBS in the literature.

CONCLUSION: Although there is no established connection between RZV and GBS, our case should alert clinicians to recognize this serious adverse effect and promptly advise their patients for hospitalization. As more post vaccination GBS cases are recognized and reported worldwide, providers will be more primed to discuss this potential side effect with their patients prior to vaccination.

A CASE OF IGG4-RD: AIP + IGG4-SC MISTAKEN FOR MALIGNANCY

Zachary G. Jacobs. Medicine, Division of Hospital Medicine, Oregon Health & Science University, Portland, OR. (Control ID #3391851)

LEARNING OBJECTIVE #1: Recognize the clinical and histopathologic features of IgG4-related disease

LEARNING OBJECTIVE #2: Describe the clinical presentation and treatment of type 1 autoimmune pancreatitis

CASE: A 73 year old female was hospitalized with two weeks of progressive jaundice, pale stools, and pruritus. Her medical history included treated hepatitis C virus (HCV) infection with sustained virologic response, as well as remote breast cancer in remission. Labs showed total bilirubin 11.7 mg/dL, alkaline phosphatase 575 U/L, alanine aminotransferase (ALT) 370 U/L, and aspartate aminotransferase (AST) 386 U/L. Malignancy was high on the differential. Multiphase computed tomography (CT) of the abdomen revealed an obstructing hilar tumor suggestive of cholangiocarcinoma, multiple vague lesions in the pancreatic body and neck, and suspicious regional lymph nodes. An endoscopic retrograde cholangiopancreatography (ERCP) with endoscopic ultrasound (EUS) and fine needle aspiration (FNA) of a pancreatic lesion was performed, along with percutaneous biopsy of the liver mass. Pathology from both demonstrated marked increase in immunoglobulin G subclass 4 (IgG4) plasma cells on immunostaining. The ratio of IgG4+ to IgG+ cells was >40% in the pancreas and nearly 1:1 in the liver. Serum IgG4 levels were 330 mg/dL (upper limit of normal: 123 mg/dL). The patient was diagnosed with type 1 autoimmune pancreatitis (AIP) and IgG4-related sclerosing cholangitis (IgG4-SC). She was started on oral prednisone at 40 milligrams per day with a plan for slow taper. Azathioprine was later added. At one year follow up she was off corticosteroids and her liver function tests had completely normalized, though serum IgG4 level remained elevated.

IMPACT/DISCUSSION: IgG4-related disease (IgG4-RD) is an increasingly recognized but still poorly understood autoimmune condition that can involve multiple organs. It typically affects middle-aged men. The prototypical form is type 1 AIP, which often co-occurs with IgG4-related sclerosing cholangitis. Clinical presentation of type 1 AIP frequently involves a pancreatic mass with painless obstructive jaundice, making it easy to mistake for malignancy. Pathologic features of IgG4-RD include a tumor-like appearance of the involved organs and tissue infiltration with IgG4-positive plasma cells. Elevated serum IgG4 level is common. While IgG4+ plasma cell infiltrates can also be seen in hepatobiliary malignancies, the ratio of IgG4+ to IgG+ cells rarely exceeds 40% in those cases. Corticosteroids are the mainstay of treatment. Natural history and prognosis are poorly described, but relapse is common.

CONCLUSION: - IgG4-RD is an autoimmune fibroinflammatory disease that can affect multiple organs

- Histopathologic features include tumor-like appearance, IgG4+ plasma cell infiltrates, and variable fibrosis

- Initial treatment involves corticosteroids; relapses are common

- Type 1 AIP, the prototypical form of IgG4-RD, often co-occurs with IgG4-related sclerosing cholangitis, its most common extrapancreatic manifestation

A CASE OF INTRACTABLE NECK PAIN DUE TO STYLOID PROCESS ELONGATION

Jonathan Macis. Medicine, Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY. (Control ID #3367386)

LEARNING OBJECTIVE #1: Identify Eagle Syndrome as a cause of neck pain.

LEARNING OBJECTIVE #2: Understand the management of Eagle Syndrome.

CASE: A 64 year-old woman presented with a 2-year complaint of progressively worsening neck pain. The pain involved the anterior and posterior right neck that was worsened with swallowing. Intravenous opiates provided temporary relief. Vital signs were normal. Cranial nerves II-XII were intact. Head was normocephalic and atraumatic; neck was without lymphadenopathy and exhibited full range of motion. Results of complete blood count, comprehensive metabolic panel, and C-reactive protein were within normal limits. Computed tomography of the neck revealed elongation of the styloids with posterior displacement of the left hyoid bone, consistent with Eagle Syndrome. The patient was started on amitriptyline and pregabalin with subsequent improvement in her pain.

IMPACT/DISCUSSION: Neck pain is a complaint commonly encountered by general internists. Eagle Syndrome is a rare, but debilitating cause of this complaint. The condition results from elongation of the styloid process, which can result in compression of the glossopharyngeal nerve or carotid artery, and irritation of the pharyngeal mucosa. Symptoms that are specific to Eagle Syndrome include neck pain associated with

neurological manifestations such as odynophagia, ear pain, pain at the base of the tongue, changes in taste, or foreign body sensation in the pharynx. Initial imaging includes plain lateral view radiographs of the skull. CT of the skull base and neck is also a valuable imaging tool as it can better demonstrate the positioning of the styloid process to its neighboring anatomical structures. Medical therapy is first-line treatment for Eagle Syndrome and includes non-opiate analgesics, tricyclic antidepressants, anticonvulsants, and local infiltration with steroids or long-acting local anesthetic agents. In cases that do not respond to medical therapy, resection of the elongated styloid process is indicated.

CONCLUSION: This case strives to increase awareness of an uncommon cause of a common complaint.

Though Eagle Syndrome is a benign condition, its symptoms can be severe. Careful use of non-opiate analgesics, tricyclic antidepressants, and anticonvulsants may effectively abate patient's symptoms. Patients that do not respond to medical treatment may undergo surgical resection of the elongated styloid process.

A CASE OF LISTERIA RHOMBENCEPHALITIS WITH PROGRESSION TO BRAIN ABSCESS

Rishi A. Charate[1]; Kamran Mahmood[2]; Nishant Patel[1]; Leslie Beavin[2]. [1]Internal Medicine, University of Louisville, Louisville, KY; [2]Infectious Disease, University of Louisville, Louisville, KY. (Control ID #3392436)

LEARNING OBJECTIVE #1: Recognize the clinical characteristics of Listeriosis and associated imaging findings to prompt early treatment

CASE: A 67 year old immunocompetent Caucasian female with a past history of mitral valve prolapse presented to an outside hospital with a prodrome of fever and headaches followed by blurry vision with initial MRI revealing rhombencephalitis. Lumbar puncture was performed showing only pleocytosis, with glucose of 49 and total protein of 90. Despite initial concern for Listeria, treatment was discontinued after CSF PCR was negative for Listeria. Blood cultures were also negative at this time. The patient was discharged on empiric treatment of encephalitis, however returned within 24 hours with new findings of left sided facial droop and left upper extremity weakness; repeat MRI revealed thalamic, internal capsule, and hindbrain brain abscesses with repeat blood cultures growing positive for Listeria monocytogenes. This prompted initiation of treatment with ampicillin and gentamicin, and transfer from outside hospital 4 days later after patient had no improvement with dual therapy alone. By this time, the patient had a mild leukocytosis to 12.5. Exam was remarkable for Left sided facial droop, 2/5 Left upper extremity muscle strength, blurry vision, and aphasia. Patient's therapy was then increased to ampicillin, gentamicin, and trimethoprim/sulfamethoxazole due to lack of response with dual therapy alone. Transesophageal echocardiogram was negative for vegetations given bacteremia, and patient's repeat blood cultures were negative. The patient began experiencing gradual improvement with this regimen, with resolution of facial droop, extremity weakness, aphasia, and blurry vision. She was discharged from the hospital with the remainder of her antibiotic course switched to oral antibiotics.

IMPACT/DISCUSSION: Listeriosis is a foodborne infection that primarily is seen in the elderly and immunocompromised usually presenting as bacteremia or meningoencephalitis whereas rhombencephalitis is more commonly seen in affected immunocompetent individuals. This case illustrates the importance of clinical suspicion when dealing with Listeriosis in an immunocompetent patient, as both blood and CSF cultures may be negative in many cases, and often CSF analysis will only result in pleocytosis. However, imaging findings of rhombencephalitis was vital in the diagnosis, as delays in treatment led to further extension in the form of abscess and bacteremia. Listeria PCR is an important diagnostic tool however may not be positive initially, and the diagnosis of Listeria should not hinge on this result alone.

CONCLUSION: Findings of rhombencephalitis are highly suggestive of Listeriosis, and treatment should be initiated at the earliest sign of clinical suspicion as shown in this case, as if left untreated brain abscesses may arise resulting in more clinically severe neurological deficits and worse prognostic outcomes.

A CASE OF MISTAKEN IDENTITY: HSV AND EBV LYMPHADENITIS MASQUERADING AS RICHTER TRANSFORMATION

Anamil Khiyami[1]; Nikita Malakhov[1]; Kimberly Bloom-Feshbach[2]. [1]Internal Medicine, New York Presbyterian- Weill Cornell, New York, NY; [2]Internal Medicine, Weill Cornell Medical College, New York, NY. (Control ID #3342445)

LEARNING OBJECTIVE #1: Identify the diagnosis of HSV/EBV lymphadenitis

LEARNING OBJECTIVE #2: Recognize disseminated viral infections due to the immunocompromised state of CLL

CASE: Our patient is a 56-year-old man with CLL without adverse cytogenetic prognostic features successfully treated with six cycles of therapy who presented one year after treatment with neck swelling, odynophagia and fatigue for two weeks. He was initially treated with penicillin for suspected streptococcal pharyngitis. Due to palpable cervical lymphadenopathy (LAD) a fine needle aspirate was performed and showed scant atypical lymphocytes. Symptoms worsened, and he presented to the ED. Vitals were notable for tachycardia, hypotension and fever. The exam was remarkable for thrush and non-tender left cervical LAD. Labs were significant for leukocytosis of 21,700, LDH of 306 and CRP of 9.2. An ultrasound of the neck revealed enlarged morphologically abnormal LAD. CT imaging revealed stable axillary/inguinal LAD; resolved intrathoracic/abdominal and pelvic LAD. Fevers persisted during his hospital course and he developed a muffled voice. Urgent laryngoscopy revealed supraglottic edema, laryngitis, and a tongue base mass that was biopsied. Steroids were initiated for airway edema. New vesicular lesions were noted on the patient's back and thighs. Infectious workup revealed an elevated serum EBV of 525 copies/ml and PCR positive HSV-2 vesicles. PET-CT was significant for cervical lymphadenopathy with SUV of 14.5 reported as 'consistent with Richter Transformation.' Bone marrow biopsy was negative for lymphoma. Histopathology from the cervical LN & tongue mass revealed areas of necrosis, eosinophilic abscesses and multinucleated giant cells consistent with viral infection without evidence of a Richter transformation. Immunostaining was positive for HSV-2/EBV co-infected cells leading to a diagnosis of HSV/EBV lymphadenitis. Steroids were discontinued, and intravenous acyclovir initiated with significant improvement in symptoms

IMPACT/DISCUSSION: This is the second reported case of lymphadenitis due to HSV/EBV co-infection, mimicking Richter transformation. In both cases, the patients had similar presentations; however, our patient was treated with an alkylating agent/monoclonal antibody combination, not a purine analog. CLL causes impaired cellular and humoral immunity, leading to an immunocompromised state. Predisposition to infection rises with increasing disease stage and prior treatment with purine analogs & monoclonal antibodies. HSV-1/2 seropositivity in the general population is estimated at 60%, with immunocompromised individuals at higher risk of reactivation. A literature review revealed a limited number of cases of disseminated HSV reactivation manifesting as lymphadenitis

CONCLUSION: Among patients with CLL with fevers and lymphadenopathy, disseminated viral infection must be considered in addition to Richter transformation. Histopathology from excisional lymph node biopsies is crucial for accurate diagnosis and effective management of lymphadenopathy

A CASE OF MISTAKEN IDENTITY: IS THIS CANCER?

Shahdeen S. Alam[1]; Nathan T. Douthit[2]; Allison P. Rogers[3]. [1]Internal Medicine, Brookwood Baptist Health, Birmingham, AL; [2]Internal Medicine, Brookwood Baptist Health, Birmingham, AL; [3]Medical Education - Internal Medicine, Brookwood Baptist Health, Birrmingham, AL. (Control ID #3376427)

LEARNING OBJECTIVE #1: Recognize the atypical presentation of sarcoidosis and its involvement with the GI tract

LEARNING OBJECTIVE #2: Recognize the diagnostic reasoning pitfalls when presented with imaging that shows "metastatic" lesions

CASE: A 46-year-old African American female presented to the ED with complaints of diffuse abdominal pain, intermittent episodes of non-bloody diarrhea and acid reflux over the period of 48-72 hours. In the ED, patient underwent a CT abdomen which was interpreted as: "Evidence most consistent with metastatic disease of unknown primary in the liver and spleen." At the time of interview, patient was tearful because of the results communicated to her by the physician in the ED. A complete history and physical exam noted mild voluntary guarding without peritoneal signs or other signs of acute abdomen. She specifically denied weight loss, night sweats, shortness of breath, flushing, and blood in stools. Patient was admitted to the hospital for further diagnostic workup including urine and blood biochemical panels.

On initial results, alkaline phosphatase was elevated to 666 U/L (Reference 38-126 U/L) and reflex GGT was elevated as well at 1,166 U/L (Reference 9-48 U/L). Other hepatobiliary, paraneoplastic and hepatitis viral markers were negative. Corrected calcium was within normal limits as well (8.8 mg/dl). Also, AMA, AFP, CEA, and 5-HIAA were negative. During this period of diagnostic workup, the patient was treated symptomatically for pain and nausea. After evaluating the biochemical workup and initial imaging from the ED, decision was made to consult interventional radiology for a CT guided liver biopsy. Pathology results in brief noted evidence of non-caseating granulomata with bile duct injury. Further histological stains excluded infectious, fungal and other etiologies. Chest x-ray was reviewed by radiology and revealed hilar adenopathy.

IMPACT/DISCUSSION: Sarcoidosis is typically viewed as primarily a pulmonary disorder with respiratory and skin findings. Observational studies from autopsies and liver biopsies note granulomas within the liver can be found in 50% to 80% of patients with sarcoidosis. Asymptomatic elevation in liver-function tests is the most common presentation in a third of patients. Clinically, liver involvement manifests itself with abdominal pain, pruritis, acid reflux and jaundice. In making the diagnosis, granulomatous lesions must be present in 2 or more organs and exclusion of alternative causes must be evaluated including but not limited to fungal infections and tuberculosis.

CONCLUSION: Lack of typical symptomatology makes it difficult to evaluate sarcoidosis in the gastrointestinal tract or other systems unless appropriate clinical and pathological findings are noted. When presented with lesions that appear metastatic in origin, it is easy to anchor on cancer as the most likely diagnosis. This case demonstrates it is imperative that tissue be obtained in order to determine whether these are malignant, infectious or autoimmune in nature.

A CASE OF MYELONEUROPATHY, NORMOCYTIC ANEMIA, AND LEUKOPENIA SECONDARY TO COPPER DEFICIENCY FROM ZINC OVERLOAD

Philip Feibusch[3]; Vatsal Bhatt[2]; Jean Miller[1]. [1]General Medicine, Hospital of the University of Pennsylvania, Philadelphia, PA; [2]Internal Medicine, Hospital of the University of Pennsylvania, Philadelphia, PA; [3]Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA. (Control ID #3373376)

LEARNING OBJECTIVE #1: Recognize the triad of myeloneuropathy, normocytic anemia, and leukopenia as signs of copper deficiency.

LEARNING OBJECTIVE #2: Distinguish functional and organic neurologic exam findings in the context of the clinical picture to prevent missing a critical diagnosis.

CASE: A 62 year old woman with a history of COPD and anxiety presented to the ED with subacute chest pain and dyspnea in the setting of progressive weakness. Acute coronary syndrome and pulmonary embolism were ruled out. At presentation, she was unable to ambulate secondary to her weakness and gait ataxia, and her initial evaluation in the ED was remarkable only for a normocytic anemia and leukopenia. She had been evaluated at an outside institution 6 months prior with a normal spinal MRI and a bone marrow biopsy concerning for myelodysplasia. Physical exam demonstrated normal vital signs except for tachycardia with an otherwise normal cardiopulmonary exam. Neurologic exam revealed 3+ reflexes throughout with 2-3 beats of clonus in the R foot, impaired proprioception in the lower extremities, impaired stereognosis (delayed identification of a pen and ring), diminished pinprick sensation in the upper extremities distal to the elbows, and a sensory level at T8, upgoing Babinski on the left foot, and a positive Romberg sign. Labs were notable for hemoglobin of 9.7 and a WBC of 2.1 with an ANC of 390. An EMG showed mild, acute, left L5 and S1 radiculopathies with no evidence of polyneuropathy or demyelination. Extensive laboratory testing was negative except for an undetectable copper level and a zinc level elevated to 243. Testing for malabsorption was negative. Her bone marrow biopsy was reviewed at our institution and showed no evidence of malignancy or myelodysplastic syndrome. With 5 days of IV copper, her copper levels normalized, her leukopenia resolved, and her myeloneuropathy improved. With physical therapy, she regained the ability to ambulate.

IMPACT/DISCUSSION: Copper deficiency is known to cause hematologic and neurologic derangements, with myeloneuropathy, anemia, and leukopenia all described in literature. Their simultaneous presentation is relatively rare. The most common neurologic presentation of copper deficiency is a myelopathy, with neuropathy described in a minority of cases. Causes of copper deficiency include malabsorption and chelation secondary to zinc overload. This clinical vignette describes a woman who presented with myeloneuropathy, anemia, and leukopenia, and was found to have copper deficiency secondary to zinc excess.

CONCLUSION: This case illustrates the difficulty of differentiating functional and organic neurologic complaints with clinical history alone. This patient with a history of anxiety and an unusual neurologic exam was worked up on the basis of her normocytic anemia and leukopenia. Copper deficiency is a rare, reversible cause of cytopenia and myeloneuropathy, and without the awareness to seek copper studies as part of her neuropathy workup, this patient's diagnosis would have been delayed or missed.

A CASE OF NEW HIV PRESENTING WITH CARDIOMYOPATHY AND NEPHROPATHY

Eric Kutscher[1,2]; Mat Kladney[2,1]. [1]Internal Medicine, NYU Langone Health, New York, NY; [2]Internal Medicine, Bellevue Hospital Center, New York, NY. (Control ID #3387346)

LEARNING OBJECTIVE #1: Differential diagnosis for acute onset heart failure and renal failure in a young adult

LEARNING OBJECTIVE #2: Understand the natural course of HIV end-organ damage

CASE: A 31-year-old woman presented with dyspnea on exertion for three months without other symptoms. Past medical history only included mild intermittent asthma. Physical exam was significant for bibasilar crackles and elevated jugular venous pressure.

Initial labs found a creatinine of 2.3, total protein of 9.5 and albumin of 3.0. Troponin was negative and BNP was 1784. Urine protein was 527, urine creatinine 43.6, and urine sodium 81. Ultrasound showed enlarged kidneys. An echocardiogram an ejection fraction of 9% and a dilated left ventricle. Heart failure workup found a normal TSH, ferritin, B12, thiamine, carnitine, selenium and ANA. Hepatitis testing was negative. An HIV test was positive (last negative in spring 2017), with a viral load of 1298 and a CD4 count of 355. Cardiac MRI showed possible infiltrative cardiomyopathy without ischemia. PYP scan showed no evidence of amyloidosis, consistent with HIV-cardiomyopathy. Kidney biopsy found collapsing focal segmental glomerulosclerosis, consistent with HIV-associated nephropathy.

IMPACT/DISCUSSION: Workup for new heart failure in a young adult includes evaluation for ischemic, autoimmune, infiltrative, nutritional, and infectious causes. In this patient with renal and heart failure, the differential was narrowed to infiltrative disease, viral end organ disease, lupus, or cryoglobulinemia.

Cardiomyopathy in patients with HIV is typically due to cardiotoxicity of antiretroviral therapy or ischemic heart disease. This patient is unusual in developing HIV cardiomyopathy so early in the course of her disease. The pathophysiology of this process is likely multifactorial with cardiomyopathy occurring at a wide range of CD4 counts and viral loads. HIV-1 has been shown to have direct toxicity on myocardial cells through cardiac macrophages and production of inflammatory mediators.

HIV-associated nephropathy (HIVAN) is likely secondary to viral infection of renal epithelial cells by HIV-1 resulting in epithelial cell proliferation and apoptosis. HIVAN is more clearly associated with CD4 counts <200 and viral load greater than 400, and usually occurs later in the disease course.

This case suggests that HIVAN itself may be able to occur earlier than previously postulated, though perhaps only in conjunction with an additional insult to the kidneys such as new-onset heart failure.

https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3842189/

https://doi.org/10.1016/j.jacc.2016.09.977

https://www.ncbi.nlm.nih.gov/pubmed/24924830

CONCLUSION: This case illustrates the potential for the development of rapidly progressive HIV complications, and thus the importance of a robust HIV screening and treatment strategy as early detection of HIV and treatment with ART can prevent these complications.

A CASE OF ORGANIZING PNEUMONIA PREDOMINANT VAPING ASSOCIATED PULMONARY INJURY

Ahmad Jarrar, Doyoung Kim, Charles Nicholson, Husna Shaik, Sirisha Gudlawar, Umang Patel, Benjamin Solomon. Internal Medicine, St. Mary Medical Center, Langhorne, PA. (Control ID #3391793)

LEARNING OBJECTIVE #1: To understand the association between E-Cigarette and pulmonary injury

LEARNING OBJECTIVE #2: To recognize 4 different types of VAPI

CASE: 22-year-old female with PMH of PTSD and significant THC/CBD use via vaporizer presented to the ED with 2 week history of dyspnea that worsened in the past 4 days. On presentation, her pulse oximetry was 88% on room air. Her dyspnea was associated with productive cough, vomiting, and pleuritic chest pain. During this interval, she had increased her THC/CBD consumption from baseline of 3-4, 30-minute sessions each day. CXR showed bilateral infiltrates in the lung. Chest CTA was significant for diffuse ground-glass opacities and bilateral infiltrates, more prominent on the right. CBC was notable for a WBC of 14.2, so she was given broad-spectrum antibiotics, IV corticosteroids, and nebulized bronchodilators. She was admitted to ICU for acute hypoxic respiratory failure from severe pulmonary injury and placed on BiPAP. ABG was significant for hypoxia with a pO2 of 68.9% on FiO2 of 65%. She became more tachypneic and hypoxic on the second day with a FiO2/pO2 ratio of less than 150, so she was intubated and required ventilator support for the next 5 days. Bronchoscopy and BAL with culture were negative for any growth, and the pathology analysis showed acute inflammation. The patient continued to receive IV steroids and finished a 7-day course of antibiotics. She was successfully extubated and continued a tapering course of steroids. Chest CT before discharge showed improved consolidation and all remaining microbial studies, including Legionella antigen, blood, and respiratory cultures were negative

IMPACT/DISCUSSION: The use of E-cigarettes has dramatically increased in recent years among young adults. These devices have been marketed as safer alternatives to traditional cigarettes by their manufacturers despite a lack of adequate safety data. The exact pathophysiology of VAPI remains unknown, however one hypothesis suggests that the initial alveolar injury is followed by leakage of plasma proteins, recruitment of fibroblasts, and fibrin formation within the alveolar lumen. Most cases presented similarly to ours with dyspnea, hypoxia, fever, and flu-like symptoms. There are four different patterns of VAPI that have been reported: acute eosinophilic pneumonia predominant, organizing pneumonia predominant, lipoid pneumonia predominant, and diffuse alveolar hemorrhage predominant. Systemic steroid and supportive care are the primary treatment for the first two patterns and have been used for the other two with no clear benefit. Bronchoscopy is primarily used to exclude infection and to help to diagnose various forms of VAPI. Given the clinical presentation, radiological, and bronchoscopic findings, this case follows the organizing pneumonia predominant pattern.

CONCLUSION: 1. E-Cigarette use is associated with VAPI associated with nicotine, Tetrahydrocannabinol (THC) and Cannabidiol (CBD) use.

2. Systemic steroid and supportive care are the mainstay of the VAPI treatment.

A CASE OF PASTEURELLA MULTOCIDA BACTEREMIA FROM A DOG SCRATCH

Demian J. Omeh[1]; Sandra Gomez Paz[1]; Shadab H. Ahmed[2]. [1]Internal Medicine, Nassau University Medical Center, East Meadow, NY; [2]Medicine/ID, Nassau Univ. Med. Ctr., East Meadow, NY. (Control ID #3391975)

LEARNING OBJECTIVE #1: Recognize rare complications of dog and cat scratch, including *Pasteurella multocida* bacteremia

LEARNING OBJECTIVE #2: Recognize the importance of obtaining pet history in the appropriate clinical setting

CASE: An 87-year-old Caucasian female presented to the emergency room with complaints of right leg pain and swelling, fever and chills, nausea, vomiting, and nonproductive cough. Her medical history includes congestive heart failure, hypertension, dementia, dyslipidemia, spinal stenosis, vertigo, and atrial fibrillation. The patient was scratched on the right leg by her dog one week ago. There was no dog bite. Physical examination was remarkable for a temperature of 101.4°F, swollen and erythematous right leg, warm, with a small wound discharging serosanguinous fluid on her shin. Blood culture grew *Pasteurella multocida.* Tetanus prophylaxis was given. The patient was successfully treated with one week of intravenous ampicillin-sulbactam, followed by one week of oral ampicillin-clavulanic acid, as well as local wound care. Repeat blood cultures while on antibiotics showed clearance of bacteremia.

IMPACT/DISCUSSION: *Pasteurella multocida* is a small, nonmotile, non-spore forming, gram-negative aerobic and facultative anaerobic bacteria. In Gram-stained specimens, they generally appear as a single bacillus, often with bipolar staining, but may also be seen in pairs or short

chains. *Pasteurella multocida* infections in humans usually result from bites of cats, and dogs; and rarely swine, lions, panthers, horses, rats, rabbits. Human infection from dog scratch is relatively uncommon, with only a few cases reported. Local cutaneous infections are most common. Other reported sites of isolation of this organism include sputum, bronchoalveolar lavage, cerebrospinal, pleural, ascitic, and joint fluid. Systemic *Pasteurella* infections occur more commonly in immunocompromised and elderly patients with various underlying co-morbidities. Mortality of up to 30% has been reported in patients with *Pasteurella* bacteremia. Our patient had multiple comorbidities, including congestive heart failure, hypertension, hyperlipidemia, which likely made her more susceptible to developing this severe infection. *Pasteurella multocida* is often susceptible to penicillins, beta- lactams, carbapenems, second and third generation cephalosporins, and tetracyclines. Our patient was successfully treated.

CONCLUSION: High index of suspicion and detailed history are vital in making diagnosis. Given the high mortality associated with P. multocida bacteremia, prompt treatment with appropriate antibiotics and other other ancillary supportive measures are necessary to guarantee good outcome.

A CASE OF PERSISTENT FEVER: THE IMPORTANCE OF THE DAILY PHYSICAL EXAM

Mauricio Kahn, Stuart Cohen. Medicine, University of Alabama at Birmingham, Birmingham, AL. (Control ID #3357710)

LEARNING OBJECTIVE #1: Identify culture-negative endocarditis as a cause of persistent fever

LEARNING OBJECTIVE #2: Recognize the importance of the daily physical exam to make a difficult diagnosis

CASE: 34 YOM presented to outside ED with 4 days of fever & headache. MR brain and LP were normal. Admitted and started on antibiotics after drawing blood cultures. After 4 days, discharged on doxycycline with negative cultures. Initially improved, but headache and fever recurred, so he went to our ED 2 weeks after symptom onset. On ROS, endorsed pain in left 3rd toe. Past medical history of ADHD on Adderall. Denied intravenous drug use (IVDU). Had recent exposure to fox urine. In our ED, BP 117/50, HR 100, and Temp 101.9 F. Normal physical exam. Labs with Hb 11.3, WBC 13K, Na 129, ALT 88, AST 53. Normal contrasted CT head. Blood cultures and serologies for zoonotic infections were sent, and he was admitted. On day 2, started on doxycycline (concern for tick-borne illness), with improvement in fever. Pain in 3rd toe persisted, and it had new erythema and purplish discoloration. A transthoracic echocardiogram (TTE) showed no vegetations. On day 3, developed numbness in left cheek, hand, & foot. Toe discoloration worsened, and a transesophageal echocardiogram (TEE) showed a large vegetation in the mitral valve. Due to paresthesias, MR brain was obtained, which showed areas of recent infarction, consistent with emboli. On day 5, blood cultures grew Haemophilus parainfluenza, and antibiotics were switched to ceftriaxone. On day 7, headache resolved. On day 8, had a mitral valve replacement. Discharged on 6-weeks of ceftriaxone.

IMPACT/DISCUSSION: Infectious endocarditis (IE) has multiple manifestations and is often severe (20% mortality). Fever is the most common symptom (90% of cases). Blood cultures are crucial in the diagnosis, but culture-negative IE represents 11% of non-IVDU native valve IE cases. In this category is H. parainfluenzae, part of the HACEK group which has a mean duration of symptoms of 30 days before diagnosis. Our patient's outside blood cultures were negative at 5 days, which shows the importance of holding them for longer in cases of persistent fever.

Our case highlights the importance of the daily patient assessment. Our initial workup was misled by the epidemiological risk factors that put zoonotic infections higher in the differential, and the repeat physical exam was most helpful in the diagnosis. Note that although our patient reported toe pain initially, he only developed discoloration consistent with septic emboli in later days, which prompted us to get a TEE despite a normal TTE. We must recognize that in spite of the predominant role of technology in medicine, the physical exam serves as a tool to rationally order ancillary tests for more definitive answers. Although often seen as redundant, if we avoid the daily examination of a patient, simple diagnoses may be missed.

CONCLUSION: The physical exam strengthens the patient-physician relationship and makes physicians more efficient.

A CASE OF PYOMYOSITIS FROM AN UNLIKELY SOURCE

Christopher Leyton[1]; Miguel Cervera[2]; Madhuri Tirumandas[2]; Priya Nori[2]. [1]Internal Medicine, Montefiore/Albert Einstein College of Medicine, New York, NY; [2]Infectious Disease, Montefiore/Einstein, Bronx, NY. (Control ID #3373355)

LEARNING OBJECTIVE #1: Recognize pyomyositis as a differential diagnosis in patients prone to complicated UTI who present with lower extremity pain and swelling.

CASE: A 79 year old man with a history of prostate cancer s/p transurethral resection of the prostate complicated by urethral stricture and retention, and recurrent deep vein thromboses (DVT) not on anticoagulation presented with swelling and redness of his right leg following a 6-hour drive 2 weeks prior to presentation. His medial right thigh was erythematous with no rashes or breaks in skin. An ultrasound of the right lower extremity revealed a right femoral DVT. He was treated with enoxaparin and later IV vancomycin and ceftriaxone as he became persistently febrile with a leukocytosis to 22. Given his lack of improvement, a CT scan of his lower extremities was ordered revealing large multiloculated collections in his bilateral quadriceps. He was HIV and hepatitis negative, and he had no history of IV drug use. He had no symptoms suggestive of a recurrence of malignancy, no recent travel, or trauma. Due to a lack in clinical improvement on antibiotics, he underwent ultrasound guided drainage of the collections which revealed frank pus. Cultures grew E. faecalis. His antibiotics were changed to IV ampicillin/sulbactam, which he received for 2 weeks post-op. He improved and was discharged on oral amoxicillin/clavulanate for 5 weeks. At follow up 1 month later, he was able to ambulate without pain, and a repeat CT scan showed complete resolution of the left thigh abscess with a decrease in size of the right thigh collection.

IMPACT/DISCUSSION: Pyomyositis is a skeletal muscle infection with abscess formation that may be caused by hematogenous spread in the setting of pre-existing muscle damage. It is usually an infection of the tropics with affected patients who are otherwise healthy. In temperate climates such as the United States, patients tend to be immunocompromised or have other major comorbidities such as diabetes. The most common culprit organism is S. aureus, whereas our patient was infected with E. faecalis. Interestingly, a urine culture collected at the beginning of his admission also resulted positive for E. faecalis. We believe our patient had a preceding urinary tract infection (UTI) with transient bacteremia and subsequent hematogenous seeding of the bilateral quadriceps. Although he had no major risk factors which could put him at risk of developing pyomyositis, he did have a significant genitourinary history requiring frequent self-catheterization and penile clamping. This likely made him prone to complicated UTI, bacteremia, and later pyomyositis with the same culprit organism.

CONCLUSION: Lower extremity erythema, warmth, pain, and edema is often mistaken for cellulitis and thromboembolic disease. In patients who are prone to complicated UTI, such as those who frequently catheterize, who present with lower extremity pain and swelling, physicians should consider pyomyositis as part of their workup.

A CASE OF RECURRENT PYOGENIC CHOLANGITIS COMPLICATED BY HEPATIC ABSCESS ORIENTAL CHOLANGIOHEPATITIS

Abdallah Beano, Priyanka Majety, Dou Huang. Internal Medicine, Tufts Medical Center, Boston, MA. (Control ID #3375841)

LEARNING OBJECTIVE #1: Diagnose oriental cholangiohepatitis in high risk populations

CASE: A 78-year-old, Chinese male with a history of recurrent pyogenic cholangitis (RPC) status post cholecystitis and Roux-en-Y hepaticojejunostomy, presented with 2 weeks of fevers, abdominal pain, and flu- like symptoms. He was prescribed a course of Levofloxacin for a presumed pneumonia as an outpatient prior. History of RPC was not documented until later during his admission. He was febrile to 38.6°C on presentation and labs were notable for leukocytosis (14K/uL; 82% neutrophils); direct hyperbilirubinemia (total 1.2mg/dL); an INR of 1.4; and normal AST, ALT, and ALK. An MRCP revealed a 7.7x7.4x7.3cm, multiseptated right hepatic abscess, intrahepatic biliary dilation, and pneumobilia. He was managed with Meropenem and IR-guided drainage. Cultures revealed pan-sensitive E. coli, while blood cultures were negative throughout his hospitalization.

IMPACT/DISCUSSION: Recurrent pyogenic cholangitis (also known as oriental cholangiohepatitis) is characterized by intrabiliary pigment stone formation, resulting in recurrent bouts of cholangitis. We present a patient from China who presented with a hepatic abscess; a rare complication of RPC.

RPC is usually seen in middle-aged individuals living in a rural, Southeast Asia. However, the incidence in the West appears to be increasing due to the immigration from endemic countries. Although there is no clear etiology, multiple theories including parasitic infections and nutritional deficiency have been proposed. This condition poses a diagnostic challenge as the presenting symptoms are similar to cholangitis due to any other cause, and can occasionally present as pancreatitis. Diagnosis is established by imaging of the liver and biliary system in patients with compatible history, and is only attained in 15-30% of patients after their first presentation. A right upper quadrant ultrasound is a useful initial test; ductal dilation and stones can be seen in 85-90% of patients. MRCP is a non-invasive test that can provide detailed visualization of the extent of biliary involvement. Complications include sepsis upon presentation, liver abscesses, cholangiocarcinoma, and cirrhosis - likely from repeated damage to bile ducts and liver parenchyma. The management of patients with recurrent pyogenic cholangitis should involve a multidisciplinary approach since endoscopic, surgical, and radiologic interventions may be required. Acute bouts of RPC are treated -as is norm for cholangitis and choledocholithiasis- with antibiotics, biliary drainage, and stone extraction. Resection of hepatobiliary segments with biliary-enteric anastamoses can be considered in a subset of patients to alleviate possible long- term complications.

CONCLUSION: Clinicians should have a high index of suspicion for diagnosing RPC in patients from endemic areas

RPC can present with liver abscess and needs thorough evaluation

The case highlights the importance of overcoming language barriers in healthcare

A CASE OF RECURRENT SYNCOPE SECONDARY TO A RIGHT CORONARY ARTERY WITH A MALIGNANT COURSE

Madeline C. Fitzpatrick[1]; Allyson Hughes[1]; Stacy Davis[2]. [1]Internal Medicine, UTHSC Nashville, Nashville, TN; [2]Cardiology, UTHSC Nashville, Nashville, TN. (Control ID #3391466)

LEARNING OBJECTIVE #1: Recognize the common presentations of a malignant RCA

LEARNING OBJECTIVE #2: Understand diagnosis and management of malignant RCA

CASE: A 40-year-old female with a past medical history of hypertension, combined systolic and diastolic heart failure, and bipolar schizophrenia presented with recurrent syncopal episodes, dyspnea, and angina. She had multiple hospital admissions with similar complaints and poor outpatient follow up.

She presented initially with angina and underwent a full cardiac workup. Stress test revealed a large but mild defect in the basal, mid, and apical anterior and basal and mid anteroseptal walls, but the study was limited by breast attenuation. Cardiac catheterization showed a dominant RCA that arose anomalously from the left sinus of Valsalva, but her coronary arteries were free of disease. Cardiac MRI was suggested, but she was lost to follow up.

One month later, she presented to the ED again with dyspnea. A CTA was done that ruled out pulmonary embolism but, unfortunately, no comment was made regarding the course of the RCA.

During her most recent hospitalization, the cardiac MRI was completed and noted a normal proximal course of the RCA, but distal course was not identified. Closer analysis of the previously performed CTA revealed her RCA passed between the ascending aorta and the pulmonary artery.

Though she was at high perioperative risk due to her super morbid obesity and severely decreased ejection fraction, operative intervention was felt necessary due to her high risk of sudden cardiac death. A single coronary artery bypass graft was successfully performed, and the patient recovered well.

IMPACT/DISCUSSION: Coronary artery anomalies are relatively common and often have no clinical significance. However, a malignant right coronary artery is a rare, and potentially fatal, congenital anomaly found in approximately 0.1% of patients undergoing angiography. A right coronary artery with a malignant course arises anomalously from the sinus of Valsalva and courses between the pulmonary artery and aorta. Many individuals are asymptomatic, but symptoms of angina, syncope, and dyspnea can occur secondary to compression of the RCA between the aorta and the pulmonary artery. Myocardial infarction or sudden cardiac death can occur in these patients in the absence of atherosclerosis. Malignant RCA is diagnosed by CT angiogram. Current literature suggests management of malignant RCA on a patient by patient basis.

CONCLUSION: While malignant RCA is rare, it is not unseen in the general population. In a patient with unexplained angina, presyncope, syncope, or cardiac arrest, malignant RCA should remain in the differential.

Special attention to the coronary arteries should be paid on CTA in order to make this diagnosis. The patient we report had risk factors for cardiac disease but did not have coronary artery disease on catheterization. Some patients can be medically managed, but single coronary artery bypass graft remains a surgical option to resolve the anatomic defect.

A CASE OF REFRACTORY NAUSEA AND VOMITING

Jankikeerthika Dharmarpandi, Anuja Kamat, Faiza Mubeen, Abdelrazig Suliman. Internal Medicine, Texas Tech University Health Sciences Center at Amarillo, Amarillo, TX. (Control ID #3376832)

LEARNING OBJECTIVE #1: Diagnose splenic vein thrombosis in a patient with a history of pancreatic surgery.

LEARNING OBJECTIVE #2: Recognize clinical features of splenic vein thrombosis.

CASE: 46-year-old male presented to the ER with nausea and vomiting of two days duration. He had associated diffuse abdominal pain that was slightly more central, with no radiation, 8/10 in intensity, sharp in character, and had no relieving factors. Patient also complained of reflux symptoms. He reported that he had not been taking his insulin for the

previous two days because he had been unable to eat. He also mentioned not taking his anti-hypertensive medication for two days as he has had a tendency to immediately vomit after taking medications.

His past medical history includes T2DM and HTN. His surgical history encompasses insulinoma resection in 2005. His home medications were amlodipine, losartan, atorvastatin, aspart, glargine. On physical exam he was found to have a soft abdomen, mild tenderness to palpation in umbilical area, lack of abdominal distension, and positive bowel sounds.

Patient was admitted a month ago for similar symptoms, at that time he was diagnosed with diabetic ketoacidosis. His symptoms resolved with insulin management and he was sent home. On his current admission to the hospital for nausea and vomiting, his blood glucose was 251 and bicarbonate was 17, he was appropriately managed with insulin. However, this time his nausea and vomiting was refractory to treatment. CT abdomen showed thickening of stomach and distal esophagus. At this time gastroenterology was consulted. EGD was performed which revealed large isolated gastric varices.

IMPACT/DISCUSSION: Splenic Vein thrombosis is a common complication of pancreatic pathologies such as pancreatic cancer, trauma, or chronic pancreatitis. Splenic vein thrombosis over the course of time will lead to collateral flow through the short gastric veins and the coronary vein; prominent gastric mural varices develop in the gastric cardia and fundus. This results in isolated gastric varices from enlargement of short gastric collaterals without portal hypertension or abnormal liver function; this phenomenon is known as left- sided or sinistral portal hypertension. These gastric varices may cause severe gastric bleeding, although the risk is less than that of esophageal varices. Patients present with UGI bleeding or with splenomegaly. If patient is asymptomatic no intervention or treatments are indicated, however, if there is bleeding, splenectomy should be considered. For a newly diagnosed splenic vein thrombosis anticoagulation not is indicated, unless there is a systemic disease leading to a hypercoagulable state present.

CONCLUSION: - Consider EGD to diagnose SVT in patients with a present or previous history of pancreatic pathology.

- Monitor for UGI bleeding in patients with SVT and secondary isolated gastric varices.

A CASE OF STREPTOCOCCUS INFANTARIUS BACTEREMIA ASSOCIATED COLORECTAL CANCER

Byung Yoo, Brooke Hooper. Internal Medicine, Eastern Virginia Medical School, Norfolk, VA. (Control ID #3392297)

LEARNING OBJECTIVE #1: Assess for colorectal cancer in patients with Streptococcus infantarius bacteremia

CASE: 73 year-old male presented to the emergency department following a positive blood culture that was drawn at his infectious disease clinic. He has past medical histories of coronary artery disease, severe aortic stenosis, coronary artery bypass surgery, open heart aortic valve replacement, endocarditis, chronic heart failure, and chronic anemia. His records revealed that he was previously treated for endocarditis of the biopresthetic valve and bacteremia due to Streptoccous infantarius spp coli. Although he had normal findings on a screening colonoscopy 3 years prior to the bacteremia, the patient was advised to follow up with gastroenterologist on discharge. However, he was lost to follow up.

Five years following the initial episode of bacteremia, he returned to our emergency department with a recurrent Streptococcus infantarius spp infantarius bacteremia. His only symptom was intermittent chills. Physical exam revealed 2/6 systolic murmur best heard in the left sternal border and trace edema of lower extremities. The workup included transesophageal echocardiogram which did not show any vegetations or periventricular abscess. Indium white blood cell scan showed an increased white cell loculation in the right lateral abdomen, and subsequent CT scans showed a mass in the ascending colon measuring 4.4 x 3.4 cm without any definite extension through the wall of colon. He underwent diagnostic colonoscopy which found a large mass in the ascending colon that occupied 2/3rd of the lumen. Right hemicolectomy was performed and the pathology confirmed pT2N0MX mucinous adenocarcinoma. Patient was discharged following a completion of antibiotics and confirmed negative repeat blood cultures.

IMPACT/DISCUSSION: Streptococcus infantarius is a subspecies of SBEC, and the taxonomy of SBEC includes 4 main subspecies: Streptococcus gallolyticus subsp. gallolyticus, Streptococcus infantarius subsp. infantarius, Streptococcus infantarius subsp. coli, Streptococcus gallolyticus subsp. Pasteruianus. The study done by Corredoira et al found that colorectal cancer in S. infantarius bacteremia occurred in 10% of the studied patients and that of S. gallolyticus subsp. gallolyticus bacteremia was 63%. Despite the lower incidence of colorectal cancer in S. infantarius bacteremia, the importance of early detection cannot be undermined as misdiagnosis can be life-threatening. Our patient had a history of S. infantarius bacteremia and endocarditis and presented with recurrent bacteremia with the same species that localized at the site of colorectal cancer. We aim to highlight that formerly known S. bovis is further classified into 4 different subspecies under a unified group, SBEC. In addition, S. infantarius bacteremia warrants a thorough investigation to rule out a potential colorectal cancer.

CONCLUSION: It is essential to investigate for colorectal cancer for an early detection in patients with S. infantarius bacteremia.

A CASE OF THE NEPHROTIC SYNDROME: AA-AMYLOID NEPHROPATHY IN A CHICAGO HEROIN USER

Rebeca Ortiz Worthington[1]; Gaurav Ajmani[1]; Kamala Gullapalli Cotts[2]. [1]Internal Medicine, University of Chicago, Chicago, IL; [2]Internal Medicine, University of Chicago Medical Center, Chicago, IL. (Control ID #3383345)

LEARNING OBJECTIVE #1: Recognize the association between subcutaneous heroin use and renal AA amyloidosis

LEARNING OBJECTIVE #2: Recognize that renal biopsy is key in identifying the etiology of nephrotic syndrome

CASE: A 53 yr old man presented with 3 days of abdominal swelling, pain, and chronic lower extremity edema. Medical history was significant for untreated hepatitis C. He was an active heroin user for >30 years, and regularly practiced “skin popping.” He had anasarca and numerous <1cm round wounds and scars throughout his extremities. Notable labs were Cr 4.2, eGFR 15, total protein 6.7, albumin 2.1, HC viral load 396,321, HIV non-reactive, Urine protein:cr 8,493, and serum cryoglobulins were elevated at 1.5%. Workup was negative for myeloma and endocarditis. Due to concern for cryoglobulinemia causing renal dysfunction he was started on high dose prednisone and diuresis. Rituximab was recommended after no improvement in renal function. However, a renal biopsy revealed diffuse AA amyloid. Steroids were tapered and he was discharged. He follows regularly in renal and hepatology clinics, is being treated for HCV, and has enrolled in a methadone clinic. He has progressed to ESRD and is on dialysis.

IMPACT/DISCUSSION: Presence of heavy proteinuria, hypoalbuminemia, and peripheral edema should prompt workup for nephrotic syndrome. Differential diagnosis for this patient accounted for his serum protein gap and untreated hepatitis C, initially most concerning for cryoglobulinemia. However he lacked other features of active disease. Renal biopsy confirmed an alternate diagnosis sparing him immunosuppression.

AA amyloidosis is a secondary amyloidosis associated with chronic inflammation. Amyloid A protein is produced by fibroblasts in sustained acute phase responses and deposits in tissues. Underlying disorders are

themselves risk factors, including chronic inflammatory disorders (e.g. rheumatoid arthritis) and infections (e.g. pressure ulcers). AA amyloidosis primarily affects the kidneys causing nephrotic syndrome and progressive damage (median time to ESRD 2.4 years) with high mortality (median 4.2 years from diagnosis).

Our patient had a classic presentation of a rare and morbid condition, which we expect will be increasing with the opioid epidemic. Subcutaneous heroin use is associated with AA amyloidosis through chronic skin abscesses. This was initially reported in the 1970s, but was then absent from the literature until recently. The risk of AA amyloidosis has been estimated at 170x higher in heroin users compared with non-users. Only halting amyloid production can slow disease progression. Therefore, in at-risk patients it is key to diagnose the condition and intervene with substance abuse resources.

CONCLUSION: - Renal biopsy is key in identifying the etiology of nephrotic syndrome

- Subcutaneous heroin use is associated with AA amyloidosis

- AA amyloidosis can present as nephrotic syndrome, progresses to ESRD, and the only treatment is to avoid further amyloid creation

A CASE OF THE SWOLLEN ANKLE, WITH A TWIST!

Michael S. Shen[1]; Sarah Leone[1]; Carrie Mahowald[2,1]. [1]Internal Medicine, New York University, New York City, NY; [2]Internal Medicine, NYU, Brooklyn, NY. (Control ID #3386582)

LEARNING OBJECTIVE #1: Recognize the clinical presentation of TB arthritis.

LEARNING OBJECTIVE #2: Broaden the differential diagnosis of the swollen joint.

CASE: A 44-year-old Chinese man with no prior medical history presented with worsening of a swollen ankle. He was in his usual state of good health until one year ago when he twisted his left ankle. He then suffered progressive swelling and pain with ambulation. One month prior to presentation, he used a nail clipper to incise the area of swelling and reported minimal drainage. He then developed worsening swelling, pain, and redness over the area and presented to the hospital. He denied fevers. His exam revealed edema and erythema over the left medial malleolus and midfoot, a pinhole ulceration, and limited ankle range of motion. There was left calf muscle atrophy without sensory deficits. An MRI revealed septic arthritis, osteomyelitis, and degenerative changes suggestive of neuropathic arthropathy. Wound cultures grew pan-sensitive S. aureus and appropriate antibiotics were started. Just prior to discharge, it was noted that he lacked neuropathic deficits to fully explain his arthropathy. Ankle biopsy returned PCR and cultures positive for M. tuberculosis (TB). Induced sputum was also positive for TB. The patient was isolated and RIPE therapy was initiated.

IMPACT/DISCUSSION: The swollen joint is a common problem encountered by general internists. Causes include crystal arthropathy, systemic rheumatic disease, osteoarthritis, reactive arthritis, and infectious arthritis. A great mimicker of these entities is M. tuberculosis, which eludes early diagnosis due to its indolent and progressive course. It is often a “cold” monoarthritis, presenting with minimal erythema or warmth. It is less painful than other types of septic arthritides, explaining how our patient had preserved ambulation for months. Populations at higher risk include those with travel to endemic areas and immunocompromised status. Suspicion should be raised when patients fail to respond to standard antibiotics or when synovial fluid samples repeatedly show sterile leukocytosis. TB arthritis also produces joint destruction that is radiographically similar to neuropathic arthropathy. This information was critical to the final diagnosis in our patient, but confirmation bias led us to initially disregard radiographic evidence inconsistent with our physical exam and anchor on S. aureus, a more common culprit in septic arthritis. This was ultimately determined to be a superinfection due to unsterile manipulation.

CONCLUSION: TB arthritis is a mimicker of many acute and chronic joint conditions and should be included in the differential for a swollen joint. Suspicion is greater in cases of indolent and progressive monoarthritis in which standard antibiotics fail and when radiologic data is inconsistent with history and exam. Risk factors include travel to endemic areas or immunocompromised state. Diagnosis is made by PCR and culture. Pulmonary TB should be ruled out, though treatment is generally the same.

A CASE OF THE WOBBLY VOICE

Kelechi Abarikwu[1,2]; Priya Radhakrishnan[3]. [1]Education, University of Arizona College of Medicine Tucson, Scottsdale, AZ; [2]Honor Health Medical Group, Scottsdale, AZ; [3]Academic Affairs, HonorHealth, Scottsdale, AZ. (Control ID #3369883)

LEARNING OBJECTIVE #1: Recognize symptomatology of Hashimoto Encephalopathy for early referral and treatment.

CASE: A 67-year-old right handed retired pediatrician presented to the clinic with complaints of voice changers, she was evaluated and treated for anxiety. She subsequently presented with worsening symptoms and was sent to the ER. She described spells that started five months ago, with progressive dysarthria and confusion. Within the last month her neurological symptoms had progressed to her left ear and hand. She also complained of a tingling sensation surrounding her left ear, decreased dexterity and coordination of her left hand, as well as new onset hypertension. She underwent an urgent MRI of her head and neck. The findings showed multifocal subcortical and cortical FLAIR signal abnormalities and was admitted to the hospital. Physical exam was notable for dysarthria. Work up: Lumbar puncture – elevated CSF proteins (NUC 0, protein 154, RBC 0, Glucose 45mg/dL). She was negative for meningitis. Lipids, Metabolic profile, and thyroid tests, and initial immune work up were negative. She was immediately treated with plasmapheresis and steroids with some relief and subsequently found to have elevated anti-TPO antibody (54 U/ml). The patient had a repeat brain MRI with the addition of a cervical and thoracic MRI. Her head MRI demonstrated signs of a possible atypical hypertensive encephalopathy, the other images were unremarkable.

She was diagnosed to have Hashimoto’s Encephalopathy (HE) and started on Prednisone and monthly IVIG infusions with improvement of symptoms.

IMPACT/DISCUSSION: HE is a rare disorder which is often not considered in the context of neurological dysfunction. The pathophysiology of HE is not clearly defined, however the disease has no correlation with thyroid dysfunction. The only definitive finding for the diffuse disruption of the cerebrum is microvascular lymphocytic infiltration of postmortem patients plagued with fatal status epilepticus. The condition is classically associated with high levels of anti-thyroid antibodies with normal thyroid function levels. However, elevated levels of anti-thyroid autoantibody do not correspond with the neurological disease progression.

Clinical manifestation of HE is characterized by altered mental status, seizures, psychosis, and myoclonus. HE can more specifically be characterized by dividing symptom manifestation into two subgroups: acute stroke like presentation or a diffuse chronically progressive pattern. The most common of the two subgroups being the latter, with general symptoms seen in both cases. HE is a rare disease that is difficult to diagnose. It is important for physicians to be aware of the disease, its association with autoimmune diseases and early treatment.

CONCLUSION: HE is an infrequent clinical siting however when encountered it is often misdiagnosed

HE diagnosed and treated swiftly lowers patient complications and overall patient well-being can be improved.

A CASE OF WALKING-STICK URETERS AND HEPATIC ABNORMALITIES ASSOCIATED WITH KETAMINE USE

Teresa Attina[1]; David Rhee[2]; Yahya Ali[1]; Daniel Sartori[2]. [1]Internal Medicine Primary Care, Family Health Center at NYU Langone, New York, NY; [2]Medicine, NYU Langone Health, Brooklyn, NY. (Control ID #3388309)

LEARNING OBJECTIVE #1: Recognize the clinical features of ketamine-associated urinary and hepatic abnormalities

LEARNING OBJECTIVE #2: Elicit a history of ketamine use or abuse in patients with unexplained urinary and hepatic abnormalities

CASE: A 40 year-old woman with history of anemia and prolonged ketamine use presented to the ED with a 2-day history of severe cramping abdominal pain, fatigue, and vomiting. Physical examination was remarkable for diffusely tender abdomen and left costovertebral percussion tenderness. Laboratory tests showed blood urea nitrogen 69 mg/dL (reference range 7-18), creatinine 4.9 mg/dL (reference range 0.5-1.3), hemoglobin 6.8 g/L, alkaline phosphatase 692 IU/L, gamma-glutamyl transpeptidase 1,503 IU/L (baseline values not available). The urinalysis was positive for large leukocyte esterase and white blood cell, with urine culture growing >100,000 Streptococcus agalactiae. A CT of abdomen and pelvis showed severe bilateral hydronephrosis and hydroureter extending to the ureterovesicular junctions but no obstructing calculus. The CT also showed moderately distended gallbladder with diffuse wall thickening and a distended common bile duct but no calcified gallstones. The patient was evaluated by pyelography with XR fluoroscopy revealing ureteral strictures in a segmental beading pattern. Bilateral ureteral stents were placed, and renal function slowly improved (discharge creatinine 2.1 mg/dL). Liver function abnormalities persisted during subsequent outpatient follow up and the patient was eventually re-admitted for acute cholecystitis with no evidence of obstruction in the common bile duct. Patient declined surgery and was discharged with oral antibiotics.

IMPACT/DISCUSSION: Ketamine is used in clinical settings primarily for analgesia and sedation and, more recently, for the treatment of depression as well as severe asthma.[1] The effects of ketamine on the urinary system and biliary system have been previously described, especially in Taiwan and Hong-Kong. [2-5] Less commonly described is the concomitant presence of ketamine-induced urinary tract damage characterized by "walking-stick ureters"[6] and liver abnormalities with bile duct dilatation, as in our patient.[7, 8] This initially led to further investigation of alternative infiltrative etiologies, including amyloidosis and IgG4 disease, and patient underwent biopsy with negative results. The exact pathogenesis of ketamine- induced damage is still under investigation, possibly involving direct or immune-related injury by ketamine or its metabolites.[9] Abstinence results in symptomatic improvement but full recovery may not be achievable depending on the severity of damage.[2]

CONCLUSION: Given the presence of large Asian communities in NYC, in which the prevalence of ketamine use is likely to be significantly higher than the overall US,[10] ketamine-induced urinary and biliary tract disease should be considered in patients with the findings described here. Immediate cessation of ketamine use will be key to recovery.

A CASE OF WORSENING LOWER BACK PAIN

Nikitha Gangasani. Internal Medicine Residency Program, Boston Medical Center, Boston, MA. (Control ID #3361348)

LEARNING OBJECTIVE #1: Recognize the signs and symptoms of high-risk back pain

LEARNING OBJECTIVE #2: Diagnose and treat spinal tuberculosis

CASE: A 38-year-old man from Ethiopia consulted his primary care physician for management of lower back pain without fevers or night sweats, which began after lifting a heavy object. He had no neurological deficits and was discharged with a diagnosis of musculoskeletal back pain and prescribed nonsteroidal anti- inflammatory drugs and physical therapy. A year later, the patient presented to clinic with daily fevers up to 103°F over the previous week. The patient reported lower back pain radiating down both legs, night sweats, and weight loss of ten pounds in five months. Physical examination revealed new midline lumbar tenderness and mild lower extremity weakness. Infectious workup including complete blood count, chest X-ray, urinalysis, and HIV testing were negative. Additional history revealed that the patient tested positive for Quantiferon-TB Gold with a negative CXR in 2013 and had previously declined treatment for latent tuberculosis (TB) infection. Computed tomography of his lumbar spine showed a lucent lesion in the L3 vertebral body. MRI of the lumbar spine revealed L3 intraosseous abscess, epidural abscess from L3-S2 causing severe canal narrowing at L5/S1, and multiple left psoas abscesses. At this point, a bone biopsy of the vertebra was performed, which showed mycobacterium-TB complex. The patient was started on rifampin, isoniazid, pyrazinamide, and ethambutol for vertebral osteomyelitis and associated epidural abscess secondary to extrapulmonary TB. This treatment would continue in the outpatient setting with a community nurse for directly observed therapy.

IMPACT/DISCUSSION: Spinal TB, or Pott disease, is rare in the United States and seen most often in immigrants from countries where TB is endemic. It often has an insidious onset, on average over 4-11 months, and chronic back pain is the most frequent symptom. Patients usually seek advice when there are constitutional symptoms such as fever or weight loss, worsening back pain or neurological symptoms such as lower extremity weakness. MRI is the most valuable imaging study but the gold standard is neuroimaging- guided biopsy for histopathological diagnosis. The optimal treatment is antimicrobial therapy similar to treatment of pulmonary TB. Surgical management may be required in select cases.

CONCLUSION: Back pain is the most common cause of occupational disability in the world. Thus, it is a common complaint in the primary care practice. This case demonstrates the importance of obtaining a thorough history and maintaining a wide differential for a frequently encountered symptom in the outpatient setting. Additional consideration should be given to spinal TB in immigrants from countries where TB is endemic.

A CASE REPORT OF FEVER OF UNKNOWN ORIGIN FROM CONCOMITANT ACUTE, IGM NEGATIVE PCR POSITIVE ANAPLASMOSIS AND WEST NILE VIRUS INFECTION

Daniel Tsang, David Perlman. Internal Medicine, Mount Sinai Beth Israel, Bronx, NY. (Control ID #3387788)

LEARNING OBJECTIVE #1: Recognize the importance of travel history in evaluating fever of unknown origin

CASE: A 62 year old female presented to the emergency department in July with fevers, headaches, and bleeding gums for 3 weeks. On presentation, she was febrile to 101.5°F.

She had travelled extensively across the Western hemisphere over the past 6 months and spent a significant amount of her time outdoors. Areas where she travelled included Tennessee 2 weeks prior, a farm in upstate New York 3 weeks prior, Vancouver 4 weeks prior for a business conference where she also went hiking, Tulum, Mexico 8 weeks prior where she went spelunking, and the Virgin Islands 5 months prior to presentation.

Labs:

White blood cells 6.1 x103/μL, Hemoglobin 13.2 g/dL, Platelets 18 x103/μL . AST 131 (11-32 U/L), ALT 101 (3-30 U/L)

Given her extensive travel history, she was evaluated for possible zoonotic infections. She was started empirically on doxycycline 100 mg IV twice daily. She continued to have fevers up to 103.5 F, and defervesced after being on doxycycline for 24 hours. Her zoonotic infection workup was notable for:

Anaplasma IgM negative, but IgG positive 1:1024

Anaplasma phagocytophilum DNA detected by PCR

West Nile Virus IgG negative, but IgM positive

Lyme IgG positive with 8/10 bands. IgM negative 0/3 bands

She tested negative for acute mononucleosis, babesiosis, histoplasmosis, blastomycosis, and Q fever.

IMPACT/DISCUSSION: Fever of unknown origin is defined as a fever of 38.3° C on several occasions for at least 3 weeks. This patient had an extensive travel history with potential exposure both to a range of insect vectors and to infections linked to spelunking (e.g. histoplasmosis), putting her at risk for multiple vector borne and other travel and exposure related infections. A detailed history elucidating her numerous diverse possible exposures provided guidance on her diagnostic evaluation which ultimately led to her diagnoses of anaplasmosis and West Nile virus infection. As anaplasmosis is transmitted by ticks, and West Nile virus by mosquitoes, this patient had two infections from two different vectors.

Although her anaplasma IgM antibodies were negative, her significantly elevated IgG titers and the positive PCR suggest active infection from Anaplasma phagocytophilum. She was also found to have IgM antibodies to West Nile Virus suggestive of an acute West Nile Virus infection. As there is no specific treatment for West Nile virus infection and as anaplasmosis requires treatment, she was treated with a 3 week course of doxycycline 100 mg orally twice daily with resolution of her signs and symptoms.

CONCLUSION: - In evaluating fever of unknown origin, patient's travel history, exposures, and timing of symptoms is important to elucidate to guide diagnostic evaluation

- Acute anaplasmosis can still be present despite negative IgM antibodies

- It is appropriate to consider the possibility of concomitant active infections, particularly when patients have multiple possible exposures

A CASE REPORT OF POSTERIOR REVERSIBLE ENCEPHALOPATHY SYNDROME

Andrew Mekaiel[1]; Hind El soufi[1]; Amna Altkrit[1]; Khalid Gafoor[1,2]. [1]Internal Medicine, Jamaica Hospital, Queens, NY; [2]Department of pulmonary and critical care medicine, Jamaica Hospital, Queens, NY. (Control ID #3392365)

LEARNING OBJECTIVE #1: Diagnose posterior reversible encephalopathy syndrome (PRES) in postpartum female with mild hypertension.

LEARNING OBJECTIVE #2: Recognize the risk factors of PRES.

CASE: A 31-year-old woman, gravida 4 para 1, with no significant past medical history presented with witnessed seizures 14 days after spontaneous vaginal delivery. She was found in the bathtub by her mother complaining of dizziness and blurry vision, with subsequent generalized tonic-clonic seizures and foaming from the mouth. Patient didn't have a fall or experience loss of consciousness. On physical exam, she was alert with no focal neurological deficit, afebrile with blood pressure (BP) of 160/90 mmhg and heart rate of 70/min. Labs were unremarkable. Head CT scan revealed right frontal hemorrhage measuring 3.6 x 2.0 x 3.0 cm for which patient was admitted to the medical ICU. Neurosurgery was consulted and recommended no intervention. Brain MRI revealed patchy areas of edema within the right cerebral hemisphere compatible with PRES. Repeat head CT scan showed stable intracranial hemorrhage along with sites of diminished attenuation in the subcortical white matter which correlates with PRES. The patient was started on nicardipine drip and eventually switched to oral nifedipine for BP control. She remained neurologically stable, BP was well controlled and patient was subsequently transferred to obstetric service on day 2.

IMPACT/DISCUSSION: PRES was first described in 1996 as a clinicoradiographic entity. Its clinical presentation varies from headache, confusion, dizziness up to seizures and focal neurological deficit.

Radiologically, it's characterized by symmetric vasogenic brain edema most commonly affecting parietal and occipital lobes seen on brain CT or MRI.

Pathogenesis is not well understood, but autoregulatory failure of maintaining cerebral blood flow along with hypertension and endothelial dysfunction remains the proposed mechanism for developing PRES. In various case reports, PRES has been established in patients with preeclampsia/eclampsia, hypertension, bone marrow transplant or sepsis. In our case, the patient didn't meet the diagnostic criteria for eclampsia, therefore hypertension was believed to be the inciting risk factor for developing PRES, even with mild elevation of BP. Treatment varies depending on the condition causing this syndrome, therefore treating the associated factors and control of BP will lead to its reversibility within days to weeks.

CONCLUSION: Hypertension plays a major role in PRES. However, many patients do not have severe hypertension making the rapid fluctuations in BP more important than the BP itself.

PRES is considered a reversible condition, therefore clinicians should always have high suspicion index in patients with risk factors like pregnancy and hypertension for early recognition and management.

ACCELERATED DECOMPENSATION IN UNTREATED CUSHING'S DISEASE

Kishan Patel, Srinivas Vunnam. Internal Medicine, University of Nebraska Medical Center, Omaha, NE. (Control ID #3390734)

LEARNING OBJECTIVE #1: Clinicians should consider all aspects of the endogenous hypercortisolism and determine the necessity of empiric treatment in the absence of definitive diagnosis

CASE: Patient was a 79 year old female with a past medical history of Hypertension, Hyperlipidemia, Type 2 Diabetes Mellitus, and recent compression fractures who presented with lethargy and failure to thrive for ten days duration. At presentation, she developed hypokalemia despite oral repletion, uncontrolled diabetes despite poor oral intake and scheduled insulin, uncontrolled hypertension with systolics regularly in the 200's, and uncontrolled pain secondary to nine new compression fractures throughout her spine. On exam, she was hypertensive and tachycardic, with ecchymosis diffusely. Her physical appearance was negative for striae, hirsutism, purpura, or hyperpigmentation. Labs were significant for Adrenocorticotropic hormone (ACTH) of 233 pg/ml, 24 hour urine cortisol of 4580 ug/d, a serum cortisol of 209 mcg/dL after low dose dexamethasone stimulation test and 71.4 mcg/dL after high dose test. A total body computed tomography scan demonstrated a 3.2 x 4.4 cm left upper lobe mass, bilateral adrenal hyperplasia, a solid thyroid nodule (classified TI-RADS 4). Magnetic resonance imaging of the sella suggested a 5 mm hypoenhancement, consistent with a microadenoma. Endocrinology determined that a lung biopsy was warranted due to concern of ectopic production of ACTH. Prior to receiving her lung biopsy, the patient became hemodynamically unstable on multiple occasions and experienced several rapid response episodes due to newly developed atrial fibrillation with rapid ventricular response. The patient passed away five weeks after presentation of symptoms.

IMPACT/DISCUSSION: The incidence of endogenous Cushing's has been approximated to 1 per 500,000 cases per year. Despite very few etiologies, the disease has complex symptomology involving cortisol production, including pituitary adenomas and exogenous production from underlying malignancies. If left untreated, this rare disease can have fatal consequences, making its accurate diagnosis important but also an ethical dilemma in moribund patients.

CONCLUSION: While Cushing's Disease is a rare clinical occurrence, the initial signs and symptoms of the disease are often nonspecific and overlap with various metabolic processes. It is important to recognize associated risk factors including malignant hypertension, hypokalemia, and hyperglycemia as these findings can cause fatal sequelae. Endocrinologists are an excellent resource when available to assess the need to start treatment along with clinical judgement. Although the annual incidence of exogenous hypercortisolism is quite low, it is important for clinicians to consider all aspects of the disease. Ultimately, disease progression may develop into an ethical dilemma as patients with severe disease often become moribund without notice and provider's should not forgo empiric treatment for definitive diagnosis.

ACCOMPANIMENT OF A MEDICALLY COMPLEX PATIENT WITH SOCIAL HEALTHCARE BARRIERS

Gregory Yungtum, Angie Seo, Dino A. Messina. Internal Medicine, Brown University, Providence, RI. (Control ID #3392239)

LEARNING OBJECTIVE #1: Assess patient priorities in medically and socially complex cases

LEARNING OBJECTIVE #2: Manage patient-centered care with a multidisciplinary team and commitment to long-term accompaniment

CASE: Ms. W is a 28 year-old woman with a medical history of hypertension, major depression (suicide attempt), Systemic Lupus Erythematous complicated by nephritis, and a hypercoagulation disorder of unknown etiology leading to a myocardial infarction, stroke, and pulmonary embolism in 2017, and a painful abdominal rash which biopsy suggested was cutaneous lupus. Her medications included hydroxychloroquine and warfarin. Her INR was chronically subtherapeutic due to medication non-adherence caused by difficulty maintaining work and benefits. She was given an hour-long visit at our multidisciplinary Comprehensive Care Clinic, resulting in referrals to specialists, education about her medications, and access to social resources. She subsequently missed her referral appointments, her INR remained subtherapeutic, and she was lost to follow-up. Several months later, she presented to a local emergency room for management of her painful abdominal rash. Our nurse care manager reached out and encouraged her to re-engage. It was discovered that she had briefly moved out of state, but decided not to return to our clinic because she felt that her rash had been inadequately prioritized. She was quickly sent to dermatology, then started on prednisone, tofacitinib, and a pain control regimen. She has since maintained a therapeutic INR on warfarin and established care with subspecialists. She has frequent contact with our nurse care manager and follows closely with the clinic.

IMPACT/DISCUSSION: Patients with frequent emergency room visits and hospitalizations are a source of disproportionate cost in the American healthcare system, so research and policy are increasingly focused on how to approach these patients.[1] In the case of this medically complex patient with frequent but uncoordinated health care contact, her treatment was initially ineffective due to multiple social barriers and a lack of trust in her healthcare providers. Once our multi-disciplinary team, lead by our nurse care manager, prioritized her goals and committed to sustained accompaniment with frequent and open communication, the patient saw significant improvement in quality of life, reduced risk of coagulopathy, and sustained treatment for her chronic medical conditions.

CONCLUSION: For medically complex patients facing social healthcare barriers, providers should prioritize patient goals and approach biopsychosocial problems with a multidisciplinary team. While it may take time to see results, and it may be difficult to measure success, we should commit to long-term accompaniment using patient-specific strategies to address patient needs.

ACHES FOR DAYS: A RARE CAUSE OF MYOPATHY

Ravi Patel, Samer Muallem, Sudhanshu Bhatnagar, Ninad Zaman, Audrey Thorp. Internal medicine, Penn State Milton S. Hershey Medical Center, Hershey, PA. (Control ID #3387596)

LEARNING OBJECTIVE #1: Identify causes of idiopathic inflammatory myopathies

CASE: A 51-year-old female with no significant past medical history presented with a 1 month history of myalgias. After coming back from a one-week vacation in India she began experiencing diffuse myalgias, predominantly in her quadriceps and hamstring group muscles. She was initially seen by her primary care physician at which time lab work revealed elevated aminotransferases with an ALT and AST of 328 units/L and 357 units/L respectively, and with a positive total anti-Hepatitis A antibodies. She was diagnosed initially with presumed Hepatitis A, but her symptoms progressed and she returned for reassessment. Lab work obtained after that visit illustrated an increased ALT and AST at 424 units/L and 441units/L, positive ANA with a 1:640 cytoplasmic pattern, and CPK strikingly elevated at 14,616 units/L. Given her symptoms with abnormal labs she was referred to the emergency department for further evaluation. Upon presentation vitals were stable with mild lower extremity proximal muscle weakness and significant pain upon extension. Labs revealed CPK of 17,749 units/L and ALT of 433 units/L and AST of 505 units/L. An autoimmune serologic workup was pursued and patient underwent muscle biopsy that revealed nonspecific mild necrotizing changes without evidence of vasculitis or inflammatory myopathy. With rheumatology guidance she was started and discharged on a prednisone taper. At follow up myositis serologies returned positive for Anti-SRP antibodies, consistent with the diagnosis of Necrotizing Autoimmune Myositis (NAM). Given her progressive symptoms with functional decline she was transitioned to azathioprine, IVIG, and thereafter rituximab with clinical improvement.

IMPACT/DISCUSSION: This case highlights an extremely rare cause of myopathy. Idiopathic Inflammatory Myopathies (IIM) consist of dermatomyositis, polymyositis, myositis associated with antisynthetase syndrome, immune-mediated necrotizing myopathy, and inclusion body myositis with an overall annual incidence of approximately 1 in 100,000 (1,3). NAM comprises 19% of IIM and is characterized by necrotic muscle fibers with absent or minimal inflammation (1). The predominant clinical feature is proximal muscle weakness as with other myopathies (2). Unfortunately, there have not been any clinical trials performed to guide therapeutic decisions. Most recommendations are extracted mostly from observational data and experience (2).

CONCLUSION: Idiopathic Inflammatory Myopathies including NAM are uncommon. It is prudent for clinicians to be aware of these spectrum of conditions in order to achieve timely diagnosis, and hopefully avoid secondary long term disability.

ACHY BREAKY AMYLOID HEART

Megan McCarty[1]; Holly N. Thomas[1]; Allie Dakroub[2]. [1]Internal Medicine, UPMC, Pittsburgh, PA; [2]Internal Medicine/Pediatrics, University of Pittsburgh Medical Center, Pittsburgh, PA. (Control ID #3387919)

LEARNING OBJECTIVE #1: Recognize the electrocardiogram and transthoracic echocardiogram findings associated with cardiac amyloidosis.

CASE: A 63 year old man presented to the hospital for chronic dyspnea on exertion and lower extremity edema for the past 9 months. He had tried ACE wraps and furosemide prescribed by his doctor without improvement for his edema. He reported 3-pillow orthopnea and weight loss of 40 pounds in the prior year. He denied chest pain and palpitations. Cardiac exam revealed regular rate and rhythm with appreciable S1 and S2 without S3. JVP was 10 cm with patient at a 45 degree angle. He had 3+ pitting edema to his hips bilaterally. Initial labs were notable for negative troponin and BNP 662. Electrocardiogram (EKG) revealed normal sinus rhythm with low voltage. Transthoracic echocardiogram (TTE) showed severe left ventricular hypertrophy and mildly decreased ejection fraction of 45-50%. Given these findings, there was concern for amyloid cardiomyopathy. Both serum and urine protein electrophoresis (SPEP, UPEP) revealed monoclonal expansion with elevated lambda light chain, raising concern for AL amyloidosis. A subsequent cardiac biopsy revealed amyloidosis involving the arteries and interstitium, confirming the diagnosis of AL amyloidosis. His symptoms improved with intravenous furosemide and he went on to establish care with hematology and a cardiac amyloid center for further treatment.

IMPACT/DISCUSSION: Cardiac amyloidosis is an infrequent, progressive cardiomyopathy that is often fatal. In diagnostic testing for heart failure symptoms, this disease will present with a low voltage EKG and ventricular hypertrophy on TTE. Typically, ventricular hypertrophy is associated with high voltage EKG, as in hypertension. This atypical pattern occurs in very few disease states, two being amyloidosis and endomyocardial fibrosis. As infiltrative cardiomyopathies, they cause enlargement of the heart wall but diminish the voltage of the EKG by insulating the electrical activity traced by the EKG leads. Since these conditions can be differentiated by further testing and subtle differences on TTE imaging, referral to cardiology is recommended for this paradoxical pattern of EKG and TTE.

In the setting of heart failure, AL amyloidosis has poor prognosis if untreated (1 year survival is 38%). Initial work-up of suspected cardiac amyloidosis begins with bloodwork including light chains, SPEP and UPEP. The mainstay of treatment involves chemotherapy and/or autologous stem cell transplant in order to eradicate the plasma cell dyscrasia. Referral to both a hematologist and cardiac amyloid specialist is recommended. Earlier diagnosis and treatment of AL amyloid can prolong survival.

CONCLUSION: Pursue work-up for cardiac amyloidosis in patients with heart failure symptoms, low voltage EKG, and ventricular hypertrophy on TTE.

ACHY BREAKY HEART: A CASE OF POST- MITRAL VALVE REPAIR (MVR) CHOREA IN AN ADULT

Anupama M. Kapadia[2]; Jaya Vasudevan[2]; Meghana Gadgil[1]. [1]Population Health & Internal Medicine, Dell Medical School, Austin, TX; [2]Internal Medicine, Dell Medical School at the University of Texas at Austin, Austin, TX. (Control ID #3387382)

LEARNING OBJECTIVE #1: Recognize chorea as a rare neurologic sequela of cardiac surgery in adults

LEARNING OBJECTIVE #2: Distinguish common and rare sequelae of adult cardiac surgery

CASE: A 61 y/o woman was admitted with left-sided weakness following her third mitral valve repair (MVR). Her history included coronary artery disease, severe mitral regurgitation requiring repeat MVRs and stroke with residual right-sided weakness. Admission CT showed evolving right middle cerebral artery territory infarction with stable occlusion of the inferior division of the right M2 segment. Within four hours, her left-sided weakness significantly improved, and neurology recommended no acute intervention. The stroke was attributed to valve thrombosis from warfarin non-adherence. Admission exam was notable for choreoathetoid movements of her left hand and foot, which she reported had started after her latest MVR twelve days prior.

On day two, the patient developed transient right-sided weakness along the distribution of her previous stroke. A repeat CTA showed short segment occlusion of the left paraclinoid internal carotid artery with collateral flow and improvement in the small acute infarcts. Disruption of the basal ganglia's corpus striatum through injury or ischemia can cause chorea. However, her neuroimaging did not demonstrate basal ganglia vascular compromise and therefore could not explain her left-sided choreoathetoid movements. A trans- thoracic echo showed mildly dilated left atrium with a negative bubble study and no thrombus. Her medication history was unrevealing. The choreoathetoid movements gradually diminished and had fully resolved by discharge on day six.

IMPACT/DISCUSSION: Our patient experienced two neurologic complications of valve replacement, one most common (CVA) and one very rare (post-pump chorea). Post-pump chorea has been described most frequently in pediatric populations. The pathophysiology is hypothesized to be due to the multifactorial effects of hypothermia, extra corporeal circulation, and aortic cross-clamping in decreasing blood flow to the basal ganglia and slowing cerebral metabolism, resulting in a reversible watershed effect. The literature describes only two other adult cases: one five days after aortic valve replacement and a second case of chorea two weeks after the repair of a thoracic aortic aneurysm. In our patient, her neuroimaging, medication history and initial acute left-sided weakness could not explain the choreoathetosis; only her recent history of MVR provided the key to the diagnosis. This case highlights that patients who undergo cardiac surgery can be at risk for subtle neurologic complications that may mimic more devastating ones like CVA.

CONCLUSION: Cardiac surgery can provoke neurologic sequelae. Common neurologic complications include encephalopathy, stroke, seizure, and peripheral nerve injury. Post- cardiac surgery chorea is more common in children and rare in adults.

A CLASSIC CASE OF PITUITARY APOPLEXY

Michael J. Ahlers, Julianna Gardner, Julie Magorien. Internal Medicine, UCLA, Los Angeles, CA. (Control ID #3391921)

LEARNING OBJECTIVE #1: Recognize pituitary apoplexy as a cause of thunderclap headache

LEARNING OBJECTIVE #2: Manage pituitary apoplexy including initiation of stress-dose steroids

CASE: A 54-year-old-male presented with headache. One week prior he had sudden onset, severe headache upon awakening. In the ER, CT head showed no acute process and the patient was discharged on oral antibiotics for incidental leukocytosis. He re-presented three days later with ongoing headache, new diplopia and mild ptosis. MRI brain identified a pituitary mass, and heparin drip was initiated for possible sinus thrombosis. His headaches and ptosis worsened which prompted him to leave and present at UCLA.

At admission to our institution, he reported ongoing headache and inability to open his left eye. Exam was notable for normal vital signs, complete left-sided ptosis and impaired extraocular movement with inability to elevate, adduct, or depress the eye. The left pupil was dilated to 8mm and fixed with normal visual fields. MRI brain showed a large pituitary mass with likely internal hemorrhage. His sodium and potassium were normal, TSH was 0.21, FT4 1.1, LH 1.0, FSH 1.4, PRL 9.7, ACTH 13, and 8 am Cortisol 4.

He was diagnosed with a non-functioning pituitary macroadenoma compressing cranial nerve III, complicated by pituitary apoplexy and panhypopituitarism. Levothyroxine and dexamethasone were given with significant improvement in headache symptoms. He underwent excision of the pituitary tumor via endonasal transsphenoidal approach, complicated by progressive hyponatremia and SIADH treated by fluid restriction, salt tabs, and a hydrocortisone taper.

IMPACT/DISCUSSION: Although pituitary apoplexy is a rare event, its early management is crucial for clinical outcome and differs from management of other diagnoses on the differential at time of presentation, highlighting the importance of recognizing its clinical features. Our case is a classic presentation featuring the two most common symptoms: headache (often thunder-clap, > 80% of cases) and visual disturbance (most commonly ocular palsy, > 50% of cases). Less common (25-75%) are signs of meningeal irritation such as nausea/vomiting and altered mental status. Of note, > 90% of cases present without prior diagnosis of pituitary adenoma or reported symptoms consistent hypothalamic-pituitary axis dysfunction. The most recognized precipitants are major surgery and initiation of anticoagulation, consistent with the worsening our patient reported following initiation of heparin.

For the internist, the most crucial step in management is initiation of stress-dose steroids to prevent or treat hemodynamic collapse from loss of cortisol, followed by neurosurgical consultation for surgical versus conservative management.

CONCLUSION: Pituitary apoplexy is a rare diagnosis often on the differential of subarachnoid hemorrhage, bacterial meningitis, cavernous sinus thrombosis, and midbrain infarct that requires unique and urgent treatment from its mimickers. Start stress-dose steroids if pituitary apoplexy is suspected.

A COMMON DRUG CAUSING AN UNUSUAL ERUPTION: FUROSEMIDE TRIGGERING BULLOUS PEMPHIGOID

Pierce Lewien[1]; Juan N. Lessing[2]; Caitlin Dietsche[1]. [1]Internal Medicine, University of Colorado School of Medicine, Aurora, CO; [2]Internal Medicine/Hospital Medicine Group, University of Colorado, Denver, CO. (Control ID #3341311)

LEARNING OBJECTIVE #1: Recognize a rare side effect of a very commonly prescribed medication.

LEARNING OBJECTIVE #2: Describe the importance of investigating medication exposure in the evaluation of bullous diseases.

CASE: A 65 year-old man with no known autoimmune disease history was hospitalized for shortness of breath and peripheral edema, diagnosed with decompensated heart failure, and treated with IV furosemide.

Within a day, he developed a 1 cm, tense, fluid-filled bullous lesion on his lower abdomen. The next day, three larger bullous lesions with surrounding erythema appeared nearby. Based on clinical appearance and timing, he was diagnosed with drug-induced bullous pemphigoid. Furosemide was stopped and treatment switched to bumetanide. Symptoms improved with no further bullae formation and he was sent home with PO bumetanide and follow-up. Furosemide was added to his list of allergies and he was counseled to avoid this medicine.

IMPACT/DISCUSSION: Furosemide, a loop diuretic, is the 20th most prescribed medication in the United States. This case illustrates a rare adverse effect known by few of a medication prescribed exceedingly commonly in the clinic and hospital. Bullous pemphigoid (BP) is an IgG-mediated autoimmune subepidermal blistering disease that targets hemidesmosomes that hold the dermis and epidermis together, causing the two layers to separate and blisters to form. Along with idiopathic causes, drugs are BP inducers, with furosemide included among them. The mechanism for drug-induced BP is poorly understood; one postulated mechanism involves drug induction of antibodies against the basement membrane through binding to a lamina lucida protein thus changing its antigenic properties. Unlike Stevens-Johnson syndrome or toxic epidermal necrolysis, in BP bullae tend to be tense, rarely involve mucosal surfaces, and often affect the lower abdomen, thighs, and forearms. Questions remain why this reaction happens with furosemide but far less commonly with bumetanide, another sulfa loop diuretic. The drug reaction in this case occurred over one day while most reported cases presented days to weeks after exposure. Still, the fact the eruption occurred with drug initiation and ceased after discontinuation strongly implicates furosemide in our patient.

CONCLUSION: As immediate medication discontinuation is critical, it is important to recognize that furosemide, a common drug used in patients, can cause bullous pemphigoid. Bullous pemphigoid should be considered in all older adults who develop tense bullae, and an exhaustive drug exposure history is critical to recognizing and discontinuing possible inciting medications.

A COMMON PRESENTATION WITH AN UNCOMMON TIMELINE

Karolina Mieczkowska[1]; Hamza Ahsan[2]; Yelena Averbukh[2]. [1]Albert Einstein College of Medicine, Bronx, NY; [2]Medicine, Montefiore Medical Center, Bronx, NY. (Control ID #3392007)

LEARNING OBJECTIVE #1: Consider malaria in a patient with a remote travel history.

LEARNING OBJECTIVE #2: Evaluate recurrent fevers in a patient with multiple risk factors.

CASE: A 40-year-old man with HIV, latent TB, and a distant history of malaria infection presented with intermittent fevers for four days. Prior to admission, he felt warm with chills and shortness of breath which prompted him to go to the emergency room. The patient was given fluids and antipyretics and discharged home. The symptoms resolved but returned two days later. The patient again presented to the hospital and was admitted for further workup. He denied any recent travel outside of the US but migrated from Nigeria 7 months ago and went camping in upstate New York 3 weeks ago. He reported having sexual intercourse with a new partner. Other than a fever of 101.3°F present on admission, physical exam was unremarkable. Chest x-ray and urinalysis were negative for any sources of infection. STD testing, including chlamydia, gonorrhea, syphilis, and hepatitis, was negative. Given recent outdoor activity, suspicion was high for babesia.

Additionally, although he emigrated from Africa months ago, malaria was also considered as the patient had been previously infected 25 years ago. Blood smear results were positive for plasmodium non-falciparum species based on the morphology of the gametocytes present in the erythrocytes.

IMPACT/DISCUSSION: Cyclical fevers are commonly associated with malaria. Patients can present with a combination of nonspecific symptoms including chills, sweats, myalgias, and headaches. The disease is spread through the bite of the *Anopheles* mosquito with an incubation period of about 7 to 30 days.

Although the time course did not suggest a recent infection, the patient exhibited typical symptoms of malaria. Given a previous malarial infection 25 years ago, relapse of *plasmodium vivax* or *plasmodium ovale* that was not properly treated is more likely than a new infection obtained 7 months ago prior to arrival in the US. These species of malaria have dormant liver parasites called hypnozoites, which are eradicated with primaquine or tafenoquine. Before administration, G6PD deficiency testing must be performed as these medications can cause hemolysis.

The patient's history also brought attention to other possible etiologies of his symptoms. His recent camping trip in upstate New York raised

concern for babesiosis. The symptoms are very similar with fevers that can also be intermittent. Given concern for STDs, chlamydia, ghonorrhea, syphilis, and hepatitis are all infections that also share the nonspecific symptoms of fever, chills, and fatigue. However, these are less likely to present in a cyclical fashion. With all these different risk factors in mind, appropriate work-up guided the team towards the diagnosis of malaria.

CONCLUSION: In patients with cyclical fevers with a distant travel history to endemic areas, malaria relapse should be highly suspected. These situations provide an opportunity for proper treatment to prevent future reactivations.

A CONCERNING EKG IN A YOUNG MALE WITH CARDIAC COMORBIDITIES

Abraham Derman[1]; Geeta Varghese[2]. [1]Internal Medicine Residency, Mount Sinai St Luke's and West, Spring Valley, NY; [2]Medicine, Mount Sinai Beth Israel, New York, NY. (Control ID #3375661)

LEARNING OBJECTIVE #1: Recognize and distinguish clinical features of ischemic ST elevations, pericarditis and benign early repolarization.

CASE: A 37-year-old male with a history of chronic hepatitis B, pericarditis 8 years prior, and chronic back pain presented to the clinic, referred by an interventional pain specialist for evaluation of an abnormal EKG with ST elevations in lead II, V2-V6. History revealed no current chest pain, dyspnea on exertion or palpitations, unlimited exercise tolerance; no family history of cardiac arrythmias or sudden deaths; no current medications. Exam revealed normal cardiopulmonary findings. Repeat EKG showed identical changes. Review of his record found almost identical EKG findings during a prior episode of pericarditis. Echocardiogram then showed normal ventricular function and pericardium without effusion. Recent lab findings revealed a minimally elevated ESR of 15 mm/hr and a mildly elevated creatine kinase level of 761 U/L.

IMPACT/DISCUSSION: Diagnosis of pericarditis can be challenging especially when presented with other comorbidities. Accurate history and elucidation of symptoms is crucial for the correct diagnosis.

Most important is to differentiate it from an ST Elevation Myocardial Infarction (STEMI). This is based on differences in symptoms, EKG findings and imaging. Exertional chest pain would favor ischemia, whereas positional or pleuritic would favor pericarditis. EKG differences: pericarditis usually retains the ST concavity waveform; the ST elevation in pericarditis is usually less than 5 mm and the distribution is in more than one vascular territory, no reciprocal changes except in V1 and avR, and no concurrent ST elevations with T wave inversions.

Although the EKG was consistent with pericarditis, this is not sufficient to diagnose pericarditis. Pericarditis requires at least two of the following findings: symptoms of pericarditis, EKG findings consistent with pericarditis, evidence of pericardial effusion and/or elevation of inflammatory biomarkers. On this presentation, only the EKG findings were consistent with pericarditis. EKG changes in pericarditis are due to a current of injury and therefore, progress over time and eventually normalize. In early repolarization, the EKG abnormality is a physiological abnormality that persists. Given the consistencies of EKG abnormalities, absence of symptoms, and documented normal echocardiogram, it was decided this was likely never pericarditis, but rather early repolarization. Upon review of the initial encounter for pericarditis, the symptoms were not consistent with pericarditis. Lab abnormalities were likely related to inflammation from his known hepatitis B but required further assessment.

CONCLUSION: Pericarditis must be differentiated from a STEMI based on symptoms and EKG criteria. Diagnosis of pericarditis requires more than EKG changes alone.

Early repolarization can be diagnosed with multiple EKGs showing consistent changes over time.

A CONSUMING CASE OF RENAL FAILURE AND THE GREAT IMITATOR

Mira John[1]; Ekaterina Sokolova[2]. [1]Internal Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; [2]Division of Hospital Medicine, Icahn School of Medicine at Mount Sinai, New York, NY. (Control ID #3387751)

LEARNING OBJECTIVE #1: Recognize active tuberculosis as a cause of secondary amyloidosis leading to renal failure

CASE: A 60-year-old South Asian man with no prior history presented with three days of subjective fevers and dry cough. He denied other symptoms. Initial vitals and exam were only notable for a fever of 38.4C. Chest x-ray showed increased markings at the left base. Labs showed 15,500 WBC with 78% neutrophils, albumin of 1.5, total protein of 4, BUN of 43, and creatinine of 7.7, up from 1.4 one year ago. He received empiric community-acquired pneumonia coverage, which resolved his presenting symptoms. His worsening renal function prompted further inpatient workup.

Urinalysis showed >1000 protein and 11-20 RBC. Total urine protein was elevated at 1360. Serum protein electrophoresis showed low total protein of 4.1, elevated a2-globulin fraction of 1.1, and two weak gamma-migrating paraproteins. Bence jones protein was negative. Urine kappa and lambda levels were unremarkable. Urine immunofixation showed no monoclonal bands. Kidney biopsy revealed a new diagnosis of AA / secondary amyloidosis.

He underwent extensive workup to determine the etiology of his AA amyloidosis. Computed tomography imaging showed findings read as characteristic of nodular parenchymal amyloidosis: a 2.7cm mass posterior to the right mainstem bronchus, peripheral nodular opacities in the left lung, and enlarged lymph nodes in the mediastinum, mesentery, and retroperitoneum. Initial quantiferon gold was indeterminate. Hepatitis, HIV, and RPR screening and extensive rheumatological workup were negative. EGD and colonoscopy only showed gastric amyloidosis. A repeat quantiferon gold, obtained weeks after initial presentation, was positive.

Sputum AFB testing was positive for Mycobacterium tuberculosis complex. His final diagnosis was active Pulmonary Mycobacterium Tuberculosis causing AA amyloidosis and renal failure.

IMPACT/DISCUSSION: Tuberculosis and other chronic infections were historically common causes of AA amyloidosis; prevalence decreased as access to effective antimicrobial agents and health services improved.

In the United States, inflammatory arthridities and inflammatory bowel disease are now frequently identified as the most common causes of underlying AA amyloidosis. In developing and TB-endemic countries, however, tuberculosis is listed as a common cause of AA and renal amyloidosis, sometimes leading to renal failure. As this patient clinically improved with empiric community-acquired pneumonia treatment and only endorsed the initial fever and cough on original presentation, there was a delay to rule-out tuberculosis, even though he previously lived in a TB-endemic country. While this is an unusual case, the general internist should be aware that untreated active tuberculosis can present with nonspecific symptoms and can induce chronic inflammation leading to secondary amyloidosis and eventual renal failure.

CONCLUSION: Though rare in the US, untreated TB can lead to secondary amyloidosis and renal failure

ACTIVE TUBERCULOSIS DIAGNOSED FROM BELL'S PALSY EVALUATION

Stephanie Jou, Kelsey B. Bryant. Internal Medicine, Columbia University Medical Center, New York, NY. (Control ID #3391986)

LEARNING OBJECTIVE #1: Identify treatable etiologies of Bell's Palsy

LEARNING OBJECTIVE #2: Recognize the importance of incidental findings and understand when further evaluation is needed

CASE: 48-year-old female with HIV/AIDS and recent Streptococcus pneumoniae bacteremia secondary to pneumonia presented to the emergency department due to acute onset of left facial droop without other neurologic symptoms. She endorsed ongoing dyspnea since her recent hospitalization, subacute worsening of her posterior neck pain, but otherwise no other symptoms including hemoptysis, weight loss, and night sweats. Family and social history was noncontributory. Her exam was notable for left lower motor neuron facial nerve palsy. CT head and CTA head and neck was negative for acute stroke. She was evaluated by neurology and deemed stable for discharge with diagnosis of Bell's palsy. However, CT scan also revealed an incidental upper lobe consolidation which was initially attributed to her recent pneumonia. On chart review, she was found to be TB Quant Gold positive. She was admitted for workup for active tuberculosis. AFB sputum cultures were positive. Given the positive sputum cultures, MRI brain was obtained to determine if Bell's palsy was a manifestation of leptomeningeal disease such as tuberculosis meningitis, which did show facial nerve enhancement in the internal auditory canal. Lumbar puncture was negative, and the patient was treated with RIPE therapy for active pulmonary tuberculosis, and valacyclovir for Bell's palsy attributed to viral infection.

IMPACT/DISCUSSION: We present the case of a patient who presented for Bell's Palsy, but was incidentally found to have pulmonary consolidation on CT scan, which led to the diagnosis of active pulmonary tuberculosis. There are two teaching points to this case. 1) While the etiology for Bell's palsy for most patients can be attributed to viral infections, immunocompromised patients such as those with HIV/AIDS are at a higher risk for tuberculosis meningitis. Although this patient fortunately did not have tuberculosis meningitis, this should still be included in the differential. Other rarer etiologies of Bell's palsy include HIV itself or stroke. 2) It is important not to immediately assume pulmonary consolidations are due to recent pneumonia, and to perform a thorough history and chart review. Active tuberculosis was almost missed in this patient, a diagnosis with both patient and public health level concern.

CONCLUSION: While tuberculosis meningitis is not a common etiology of Bell's palsy, this should remain in the differential for immunocompromised patients. Internists should also view all incidental findings as valuable, and they should always be further evaluated.

A CURIOUS CASE OF HYPEREOSINOPHILIA

Nandini Sarma[1]; Paul Aronowitz[2]. [1]Internal Medicine, UC Davis, Sacramento, CA; [2]Internal Medicine, University of California, Davis, Sacramento, CA. (Control ID #3391959)

LEARNING OBJECTIVE #1: Review the differential diagnosis of eosinonophilia

LEARNING OBJECTIVE #2: Recognize Hypereosinophilic Syndrome and the challenges in diagnosing it

CASE: Hypereosinophilic syndrome (HES) is a rare but potentially morbid condition consisting of peripheral eosinophilia with organ involvement. In this case, a 61 year-old woman with history of hypertrophic obstructive cardiomyopathy, hypothyroidism, and asthma presented with acute painful submandibular lymphadenopathy, sudden- onset abdominal pain, nausea, vomiting, and diarrhea. Of note, she had been evaluated for peripheral eosinophilia two years prior with a trans-bronchial lymph node biopsy that revealed a reactive process of unclear etiology. The abdominal pain was in the right lower quadrant, radiating to the back, and associated with 2 weeks of anorexia and a faint abdominal rash. The patient denied changes in diet, exposures to new materials, travel or sick contacts. She was recently hospitalized for acute decompensated heart failure with preserved ejection fraction and had been discharged five days prior to presentation. Courses of Doxycyline and Trimethoprim-Sulfamethozazole had been recently completed for suspected pneumonia. Exam was significant for a faint maculopapular rash on the abdomen, a large submandibular ecchymosis, submandibular lymphadenopathy, and right upper quadrant tenderness to palpation. The patient was found to have significant peripheral eosinophilia (Eosinophil Count 7900/μL, White Blood Cell 19,900/μL), normal hemoglobin and elevated Mean Corpuscular Volume (103 fL) and acute kidney injury. Tryptase and Vitamin B12 levels were both markedly elevated. Computed tomographic imaging of the abdomen revealed multiple renal infarcts and mesenteric panniculitis. A bone marrow biopsy was negative for malignancy. Given her chronically mild elevation of MCV, tryptase and B12, along with her history of an unremarkable work-up 2 years previously, she was given a presumptive diagnosis of myeloid-related hypereosinophilia syndrome. The patient was begun on steroid therapy by the Hematology-Oncology Service and has done well.

IMPACT/DISCUSSION: Hypereosinophilic syndrome (HES) includes the presence of elevated peripheral eosinophilia with organ involvement. In this case, it is assumed that the patient had organ involvement given her multiple renal infarcts and panniculitis. HES is a rare and difficult to diagnose condition, as seen in this case where the patient did not meet all criteria for myeloid-type HES but given suspected progression to multiple organ involvement, was treated as such.

CONCLUSION: Hypereosinophilic syndrome (HES) is a rare but potentially morbid condition that is difficult to diagnose. Appropriate identification and treatment is essential to acheiving positive outcomes.

A CURIOUS CASE OF TAMPONADE

Arun Philip. Internal Medicine, Methodist Dallas Medical Center, Dallas, TX. (Control ID #3390857)

LEARNING OBJECTIVE #1: Distinguish between etiologies of pericardial effusion

LEARNING OBJECTIVE #2: Recognize and manage cardiac tamponade

CASE: 77 year old male with history of complete heart block with permanent pacemaker placement and recent diagnosis of nonvalvular atrial fibrillation on apixaban presented to the emergency department with chief complaint of abdominal pain and dyspnea on exertion. The complete blood count, electrolyte panel, and serum creatinine were unremarkable. The initial troponin was elevated and EKG showed sinus tachhycardia. Transthoracic echocardiogram (TTE) showed circumferential pericardial effusion with findings concerning for tamponade. Cardiology was consulted and emergent pericardiocentesis was performed with removal of 560 milliliters of hemorrhagic fluid. A repeat TTE showed no pericardial effusion after drainage. Gram, fungal, and mycobacterial stains were negative and bacterial, fungal, and mycobacterial cultures on pericardial fluid showed no growth. Cytology was negative for malignancy and serum TSH was normal.

After ruling out hypothyroidism, malignancy, and infectious etiologies, the patient's cardiologist was noted to have adjusted pacemaker leads 2 weeks prior to admission. It was determined that the pericardial effusion was most likely iatrogenic due to microperforation of the right ventricle during pacemaker lead adjustment, with bleeding exacerbated by apixaban use.

IMPACT/DISCUSSION: Pericardial effusions have a wide range of etiologies including infection, inflammation, and malignancy. Right

ventricular perforation is an uncommon cause of pericardial effusion, occurring in 0.1-0.8% of pacemaker placements. Risk factors for ventricular perforation include the use of active fixation leads compared to passive fixation leads, low volume operators (less than 50 annual cases), female gender, age greater than 75 years, BMI less than 25, chronic lung disease, and history of coronary intervention. Symptoms can range from asymptomatic to life-threatening and include chest pain, syncope, abdominal pain, and dyspnea. In this instance, due to tamponade, an emergent pericardiocentesis was performed; however, lead extraction was not deemed necessary during this admission. The necessity of lead extraction, and the optimal mean of extraction, whether percuaneous or surgical, remains a matter of controversy.

CONCLUSION: Cardiac perforation is an extremely rare etiology of pericardial effusion; however, it is associated with significant morbidity and mortality.

ACUTE CALCIUM PYROPHOSPHATE CRYSTAL DEPOSITION DISEASE (CPPD): A DIAGNOSTIC CHALLENGE

Nikita Jain[1]; Rosemina Patel[1]; Anchit Bharat[2]; Prashant Sura[1]. [1]Internal Medicine, Chicago Medical School, RFUMS, Northwestern Medicine, McHenry, McHenry, IL; [2]Internal Medicine, IU Health Ball Memorial Hospital, Muncie, IN. (Control ID #3367285)

LEARNING OBJECTIVE #1: CPPD, though a common occurrence, can sometimes pose real diagnostic difficulties. Through the following case, we aim to highlight the importance of an interdisciplinary approach to care, crucial to the practice of Internal Medicine.

LEARNING OBJECTIVE #2: Recognize the value of gelatinous aspirate in cases of dry tap and employ alternative diagnostic modalities for the diagnosis of CPPD.

CASE: An 82-year old male with a history of osteoarthritis and bilateral rotator cuff tears presented with severe left shoulder pain and a productive cough. Initial workup revealed signs of severe sepsis with consolidation on chest XR and chronic arthritic changes on XR of the left shoulder. Empiric antibiotics were initiated for community-acquired pneumonia and a follow-up MRI left shoulder was scheduled for further evaluation of shoulder pain. This was notable for a large joint effusion. Blood cultures grew group A streptococcus which raised suspicion for septic arthritis, necessitating an arthrocentesis. This yielded a dry tap. Symptoms continued to progress to migratory joint pain involving the right wrist and bilateral ankles. Negative RF, anti-CCP, cryoglobulin, ANA, complement, parvovirus, Lyme, hepatitis serologies and a persistent dilemma between septic arthritis and crystal arthropathy prompted an in-depth imaging review in consultation with Interventional Radiology and Rheumatology. The consensus was to repeat arthrocentesis. 1.5 ml of gelatinous material was obtained, enough to perform a single test only. Given the overall clinical picture, crystal analysis was performed and revealed calcium pyrophosphate crystals, establishing the diagnosis of CPPD. The patient was started on steroids with improvement in joint pain and was discharged to rehabilitation care.

IMPACT/DISCUSSION: Acute CPPD can be difficult to distinguish from septic arthritis and gout due to its similar presentation. Definite diagnosis requires arthrocentesis. Occasionally, aspiration of synovial fluid is difficult due to its increased viscosity. A dry tap presents with diagnostic challenges especially with septic arthritis in the differential. Sometimes, a drop of synovial fluid from the needle of a dry tap, can be extremely valuable for the identification of crystals.

CONCLUSION: This case highlights the value of close communication with different specialties, useful in exploring additional options such as repeating arthrocentesis using ultrasound guidance as well as using gelatinous material for analyses. Additional diagnostic tests such as musculoskeletal ultrasound and dual- energy CT (DECT) scan have been used increasingly for the identification of monosodium urate crystals (MSU) and articular calcium deposits. Some prospective studies have shown, DECT can effectively differentiate CPPD and MSU crystals. When available, it is a valuable, noninvasive modality that can help rule out crystal arthropathy and should be considered in appropriate clinical settings like when septic arthritis is suspected and aspiration of fluid is difficult.

ACUTE ISCHEMIC STROKE SECONDARY TO VERTEBRAL ARTERY DISSECTION IN A YOUNG FEMALE PATIENT

Daniel Karel[1]; Emily Schutzenhofer[2]. [1]Medicine, The George Washington University, Washington, DC; [2]Psychiatry, The George Washington University, Washington, DC. (Control ID #3378811)

LEARNING OBJECTIVE #1: Recognize a common cause of acute stroke in young patients

LEARNING OBJECTIVE #2: Manage brain ischemia secondary to vertebral artery dissection

CASE: A 31-year-old woman with history of bipolar disorder and migraines presented to the Emergency Department hours after the sudden onset of unrelenting vomiting, diplopia, and vertigo that worsened with movement. She denied recent trauma or ingestions. Home medications included alprazolam, lamotrigine, lithium, and trazodone.

Vital signs were normal. Physical exam was notable for severe distress and nystagmus on primary gaze and in all directions, with intact cranial nerves and motor function in all extremities without sensory deficits. Exam was limited, as the patient could not move her head without severe nausea.

CT head was normal. MRI brain revealed a small acute infarct involving the right side of the inferior cerebellar vermis. CTA head and neck were normal. However, MRA neck revealed a short dissection between segments V2 and V3 of the right vertebral artery. The patient was prescribed aspirin 81 mg and atorvastatin 40 mg, and diazepam as needed and scopolamine patch for vertigo. She was discharged with instructions to repeat MRA in 3-6 months

IMPACT/DISCUSSION: This case involves a young woman presenting with new, nonspecific but severe neurological symptoms. Though the patient's symptoms, age, and lack of risk factors may have suggested benign positional vertigo or migraine as explanations, her overall clinical appearance and exam heightened clinical suspicion of a more dangerous etiology—ischemic disease. The location of her acute infarct was consistent with her vertigo. MRA identified vertebral artery dissection as the underlying cause of the stroke. Cervical artery dissection (CAD), including vertebral artery dissection accounts for 1-2% of all ischemic strokes but up to 25% of strokes in middle-aged or younger patients (2). CAD most commonly presents as transient ischemic attack or ischemic stroke (67% of cases) (3).

While CTA is generally the preferred diagnostic modality to diagnose CAD (1-5), MRA is preferred in the setting of neurologic deficits, contraindication to IV contrast, or high clinical suspicion for carotid dissection. MRA was critical in this case.

Guidelines recommend treating ischemic cerebral events secondary to dissection with tPA as indicated, followed by anticoagulation or antiplatelet therapy (5). In cases involving subarachnoid hemorrhage, pseudoaneurysm, progression of dissection or acute massive stroke, endovascular therapy or surgical repair may be warranted.

CONCLUSION: Ischemic brain injury must be considered in younger patients experiencing nonspecific neurological symptoms; CAD is a common cause.

Treatment consists of tPA (if appropriate) and antiplatelet therapy/therapeutic anticoagulation. Endovascular intervention or vascular surgery may be warranted after large vessel occlusion.

ACUTE LIMB ISCHEMIA AS PRESENTATION OF OCCULT HEPATOCELLULAR CARCINOMA

Isabel C. Guerrido Martinez, Frederick Rozenshteyn, Steven Tsistrakis, Ana Velazquez. Internal Medicine, Mount Sinai Beth Israel, Brooklyn, NY. (Control ID #3391924)

LEARNING OBJECTIVE #1: Diagnose arterial thrombosis as a complication of malignancy

CASE: A 62-year old male with history of prior cocaine abuse and 25 pack year tobacco use presented with acute worsening left leg pain associated with distal numbness and tingling up to the left knee. Vitals were unremarkable and physical exam was notable for a cool left lower extremity and non-palpable pulses without motor or sensory deficits. CT angiogram of the abdomen and lower extremities showed occlusion of the left common, external iliac, and superficial femoral arteries. The patient was taken urgently for left leg open thrombectomy and angioplasty with stent placement. The CT angiogram also showed an incidental finding of a large hypervascular liver mass measuring 9 x 8 x 7cm with several small hypervascular nodules and a 1.2 cm hypervascular focus in the gallbladder. A subsequent MRI revealed a 10 x 10 cm heterogeneous hypervascular hepatic mass compatible with hepatocellular carcinoma with mass effect on the right hepatic vein. Laboratory tests revealed positive hepatitis C antibody with a hepatitis C viral load of 32,865 IU/mL and genotype 1A. Hepatitis B serology and alpha-fetoprotein were normal. It was later discovered that the patient had a remote diagnosis of hepatitis C at an outside hospital, but had never followed up for treatment.

The patient ultimately underwent transarterial chemoembolization and subsequent right hepatectomy during a complicated and prolonged hospital course.

IMPACT/DISCUSSION: Traditionally, cancer has been associated with increased risk of venous thromboembolism given alteration in clotting factors. However, the risk of arterial thrombosis is not well established and more recently it is being recognized as a serious complication of malignancy. Few cases of spontaneous arterial thrombosis with no iatrogenic or atherosclerotic cause in cancer patients have been reported in the literature and these have been associated with poor prognosis. This case highlights the diagnosis of a primary malignancy of hepatocellular carcinoma during the management of acute limb ischemia caused by the primary malignancy and shows the high morbidity of such complications and the need to be aware of the thrombotic risks of cancer. Therefore, further studies need to be conducted to determine whether patients with cancer would benefit from receiving antiplatelet or anticoagulation medications to prevent arterial thrombosis in an effort to improve long-term survival outcomes.

CONCLUSION: 1. Arterial thrombosis is a potentially life-threatening complication of malignancy and therefore should always be at the top of the differential diagnosis for patients presenting with symptoms of limb ischemia in the setting of known malignancy.

2. Unexpected arterial thrombosis should raise suspicion for an undiagnosed malignancy as a can't miss diagnosis.

ACUTE MYOPERICARDITIS AS THE ATYPICAL PRESENTATION OF ACUTE MYELOID LEUKEMIA (AML)

CATHERINE L. TENG. Internal Medicine, Greenwich Hospital, Greenwich, CT. (Control ID #3351996)

LEARNING OBJECTIVE #1: Recognize AML as an uncommon and rapidly lethal etiology of acute myopericarditis

LEARNING OBJECTIVE #2: Manage ischemic event among AML patients who have high bleeding risk

CASE: A 56-year-old male presented with chest pain that worsened with inspiration and improved when leaning forward. He was found to have fever, tachycardia, with elevated troponin and diffuse ST-T elevation on electrocardiogram. Echocardiogram was normal. He had mild pancytopenia with 3.9 x 10^9/L white cell count, 11.5 g/dl hemoglobin and 84 x 10^9/L platelets. A diagnosis of acute myopericarditis in the setting of presumed viral infection was made. Despite treatment, the patient deteriorated rapidly. Within 24 hours he developed atrial fibrillation, hypoxia necissating intubation and acute renal failure that eventually required dialysis. His pancytopenia continued to worsen gradually. Repeat echocardiogram demonstrated new moderate pericardial effusion.

Given the concern for hemodynamic compromise, the patient underwent pericardiocentesis with 250ml clear fluid removed. Extensive infectious and homogenous workups were initially unremarkable. On hospital stay day eight, flow cytometry eventually revealed 3% myeloblast and subsequent bone marrow biopsy showed 26% myeloblasts, consistent with AML. He received daunorubicin and cytarabine, but he then suffered from tumor lysis syndrome. Additionally he was noted to be minimally unresponsive. Magnetic Resonance Imaging of brain revealed a large ischemic stroke. Weighing risks and benefits, he was placed on heparin intravenously and it resulted in hemorrhagic conversion of stroke and herniation. The patient passed away after 44 days of hospitalization.

IMPACT/DISCUSSION: This case has several teaching points as follows. First, cardiac catheterization is not always warranted if suspicion of myopericarditis is high. Left heart catheterization might delay the diagnosis of underlying disease. Second, despite a CHADSVASC score of 3, anticoagulation should be started with caution as patients with AML have a high risk of clinically significant bleeding. Third, though the underlying pathophysiology is not completely known, including AML as an uncommon etiology of myopericarditis is essential and could potentially be life saving.

CONCLUSION: AML is lethal if early diagnosis is not made or early intensive chemotherapy is not initiated. The overwhelmingly rapid progression and high mortality calls for early recognition and diagnosis of this disease. Clinicians must be familiar with the typical and atypical manifestations of AML for early diagnosis.

ACUTE PANCREATITIS IN A PATIENT WITH PULMONARY SARCOID

Akshay Kohli[1]; Avinash Sharma[1]; Rabin Neupane[2]. [1]Internal Medicine, Medstar Washington Hospital Center, Washington, DC; [2]Internal medicine, Medstar Washington Hospital Center, Silver Spring, MD. (Control ID #3391888)

LEARNING OBJECTIVE #1: Pacreatitis as a result of hypercalcemia from sarcoidosis

LEARNING OBJECTIVE #2: Rare cause of pancreatitis in a patient of pulmonary sarcoid.

CASE: A 55 year old female with pulmonary sarcoidosis presented to our hospital with 2 weeks of progressive nausea, non-bilious, non-bloody vomiting and abdominal pain. She also noted generalized weakness and fatigue for the same time. She was found to have a calcium level of 15.6mg/dL and Lipase of 2033 units/L. Parathyroid hormone(PTH) levels were normal and no parathyroid hormone related peptide was detected. Imaging studies including Computed Tomography(CT) of the abdomen showed intraparenchymal pancreatic and mesenteric fluid collection with peripancreatic stranding suggestive of acute pancreatitis. She was treated with calcitonin and zoledronate in addition to intravenous fluid resuscitation.

She was also started on prednisone 30mg/ day for her pulmonary sarcoid which was thought to be the cause of her hypercalcemia. As she continued to remain symptomatic, an MRI of the abdomen was done

which revealed a retrogastric pseudocyst. A stent was placed to drain the fluid which lead to marked symptomatic improvement. She was finally discharged home on a maintenance dose of corticosteroids.

IMPACT/DISCUSSION: Hypercalcemia is a well known complication of sarcoidosis with a prevalence of about 40-60% in published literature. Although most cases are asymptomatic, clinically significant hypercalcemia occurs in about 5% of the patients. Often causing renal impairment with complications like nephrolithiasis and chronic renal failure from long standing hypercalcemia, symptomatic hypercalcemia as a complication of sarcoidosis leading to pancreatitis is extremely rare.

Although hypercalcemia is a common etiological factor in pancreatitis, most cases of hypercalcemia causing pancreatitis are a result of hyperparathyroidism which in turn is most commonly due to a parathyroid adenoma. Sarcoidosis does not usually lead to hypercalcemia to levels high enough to cause pancreatitis. On one hand, our case emphasises on the importance of being vigilant about the different causes of hypercalcemia in a patient with pancreatitis. On the other hand, this case also highlights the possibility of symptomatic hypercalcemia including acute pancreatitis in patients with pulmonary sarcoidosis.

CONCLUSION: Our case describes an interesting combination wherein a common complication of a disease process (hypercalcemia from sarcoidosis) triggered another common disease process. (Pancreatitis from hypercalcemia). Although both entities are commonly encountered in isolation, their combination is very rarely seen.

ACUTE PERICARDITIS MIMICKING BRUGADA SYNDROME

Malik Shehadeh[2]; John Costello[1]; Vijaywant Brar[1]; Susan O'Donoghue[1]. [1]Electrophysiology, Medstar Washington Hospital Center, Washington, DC; [2]Internal Medicine, Medstar Washington Hospital Center, Washington, DC. (Control ID #3392406)

LEARNING OBJECTIVE #1: Recognize the features of pericarditis and Brugada syndrome on electrocardiogram and to avoid further unnecessary interventions.

CASE: A 35-year-old male patient without significant medical history presented to our hospital with substernal chest pain of 1-day duration. Patient described his substernal chest pain as radiating to his back and worsening with inspiration and leaning forward. His history was remarkable of having a cold 2 weeks prior to his presentation.

Upon arrival to the hospital, his vitals were unremarkable. His labs showed normal while blood counts, normal lipid profile and hemoglobin A1c. A chest X ray didn't show any evidence of pneumonia. A chest computed tomography angiography was negative for pulmonary embolus or aortic dissection.

Two assays of troponin were performed 6 hours apart and were negative. His electrocardiogram (ECG) showed diffuse ST-PR discordance which was highly concerning of pericarditis along with type II Brugada pattern which manifested in lead V2 as saddle-back pattern with a least 2 mm J-point elevation and at least 1 mm ST elevation with a positive T-wave. An Echocardiogram was performed and showed normal left ventricular ejection fraction of 55% without regional wall motion abnormality or pericardial disease.

Patient was treated with nonsteroidal anti-inflammatory drugs for 2 weeks with significant improvement in his symptoms and complete resolution of his ECG features.

IMPACT/DISCUSSION: Brugada syndrome is a genetic heart disease characterized by disturbances affecting the electrical activity within the heart. Patients with Brugada syndrome might experience syncope or sudden cardiac death due to serious abnormal heart rhythms such as ventricular fibrillation.

Brugada syndrome is diagnosed by identifying certain patterns on ECG. However, similar ECG patterns might be seen in a variety of other conditions such as electrolyte disturbances or with the use of certain medications such as sodium channel blockers. In these different conditions, the Brugada ECG pattern is expected to disappear within a few days of withdrawal of the provoking factor.

Here we reported a case of a patient with acute pericarditis who developed a Brugada ECG pattern that completely resolved with the treatment of the underlying pericarditis.

CONCLUSION: Acute pericarditis may mimic Brugada syndrome. The ECG pattern of Brugada syndrome shouldn't be considered as a specific marker of the syndrome, but rather as a sign of electrical heart disease that can be due to various other conditions.

ACUTE PROSTATITIS PRESENTING WITH ITS FEARSOME COMPLICATION

Nandar Mon[1]; Clarissa A. Ramirez[2]; Assad Mohammedzein[3]; ASM ISLAM[1]. [1]Internal Medicine, Texas Tech University Health Sciences Center, Amarillo, TX; [2]School of Medicine, Texas Tech University Health Sciences Center, Amarillo, TX; [3]Internal Medicine, Texas Tech University Health Science Center, Amarillo, TX. (Control ID #3390594)

LEARNING OBJECTIVE #1: Recognize the importance of early diagnosis and treatment of acute bacterial prostatitis to prevent complications

LEARNING OBJECTIVE #2: Assess for risk factors for Methicillin Resistant Staphylococcus Aureus(MRSA) prostatic abscess

CASE: A 55-year-old male with no known past medical history presented to the ER with dysuria, difficulty in micturition and perineal pain for 1 week. He denied fever, chills, nausea, vomiting, abdominal pain, hematuria or urethral discharge. He admitted current use of amphetamine and heroin. No high risk sexual behavior. His vitals were stable, physical exam was unremarkable except for boggy and tender prostate on DRE. Initial labs reveal neutrophilic leucocytosis, UA shows: Leukocyte esterase 3+, nitrate negative, glucose 3+, WBC >50, RBC 11-20, HbA1c 11.3, HIV -ve. CT pelvis reported complex multilocular fluid collection in the prostate gland and the inferior left hemipelvis. CT-guided percutaneous drainage of hemipelvic abscess yielded 40cc of pus. He was treated with Vancomycin and Meropenem. TURP with foley catheter insertion was performed. Urine, fluid and blood culture grew methicillin resistant Staph aureus. He was discharged to finish 4 weeks of Daptomycin.

IMPACT/DISCUSSION: Though prostate infections are commonly related to UTI-causing Gram-negative organisms, acute *Staphylococcal* prostatitis can lead to rare cases of MRSA prostatic abscess, 26 documented per literature review in 2017. Although 90% of cases in that review resolved with timely treatment, 3 cases had fatality. Considering such outcomes, it's important to early identify those patients, they are often sick and septic, deep perineal pain with signs of urinary obstruction should warrant imaging with either US or CT. Our patient presented with risk factors consistent with previously reported cases such as newly diagnosed diabetes mellitus and polysubstance use. No other risk factors were present in this such as urethral instrumentation and Hepatitis C. MRSA prostatic abscesses warrant prompt treatment with appropriate antibiotic coverage and urological consultation for management of the abscess. After pelvic drain and TURP, subsequent imaging showed no residual pelvic collection. Daptomycin was chosen in this case due to ease of administration and monitoring in the outpatient setting.

CONCLUSION: MRSA prostatic abscess is an uncommon complication of acute bacterial prostatitis. We report a case of newly diagnosed diabetic and previous IVDU who presented with dysuria, difficulty in micturition and perineal discomfort. He was diagnosed with MRSA prostatic abscess

with complications of extraprostatic extension of abscess in hemipelvis and bacteremia which was successfully treated with CT- guided percutaneous drainage, transurethral resection drainage and intravenous antibiotics. MRSA prostatic abscess is very rare in immunocompetent host and has high mortality rate unless diagnosed early and treated with proper antibiotic and abscess drainage.

ACUTE RHABDOMYOLYSIS: A NON-PULMONARY VAPING-RELATED TOXICITY?

Samuel Maltby[2]; Maria G. Frank[1,2]. [1]Hospital Medicine, Denver Health Hospital Authority, Denver, CO; [2]University of Colorado, School of Medicine, Aurora, CO. (Control ID #3349556)

LEARNING OBJECTIVE #1: To promote awareness about non-pulmonary vaping- related toxicity

LEARNING OBJECTIVE #2: To describe a case of acute rhabdomyolysis in a young male with heavy liquid nicotine consumption

CASE: A previously healthy 21 year-old male presented to the emergency department complaining of 4 days of myalgia and dark urine. Patient reports extreme exercise 5 days prior to presentation followed by myalgia and dark urine within 24 hours. Because of persistent and worsening pain, he presented to our institution 4 days after symptom onset and was admitted for acute rhabdomyolysis. Other than exertion, there were no identified triggers. No trauma, no seizures, no over-the-counter or prescribed medications, no recent travel to tropical area, no evidence of infectious pyomyositis, no known family history of myopathy. His initial CK was 168,000 U/L. There was no evidence of acute kidney failure or hyperkalemia. No significant past medical or surgical history. Social history revealed tobacco dependence and heavy liquid nicotine (vaping) use. Physical examination was noteworthy for marked tenderness to palpation over muscles. His work up included a negative UTOX, evidence of transaminitis AST>ALT, with unrevealing BMP and CBC. He received fluid resuscitation. At day 2, CK was 48,000 U/L. He was discharged home with exercise precautions, and oral hydration recommendations. Special attention was paid to counselling about liquid nicotine use.

IMPACT/DISCUSSION: Liquid nicotine use has been increasing in popularity, but the safety of the products is still in question. In addition to the pulmonary complications that have been reported with liquid nicotine use, another potential concern is rhabdomyolysis. Liquid nicotine use and rhabdomyolysis are connected due to toxicity of chronic nicotinic exposure. Nicotine poisoning can manifest in several different presentations based on its effects on both muscarinic and nicotinic receptors, including rhabdomyolysis (nicotinic muscle receptors). Initially it was believed that liquid nicotine devices would have very low peripheral effects due to the low affinity of peripheral nicotinic acetylcholine receptor compared to those found in the brain, but recent studies have shown that chronic nicotinic exposure results in changes to peripheral tissues like skeletal muscle. These studies have shown elevated resting membrane potentials in skeletal muscle after just one month of chronic nicotinic exposure. It has also been shown that nicotinic plasma levels has increased with newer generations of devices by up to 72% and increases up to 54% as the user becomes more comfortable with using their devices. Our case demonstrates that liquid nicotine use can potentially lead to extra-pulmonary complications like rhabdomyolysis

CONCLUSION: With the raising popularity of liquid nicotine use, it is imperative to be vigilant for additional complications when a patient's social history is significant for heavy liquid nicotine use.

ACUTE RHEUMATIC FEVER PRESENTING AS A MIMICKER OF SEPTIC ARTHRITIS

Ikechukwu o. Achebe[1]; Kifah Hussain[2]; Annette Abraham[1]; Ahmed Nauman[1]. [1]Internal Medicine, John H. Stroger Hosp of Cook County, Chicago, IL; [2]Internal Medicine, John H Stroger Hospital of Cook County, Barrington, IL. (Control ID #3350537)

LEARNING OBJECTIVE #1: Work though the diagnostic challenge of differentiating atypical acute rheumatic fever (arthritis) from its mimickers (i.e. post strep reactive arthritis); and understand the importance of doing so

LEARNING OBJECTIVE #2: Treat the arthritis of acute rheumatic fever and post strep reactive arthritis

CASE: History of Present Illness: A 39-year-old man with no medical comorbidities presented with abrupt onset left wrist pain, swelling, and fever for one day. The patient reported history of similar pain and swelling around his ankles a week before that resolved with NSAIDS use. On review of systems, the patient had sore throat 1 month prior to presentation but denied any history of urethritis, conjunctivitis, recent alcohol use, and or any tick bites.

Physical Exam: Febrile with (temp. 102.2F), tachycardic (HR 129). Painful range of motion of the left wrist, with erythema and swelling

Diagnostic Workup: Leukocytosis (17,200). Synovial fluid analysis from the left wrist aspirate revealed 23,000 WBCs, no crystals, and was culture negative. Blood cultures were negative. ESR and CRP levels were elevated.

Inpatient Course: Empirically started on IV antibiotics for suspected septic arthritis. However, patient continued to spike fevers. By Day 2, pain and swelling in the left wrist resolved. New onset pain and swelling was noted in his ankles (b/l) and right hip.

Further Diagnostic Workup: Investigations including, syphilis EIA, heterophile monospot, ANA, Complement levels, Rheumatoid factor, Anti-CCP, ANCA levels, Gonorrhea/Chlamydia urine, pharyngeal and rectal swab, and Urine Histoplasmosis, were negative. Based on history of sore throat that was partially treated, Antistreptolysin titers were ordered and returned significantly elevated (533).

IMPACT/DISCUSSION: Diagnosis: With migratory polyarthritis, fever, and elevated acute phase reactants, our patient fulfilled 1 major, and 2 minor components of the Jones criteria, and was diagnosed with Acute Rheumatic fever. He was started on NSAIDs, and had resolution of his arthritis within 48 hrs. of initiation. Post streptococcal reactive arthritis was considered among other differentials. However, considering our patient's quick response to NSAIDs, and his presentation satisfying the Jones Criteria, ARF was deemed more likely. Patient was discharged with Ibuprofen and prophylactic IM Penicillin Benzathine x 5 years

CONCLUSION: - In regions, where ARF incidence is high, its incidence is more common in children aged 5-14 years and ARF incidence ranges from 2-3.2 % in the 35-44-year age group.

- Migratory polyarthritis is earliest symptomatic manifestation of ARF (< 3 wks. of GAS)

- The arthritis of ARF typically affects large Joints: ankles, knees, elbows, wrists

- Arthritis of ARF is very responsive to NSAID's and leaves no residual joint deformity

- Identifying PSRA as an ARF variant has important implications for secondary prophylactic treatment

ACUTE SYPHILITIC HEPATITIS: AN UNUSUAL PATTERN

Elliott Goldberg[1]; Sara Mauney[2]; Kaleigh Krill[1]. [1]Department of Internal Medicine, Penn State College of Medicine, Hummelstown, PA; [2]Department of Neurology, Penn State College of Medicine, Hershey, PA. (Control ID #3390757)

LEARNING OBJECTIVE #1: Recognize acute hepatitis and jaundice as a presentation of syphilis.

LEARNING OBJECTIVE #2: Identify serology tests that can be falsely positive in bacterial infections.

CASE: A 31-year-old man presented with one week of cough, headaches, and abdominal pain. Initial laboratory evaluation revealed a total bilirubin level of 15.6 mg/dL, ALP 181 U/L, ALT 518 U/L, AST 829 U/L. Lipase was not elevated. Chest and abdominal imaging showed no abnormalities. He had a 13 pack-year smoking history but no alcohol or recreational drug use. Urine drug screen was negative, and acetaminophen level was undetectable. There was no relevant family history, recent travel, or new sexual partners. On examination, he was jaundiced with RUQ tenderness and hepatomegaly. He had multiple homemade tattoos.

Investigation confirmed vaccination against hepatitis A and B. Viral studies for hepatitis C, HIV, EBV, CMV, ADV, and VZV were negative. Further studies demonstrated a positive ANA (1:640) and AMA. HSV IgM was positive, while IgG was negative for which he was treated with IV acyclovir for suspected HSV hepatitis. Despite the treatment, his bilirubin and transaminases continued to rise.

On day six, he developed a maculopapular rash over the torso, palms and soles. Testing for syphilis revealed a positive RPR titer and a reactive treponemal antibody test. One dose of 2.4 MU of penicillin G benzathine was administered. Liver biopsy obtained the next day showed portal and lobular hepatitis and hepatocyte necrosis. HSV-1 and HSV-2 immunohistochemical stains were non-reactive, and spirochetes were not visible on Steiner stain. Following penicillin administration, transaminases trended downwards and he reported profound symptomatic improvement.

IMPACT/DISCUSSION: Syphilis is often considered in the context of painless genital ulcers, lymphadenopathy, and cutaneous manifestations in high-risk populations. Hepatitis is an uncommon manifestation of syphilis. Reported findings typically follow a cholestatic pattern with marked elevations in ALP and GGT and milder elevations in aminotransferases. This case is remarkable due to mild ALP elevations and impressive elevations in AST and ALT. Several possible diagnoses competed before testing for syphilis occurred, including HSV hepatitis. In this case, despite antiviral medication, transaminitis continued to worsen until penicillin was administered. Falsely positive ANA and AMA have been previously reported in patients with bacterial infections, including syphilis. The diagnosis of syphilitic hepatitis was made based on the dramatic clinical and laboratory improvement seen after penicillin administration. Moreover, the biopsy findings in this case were consistent with a systematic review of 55 liver biopsies taken from patients with syphilitic hepatitis.

CONCLUSION: Syphilis should be suspected as a possible cause in patients with acute hepatitis and jaundice.

Liver enzymes can be markedly elevated in syphilitic hepatitis with mild increases in ALP. False positive serology testing can occur in syphilis.

ACUTE VASO-OCCLUSIVE CRISIS WITH SPLENIC SEQUESTRATION IN A PERSON WITH SICKLE CELL DISEASE FOLLOWING PERFLUTREN LIPID MICROSPHERE ADMINISTRATION FOR CARDIOVASCULAR ULTRASOUND ENHANCEMENT

Alex D'Amico[1]; Nabiel Mir[2]; Nicholas Van Wagoner[2]; Hunter Wilkerson[2]; Julie Kanter[3]. [1]School of Medicine, University of Alabama at Birmingham, Birmingham, AL; [2]Department of Medicine, University of Alabama at Birmingham, Birmingham, AL; [3]Department of Hematology & Oncology, University of Alabama at Birmingham, Birmingham, AL. (Control ID #3391118)

LEARNING OBJECTIVE #1: Recognize the risks of using Perflutren Lipid Microsphere in sickle cell disease patients

CASE: A 53-year-old African American female with a past medical history of sickle cell-beta+ thalassemia presented for routine echocardiogram with Perflutren Lipid Microspheres (PLM). Prior to the procedure, patient was in her usual state of health with no complaints of pain or other vaso-occlusive crisis (VOC). Shortly after the procedure, she experienced acute pain in her lower extremities that progressed caudally to her abdomen and chest. At presentation to the Emergency Department, she was hypoxic and tachypneic. Physical exam revealed diffuse chest pain reproducible with palpation. Laboratory analysis was remarkable for microcytic anemia and neutrophilia. Chest radiograph revealed an ill-defined opacity in the right middle lobe. She was admitted for VOC with acute chest and subsequently developed fever and tender left upper quadrant abdominal pain. Laboratory analysis revealed thrombocytopenia, leukocytosis, and worsening anemia. Infectious disease workup was negative. Acute splenic sequestration crisis (ASSC) was suspected. Abdominal ultrasound revealed splenomegaly and an exchange transfusion was performed. Post-transfusion laboratory analysis initially revealed worsened hemolysis (elevated lactate dehydrogenase, direct hyperbilirubinemia, and increased anemia) and acute kidney injury concerning for hyperhemolysis and multi-organ failure syndrome. She was treated with ongoing transfusion support, intravenous immune globulin infusion, and supportive care. Over two days, the patient's hemolytic parameters and her abdominal pain improved.

IMPACT/DISCUSSION: The patient's clinical course included a VOC complicated by ASSC and multi-organ failure syndrome in an adult with sickle cell disease (SCD). We suspect that her VOC and ASSC were related to the echocardiogram contrast agent (ECA), PLM. Review of the literature reveals no documentation of VOC or ASSC with ECA use. However, at our institution, this is the second patient with SCD who experienced VOC following PLM use. In 2017, the FDA revised the black box warning for ECAs (initiated in 2007 after four deaths in patients without SCD), which included the deletion of the mandated 30-minute monitoring period following ECA use. Further, a previous abstract awarded for a small business investigation research grant mentions an increased concern in patients with SCD, but no follow-up data is available. Interestingly, the VOC in the two patients at UAB began within, or close to, this monitoring period. Avoiding PLM in individuals with SCD or further monitoring patients with SCD receiving ECA should be considered.

CONCLUSION: -Perflutren Lipid Microsphere's safety profile in SCD patients warrants examination

-Clinical judgment should be used to determine if ECA use is necessary for cardiac evaluation in SCD patients or if alternative methods should be used (such as cardiac MRI)

-VOC can be complicated by ASSC in adults with SCD

A DAGGER TO THE HEART: STIMULANT USE AND SPOTANEOUS CORONARY ARTERY DISSECTION

Mary L. Guan[1]; Marilyn Chacko[1]; David Rhee[3]; Olena Ksovreli[2]. [1]Internal Medicine, New York University, Brooklyn, NY; [2]Medicine, NYU Langone Health, Brooklyn, NY; [3]Internal Medicine, New York University School of Medicine, New York, NY. (Control ID #3373940)

LEARNING OBJECTIVE #1: Recognize the presentation of spontaneous coronary artery dissection (SCAD).

LEARNING OBJECTIVE #2: Recognize amphetamine use as a potential risk factor for SCAD.

CASE: A 33-year-old woman with a history of anxiety and ADHD on dextroamphetamine and amphetamine presented with acute onset sharp,

substernal chest pain radiating to her left arm and neck since the morning. It felt similar to a "heartburn" episode a month ago. While in EMS, she felt nauseous, vomited, and described a "sensation of doom." She denied any dyspnea, cough, or lightheadedness. She endorsed a remote history of cocaine use and recent stressors at work causing increased anxiety.

Her physical exam was unremarkable. EKG showed 0.5-mm ST-depression in leads V4-V6, III and aVF with T-wave inversions in leads V1-V3. She received aspirin 325mg, aluminum-magnesium hydroxide-simethicone, and famotidine 20mg. Initial troponin I was 0.11ng/mL. D-dimer, urine drug screen, chest x-ray, and echocardiogram were normal. Repeat troponin 6 hours later was 11.3 and the EKG remained unchanged. Cardiac catheterization revealed a spontaneous coronary artery dissection (SCAD) in her distal left circumflex artery causing a 95% occlusion. No intervention was performed. She was discharged on aspirin and clopidogrel. Dextroamphetamine and amphetamine was discontinued.

IMPACT/DISCUSSION: SCAD is a common cause of non-atherosclerotic coronary artery disease in women under age 50, accounting for 24% of myocardial infarctions [1] and recurrence is common. Young women with anxiety or GERD are often assumed to have non-cardiac chest pain and may not be considered for coronary catheterization [2]. This may lead to underdiagnosis of SCAD. Pathophysiology of SCAD is not completely understood, but the proposed mechanism is an intimal tear or bleeding of vasa vasorum, causing a false lumen with an intramural hematoma. Early coronary angiography is critical for diagnosis. Risk factors include connective tissue disease, pregnancy, physical and emotional stress. Our patient was not pregnant and did not have a connective tissue disorder. While cocaine is typically associated with SCAD [3,4], her use was remote and urine test was negative. Interestingly, there are a few case reports showing an association between amphetamine use and risk of SCAD [5,6]. The scarcity of data could be due to rarity of the condition as well as under-diagnosis from lack of awareness that amphetamine use is a risk factor for SCAD. Appreciating amphetamine use as a possible risk factor for SCAD may prompt earlier recognition and treatment. Furthermore, heightening awareness among providers may trigger education of patients on the dangers of misusing or overusing amphetamines.

CONCLUSION: Patients with SCAD typically do not have risk factors for coronary artery disease; they are young, healthy and predominantly female. It is critical to maintain a high level of suspicion for SCAD in healthy patients who present with cardiac chest pain and to recognize stimulant medication use as a potential risk factor.

ADDRESSING THE GAP: AIDS PRESENTING AS HERPES ZOSTER POLYCRANIAL NEURITIS WITH A GLOBULIN GAP AND PAROTID LYMPHOEPITHELIAL LESIONS

Theresa Schwitalla[1]; Jacqueline D. Mir[2]; Elizabeth Melzer[2]. [1]Psychiatry, Univerisity of South Florida, Tampa, FL; [2]Internal Medicine, USF, Tampa, FL. (Control ID #3392318)

LEARNING OBJECTIVE #1: Diagnose HIV in patients presenting with Herpes Zoster, a globulin gap, or with lympoepithelial lesions.

LEARNING OBJECTIVE #2: Recognize that Herpes Zoster can present with polycranial neuritis.

CASE: A 37 year-old-female presented with a painful, burning rash on the left face that spread to the oropharynx over the course of three days. Associated symptoms include dysgeusia, otalgia, vertigo, headache, and pain with opening her jaw. She denied fatigue, night sweats, fevers, weight loss, hearing loss, or ocular symptoms. On exam, she was afebrile with normal vital signs and appeared uncomfortable. There was a vesicular rash on the left external auditory canal, auricle, cheek, chin, and lower lip. Ulcerations were present on the left tongue, soft palate and anterior tonsillar pillar that did not cross midline. There was no ocular involvement. A left-sided facial nerve palsy and cervical lymphadenopathy were noted. Labs noted lymphopenia, globulin gap, and HIV positivity with a CD4 count of 54 (normal >500). Maxillofacial CT revealed parotid lymphoepithelial lesions and nasopharyngeal abscess superimposed on a herpes zoster (HZ) cluster. She was diagnosed with HZ with polycranial involvement (cranial nerves V and VII) in the setting of newly diagnosed Acquired Immunodeficiency syndrome (AIDS). Treatments included IV acyclovir, prednisone, empiric antibiotics for the abscess not amenable to drainage, cortisporin otic drops, and supportive care. She was started on bictegravir/emtricitabine/tenofovir as acute retroviral syndrome could not be ruled out. The patient clinically improved and was discharged with close follow-up.

IMPACT/DISCUSSION: Ramsay Hunt Syndrome (HZ Oticus) classically presents with HZ reactivation involving the facial nerve with ipsilateral facial palsy and rash in the ear and mouth. HZ can also involve the trigeminal nerve. The ophthalmic branch is most commonly affected; the maxillary and mandibular branches are rarely involved. Here we describe a rare presentation of HZ with polycranial involvement of both the facial and the mandibular branch of the trigeminal nerve. Patients with HZ should be monitored closely for development of ocular involvement which is associated with significant morbidity. Other complications of HZ include abscess formation as varicella infection predisposes to secondary bacterial infection as seen in this patient. Another important point is that this patient initially presented to an outside hospital and was diagnosed with HZ; however, her globulin gap was not evaluated and her HIV status was not assessed. In this case, why would a young patient present with Herpes Zoster with a globulin gap and parotid lympoepithelial lesions? Immunodeficiency must be considered and recognition will result in earlier diagnosis with improved outcomes.

CONCLUSION: HIV status should be assessed in patients presenting with Herpes Zoster, a globulin gap, or lymphoepithelial lesions. Herpes Zoster can present with polycranial neuritis and timely treatment is essential to decrease morbidity.

A DETOUR THROUGH THE DIAPHRAGM – AUSTIN REZIGH MD, DIVNEET MANDAIR MD, MARISA ECHANIZ MD

Marisa Echaniz[1]; Austin Rezigh[2]. [1]Internal Medicine, University of Colorado - Denver Health, Denver, CO; [2]Internal Medicine, University of Colorado-Denver, Aurora, CO. (Control ID #3392145)

LEARNING OBJECTIVE #1: Recognize patients at risk for pancreaticopleural fistula.

LEARNING OBJECTIVE #2: Select the appropriate imaging study for diagnosis of pancreaticopleural fistula

CASE: 33 year old male with PMH: smoking, alcohol abuse presented with dyspnea. One month prior to admission, our patient developed shortness of breath. He noted a dry cough x 1 week that caused him to stop smoking, and pleuritic chest pain, N/V/D.

CXR noted a LLL consolidation and large L effusion. The patient was initially treated for CAP. Thoracentesis was performed, revealing an exudative effusion with an amylase level of 37,350. Pleural fluid cytology and culture were negative.

At this point, pt went for CT chest/abdomen/pelvis which demonstrated large bilateral pleural effusions, peripancreatic fat stranding and possible pseudocyst posterior to the pancreatic tail. A diagnosis of pancreaticopleural fistula (PPF) was made and was initially managed medically. ERCP was later performed, which revealed ductal injury in the pancreatic genu with downstream stricture for which a plastic stent was placed. The stent was upsized 5 days later given continued reaccumulation of the effusions. His effusions and dyspnea subsequently resolved, and he underwent uneventful stent removal 6 weeks later.

IMPACT/DISCUSSION: Pleural effusions that develop from PPF are rare, occurring in <1% of cases[1]. These are distinct from the more common sympathetic effusions seen in ~17% of cases of acute pancreatitis[1,2]. PPFs generally form from a ruptured or incompletely formed pseudocyst that allows leakage of pancreatic enzymes across fascial planes. To drain into the pleural space, a fistulous tract often forms across the aortic or esophageal hiatus of the diaphragm[2].

Central to diagnosing PPF is understanding the clinical context in which it occurs. Most patients present with dyspnea sans abdominal pain, often delaying the diagnosis by >1 month[2]. Evidence of chronic pancreatitis in patients with refractory effusions should raise suspicion for PPF. Chronicity of pancreatitis, more than chronologic age, is a risk factor for formation[3]. Amylase levels from pleural fluid are often diagnostic. Many conditions, from pulmonary TB to esophageal perforations, may present with elevated pleural amylase; but levels >10,000 are seen, almost exclusively, in PPF[4,5].

Diagnosis is often made by non-invasive imaging modalities. MRCP is the gold standard as it excels in visualization of pancreatic ductal anatomy[6]. CT has an acceptable performance, visualizing the fistula in ~70% of cases[3]. While minimal ductal dilations may be managed medically, disruptions in the pancreatic head or body, or a stricture, are best managed with ERCP. Surgery is favored when complete ductal disruption or obstruction distal to a fistula is seen[2,4].

CONCLUSION: PPF can be difficult to diagnose without a high clinical suspicion. Amylase levels in pleural fluid are often diagnostic. Non-invasive imaging modalities, such as MRCP and CT, are essential for guiding appropriate management.

A DIFFERENT DIFFERENTIATION SYNDROME: A CASE WITH AZACITIDINE

Zoya Iqbaluddin, Stephanie Spangler. Internal Medicine, Christiana Care, Newark, DE. (Control ID #3390882)

LEARNING OBJECTIVE #1: Recognize differentiation syndrome caused by an atypical drug

CASE: A 76 year old male with history of prostate adenocarcinoma status post radical prostatectomy, leuprolide, and external beam radiation subsequently developed myelodysplastic syndrome as a consequence of prior radiation exposure. Initial treatment with erythropoietin stimulating agents failed. Treatment with azacitidine was pursued. Two weeks later, he presented to the hospital with chief complaints of dizziness, malaise, and shortness of breath. He was hypoxic requiring 4LNC but otherwise hemodynamically stable. Initial lab workup revealed: new leukocytosis of ~60,000 with 50% blasts, worsening anemia (6.7 g/dL) and thrombocytopenia (26/nL) without DIC, and acute kidney injury with associated elevated uric acid and LDH. Chest CT revealed small subsegmental filling defects suggestive of pulmonary emboli vs. leukostasis, patchy ground glass opacities, and pleural effusions. Broad spectrum antibiotics were initiated for possible pneumonia. Due to concern for possible malignant transformation and questionable hyperleukocytosis, hydroxyurea was initiated. He was also treated for tumor lysis syndrome. Despite treatment, he had worsening leukocytosis and a deteriorating clinical picture with hypotension, worsening respiratory failure, decreasing renal function, and new altered mentation raising concern for differentiation syndrome. Patient was treated with IV dexamethasone 10mg BID with profound clinical improvement noted within 24 hours. Peripheral blood flow cytometry for blast characterization revealed chronic myelomonocytic leukemia vs. possible acute myelomonocytic leukemia.

IMPACT/DISCUSSION: Differentiation syndrome (DS) is known to be caused by the treatment of acute promyelocytic leukemia with all-trans retinoic acid or arsenic trioxide as induction therapy. Other drugs associated with DS include ivosidenib, enasidenib, and gilteritinib. Onset is typically days to weeks following induction therapy. It is a clinical diagnosis that is usually associated with respiratory distress, hypotension, kidney injury, pleural effusions/infiltrates/opacities on radiological studies, fevers, and/or weight gain where no clear cause could be determined. An elevated WBC count is commonly associated with initial presentation; however, it can also present with a normal WBC count. A profound response to IV steroids with the above clinical findings points to a diagnosis of DS.

Azacitidine is a chemotherapy drug commonly used to treat myelodysplastic syndrome. It can also be used to treat acute myeloid leukemia (AML). As with most chemotherapy agents, adverse effects include nausea, fatigue, pancytopenia, etc. To date, reported cases of DS from azacitidine are limited. One report has been found presenting a case of DS following treatment of azacitidine for AML.

CONCLUSION: This report presents a case of differentiation syndrome following induction therapy with azacitidine - a drug that is atypical to cause DS.

A DOUBLE TAKE ON THE DOTATE SCAN!

Shivani Sharma[1]; Vijayalakshmi Donthireddy[2]. [1]Internal Medicine, Henry Ford Hospital, Detroit, MI; [2]Hematology and Oncology, Henry Ford Hospital, Detroit, MI. (Control ID #3389982)

LEARNING OBJECTIVE #1: Diagnosis of neuroendocrine tumors (NET) by utilizing ^{68}Gallium DOTATE PET/CT scan.

LEARNING OBJECTIVE #2: Definition of splenosis and when to suspect it.

CASE: A 62-year-old male with medical history of traumatic spleen rupture twenty years back, presented to the Emergency Room with sudden onset abdominal pain, nausea and vomiting. Physical examination revealed left lower quadrant tenderness. Initial laboratory tests were within normal limits. Computed Tomography showed a 4* 5 mm proximal left ureteral stone. It also showed incidental findings of a lobulated 4*3*4 cm soft tissue mass within the mesenteric root and a 2.5* 1 cm pleural based nodule within the left lung base. Patient's symptoms were thought to be from ureteric colic. The soft tissue mass seen on the CT was concerning for a neuroendocrine tumor, so he had further workup. His serotonin level was elevated at 300 (56-244 ng/ml), Chromogranin A level was 1400 (0-160 ng/ml) and 24- hour urine HIAA was 19.7 (<10 mg/24 hr.). ^{68}Gallium DOTATE scan showed intense uptake in the mass within the root of mesentery and also in the pleural based lung nodule. He underwent small bowel resection and mesenteric lymphadenectomy. Pathology was consistent with a well differentiated neuroendocrine tumor. Since it is unusual to have pleural metastasis from small bowel carcinoid, a biopsy of the nodule was performed, which showed benign lymphoid tissue with small lymphocytes consistent with spleen.

IMPACT/DISCUSSION: ^{68}Gallium DOTATE is a somatostatin analogue that has high affinity for somatostatin receptor type 2. ^{68} Ga-DOTA-DPhe[1], Tyr[3]- octreotate (^{68} Ga-DOTATE) PET/CT scan is more accurate than conventional imaging like Octreoscan, PET scan in the diagnosis of neuroendocrine tumors. It can greatly impact management by directing patients to curative surgery by identifying a primary tumor site and directing patients with multiple metastasis to systemic therapy. Various physiologic and pathologic processes express somatostatin type 2 receptor resulting in false positive results. Most notable are pancreatic uncinate process, splenic tissue, osteoblastic and inflammatory processes. Ectopic autotransplantation of the splenic tissue after surgery or trauma is called splenosis. It is mostly an incidental finding on the imaging done for other purposes. Once the diagnosis of splenosis is made, no further intervention is required unless the patient is symptomatic.

CONCLUSION: Splenosis should be kept in mind for the patients with history of splenectomy or splenic rupture. This has management implications to prevent the patients from getting unnecessary workup and systemic therapy in cases of concomitant tumors. In our patient, since the biopsy from the pleural nodule showed splenic tissue, he did not receive systemic chemotherapy and is undergoing periodic surveillance imaging following his surgery.

ADULT STILL'S DISEASE: MACROPHAGE ACTIVATION SYNDROME SECONDARY TO MYCOPLASMA PNEUMONIAE

Devin Sullivan[1]; Maryah Mansoor[2]. [1]ChristianaCare Branch Campus, Philadelphia College of Osteopathic Medicine, Hockessin, DE; [2]Rheumatology, ChristianaCare, Newark, DE. (Control ID #3392407)

LEARNING OBJECTIVE #1: Diagnose Adult Still's disease (ASD) with macrophage activation syndrome (MAS)

LEARNING OBJECTIVE #2: Recognize Mycoplasma pneumoniae (M. pneumoniae) as a potential trigger for MAS

CASE: A 40-year-old male presented to the hospital with nausea, vomiting, diffuse abdominal pain, fever and chills for 2 days. He had arthralgias and a dry cough over the past week. Medical history included juvenile idiopathic arthritis (JIA) and GERD; he takes omeprazole and ibuprofen. He was febrile, hemodynamically stable, ill-appearing, with a blanchable, erythematous rash on his back and arms. He had micrognathia, mild abdominal tenderness, no hepatosplenomegaly, and restricted range of motion in bilateral joints. Labs showed leukocytosis, transaminitis, hypertriglyceridemia, elevated ferritin and CRP. Chest X-ray, RUQ ultrasound, and portal system doppler were unremarkable. Abdominal and pelvic contrast CT revealed colitis and degenerative joint changes. Urinalysis, respiratory viral panel, hepatitis panel, stool enteric pathogens and blood culture were negative. ANA, RF, CCP, ASMA, AMA, ceruloplasmin, hemochromatosis HFE gene, and alpha 1 antitrypsin tests were unremarkable. EBV, CMV, tick-borne viruses, hantavirus, fungal and tuberculosis tests were negative. However, M. pneumoniae IgG was positive and IgM reactive.

Broad spectrum antibiotics upon admission were narrowed to doxycycline. Infectious disease, gastroenterology, rheumatology and hematology were consulted and the diagnosis of ASD was made. On day 5, he developed leukopenia, thrombocytopenia, hemolytic anemia, worsening ferritinemia and transaminitis; meeting criteria for MAS. He was started on high dose oral steroids and Anakinra; labs and symptoms significantly improved. He was stable for discharge by day 8 with outpatient rheumatology follow-up.

IMPACT/DISCUSSION: ASD is characterized by daily fevers, arthralgias, rash, leukocytosis, elevated ferritin and may include cardiopulmonary involvement, liver disease, abdominal pain and nausea. As a diagnosis of exclusion, alternative systemic rheumatologic diseases, malignancy, infection, and drug reactions must be ruled out. MAS, a form of hemophagocytic lymphohistiocytosis, is a severe complication that occurs in a minority of JIA and ASD patients. Elevation of serum ferritin and CRP, anemia, leukopenia, thrombocytopenia, transaminitis and hypertriglyceridemia in the setting of ASD should raise concern for MAS. Typically seen in pediatrics, MAS rarely occurs in adults, but diagnosis and prompt treatment is critical as it can be life threatening. A common cause of MAS is infection; most often viral such as EBV.

Bacterial infections, specifically M. pneumoniae, have been reported in childhood MAS and in one adult case report.

CONCLUSION: In a patient with a history of JIA, consider the development of ASD and MAS. As a diagnosis of exclusion, the differential for ASD should be broad. The workup of infectious etiologies should include bacteria like M. pneumoniae, recognizing that this infection can trigger MAS in ASD.

ADVERSE HEMATOLOGICAL REACTIONS ASSOCIATED WITH DAPSONE USE

Murali K. Duggirala. Internal Medicine, Mayo Clinic, Rochester, MN. (Control ID #3374977)

LEARNING OBJECTIVE #1: Recognize adverse hematological reactions associated with dapsone use.

LEARNING OBJECTIVE #2: Blood test monitoring for patients taking dapsone.

CASE: A 78-year-old woman presented for evaluation of a pruritic skin rash. Her past health history included hypertension, hysterectomy for fibroid uterus and mild mitral valve regurgitation. Skin rash developed 3 years ago and she had tried various over-the-counter remedies without benefit. Subsequently she was prescribed triamcinolone cream and oral non-sedating antihistamines. After a skin biopsy by the local dermatologist, she was diagnosed with IgA bullous dermatosis. She was started on 25 mg of dapsone initially and the dosage was increased to 6-7 tablets daily. On routine laboratory testing, she was found to have hemoglobin of 12 with normal white count and platelet count. MCV was elevated to110.7 with normal B-12 and folic acid levels. Electrolytes, liver function tests, serum creatinine were also normal. Further testing showed an elevated reticulocyte count (6%) and absent serum haptoglobin. Peripheral smear demonstrated bite cells. Urinalysis was normal.

IMPACT/DISCUSSION: Our patient had a significantly elevated MCV with normal B12 and folic acid levels. Elevated reticulocyte count, absent serum haptoglobin and the presence of bite cells in the peripheral smear suggested hemolysis. This was felt to be secondary to dapsone related oxidative stress. Dapsone has been used to treat various forms dermatitis, severe apthous ulcers, prophylaxis and treatment pneumocystis pneumonia and toxoplasma. Adverse hematological reactions are not uncommon from this treatment. They include reticulocyte increase (2% to 12%), hemolysis (>10%; dose related; seen in patients with and without G6PD deficiency), hemoglobin decrease (>10%; 1-2 g/dL), methemoglobinemia (>10%), shortened red cell life span (>10%), Agranulocytosis, leukopenia can also occur. It is important to recognize the side effects relating to dapsone use and institute monitoring. It is suggested that CBC and reticulocyte counts every 2 to 3 days during the first 2 to 3 weeks, monthly for the first 3 months, and then every 6 months.

She was recommended a visit the dermatologist to discuss alternative treatments for her skin condition. G6PD testing was not done because it may not be reliable in the acute setting. She is recommended to have this test done after resolution of hemolysis.

CONCLUSION: It is important to recognize hematological side effects relating to dapsone use and institute monitoring.

A FACE SHIFTED: AN UNCOMMON PRESENTATION OF A RARE CARCINOMA

Farhana Chowdhury[2]; Jill Allenbaugh[1,2]. [1]Medicine, Lewis Katz School of Medicine at Temple University, Philadelphia, PA; [2]Internal Medicine, Temple University Hospital, Philadelphia, PA. (Control ID #3386012)

LEARNING OBJECTIVE #1: Cite the full differential diagnosis of persistent ear pain

LEARNING OBJECTIVE #2: Recognize discordant data as a reason for reassessment of a "common diagnosis"

CASE: 64-year-old female with a history of heart failure, diabetes mellitus, CAD s/p CABG, HTN and HLD presented as a new patient to establish care. Her only complaint was 2 weeks of left ear pain. On the initial visit, physical exam was remarkable for pre-auricular tenderness to palpation, erythema and edema around the ear. She was treated for

superficial inflammation with cold compresses and ibuprofen for pain. However, over the next few weeks she continued to experience left ear pain despite improvement in the swelling. CT temporal bone revealed an effusion with concern for chronic mastoiditis and a referral to ENT was made. A month later, she was prescribed Clindamycin for presumed parotitis by ENT. At a follow up visit 1 month later with her PCP, she noted new left sided facial paralysis and a "shifted" face which she stated had been worsening over time. A repeat CT of her head and neck revealed a necrotic mass of the parotid gland with lymph node involved highly suspicious for malignancy. Multiple subspecialists, including ENT, plastic surgery, cardiology, and oncology weighed the risks and benefits of treatment, and the patient began chemotherapy with Pembrolizumab rather than pursuing surgery. Subsequent scans gave a final diagnosis of primary squamous cell carcinoma of the salivary gland with metastases to the lymph nodes and liver. Over the course of many months, the left facial paralysis started to improve and the patient was relieved that her face was no longer shifted to the right, and her multidisciplinary team was working toward a positive outcome.

IMPACT/DISCUSSION: This case gives multiple learning points from both a medical knowledge and multi-disciplinary approach standpoint. This case involved multiple physicians, both GIM and subspecialists- who anchored on her seemingly simple outpatient presentation, and treated her for cellulitis, otitis media, and parotitis over multiple months before clear facial paralysis forced a reexamination of the differential and additional imaging, which lead to the diagnosis of metastatic primary squamous cell carcinoma of the salivary gland. This case is an example of an almost missed- "zebra"- case that can occur in medicine. While it is always important to treat common things first, acute reassessment with discordant data is necessary to avoid anchoring bias and appropriately diagnose and treat patients.

CONCLUSION: Salivary gland carcinoma is a rare carcinoma that occurs usually in the elderly with history of radiation exposure. The most common presenting symptoms include a swelling in the jaw/mouth, or numbness of the face, but can present in a variety of ways, and should be considered when persistent facial pain and swelling do not improve over time. This case can alert internists to expand their differential when treating common complaints that worsen despite appropriate therapy.

A FATAL CASE OF HEPATIC KAPOSI SARCOMA IN AN UNTREATED HIV PATIENT

Amna Aijaz, Shamit Patel. Internal Medicine, Mount Sinai Beth Israel, New York, NY. (Control ID #3361892)

LEARNING OBJECTIVE #1:

Hepatic KS is more commonly asymptomatic but it can have lethal complications. It must be a consideration in patients with uncontrolled HIV/AIDs.

LEARNING OBJECTIVE #2: Hepatic KS has specific lesions on imaging

CASE: A 30 year old man from Thailand with untreated HIV (diagnosed 7 years prior) presented with fever, night sweats, weight loss, fatigue, cough and epigastric pain. On examination, he had severe wasting, with cervical and inguinal lymphadenopathy. Labs on presentation showed Hb 6.3, ALP 581, AST 65, ALT 53 and a normal bilirubin. He was found to have a high viral load, a CD4+ cell count of 15/mm3 and pancytopenia. Hepatitis viral panel was negative. CT scan on admission showed numerous pulmonary nodules, retroperitoneal lymphadenopathy, and hypodense liver lesions. Antiretroviral therapy was started and a cervical lymph node biopsy was done which showed Kaposi Sarcoma (KS). AFB cultures done grew Mycobacterium Avium Intracellulare and treatment was initiated. He developed progressive jaundice noted initially on day 10 which worsened up to a TB of 38, DB 30, ALP 913, AST 123, and ALT 91. A biliary drain placement with liver biopsy was done which showed lesions due to KS. However, the patient's condition kept deteriorating with a GI bleed (likely variceal from portal hypertension) and worsening kidney function, suspected to be due to HRS, culminating in the need for hemodialysis which was not tolerated due to hemodynamic instability. Chemotherapy for Kaposi Sarcoma could not be initiated due to worsening hepatic and renal dysfunction. The patient's mental status declined due to hepatic/uremic encephalopathy and multi-organ failure leading to his death on inpatient day 31.

IMPACT/DISCUSSION: KS is seen in 35% of AIDS patients, and generally occurs at CD4 <150 cells/mm. Hepatic KS is mostly found incidentally and less commonly with clinical manifestations of liver disease. Autopsies have shown 35% of KS patients with hepatic KS lesions. Liver US shows nonhomogeneous lesions with multiple hyperechoic periportal bands and nodules. CT generally reveals numerous small liver nodules, often in the periportal area with portal and hilar contrast enhancement. On MRI, these appear as hypointense T1-weighted and hyperintense T2-weighted nodules. This has been seen in the few cases of hepatic KS reported in literature and were also seen in our patient. Pulmonary involvement in KS occurs in 20% of the patients and is the most life-threatening form of the disease. HRS is a much-dreaded outcome of liver failure. It has a poor prognosis with an expected mortality within weeks to months and is generally seen among decompensated cirrhotics. However, there has been one case in literature where a liver mass (suspected to be HCC) caused portal hypertension and HRS.

CONCLUSION: Disseminated KS should be considered early in the differential of patients with uncontrolled AIDS with jaundice and liver lesions since hepatopathy can progress rapidly and if tissue diagnosis and treatment is delayed, the condition may prove fatal.

A FROST FROM THE TROPICS

Katherine A. Reifler[1]; Eleni Pilitsi[2]. [1]Internal Medicine, Boston Medical Center, Boston, MA; [2]Boston University, Boston, MA. (Control ID #3375040)

LEARNING OBJECTIVE #1: Recognize cultural aspects of caring for patients who practice Vodou

LEARNING OBJECTIVE #2: Consider the cost borne by an individual to engage in hemodialysis

CASE: A 61-year-old Haitian-Creole speaking male construction worker with no past medical history presented with shortness of breath, leg swelling and dyspnea for two months. He had moved to the U.S. to earn money for his Haitian family. Exam revealed pelvic dullness to percussion, bilateral lower extremity edema and white facial crusting consistent with uremic frost. Bladder straight catheterization removed two liters of urine. He was admitted to the ICU with acute renal failure (BUN/Cr 125/28, potassium 7.2, pH 7.2) in the setting of urinary retention. He received hemodialysis (HD) for three days. On the fourth day of hospitalization his labs remained consistent with renal failure requiring long-term HD and he appeared became agitated. He felt better overall and wanted to return to work. The patient explained through an interpreter that he was upset because his nurse had woken him too early and so his spirit wouldn't return to him. Our interpreter clarified this as a belief based in his practice of Vodou.

IMPACT/DISCUSSION: Caring for our patient in a culturally appropriate way required understanding his reasons for delay and in seeking and accepting our care recommendations. He presented with uremic frost, a rare (0.8-3%) sign of advanced uremia usually associated with BUN levels above 200 mg/dl. He delayed due to cost concerns and his spiritual framework for health.

Even when covered by health insurance, dialysis has significant financial burdens. Assuming our patient takes two or three weekdays off of

work for HD, his income would be reduced by 30-40%. Peritoneal dialysis and nocturnal HD are more cost-effective compared to center-based HD. To travel to Haiti our patient would also face complex arrangements for any dialysis method.

Much of the published literature on caring for Vodouoists comes from the HIV/AIDS epidemic. In the mid-1990's, some Haitian Vodouoists believed spirits protected them from HIV/AIDS and the epidemic was a myth introduced by Western medicine. They demonstrated a distrust of medicine seen in many faith communities globally, and influenced by the cultural repercussions of Haitian colonization and slavery. Our patient sought care from a Vodou priest first, perhaps influenced by this historical mistrust.

He believed that his spirit left him every evening and returned in the morning, and that ill spirits or ignoring his spirit caused sickness. Dialysis did not address his spiritual framework, and early wakening challenged it. Beyond language interpretation, our patient's recovery might have been aided by concurrent cultural interpretation and spiritual consultation.

CONCLUSION: Uremic frost is a rare manifestation of renal failure and a marker of our patient's reluctance to seek medical care. Our treatments and interventions were financially inconvenient and failed to address his spiritual framework of health.

A FUZZY DIAGNOSIS

Kevin D. He[1]; Ken He[2]; Paul B. Cornia[3]. [1]Sidney Kimmel Medical College, Thomas Jefferson University, Philadelphia, PA; [2]Medicine, VA Pittsburgh HCS & University of Pittsburgh SOM, Sewickley, PA; [3]Medicine, VA Puget Sound HCS & University of Washington SOM, Seattle, WA. (Control ID #3391447)

LEARNING OBJECTIVE #1: Recognize vision change as a symptom of metabolic disturbance

LEARNING OBJECTIVE #2: Identify the rapid progression of latent autoimmune diabetes

CASE: A 33-year-old white man presented to clinic for a well exam. He was obese with history of episodic elevated blood pressure. He reported 6 months of new onset, intermittent, self-resolving episodes of binocular blurry vision lasting 1 hour without headache or systemic symptoms. He denied polyuria, polydipsia, polyphagia or paresthesia. He used alcohol occasionally. He had a family history of premature cardiovascular disease and an aunt with diabetes. He was well appearing, temperature 98.2°F, HR 66, RR 20, BP 120/90. Cardiopulmonary, skin and neurological exams were normal. Labs one year ago: normal metabolic panel, glucose 86 mg/dL, LDL 121 mg/dL and total cholesterol 191 mg/dL. Ophthalmologic exam showed normal visual acuity, lens, and fundus. Head and neck imaging did not reveal neurological or vascular abnormalities.

One month later, he presented to the ED with worsening blurry vision and new dyspnea. Visual acuity and cardiopulmonary evaluation were normal. However, glucose of 323 mg/dL triggered additional labs revealing HbA1C of 9.1%. Metformin and glipizide were started. Two months later, blurry vision and HbA1C (7.8%) had improved. Elevated anti-GAD65 antibodies (222 U/mL, range 0-5) with adequate beta cell function (serum insulin 108 IU/mL, range 3-25 and C-peptide 9 ng/mL, range 1-4 during glucose challenge) led to the diagnosis of latent autoimmune diabetes in adults (LADA).

IMPACT/DISCUSSION: We describe a case of LADA presenting with isolated episodic blurry vision. Episodic blurry vision as the sole symptom of LADA is rare. Although chronic diabetic eye disease encompassing retinopathy, macular edema, cataracts and glaucoma is well recognized, reversible changes localizing to the lens is less so. Transient increases in the aqueous humor glucose content and its enzymatic conversion to sorbitol in the lens increases osmotic pressure within the lens fibers. Resultant swelling of the lens causes acute myopic shifts and loss of refractive power leading to blurred vision. Patients with LADA may progress to severe hyperglycemia faster than type 2 diabetes due to coexistence of a type 2 diabetes phenotype and anti-islet cell antibody positivity; the prevalence of autoantibodies in type 2 phenotypes may be upwards of 10%. This results in earlier insulin dependency, but insulin initiation is often delayed due to misdiagnosis as type 2 diabetes. Episodic blurry vision in the absence of other symptoms should raise suspicion for a metabolic process. Moreover, knowledge of diabetic phenotypes may prompt earlier glucose testing, as well as autoantibodies in the appropriate clinical context, potentially obviating more extensive workups.

CONCLUSION: Isolated episodic blurry vision should prompt consideration for transient hyperglycemia. More rapid progression in apparent type 2 diabetes should prompt evaluation for autoimmune-induced diabetes, such as LADA.

A HAIRY SITUATION: AN UNUSUAL CAUSE OF HIRSUTISM

Stephanie L. Grach, Dana Erickson, Ericka Tung. Mayo Clinic, Rochester, MN. (Control ID #3355476)

LEARNING OBJECTIVE #1: Describe the workup of hirsutism in a female patient

LEARNING OBJECTIVE #2: Differentiate between pathologies that can lead to hirsutism

CASE: A 51 yo cisgender female with history of lupus and left 1.2cm adrenal adenoma presented to clinic with new facial hair growth. She did not report acne, voice changes, baldness, or hair-thinning. She had been amenorrheic since IUD removal 7 months prior. Dark, coarse hair above the lip as well as soft hair in the distribution of a beard was noted.

Total testosterone was elevated at 323 ng/dL [ref: 8-60]. Androstenedione was elevated at 331 ng/dL [ref: 30-200] and 17-hydroxprogesterone also at 466 ng/dL [ref: <80 follicular, <285 luteal, or <51 postmenopausal]. Dehydroepiandrosterone Sulfate (DHEAS) was low at 9.6 mcg/dL [ref: 27-240]. Transabdominal and transvaginal ultrasounds demonstrated normal ovaries. CT-Abdomen showed a stable 1.2cm left adrenal adenoma. MR-Pelvis was ordered for reevaluation of an ovarian source, revealing enhancing hypervascular lesions of the ovaries bilaterally, 1.4cm on the right and 0.9cm on the left.

Given new ovarian findings and stability of the adrenal mass, the presentation was felt to be secondary to one or both of the ovarian lesions. Bilateral salpingooophorectomy was performed. Pathology revealed nodular stromal hyperthecosis of the left ovary and a right 1.5cm steroid cell tumor. Repeat laboratory tests 3 weeks later showed complete normalization of testosterone. The hirsutism was resolved upon return to the clinic.

IMPACT/DISCUSSION: It is essential for the internist to be familiar with the key elements of history, examination, and diagnostic workup of hirsutism. Polycystic ovarian syndrome is the most common cause of hirsutism in premenopausal women. Ovarian hyperthecosis, the presence of nests of luteinized thecal cells in the ovarian stroma, is common in peri- and post-menopausal women. Virilizing ovarian tumors can present similarly to ovarian hyperthecosis. With rapid onset of symptoms, significant testosterone elevations (>150 ng/dL) are more suggestive of neoplastic etiology, ovarian or adrenal. In such cases, imaging with pelvic US is indicated. A technique in our workup that has been infrequently utilized is use of pelvic MRI following a negative ultrasound. Data are currently limited but encouraging regarding MRI in identification of hormone-secreting ovarian tumors, suggesting high sensitivities; this case supports the potential for evaluations of hyperandrogenism. DHEAS may help differentiate out adrenal pathology. In this case, DHEAS was low and the adrenal tumor stable from prior imaging, making an adrenal source

less likely. Our patient was found to have two potential ovarian causes; however, given the acute development of hirsutism, the primary cause of her symptoms was likely the right-sided steroid cell ovarian tumor.

CONCLUSION: Hirsutism in women is typically a sign of excess androgen from diverse etiologies. Initial workup including morning testosterone, DHEAS, and pelvic US can guide diagnosis and management.

A HANDY CLUE IN DIAGNOSIS: MALIGNANT BRACHIAL PLEXOPATHY AS A PRESENTATION OF RECURRENT DUCTAL BREAST CARCINOMA

Channing G. Brown[2]; Starr Steinhilber[1]. [1]Internal Medicine, University of Alabama at Birmingham, Birmingham, AL; [2]Internal Medicine/Pediatrics, University of Alabama at Birmingham, Birmingham, AL. (Control ID #3376009)

LEARNING OBJECTIVE #1: Recognize the presentation of brachial plexopathy (BP) and identify an approach to the diagnosis of its cause.

LEARNING OBJECTIVE #2: Maintain a high suspicion to pursue diagnostic workup for malignancy when the diagnosis of BP is identified.

CASE: A 65 year-old female with remote history of stage III ER/PR + ductal carcinoma (DC) of the right (R) breast, peripheral neuropathy, and type 2 diabetes mellitus presented with six months of progressive neuropathic pain in her R hand and wrist. She noted redness and occasional purple discoloration of her hand. NSAIDs, acetaminophen, and gabapentin provided no relief. She denied any fullness in her axilla but noted "knots" in her R chest wall. She had a history of lymphedema in her R upper extremity (UE), secondary to axillary lymph node dissection. Use of a compression sleeve provided no relief. Her DC was treated with lumpectomy and radiation, followed by hormonal therapy. Mammogram was negative three months prior.

On exam vitals were normal. RUE Non-pitting edema and hyperemia were noted. She had hyperesthesia on the dorsal and palmar surface of the R hand. Sensation and motor function were intact in bilateral UEs. Strength exam was limited by pain with range of motion in R wrist and fingers. UE pulses and capillary refill were normal bilaterally. Breast exam revealed nontender nodules in the upper outer quadrant of the R breast and R axillary lymphadenopathy (LAD).

Doppler ultrasound was negative for deep venous thrombosis, but showed axillary and supraclavicular LAD. A contrasted CT chest was performed, which showed R axillary and supraclavicular LAD confluent with an irregular soft tissue mass invading the R axillary artery. Biopsy of the mass was performed confirming ER/PR+ DC. Oncology was consulted and prescribed palliative chemotherapy in the setting of non-resectable, locally recurrent disease. Following initiation of treatment, the patient had improvement of her pain at six month follow-up.

IMPACT/DISCUSSION: BP is an uncommon neurologic complication in which the brachial plexus is compromised by trauma, ischemia, radiation damage, or direct compression. It is cited to have an incidence of 0.4% in patients with a history of malignancy (most commonly breast and lung cancer) and 2-5% of patients who have undergone radiation therapy. The diagnosis of BP should be suspected in patients with unilateral progressive neuropathic UE pain with a history of malignancy or radiation. Presenting symptoms include vague, neuropathic pain while late findings include sensory loss, weakness, atrophy, and Horner's Syndrome. The diagnostic workup should include nerve conduction studies/electromyography. Brachial plexus ultrasound and chest CT/MRI are recommended in patients with a history of malignancy to evaluate for a compressive mass.

CONCLUSION: - A high suspicion should be maintained to pursue advanced imaging in patients with a history of malignancy and new neurologic complaints.

- Negative surveillance imaging may not be sufficient to rule out recurrence of malignancy.

A HEAD-SCRATCHER WITHOUT AN ITCH: PRESUMPTIVE PRIMARY BILIARY CHOLANGITIS IN AN ELDERLY MAN

Karl Greenblatt[1,2]; Juan N. Lessing[3,2]; Ethan U. Cumbler[4,2]. [1]Internal Medicine Residency Training Program, University of Colorado School of Medicine, Denver, CO; [2]University of Colorado Hospital, Denver, CO; [3]Internal Medicine/Hospital Medicine Group, University of Colorado, Denver, CO; [4]Medicine, University of Colorado School of Medicine, Aurora, CO. (Control ID #3389622)

LEARNING OBJECTIVE #1: Develop a rational approach to the evaluation of liver disease of unknown etiology.

LEARNING OBJECTIVE #2: Diagnose primary biliary cholangitis (PBC) according to clinical and biochemical criteria, and understand how shared decision-making may impact consensus recommendations for obtaining liver biopsy.

CASE: A 73-year-old homeless man with no prior medical diagnoses presented with acute abdominal pain, diarrhea, and hematochezia. He reported unintentional weight loss but denied fatigue or itching. He took no prescription medications or supplements and denied alcohol or injection drug use. Physical exam revealed lean habitus and ascites, without jaundice, scleral icterus, asterixis, or other significant findings. Initial imaging revealed ascites, esophageal and gastric varices, and a cirrhotic-appearing liver. The portal veins were patent. Liver function tests, including alkaline phosphatase (ALP), were normal other than mildly low protein and albumin. Coagulation studies and lipid panel were normal. The patient was diagnosed with decompensated cirrhosis and an etiology was pursued. Viral hepatitis panel, HSV, HIV, iron studies, alpha-1 antitrypsin, and ceruloplasmin were unrevealing. An expanded autoimmune workup was sent and returned positive only for anti-mitochondrial antibody (AMA) at a high titer of 1:324. Given the high specificity of this serologic test, he was presumptively diagnosed with primary biliary cholangitis (PBC).

IMPACT/DISCUSSION: Liver disease is commonly encountered by general internists. Usually, history and basic tests reveal an etiology. In this case, we first excluded common causes, then rationally evaluated for increasingly rare conditions.

PBC is an autoimmune disease leading to progressive destruction of intrahepatic biliary ducts. Several features of our patient's presentation are atypical, namely his demographics (elderly, male), lack of fatigue or jaundice, and normal ALP. A positive AMA is 98% specific for PBC, though this remains difficult to interpret in the setting of low pre-test probability. Reports of new diagnoses of PBC in males of this age are uncommon [PMID: 20016440]. In the absence of elevated ALP, definitive diagnosis of PBC requires liver biopsy. However, this was deferred after shared decision-making, as the results would not significantly alter management. Treatment with urosdeoxycholic acid was not pursued; benefit was felt unlikely given the patient's already advanced liver disease.

CONCLUSION: AMA is a highly sensitive and specific serologic test for PBC. Thus, liver biopsy is not always required for diagnosis [PMID: 15017500].

When a diagnosis is uncertain, a rational approach is preferred over "shotgun" testing. Shared decision- making is advised when diagnostic tests will not alter management.

A HEEL OF A PRESENTATION OF CRYPTOCOCCUS

Alana Siev[1]; Mohammad H. Mustehsan[1]; Deepika Slawek[2]. [1]Internal Medicine, Montefiore, New York, NY; [2]Medicine, Albert Einstein College of Medicine, Bronx, NY. (Control ID #3390608)

LEARNING OBJECTIVE #1: Identify the differential of heel pain

LEARNING OBJECTIVE #2: Recognize Cryptococcus as an etiology of isolated heel osteomyelitis

CASE: A 42 year old male with HIV on antiretrovirals (ARV), an undetectable viral load (VL), and CD4 of 364 cells/mm^3 (28.31%) presented with a 3-month history of left heel pain with a 60-pound weight loss, and no rashes, fevers, or chills. He was treated conservatively for suspected plantar fasciitis. Due to lack of improvement he received a local corticosteroid injection. Interval worsening of symptoms and development of a firm mass at the injection site prompted an outpatient MRI revealing a posterior calcaneus mass extending into the surrounding soft tissue concerning for neoplasm. An open biopsy revealed lymphocytes, inflamed granulation tissue with necrosis, and granulomatous inflammation with multinucleate giant cells. Fungal culture grew budding yeast. Serum cryptococcal Ag was positive with a titer of 1:320. CT chest and CSF analysis were negative for involvement. The patient was treated for cryptococcal osteomyelitis with two-weeks of amphotericin B and flucytosine, to be followed by treatment with fluconazole guided by clinical response and cryptococcal titers.

IMPACT/DISCUSSION: Heel pain is common and the differential includes trauma, infection, inflammation, neoplasm, metabolic, and neurologic causes. Patients who are immunosuppressed are at higher risk for infection– particularly opportunistic infections that can occur in patients who have HIV, even with an undetectable VL. Initially, plantar fasciitis, bone spur, nerve entrapment, and heel pad syndrome were the most likely causes for the patient's symptoms. Enlarging mass and worsening pain following corticosteroid injection increased the likelihood of an alternative diagnosis. Imaging and biopsy of the mass were consistent with cryptococcal osteomyelitis. Cryptococcus is the most prevalent and fatal fungal disease worldwide. It became recognized as a major health threat in persons living with HIV in the 1980s during the peak of the AIDS epidemic. Cryptococcus infections commonly present as meningitis or pulmonary disease with significant mortality and morbidity. Bony involvement has an estimated prevalence of only 5% and is associated with disseminated disease. Isolated cryptococcal osteomyelitis is exceedingly rare. It is unclear if osteomyelitis was present prior to the corticosteroid injection or was an iatrogenic complication. Corticosteroids can cause local immunosuppression, which could lead to reactivation of a latent infection. Cryptococcus has a long latency period in host cells and it is theorized that most cases of Cryptococcus represent reactivation of asymptomatic infection, which is possible in this case.

CONCLUSION: This case demonstrates the possibility of localized opportunistic infections in patients with HIV, even with CD4 counts greater than 250 cells/mm^3 and undetectable VL. Clinicians should remain vigilant when encountering seemingly innocuous symptoms in people living with HIV.

A HICCUP IN THE WORKUP OF ALTERED MENTAL STATUS

Laura Hill, Carly Kuehn. Internal Medicine, University of Iowa, Iowa City, IA. (Control ID #3390743)

LEARNING OBJECTIVE #1: Recognize the clinical significance of persistent hiccups.

LEARNING OBJECTIVE #2: Generate a differential diagnosis for persistent hiccups.

CASE: Mr. LJ is an 80 year-old man with past medical history significant for recently diagnosed chronic lymphocytic leukemia (CLL) who presented with subacute onset of generalized weakness and confusion. On admission the patient was found to be febrile to 38C and hemodynamically stable. He was oriented to self only and unable to identify family members. Four weeks prior to presentation the patient was diagnosed with CLL following prolonged upper respiratory illness. He received treatment with Imbruvica for three days, but this was discontinued due to worsening confusion. Three weeks ago, Mr. LJ was still working as a farmer and his family denied prior medical conditions or medications. There were no focal deficits, but he was unable to stand due to generalized weakness. Frequent hiccups were also noted. The WBC was 204 (lymphocytic predominance) and potassium 5.5. CT head, chest X-ray, and urinalysis results were unremarkable. Flow cytometry consistent with CLL and did not demonstrate evidence of transformation to higher grade of disease.

Due to continued fevers the patient was started on vancomycin and cefepime on hospital day 2. However, he showed no improvement and urine and blood cultures remained negative. During this time patient continued to have persistent hiccups.

On hospital day 4 patient underwent lumbar puncture (LP) that demonstrated positive Cryptococcal antigen and fungal culture. Treatment was initiated with Amphotericin B and Flucytosine. After three days of treatment hiccups resolved and patient became more alert. After six weeks of treatment repeat LP showed positive Cryptococcal antigen with negative fungal culture. After discharge Mr. LJ continued to show improvement in cognition, energy, and strength.

IMPACT/DISCUSSION: Patients with CLL are at risk for opportunistic infections and general internists often care for patients with CLL. In this case, hiccups raised clinical suspicion for meningitis. The etiology of persistent hiccups (lasting >48 hours) can be divided into central (ex. stroke, meningitis, mass lesions) and peripheral (ex. diaphragmatic irritation from surgery or gallbladder pathology) etiology. Workup is driven by symptoms, so by recognizing common central and peripheral causes and applying them to individual scenarios is crucial. In this case altered mental status with immunosuppression led us to suspect meningitis, and Cryptococcal meningitis specifically can elevate intracranial pressure, which may have contributed as well. Recognition of persistent hiccups can serve as an important diagnostic clue.

CONCLUSION: Persistent hiccups should be investigated

Use patient characteristics to guide workup directed at uncovering central and peripheral causes of hiccups

A KNEE'D-TO-KNOW DIAGNOSIS: RISK FACTORS FOR PSEUDOMONAS JOINT INFECTION

Nicholas Drain[1]; Andrew Lutz[2]; Michael G. Simonson[1,2]. [1]University of Pittsburgh School of Medicine, Pittsburgh, PA; [2]UPMC Presbyterian-Shadyside, Pittsburgh, PA. (Control ID #3363992)

LEARNING OBJECTIVE #1: Recognize injection drug use as a risk factor for Pseudomonas septic arthritis

LEARNING OBJECTIVE #2: Appreciate the limited sensitivity of synovial fluid WBC count in diagnosing septic arthritis

CASE: A 61-year-old male with a history of atrial fibrillation, osteoarthritis, and recent injection drug use presented with concern for heat exhaustion after one day of confusion and fever. He was febrile to 39.5C with blood pressure 106/56. On examination, a large effusion with associated warmth, erythema, and pain with passive movement was noted at the right knee joint. Labs were notable for WBC 13.1, ESR 39, and CRP 6.1. Knee radiographs revealed tricompartmental osteoarthritis with a large effusion. Arthrocentesis was performed and empiric treatment with vancomycin was initiated. Synovial fluid analysis revealed 16,000 WBCs (97% neutrophils) with a negative gram stain and no crystals. Synovial fluid cultures grew Pseudomonas aeruginosa, so piperacillin-tazobactam was added to broaden coverage prior to operative washout of the joint. Post-operatively, antibiotics were narrowed to ciprofloxacin based on sensitivities.

IMPACT/DISCUSSION: Septic arthritis is a commonly encountered diagnosis with significant associated morbidity. Diagnosis is based on clinical presentation, synovial fluid analysis and synovial fluid culture data. In immunocompetent individuals, septic arthritis often presents with a synovial WBC count above 50,000cells/mm. Despite this, many studies have shown that using a diagnostic cutoff of 50,000cells/ mm lacks the

sensitivity to rule out septic arthritis and may miss as many as 30% of infections. Lower cutoffs have higher sensitivity but lower specificity. There is some evidence showing WBC differential (%neutrophils greater than 80 or 90) may be a more sensitive predictor of adult non-prosthetic joint infection than the absolute WBC count. Except in cases of direct penetrating trauma, infections are usually monomicrobial with Staphylococcus aureus being the most common isolated pathogen. Gram negative bacteria are uncommon; risk factors for such infections include immunosuppression, injection drug use, and direct trauma. A history of injection drug use should raise suspicion for gram-negative infection and inclusion of an anti-Pseudomonal agent in empiric antibiotic coverage.

CONCLUSION: This case emphasizes both the importance of obtaining a relevant patient history and the limitations of common diagnostic testing. Identifying risk factors for gram negative infection is needed to optimize empiric antibiotic coverage. In the context of injection drug use and clinical symptoms of septic arthritis, empiric treatment should consist of both gram-positive and gram-negative coverage. Importantly, synovial fluid WBC count less than 50,000 cells/mm does not exclude infection. Other synovial fluid studies such as glucose, lactate, and WBC differential (%neutrophils) may be helpful and clinicians should consider all available diagnostic information when considering the diagnosis of septic arthritis.

A LEGAL GUARDIAN'S REFUSAL OF LONG-ACTING REVERSIBLE CONTRACEPTION FOR A SEXUALLY ACTIVE ADULT WITH AN INTELLECTUAL DISABILITY

Samuel G. Ruchman[1]; Alexandra Dembar[1]; Lily Chu[1]; Luis E. Seija[2]; Alexis Tchaconas[1]; Brittany Glassberg[3]; Joseph Truglio[4]. [1]Med-Peds, Icahn School of Medicine at Mount Sinai, New York, NY; [2]Medicine, Icahn School of Medicine at Mount Sinai, New York, TX; [3]School of Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; [4]Internal Medicine, Pediatrics and Medical Education, Icahn School of Medicine at Mount Sinai, Maplewood, NJ. (Control ID #3392169)

LEARNING OBJECTIVE #1: Distinguish between court-assessed competency and capacity for individual decisions for adults with intellectual or developmental disabilities (IDD).

LEARNING OBJECTIVE #2: Describe the approach when a legal guardian disagrees with an incompetent patient who demonstrates capacity for a specific decision.

CASE: MC is a 24-year-old nulliparous cisgender woman with a history of well-controlled migraine headaches without aura, ventriculoatrial shunt, and intellectual disability who presented to the outpatient clinic for a Pap smear. She reported sexual activity with one cisgender man and one cisgender woman, using condoms inconsistently with her male partner. After counseling on contraceptive options, the patient was referred for insertion of an etonogestrel-releasing implant as long-acting reversible contraception (LARC), requesting confidentiality on arrival at the clinic. She denied having unprotected sex with her male partner since her last menstrual period, and a urine pregnancy test was negative. The patient appeared to have capacity for this decision: she expressed a clear choice for LARC; showed understanding of its benefits, risks, and alternatives; and provided a rationale consistent with her values e.g., demonstrated by her attempted use of barrier protection. MC's mother, her court-appointed guardian, refused LARC insertion on her behalf. Follow up was scheduled with a social worker for additional assessment of capacity.

IMPACT/DISCUSSION: Courts determine competency for global decision making, accounting for individuals' level of cognitive impairment, and appoint guardians commensurately. Although MC is legally incompetent to make significant decisions in general, she demonstrated capacity to make a specific decision at a given time. Clinicians should assess capacity, and in the event of disagreement between patient and caregiver, attempt to build consensus, focusing on the alignment of goals. Taking into account the likelihood and immediacy of negative consequences of non-intervention, clinicians should offer less invasive options (e.g., injectable or emergency contraception) while pursuing caretaker buy-in, which is a practical necessity for safe use of LARC in patients with IDD. Clinicians should also seek ethics and legal consultation, as laws and exceptions vary by state. A common legal standard is that guardians' decisions should accord with the reasonable best interests of their wards; however, a ward's stated or presumed preferences may help shape what is in their best interests. Reproductive health conversations are also an opportunity for clinicians to counsel patients with IDD and their caretakers in the context of limited sex education, disparate access to LARC, grey areas of sexual consent, and high rates of sexual abuse.

CONCLUSION: Legally incompetent patients with IDD may still demonstrate capacity for specific reproductive decisions. Clinicians should counsel patients and caretakers on multiple aspects of preventative sexual health.

A LIVER FOR A LIVER: BARRIERS TO TRANSPLANT FOR UNAUTHORIZED IMMIGRANTS

Lauren A. Kelly[1]; Zev A. Weinberg[2]; Brian P. Lee[2]. [1]Internal Medicine, New York Presbyterian - Weill Cornell Medical Center, New York, NY; [2]Department of Medicine, University of California San Francisco, San Francisco, CA. (Control ID #3388356)

LEARNING OBJECTIVE #1: Highlight the disparities in access to liver transplant (LT) for unauthorized immigrants (UI) with end-stage liver disease (ESLD)

LEARNING OBJECTIVE #2: Recognize the differences in local policies, resources and services available to this population

CASE: A 51 year old male UI from Mexico with a history of T2DM, cirrhosis and EtOH abuse in remission was admitted for worsening ascites and abdominal pain. Due to lack of insurance and psychosocial stressors in the months preceding admission, he was not engaged in care or taking medications. During his course, he developed hepatorenal syndrome with MELD uptrending to 38. He did not improve on midodrine, octreotide and albumin however he did not yet meet criteria for dialysis. He was evaluated by the LT service and due to his UI status he was deemed ineligible for LT at our center. He was seen by the palliative care team and discharged with home hospice services and follow up care at a safety net hospital.

IMPACT/DISCUSSION: There are many barriers to LT for UI, including stringent psychosocial and financial criteria, language and health literacy challenges, fear of disclosure of documentation status when engaging with care and the possibility of being deported, losing access to aftercare and medications needed for survival. Perhaps the single most important factor for achieving LT is insurance status. There is no strictly medical reason that UI should be ineligible for LT, as recent data has shown similar patient and graft survival outcomes among UI and citizens. Yet, while UI comprise an estimated 3% of deceased organ donors, they represent only 0.4% of LT recipients. Because there are no specific national guidelines for LT access among UI, LT centers set their own policies and differ geographically with California and New York offering the greatest proportion of LT to UI and Texas and Florida the fewest. The majority of UI who have received LT have purchased private insurance or obtained Medicaid in states like California where Medicaid can be extended to UI. General internists are often the first to encounter these

patients, thus it is important to be familiar with local policies, resources and services to link vulnerable patients to culturally competent care. Benefits and services for UI may include public insurance, cash assistance, transportation vouchers and free legal aid. Additional healthcare resources for UI include public hospitals and community clinics where advocacy and case management services can be offered in native languages, treatment centers for mental health and EtOH use disorder, early involvement of palliative care for symptom management and charity hospice services.

CONCLUSION: Recognize the great urgency, need and benefit for LT among UI with ESLD who face significant barriers to care Become familiar with local policies, resources and services which vary by location and LT center

ALKALINE PHOSPHATASE ELEVATION AS THE SOLE MANIFESTATION OF HEPATIC ADENOMATOSIS

Dedeepya Konuthula[1]; Reed Van Deusen[2]. [1]Internal Medicine-Pediatrics, University of Pittsburgh Medical Center, Pittsburgh, PA; [2]Internal Medicine, University of Pittsburgh, Pittsburgh, PA. (Control ID #3391667)

LEARNING OBJECTIVE #1: Distinguish the clinical features of hepatic adenomatosis from those of isolated hepatic adenomas.

LEARNING OBJECTIVE #2: Recognize barriers to timely diagnosis in patients with intellectual disabilities.

CASE: A 25 year old woman with history of intellectual disability, autism spectrum disorder, epilepsy, obesity, and dysmenorrhea on OCPs for over 12 years was incidentally noted to have an elevated alkaline phosphatase (ALP) of 150 in 2017 without jaundice or scleral icterus. ALT, AST, and bilirubin were normal. This ALP elevation persisted, prompting further workup. gGTP was also elevated at 196. ANA and AMA were negative. The patient was not able to tolerate a complete abdominal exam or abdominal ultrasound without sedation so MRCP was completed under general anesthesia. MRCP showed numerous large bilobar hepatic lesions measuring up to 7.3cm with features suggestive of hepatic adenomas. Hepatology plans to discontinue OCPs and repeat imaging in several months to determine whether to pursue biopsy, embolization of the larger lesions, and/or liver transplant.

IMPACT/DISCUSSION: Classic risk factors for hepatic adenomas include OCP use in women, anabolic steroids, genetic syndromes including glycogen storage disorders, and obesity. Hepatic adenomatosis, which is characterized by at least 10 hepatic adenomas and was first described separately in 1985, does not show the same dose-dependent association with estrogen exposure or regression with withdrawal of OCPs or steroids. Patients are often asymptomatic, and elevated ALP and gGTP may be the only abnormalities noted prior to imaging. While hepatic adenomas are benign tumors, their hypervascularity increases the risk for intralesional hemorrhage which can spread to the liver and peritoneum (incidence up to 62.5%). Malignant transformation to HCC is also possible (<10%). The risk of these complications is much higher with hepatic adenomatosis as compared to solitary hepatic adenomas. Many diagnoses including this one are more difficult to make in a timely manner in patients with disabilities that make them unable to provide details of the history or tolerate thorough exams or imaging. As an example, the first line imaging modality for this patient with elevated ALP and gGTP would have been RUQ ultrasound which could have been obtained relatively quickly - instead this patient had to wait to undergo MRCP under general anesthesia. Had she been receiving care in a lower resource setting, this likely would have been further delayed or missed entirely.

CONCLUSION: 1) Hepatic adenomatosis (HA) is a separate entity from solitary hepatic adenomas and does not show the same dose-dependent association with OCP use. 2) HA can present with isolated alkaline phosphatase and gGTP elevation and has a higher risk of complications including hemorrhagic shock and malignant transformation to HCC. 3) Delays in obtaining necessary imaging tests due to the need for sedation are only a subset of the barriers to timely diagnosis in patients with intellectual disabilities.

ALL THAT IS YELLOW IS NOT JAUNDICE

John D. Fernandez[1]; Athanasia Vasiliadis[2]. [1]Internal Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; [2]Medicine, Mount Sinai, New York, NY. (Control ID #3391549)

LEARNING OBJECTIVE #1: Describe the clinical findings of carotenemia and how it differs from jaundice

LEARNING OBJECTIVE #2: Identify the differential diagnosis of carotenemia

CASE: A 55-year-old woman with no significant past medical history presented to clinic with a chief complaint of a 2-month history of yellow discoloration of her palms and soles. She denied pain, pruritis, or systemic symptoms. She has no known past medical history. The patient reported that she takes no medications but takes the following vitamin supplements: vitamin D, iron, folic acid, calcium, and magnesium. The patient's social history was significant for no prior incarcerations, no history of IV drug use, and no new sexual encounters. However, on diet history it was discovered that she recently started to drink several green smoothies most days of the week in an effort to have a healthier diet.

Physical Exam: Notable findings included: absence of scleral icterus, presence of pink sublingual coloration, no abdominal distention, no hepatomegaly, skin findings of yellow coloration of bilateral palms of hands, yellow coloration of bilateral soles of feet, and normal coloration of the rest of the skin.

The following labs were normal (lipid panel, hepatic function panel, hepatitis panel, hemoglobin A1c, thyroid function test, and basic metabolic panel) and ruled out other etiologies of yellow skin discoloration. A diagnosis of carotenemia was made due to the patient's increased dietary consumption of beta-carotene in her kale, carrot, and beet smoothies.

IMPACT/DISCUSSION: Carotenemia is a yellow-orange discoloration of the skin due to increased serum concentration of beta-carotene. It is important to distinguish the discoloration of carotenemia from that of jaundice, as the differential diagnosis changes significantly. Jaundice is caused by increased serum bilirubin and can be seen as sublingual icterus, scleral icterus, and global yellow discoloration of the skin. In carotenemia, there is no sublingual or scleral icterus; instead yellow discoloration of the tip of the nose, palms, soles, and nasolabial folds is more prominent and can sometimes extend to the rest of the body. Additionally, jaundice and carotenemia can be distinguished by the presence of pruritis which, if present, is more specific to jaundice.

Finally, the differential diagnosis of carotenemia includes etiologies other than the ingestion of beta-carotene rich foods. Case reports of carotenemia have been described resulting from diabetes mellitus, hypothyroidism, chronic liver disease, chronic kidney disease and even hyperlipidemia. Additionally, some medications like tyrosine kinase inhibitors have been thought to cause carotenemia.

CONCLUSION: – Carotenemia can be from benign etiologies, like ingestion of beta-carotene rich foods, but can also be a harbinger of a serious medical condition or chronic disease

– It is important to recognize the physical findings that differentiate carotenemia from jaundice, like lack of discoloration of the sublingua or sclera and lack of pruritis

ALTERED MENTAL STATUS AND ACUTE DECOMPENSATED HEART FAILURE WITH INCREASED ABDOMINAL GIRTH AS AN INITIAL PRESENTATION OF PRIMARY EFFUSION LYMPHOMA IN A HUMAN IMMUNODEFICIENCY VIRUS-NEGATIVE (HIV) AND NON- ORGAN RECIPIENT INDIVIDUAL: A CASE REPORT

Mithi Hossain, Marisabel Hurtado, Jessica Cho, Jung-Eun Ha. Internal Medicine, New York University Langone Health, Bronx, NY. (Control ID #3391285)

LEARNING OBJECTIVE #1: Recognize need for early diagnostic fluid study for patients presenting with new ascites or effusion and constitutional symptoms, despite history of CHF

LEARNING OBJECTIVE #2: Diagnose and manage HIV-unrelated, HHV-8-associated PEL in patients presenting with unusual clinical presentation

CASE: 70-year-old HIV-negative male with advanced heart failure presented with altered mental status and mild hypotension. Physical exam was remarkable for increased abdominal girth concerning for new ascites and lab work was remarkable for mild leukocytosis, hypercalcemia and supratherapeutic INR. With no history of liver cirrhosis, ascites was thought to be secondary to heart failure and congestive hepatopathy and paracentesis was delayed due to elevated INR. Patient remained lethargic despite negative stroke work up, and was treated for aspiration pneumonia. Patient was eventually transferred to ICU for worsening delirium, hypotension, atrial fibrillation with RVR, and new fever of 103 F. Paracentesis with cytology confirmed a new diagnosis of primary effusion lymphoma. Patient tested negative for HIV and Epstein-Barr Encoding region (EBER), but was positive for Human Herpesvirus Type 8 (HHV8). Clinical course was complicated by aspiration pneumonia, C. difficile infection, and persistent hypotension, making him a poor candidate for chemotherapy treatment.

IMPACT/DISCUSSION: Primary effusion lymphoma (PEL) is a rare, high-grade non-Hodgkin's lymphoma (NHL) that typically develops in immunocompromised patients, with HIV or following organ transplant, and often associated with HHV8 or Ebstein-Barr virus. Patients often present with constitutional symptoms and effusions in body cavities with no defining mass or overt sign of malignancy. Our patient presented with new ascites but diagnosis was delayed due to elevated INR and attribution to acute decompensated heart failure with congestive hepatopathy. Recognition of unexplained hypercalcemia and constitutional symptoms followed by early diagnostic paracentesis may have expedited the diagnosis and affected patient's clinical course.

CONCLUSION: Primary effusion lymphoma is a very rare disease that almost exclusively occurs in HIV positive or immunocompromised patients, representing only 4% of NHL cases associated with HIV and only 0.1% to 1% of all lymphomas in patients with other types of immunodeficiency. This case highlights HIV- negative/EBV-negative/HHV-8-positive PEL in a patient presenting unusually as acute decompensated heart failure and altered mental status treated for aspiration pneumonia. It is imperative that patients presenting with new ascites or pleural effusion get an early diagnostic fluid study with a high suspicion of malignancy especially with other constitutional symptoms and metabolic encephalopathy with unexplained hypercalcemia and negative infectious workup. Early recognition in patients particularly with underlying CHF may lead to timely treatment initiation and further reduce complications.

A MASS-IVE TURN OF EVENTS: A CASE OF HEPATIC ACTINOMYCOSIS MIMICKING MALIGNANCY

Christopher Kim, Paul Guzik, Kristin Mondy. Internal Medicine, University of Texas at Austin Dell Medical School, Austin, TX. (Control ID #3376226)

LEARNING OBJECTIVE #1: Diagnose and treat a rare infectious etiology of a hepatic mass

CASE: A 71-year-old man with cirrhosis and prior prostate cancer 9 years ago treated with radiation presented to his urologist with acute right-sided abdominal pain and night sweats. CT revealed a 5.2 cm mass concerning for hepatocellular carcinoma. He was referred to oncology for further evaluation and a fine needle aspiration (FNA) biopsy was performed. The FNA showed rare benign stromal cells without evidence of malignancy. A core liver biopsy was thus recommended, and pathology revealed fibrous and granulation tissue without malignant cells. He was then referred for surgical resection of the mass. Of note, during this period of less than two months between outpatient appointments, he developed a painful 3 cm protruding mass out of his right upper abdomen. An MRI showed an interval increase of the liver mass to 8.4 cm with an adjacent multiloculated fluid collection. Given the symptomatic and rapid growth of the mass, he was sent to the hospital for further management. A repeat core biopsy of the liver was performed, and the histologic features suggested an abscess. Fluid cytology was notable for polymorphonuclear leukocytes and bacterial colonies morphologically consistent with Actinomyces. Infectious Diseases was consulted and the patient was diagnosed with hepatic actinomycosis. A 6-week course of intravenous ampicillin-sulbactam was initiated, and a 12-month course of amoxicillin was planned following completion of his IV antibiotics. The patient also underwent incision and drainage of his abscess prior to hospital discharge.

IMPACT/DISCUSSION: The diagnosis of primary hepatic actinomycosis is often difficult due to its rarity (5% or less of actinomyces infections) and non-specific clinical presentation, often consisting of abdominal pain with imaging findings of a hepatic mass. In patients with underlying risk factors for a malignant liver lesion like cirrhosis or a prior cancer history, such a mass may not prompt an infectious work-up immediately. The main risk factor for hepatic actinomycosis is prior abdominal surgery, but the majority (80%) of cases are cryptogenic. Definitive diagnosis for hepatic actinomycosis is based on microscopic exam of biopsies which reveal the characteristic basophilic filament aggregates and prototypical "sulfur granules".

Blood cultures are positive in only 15% of cases and the yield of percutaneous biopsy is not high. Once the diagnosis is made, treatment usually entails a combination of a prolonged antibiotic course (3-12 months), surgical resection and percutaneous drainage, with very successful post-treatment outcomes reported. **CONCLUSION:** Hepatic actinomycosis is a rare but established cause of a hepatic mass that is difficult to diagnose and can be mistaken for malignancy, particularly when the risk for a hepatic malignant lesion is already high. Once diagnosed, a combined medical and surgical treatment approach has been shown to produce very successful outcomes.

A METASTATIC MYSTERY

Aimee Sutherland, Jacqueline Witt. Medicine, Tulane University School of Medicine, New Orleans, LA. (Control ID #3391307)

LEARNING OBJECTIVE #1: Identify melanoma as an increasing cause of skin cancer in the United States

LEARNING OBJECTIVE #2: Recognize the importance of the skin examination as part of an evaluation for systemic medical illness

CASE: A 36-year-old man presented with a two-month history of progressive lower back pain, now with associated bowel and urinary incontinence, saddle anesthesia, and difficulty maintaining an erection. No history of trauma was reported. He was tachycardic at 101 beats per minute and had an elevated blood pressure of 170/115 mmHg. There was decreased sensation around the anus, scrotum and penis. Decreased sensation was also noted over the left forearm. There was tenderness to

palpation along the spine. No concerning skin lesions were identified. MRI of the spine revealed numerous intradural extramedullary lesions throughout the spinal canal. Neurosurgery was consulted with recommendations of obtaining imaging of the brain. MRI of the brain revealed extra-axial enhancing intracranial lesions. Multiple bilateral pulmonary nodules were appreciated on CT of the chest. Initial considerations on the differential included meningioma, metastatic ependymoma, nuerofibromatosis-2, and non-CNS primary with metastases. Pathology from a core biopsy of a left lower lobe nodule revealed focal diffuse atypical cellular infiltrate that was positive for Melan A and S100, consistent with metastatic melanoma.

IMPACT/DISCUSSION: The incidence of melanoma continues to rise annually in the United States, with the highest incidence and death rates occurring in the non-Hispanic white male population. Close to 97% of melanomas begin as cutaneous lesions, therefore it is imperative that internists regularly perform skin exams especially when metastatic cancer is on the differential. Melanoma often can be identified using the "ABCDEs": Asymmetrical Shape, uneven Border, Color variation, Diameter (6mm or greater- the size of a pencil eraser), and Evolution. Melanoma most commonly metastasizes to the lung, but brain metastasis is estimated to occur in roughly 50% of stage IV melanoma patients. Those with brain metastasis have a seven- fold higher risk of death than patients with lung metastasis. Most cases of melanoma arise from an identifiable primary cutaneous lesion; Melanoma of an unknown primary (MUP) occurs in only 3.2% of all melanomas.

Cases of metastatic melanoma resembling malignant peripheral nerve sheath tumors on pathology have been reported with often no identifiable primary cutaneous melanoma. S-100 and HMB-45 stains help to identify these otherwise inconspicuous tumors. It is hypothesized that the neuroendocrine origin of melanocytes may be responsible for this phenomenon. Furthermore, metastatic melanoma often mimics meningiomas on radiologic imaging.

CONCLUSION: Although a rare entity, melanoma of an unknown primary should be included in a practitioner's differential when working up symptoms suspicious for underlying malignancy. A primary cutaneous melanoma was never identified in our patient despite a thorough skin exam.

A METH-Y SITUATION: PULMONARY ARTERIAL HYPERTENSION (PAH) CAUSED BY METHAMPHETAMINE AND COCAINE ABUSE

Syed S. Hassan, Alan Baggett. Internal Medicine, UAB Huntsville, Huntsville, AL. (Control ID #3392443)

LEARNING OBJECTIVE #1: Assess and treat a patient with Pulmonary Hypertension

LEARNING OBJECTIVE #2: Recognize illicit drugs as an important cause of Pulmonary Arterial Hypertension

CASE: 41-year-old Caucasian female presented to the ED with progressively worsening dyspnea on exertion which began 2 months ago and 1-day history of chest tightness. On arrival, she was tachycardic, and hypotensive. She had no pertinent PMH. She was a 20 pack-year active smoker, active methamphetamine and cocaine smoker. Physical exam was significant for parasternal heave and JVP of 10 cm. Labs were remarkable for negative troponin, urine screen positive for methamphetamines and cocaine. EKG showed sinus tachycardia, right strain pattern. CT Chest ruled out pulmonary embolism, showed enlarged main pulmonary artery as well as right ventricle and atrium, findings consistent with PAH. Transesophageal echo showed enlarged right ventricle and RV hypokinesis. She then underwent a right heart catheterization to confirm right-sided pressures. The PCWP was 5 mmHg (6 - 16), mean PA pressure 47 mmHg (normal < 20 mmHg), pulmonary vascular resistance 16 Wood units (1.9 – 3.1), and the cardiac index was 1.8 (2.8 – 4.2). These findings were consistent with severe pulmonary hypertension and reduced cardiac index, as well as normal right- and left- filling pressures. She was diagnosed with PH Group 1, admitted to the CCU for vasodilator therapies, and discharged home on Sildenafil and Ambrisentan dual-therapy with plans for close follow-up.

IMPACT/DISCUSSION: PH is classified under 5 groups of causes: PAH, left heart disease, lung disease/hypoxia, pulmonary artery obstruction and idiopathic PH respectively. It is important to distinguish the cause of PH, as treatments and prognosis varies greatly. Assessment involves CT chest which in our patient ruled out ILD (Group 3), pulmonary embolism (Group 4) and TTE which ruled out Group 2. RHC confirmed a low PCWP, as well as severely elevated pulmonary artery pressure, which was consistent with Group 1.

PAH is a rare disease that affects 5 – 52 people in a million, with a female to male ratio of 1.7 – 4.8:1. After idiopathic and heritable causes, drugs and toxins are the most important etiology. Cocaine and methamphetamine use have both been associated with a high risk of PAH, and deserve respect as an important cause in the right clinical setting. This case of a young, otherwise healthy, female highlights the steps needed to diagnose PAH, as well as emphasizes the need for a thorough social history to recognize rare causes of this already under-recognized condition.

CONCLUSION: PH should always be considered in young patients with new or sub-acute dyspnea on exertion. While connective tissue disease and heritable causes are significant, illicit drugs continue to be an important cause in PAH. RHC is an essential tool to help diagnose and guide therapy, which includes PDE-5 inhibitors and ERAs.

A MISSED CASE OF MIXED CRYOGLOBULINEMIA

Sean B. Bernfeld[1]; Heather Balch[2]. [1]Internal Medicine, University of Utah, Salt Lake City, UT; [2]Department of General Internal Medicine, University of Utah, Woods Cross, UT. (Control ID #3390145)

LEARNING OBJECTIVE #1: Recognize the clinical and laboratory manifestations of mixed cryoglobulinemia

LEARNING OBJECTIVE #2: Diagnose and treat mixed cryoglobulinemia

CASE: Mr. J was a healthy 64 year old male who presented with two weeks of progressive weakness in all four extremities. This had been preceded by a brief flu-like illness with fever and cough. He presented because he could not rise from a chair. On exam, he had flaccid paralysis below the knees, absent patellar reflexes, cold/mottled feet, and reduced upper extremity strength. Laboratory work-up notable for CK 2300, ESR 54, CRP 3.4, normal C3 at 103, undetectable C4, hemoglobinuria on UA, and SPEP with two monoclonal gamma region spikes. EMG showed "patchy axonal denervation changes." IVIG was initiated for a presumed diagnosis of atypical GBS. He initially improved; however, his weakness returned, and palpable purpura developed over his feet. Cryoglobulins from the initial work-up returned elevated, and skin biopsy revealed a leukocytoclastic vasculitis. With his axonal neuropathy, purpuric rash, hemoglobinuria, elevated cryoglobulins, and leukocytoclastic vasculitis, his condition was recognized as mixed cryoglobulinemia. He received plasma exchange and was discharged on rituximab and steroids. Unfortunately, he was still unable to walk.

IMPACT/DISCUSSION: Cryoglobulinemia is uncommon and can be difficult to untangle, with potentially devastating effects if not caught early. Cryoglobulins are proteins that precipitate out of blood at <37 ^{o}C. They are composed of immunoglobulins which may form complexes with complement components. Deposition of these complexes in the walls of small vessels leads to local destruction and inflammation. Clinical manifestations include palpable purpura, glomerulonephritis, arthralgias, and multiple mononeuropathy. Symptoms vary and present at different times during the course. Laboratory findings include elevated cryoglobulins, low C4 (C3 often normal), positive RF, and elevated ESR/CRP. Skin biopsy may show a small vessel leukocytoclastic vasculitis. Cryoglobulinemia should be suspected when patients present with these findings, especially in the setting of multiple

myeloma, chronic autoimmune disease, lymphoproliferative disorders, or chronic infection. Additional work-up should attempt to identify any underlying disorder, rule-out other vasculitides, and assess the degree of organ involvement. Treatment involves management of the underlying disorder, supportive care, and systemic glucocorticoids + rituximab or cyclophosphamide for moderate-to-severe disease. Plasma exchange has a role in severe disease. Prognosis varies greatly depending on the precipitating disorder and extent of organ involvement.

CONCLUSION: In the case presented, work-up was ultimately negative for an identifiable underlying disorder, and the etiology was considered idiopathic type III mixed cryoglobulinemia, perhaps due to his preceding viral illness. We anticipate a good chance at survival with uncertainty about the recovery of peripheral motor function.

A MULTILOCULATED PSOAS ABSCESS FOUND TO BE MYCOPLASMA TB POSITIVE IN A MIDDLE AGED WOMAN

Joseph Souto. Internal Medicine, Donald and Barbara Zucker school of medicine at Hofstra/Northwell, Floral Park, NY. (Control ID #3387760)

LEARNING OBJECTIVE #1: Recognize the atypical clinical, radiological, and laboratory features of disseminated TB

CASE: 50 YOF from India with PMHx of LTBI s/p INH, RA on Tofacitinib, HTN, anemia, and osteoporosis presented with a chief complaint of intermittent fevers, chills, 10-15 pound weight loss, decrease in appetite, severe back and left lower extremity pain. Her presenting VS were within normal limits. The PE was significant for 4/5 strength in the left lower extremity with both flexion and extension associated with discomfort and firm swelling of the lateral aspect of the left tibia. In addition, there was tenderness to palpation in the left lateral knee and the left lateral mid-shin. Laboratory workup was remarkable for a Hgb of 8.3, Na of 132 and an albumin level of 2.7. Initial MR imaging was significant for a hyper-intensive mass/collection in the anterior compartment musculature at the head of tibial metaphysis. An ultrasound of the LLE revealed a loculated complex fluid collection in the anterior lateral aspect of the left knee area. This fluid collection was then biopsied and was positive for Mycoplasma TB via PCR. An open decompression procedure of the left tibia and fibula grew acid-fast bacilli. CT chest showed cavitary lesions in the left upper lobe with bilateral nodular and tree in bud opacities concerning for TB reactivation and endobronchial spread. MR of the abdomen, pelvis lumbar spine and left tibia/fibula showed a multi-loculated left psoas abscess with adjacent left retroperitoneal necrotic adenopathy. L1-L4 tuberculosis abscess infiltration of the left proximal and mid-shaft of the tibia with cortical breakthrough and soft tissue mass component was seen.

IMPACT/DISCUSSION: The diagnosis of disseminated TB is often missed due to the nonspecific nature of the presentation and because of the relatively low prevalence and incidence of tuberculosis in the United States. Furthermore, the symptoms are often confused with other disorders. In our case, we attributed the patient's symptoms to a type of Lymphoma based on the initial MR imaging. In addition, some of the initial labs on admission were suggestive of miliary TB including hyponatremia. It is important to consider reactivation of TB despite being treated with INH according to a meta-analysis and systematic review study that looked at different regimens for treating latent TB. The specific reasons include complex immune system interactions and poor compliance with INH. In terms of disseminated TB, the lungs, liver, and spleen are the most commonly affected organs (80-100%) followed by the kidneys (60%), and the bone marrow (25-75%).

It is important to note that in addition to Pott's disease of the spine, abscesses can also be seen in other regions of the body that should raise clinical suspicion for disseminated TB.

CONCLUSION: Clinical suspicions should always be raised in a patient with a history of LTBI who presents with a several month history of fevers, weight loss, and pain with imaging suggestive of an abscess.

AMYLOIDOSIS, WHERE ALL ROADS LEAD TO ONE

Jianxiang Xia, Trisha Menon, Eileen Kim. Internal Medicine, Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY. (Control ID #3351571)

LEARNING OBJECTIVE #1: Recognize the clinical presentation of amyloidosis with renal and cardiac involvement

LEARNING OBJECTIVE #2: Diagnose AL amyloidosis with renal and cardiac involvement

CASE: A 53-year-old woman with a history of irritable bowel syndrome, chronic pain syndrome and years of nonspecific symptoms including chronic diarrhea and neuropathy, presented with bilateral lower extremity edema. Multiple outpatient studies demonstrated questionable monoclonal gammopathy of undetermined significance (MGUS) and a presumed diagnosis of fibromyalgia. Physical exam demonstrated hypotension with a SBP of 90 mmHg and pedal edema. Labs showed anemia (Hb 9.3 g/dL), AKI (Cr 2.23 mg/dL), elevated BNP (9682 pg/dL), proteinuria (100 mg/dL protein) and protein/creatinine ratio 1086 mg/g. Infectious workup including HIV and hepatitis were negative. Complete autoimmune workup only revealed low C3 complement level (63 mg/dL). Serum protein electrophoresis demonstrated hypogammaglobulinemia and elevations in Kappa (2.87 mg/dL) and Lambda (16.99 mg/dL) light chains, with low Kappa/Lambda ratio (0.17). She was started on furosemide for lower extremity edema without improvement. Transthoracic Echocardiogram demonstrated severe diastolic dysfunction. Cardiac MRI showed infiltrative cardiomyopathy, with subsequent nuclear scan equivocal for transthyretin cardiac amyloidosis. Due to worsening kidney function, a renal biopsy was performed and revealed amyloid fibrils. Final bone marrow biopsy confirmed the diagnosis of Primary Amyloidosis, AL-type. Chemotherapy was initiated.

IMPACT/DISCUSSION: This patient's long history of diarrhea, neuropathy, hypotension, and questionable MGUS went undiagnosed for years but rather misdiagnosed as fibromyalgia. Her presentation with lower extremity edema led to a cardiac workup that demonstrated infiltrative disease. Typically, amyloidosis affects either the cardiovascular or renal system. However, this patient's constellation of symptoms and labs demonstrated both cardiac and renal involvement, which is a rare entity with only two cases in the literature. AL amyloidosis should be considered in patients presenting with concomitant diastolic heart failure and renal failure in the setting of elevated serum immunoglobulin light chains. Chemotherapy is the standard treatment with hematopoietic cell transplant as the goal. AL amyloid has varying degrees of response to chemotherapy depending on the extent of disease. The hematologic response is as high as 60% with response rates dropping to 17% and 25% with cardiac and renal involvement, respectively. With localized disease, median survival is typically five years, with poorer prognosis in diffuse involvement.

CONCLUSION: The rarity of amyloidosis, especially with both renal and cardiac involvement, should not deter clinicians from considering the diagnosis in the setting of a constellation of symptoms. Although it may not always be likely, this case highlights the importance of tying together all organ systems in the hopes of identifying a unifying diagnosis.

A MYSTERIOUS CASE OF SEPTIC SHOCK BY KLEBSIELLA FROM PANCREATICOPLEURAL FISTULA

Tanzia A. Nijhum[1]; Shengnan Zheng[1]; Gul Madison[2]. [1]Internal Medicine, Mercy Catholic Medical Center, Yeadon, PA; [2]Medicine, Mercy Philadelphia Hospital, Philadelphia, PA. (Control ID #3372149)

LEARNING OBJECTIVE #1: Recognize pancreaticopleural fistula (PPF) as a rare complication of chronic alcoholic pancreatitis.

LEARNING OBJECTIVE #2: Recognize magnetic resonance cholangiopancreatography (MRCP) as the imaging study of choice for diagnosis of PPF.

CASE: A 45-years-old African American male with a past medical history of seizure disorder, chronic alcohol abuse, and cervical spine injury, presented to hospital after a witnessed tonic-clonic seizure episode that resolved spontaneously. Initial evaluation revealed hypotension (90/57mmHg), tachycardia (145), tachypnea (36), temperature of 39.1 degrees celsius, leukocytosis (24.2x10^3/microliter) with bandemia, and lactate of 5.7mmol/L. Seizure was presumed secondary to alcohol withdrawal, and patient was admitted to Intensive Care Unit for further management of septic shock. Patient also developed worsening dyspnea, desaturating to 84% on room air. Patient reported chronic diarrhea (with lipase elevated at 149 U/L) likely secondary to pancreatic insufficiency, for which he was started on Creon with meals. Computed Tomography of chest and abdomen showed pancreatic duct dilatation with PPF extending from the pancreatic duct, through the left upper abdominal quadrant (containing several gas foci) to the left lower lobe of the lung. Left pleural space with thick-walled cavitation. Thoracocentesis attempted, no fluid was obtained. Endoscopic retrograde cholangiopancreatography confirmed a dilated pancreatic duct with a leak in the distal tail, and a pancreatic stent was placed to allow drainage into the duodenum. Blood cultures resulted in positive for Klebsiella pneumonia, source attributed to the PPF. Patient initially received empiric antibiotics (intravenous Vancomycin and Zosyn) which was deescalated to intravenous ceftriaxone according to culture and sensitivities. The patient clinically improved with shock resolved and was discharged on oral ciprofloxacin with a follow-up in two weeks for a repeat CT scan.

IMPACT/DISCUSSION: PPF (incidence only ~0.4%) occurs when a posterior pathway forms between the pancreatic duct and the pleura. The most common presentation include dyspnea (65%), abdominal pain (29%), chest pain (23%), and cough (27%). MRCP has higher sensitivity (80%) compared to CT scan (47%), or even ERCP (78%) as in our patient.

The literature revealed no consensus on the appropriate management of PPF but suggests that first-line medical management focuses on conservative approaches, such as thoracentesis, octreotide, antibiotics, and total parenteral nutrition for 2-3 weeks. If failed, endoscopic treatment with balloon dilation and placement of intraductal stenting can be attempted to restore anatomic continuity. Surgery consisting of internal pancreatic drainage and/or pancreatic resections is often the last resort.

CONCLUSION: PPF is a rare complication that may be seen in chronic alcoholic pancreatitis patients and requires a high index of clinical suspicion to diagnose, especially in patients with nonspecific symptoms such as dyspnea or chest pain.

A MYSTERIOUS CAUSE OF CAUDA EQUINA SYNDROME

Ryan Leibrandt[1]; Lesley Wu[1]; Ana Velazquez[2]. [1]Internal Medicine, Mount Sinai Beth Israel, New York, NY; [2]University of California, San Francisco, San Francisco, CA. (Control ID #3390986)

LEARNING OBJECTIVE #1: Recognize the clinical presentation of cauda equina syndrome

LEARNING OBJECTIVE #2: Recognize intravascular lymphoma as a rare cause of cauda equina syndrome

CASE: A 68-year-old male with gout presented with 1 month of numbness and pain in bilateral feet. He also endorsed gait unsteadiness, constipation, urinary incontinence, and an unintentional 15-pound weight loss. Physical exam revealed markedly diminished pinprick and vibratory sensation in bilateral lower extremities (LE), absent LE reflexes, and inability to ambulate independently due to a wide-based, unsteady gait. Rectal tone and perianal sensation were normal.

Lab work was notable for elevated LDH 2,201 U/L, CRP 17.6 mg/dL and ESR 62 mm/hr. MRI of cervical, thoracic and lumbar spine ruled out cord compression. MRI brain showed no acute pathology. CSF analysis was negative for infection and malignancy. EMG and nerve conduction studies demonstrated lumbosacral polyradiculopathy affecting bilateral L3/L4 and L5/S1. Pulse dose steroids were administered for 5 days without clinical improvement.

On hospital day 7, repeat MRI spine without contrast was unchanged, contrast-enhanced portion was severely limited by motion artifact but suggested possible enhancement of lumbar nerve roots. On hospital day 15, repeat MRI with contrast confirmed lumbar nerve root enhancement consistent with cauda equina syndrome (CES). IVIG was started empirically for possible autoimmune etiology without improvement. Repeat CSF analysis and cytology were unrevealing. Flow cytometry of peripheral blood and bone marrow biopsy were non-diagnostic. Finally, biopsy of superficial peroneal nerve and peroneus brevis muscle revealed intravascular large B-cell lymphoma (IVLBCL).

Treatment with chemotherapy was initiated with R-CHOP and high-dose methotrexate. After 2 cycles of therapy, his LE strength and sensation gradually improved. MRI spine showed resolution of cauda equina enhancement. He was discharged to an acute rehab and continued to receive chemotherapy.

IMPACT/DISCUSSION: Recognizing signs and symptoms of CES is critical so that urgent neuroimaging can identify a cause. Common etiologies include disc herniation, abscess, or malignancy. IVLBCL is a challenging diagnosis as there is no radiographically identifiable lesion and it does not classically involve the bone marrow, lymph nodes, blood, or CSF. In IVLBCL, lymphoma cells proliferate within the lumen of arterioles, capillaries and venules causing a wide variety of symptoms including: constitutional symptoms, skin lesions, cerebrovascular events, and neuropathy. Often multiple biopsies of involved tissue are required to yield a diagnosis in order to initiate chemotherapy.

CONCLUSION: Early recognition of CES is imperative to prevent further neurologic complications. Urgent MRI of the entire spine should be obtained to establish a diagnosis. When evaluating atraumatic causes of CES, clinicians should consider common and rare malignancies in their differential.

A MYSTERIOUS RASH THAT DOESN'T ITCH

Justin E. Lewis[1]; Dianne Goede[2]. [1]Department of Medicine, University of Florida College of Medicine, Gainesville, FL; [2]Internal Medicine, University of Florida, Gainesville, FL. (Control ID #3361714)

LEARNING OBJECTIVE #1: Distinguish between the subsets of Cutaneous Lupus Erythematosus

LEARNING OBJECTIVE #2: Describe rare subtype Drug-Induced Subacute Cutaneous Lupus Erythematosus

CASE: A 58 y.o. female with history of hypertension, anemia, and GERD presented with complaint of "red bumps on my legs". She described the rash as a painful, erythematous rash which ascended from her lower extremities to the torso and upper extremities within a 3-day period. No associated fevers, chills, changes to her dish/laundry detergent, diet, or new environmental exposures. Her medications included: Hydroxyzine and Hydrochlorothiazide. Physical Examination revealed a diffuse, non-blanching maculopapular exanthem of her torso, bilateral upper/lower extremities with associated non-pitting lower extremity edema. She tried Hydroxyzine and Triamcinolone cream without improvement.

Laboratory values revealed mild leukopenia and creatinine elevation. Rheumatologic serologies demonstrated a positive cytoplasmic-ANA and elevated ESR, CRP, Kappa, and Kappa/Lambda ratios. Negative C3, C4, anti- dsDNA, histone abs, SSA/SSB, and ANCA labs.

Suspecting a drug eruption or lupus with cutaneous involvement, she was instructed to discontinue HCTZ and referred to Dermatology. Punch biopsy resulted in findings consistent with cutaneous lupus erythematosus. Rheumatologic consultation confirmed no evidence for systemic lupus erythematosus. Dermatology prescribed topical mometasone and agreed with continued discontinuation of HCTZ. The skin lesions resolved, and the patient felt well on follow up.

IMPACT/DISCUSSION: This case illustrates a rare finding of drug-induced subacute Cutaneous Lupus Erythematosus (SCLE) due to HCTZ. Drug-induced Lupus (DIL) often presents with systemic symptoms mimicking idiopathic systemic lupus erythematous (SLE). However, our patient lacked systemic symptoms such as arthralgia, myalgia, fatigue, and serositis, which are required for the diagnosis of SLE.

Dermatologic disease manifestations are typically seen in 80% of patients with SLE, the majority occurring as acute cutaneous lupus erythematous, generally encompassing localized malar and butterfly rashes. A second subset of skin involvement is SCLE, which includes both idiopathic and drug-induced. SCLE skin lesions are typically small, scaly erythematous rashes on sun-exposed areas. The last category is chronic cutaneous lupus or discoid lupus, which presents as red-to-purple rashes with discoloration and significant scarring.

CONCLUSION: Drug-induced Lupus is most commonly caused by antifungals, anti-hypertensives, proton pump inhibitors, and lipid-lower agents. Affected skin areas include the neck, shoulders, forearms, and upper torso.

Diagnosis of DIL can be made based on clinical history and physical examination alone. However, 80% of patients with SCLE lesions are positive for anti-Ro/SSA antibodies. Histopathology obtained via skin biopsy demonstrates leukocytoclastic vasculitis.

Treatment includes discontinuation of the offending agent. Symptoms typically improve within days to weeks.

AN ABNORMAL PRESENTATION OF STATIN-ASSOCIATED AUTOIMMUNE MYOPATHY.

Taylor J. Lemoine[1]; Alissa Ice[2]; William Benton[3]. [1]LSUHSC Medical School, Louisiana State University Health Sciences Center New Orleans, New Orleans, LA; [2]Internal Medicine Residency Program, Louisiana State University Health Sciences Baton Rouge, Baton Rouge, LA; [3]Internal Medicine, Louisiana State University Health Sciences Center, Baton Rouge, LA. (Control ID #3379516)

LEARNING OBJECTIVE #1: Recognize the spectrum of statin related myotoxicity, including the rare entity of anti-HMGCR positive immune mediated necrotizing myopathy (IMNM).

CASE: A 71-year-old African American male with a past medical history of hypertension, hyperlipidemia, diabetes mellitus type two, and prior history of tobacco use disorder presented to the ED with three months of progressive proximal muscle weakness associated with dysphagia and urinary retention. His medications included long-term 20 mg atorvastatin, amlodipine, olmesartan-hydrochlorothiazide, linagliptin, and metformin. The patient was thin with temporal wasting with a normal skin exam, 3/5 strength in the proximal extremities, 5/5 strength in the distal extremities, and areflexia. Laboratory results showed markedly elevated CPK (16,515), AST (425), ALT (400), ESR (20), and UA with large hemoglobin and 1-5 RBCs.

His statin was discontinued, and he received IV normal saline and high dose steroids with subsequent decline in CPK to 5443 during his hospitalization. He underwent an extensive autoimmune and neuromuscular workup and had a negative anti-Jo1. A muscle biopsy revealed necrotizing myopathy with focal mild necrosis. Subsequently, his anti-HMG-CoA reductase antibody was strongly positive (>200 U/mL). He was discharged on oral prednisone to a skilled nursing facility where he showed no change in weakness or urinary retention 2 weeks post discharge.

IMPACT/DISCUSSION: The range of statin related myotoxicity includes: asymptomatic elevated CPK, myalgia, myopathy, rhabdomyolysis, and anti-HMGCR positive myopathy, an IMNM [1]. IMNMs are rare with an estimated incidence of 4 in 100,000 person years and are subcategorized into anti-SRP, anti-HMGCR, and autoantibody negative [2,3]. Anti-HMGCR myopathy was first recognized in 2010, and its predominance is among those with prior exposure to statins with an estimated incidence of 2-3 cases per 100,000 patients on statin therapy per year [3-5]. Between 2012-2013, 39.2 million Americans were prescribed statins; therefore, it is important to be aware of this adverse effect as immunosuppressive therapy is often indicated and it is seldom self-limited [6]. Although it can manifest with a variety of presentations, the diagnosis is confirmed by the presence of myofiber necrosis on muscle biopsy and anti-HMGCR autoantibodies commonly in the context of proximal muscle weakness and elevated CPK [1,3,4,7]. This vignette offers a unique case of an individual with statin associated anti-HMGCR myopathy who presented with the expected proximal muscle weakness and elevated CPK, while also demonstrating areflexia, dysphagia, and urinary retention.

CONCLUSION: Although an uncommon form of statin related myotoxicity, anti-HMGCR should remain on the differential, particularly given its implications on management and clinical course.

Refractory proximal muscle weakness following the discontinuation of statin therapy should prompt anti- HMGCR antibody assessment and consideration for biopsy to evaluate for IMNM.

AN ATYPICAL CASE OF ANTI GLOMERULAR BASEMENT MEMBRANE (GBM) DISEASE WITH ISOLATED RENAL INVOLVEMENT

Sydney Weill[1]; John Beckham[2]; Emmanuelle B. Yecies[2]. [1]University of Pittsburgh School of Medicine, Pittsburgh, PA; [2]Internal Medicine, University of Pittsburgh Medical Center, Pittsburgh, PA. (Control ID #3388310)

LEARNING OBJECTIVE #1: To recognize typical and atypical presentations of Anti GBM disease

LEARNING OBJECTIVE #2: To consider aggressive management of suspected Anti GBM disease while definitive diagnosis is pursued

CASE: Mr. T is a 65 year old Caucasian veteran with a history significant for diabetes mellitus and hypertension on lisinopril who presented with rapidly declining renal function. He initially presented to urgent care with 2 weeks intermittent fevers, 1 week sinus congestion, myalgias, 1-2 large volume watery stools daily, and decreased appetite. Cr was notably 2.3 mg/dL. He was felt to have a viral syndrome, and close outpatient follow-up was recommended. Four days later, Mr. T presented to our hospital with persistent fevers, diarrhea, and oliguria (100-200cc daily). Physical exam was notable only for 1+ peripheral edema. Admission Cr was 7.3 mg/dL, eventually peaking at 16.1 mg/dL on day 3 of admission despite supportive care. Infectious work-up, including blood and urine cultures, stool studies, viral studies, and chest and abdominal imaging was unrevealing. Rheumatologic workup returned on day 5 with markedly positive Anti- GBM antibodies at a titer of 177 U/mL (normal <20 U/mL). Renal biopsy demonstrated all glomeruli with cellular crescent (more than 50% of glomerular capsular circumference) and fibrinoid necrosis consistent with Anti GBM glomerulonephritis. Despite the initiation of steroids, the patient's renal function failed to improve, and he has required ongoing hemodialysis.

IMPACT/DISCUSSION: Anti-GBM disease is a rare autoantibody mediated small vessel vasculitis (incidence 0.1 cases per million) that typically presents with a characteristic triad: pulmonary involvement,

renal injury, and anti-GBM antibodies. While the majority of cases present with both pulmonary and renal findings, isolated renal involvement has been described, particularly in patients over 50 with less indolent courses. Most cases of anti-GBM disease are thought to be triggered by an insult to the renal basement membrane or cross reactivity with exogenous epitopes (i.e. infection, toxins, neoplasia, or renal injury) and many patients present with additional systemic symptoms such as fever, which is found in 67% of presentations.

Emergent management with plasmapheresis, cyclophosphamide, and steroids is needed to treat rapidly progressive anti-GBM disease. Unfortunately, many of the tools used for definitive diagnosis (such anti- GBM antibodies and renal biopsy) often require several days to complete. In addition, there is often concern for infection on presentation. These factors often lead to delays in the initiation of appropriate therapy.

CONCLUSION: Anti GBM disease can present without the typical triad of lung involvement, renal injury, and anti-GBM antibodies. This patient case underlies the need to consider prompt initiation of treatment in rapidly progressive clinical deterioration despite delays in confirming a definitive diagnosis.

AN ATYPICAL CASE OF ATYPICAL HEMOLYTIC UREMIC SYNDROME

Romik Srivastava[1]; Alexandria Avery[2]; Samuel O. Schumann[1]. [1]Internal Medicine, Medical University of South Carolina, Charleston, SC; [2]Pathology, Medical University of South Carolina, Charleston, SC. (Control ID #3392253)

LEARNING OBJECTIVE #1: Recognize atypical hemolytic uremic syndrome (aHUS) as a distinct clinical phenotype

LEARNING OBJECTIVE #2: Discuss the role of eculizumab in treatment of aHUS

CASE: KH is a 24-year old previously healthy woman who presented as an outside hospital transfer for evaluation of suspected aHUS.

Three weeks prior, she had a self-limited non-bloody diarrheal illness and her family experienced similar symptoms. One week after, she developed bilateral flank pain and anuria, prompting emergency room presentation. She denied fevers, headaches or confusion. She denied a family history of thrombotic or autoimmune disease. Her only medication was orthotricyclen, an oral contraceptive (OCP) started 4 months prior. Her exam was remarkable for costovertebral angle tenderness, and her lab evaluation was notable for a hemoglobin of 13g/dL, platelet count of 195K/cmm (baseline 384), LDH of 238IU/L, haptoglobin of 80mg/dL, and a serum creatinine of 6.5mg/dL. Peripheral blood smear contained schistocytes and renal biopsy revealed diffuse thrombotic microangiopathy (TMA). She was started on hemodialysis with plasmapheresis. Her ADAMTS-13 level was 67% and stool studies were negative for Shiga toxin and E. coli. Autoimmune workup was negative. She was transferred to our center for evaluation and consideration for eculizumab therapy.

Upon arrival she did not appear toxic nor did she have costovertebral angle tenderness on exam. Her GI PCR was positive for clostridium difficile and adenovirus. Complement levels were normal. Given TMA induced renal failure and stool studies without Shigella or E. coli she was diagnosed with aHUS and initiated on eculizumab.

IMPACT/DISCUSSION: TMA typically consists of thrombocytopenia, acute renal failure, and hemolytic anemia. Classically aHUS is defined as a primary TMA not driven by Shiga toxin (typical HUS) or ADAMTS-13 deficiency <5% (TTP). As much as 50% of aHUS cases are associated with complement pathway mutations. While our patient had a normal complement panel, her patient's risk factors included OCP use and active C. diff and adenovirus infections. Lack of thrombocytopenia and the low level of schistocytes on our patient's smear made her case unconventional, delaying diagnosis and treatment.

When diagnosis is uncertain, patients with suspected aHUS warrant immediate plasmapheresis due to the risk of rapid progression to ESRD. All aHUS patients are trialed on Eculizumab, a monoclonal antibody that targets C5 and membrane attack complex formation, inhibiting cell lysis. In two multicentered, multinational prospective studies, early treatment with Eculizumab was associated with a time-dependent improvement in renal function.

CONCLUSION: General internists frequently treat patients with the constellation of acute illness, anemia, thrombocytopenia and renal failure.

Prompt diagnosis and initiation of treatment for aHUS is critical for early initiation of therapy and subsequent patient recovery.

Confirming the diagnosis should not delay plasmapheresis and consideration of eculizumab therapy.

AN ATYPICAL CASE OF LEGIONELLA MYOCARDITIS

Ninad Zaman[1]; Maria Ortiz Caicedo[2]. [1]Internal Medicine, Penn State Hershey Medical Center, Hershey, PA; [2]Physician Assistant Program, Pennsylvania State University, Hershey, PA. (Control ID #3387828)

LEARNING OBJECTIVE #1: Recognize one of the atypical clinical features of legionella infection.

CASE: 42-year-old female, with a history of tobacco use, presented to the Emergency Department (ED) with acute onset shortness of breath. She had been having subjective fever, chills, cough, runny nose, and severe myalgia for about a week before the presentation. A chest x-ray was significant for multifocal airspace opacities, consistent with pneumonia. In the ED, she was found to be in severe respiratory distress, and her ABG revealed a pH of 7.43, pCO_2 of 29, and pO_2 of 49 while on 40 liters of high-flow nasal cannula at 100% FiO_2. She was then intubated and admitted to the Intensive Care Unit. She was started on low tidal volume ventilation protocol for severe Acute Respiratory Distress Syndrome (ARDS). She was started on broad-spectrum antibiotics for likely Community-Acquired Pneumonia (CAP) with Piperacillin-Tazobactam and Azithromycin. Her oxygen saturation continued to be low on the ventilator.

The next morning, a complete echocardiogram showed a severely reduced left ventricular ejection fraction of 30% with diffuse hypokinesis. Her troponin was elevated, and an electrocardiogram showed sinus tachycardia. At this time, decision was made to put the patient on veno-arterial extracorporeal membrane oxygenation (VA-ECMO) for cardiogenic shock. Two days after being placed on ECMO, urine Legionella antigen returned positive. Broad-spectrum antibiotics were stopped, and she was started on a 21-day course of Levofloxacin. Further questioning of the patient's family revealed that she had prolonged exposure to floodwater in her basement before getting ill. Her clinical course eventually improved. She was extubated and came off the VA-ECMO. She was eventually discharged home after being in the hospital for 22 days.

IMPACT/DISCUSSION: Legionella is well-known for causing pneumonia. However, it can have other clinical manifestations, such as osteomyelitis, meningitis, endocarditis, pericarditis, and myocarditis. There have been previous case reports of Legionella causing myocarditis in otherwise healthy patients. These patients usually get really ill with multifocal pneumonia and then usually cardiogenic shock. This case illustrates the importance of Legionella causing other clinical conditions besides pneumonia. This patient initially suspected to have respiratory failure from CAP ended up going into cardiogenic shock likely from Legionella myocarditis. It is particularly important to get a history focusing on prior exposures including standing water when considering atypical infections because they can manifest surreptitiously.

CONCLUSION: Myocarditis is an uncommon entity in the spectrum of diseases caused by Legionella. However, it is very important for all clinicians

to recognize and treat this condition early with appropriate antibacterial to prevent morbidity and mortality. Further studies are needed to better characterize this condition as only case reports are currently available.

AN ATYPICAL ETIOLOGY OF INTENSE ABDOMINAL PAIN: NON-FUNCTIONAL PANCREATIC NEUROENDOCRINE TUMORS

Sam Sauerwein, Kuntal Chowdhary, Andrew Henderson. Internal Medicine, UPMC, Pittsburgh, PA. (Control ID #3392579)

LEARNING OBJECTIVE #1: Recognize the atypical presentation of pancreatic neuroendocrine tumor (pNET)

CASE: A 48-year-old male with no significant past medical history presented to an outside hospital with recent onset abdominal pain associated with nausea and vomiting. The burning pain began 4 days ago and was reported to be the "worst pain of his life." His exam and initial lab work-up were unrevealing. He subsequently underwent a CT abdomen/pelvis, remarkable for a large heterogeneous mass of the pancreatic body. He then presented to UPMC Presbyterian for further work up. During his hospitalization, the patient continued to experience excruciating pain that was poorly controlled despite a robust opioid-based pain regimen. Given the intractable nature of the pain, the decision was made to perform a celiac plexus block during a diagnostic EUS FNA procedure. This intervention resulted in a massive symptomatic improvement and the patient was discharged pain-free with instructions to follow-up outpatient for continued management of newly diagnosed pNET.

IMPACT/DISCUSSION: Non-functional pNETs account for approximately 2% of all pancreatic malignancies. Given that they are non-functional, the presentation is often vague with signs and symptoms including abdominal pain (35–55%), jaundice (25–40%), weight loss (30–45%) and/or an abdominal mass (10–40%). Rarely, patients with pNETs will present with the lone symptom of acute abdominal pain, usually secondary to sudden neural invasion due to mass effect. This patient did not have typical symptoms or lab findings that clinicians classically associated with a pancreatic mass, including jaundice, weight loss or abnormal liver function tests. Thus, it is worthwhile to consider an invasive process, such as pNET, in the differential diagnosis of acute abdominal pain after other common etiologies have been ruled out. Furthermore, in this case of severe pain with inadequate pain control on an oral opioid regime, it was crucial to involve our pain medicine colleagues for urgent intervention for pain relief.

CONCLUSION: - Although non-functional pNETs are rare causes of abdominal pain, mass effect secondary to invasive processes, such as malignancy, should be considered when evaluating acute abdominal pain, particularly if other common causes of abdominal pain have been ruled out.

Early recognition of severe pain resulting from tumor invasion of the surrounding nerve bundles was difficult to manage with oral and intravenous pain medication. Thus, early intervention with celiac plexus allowed for prompt pain relief.

AN ATYPICAL NEUROLOGIC PRESENTATION OF WEST NILE VIRUS

Benjamin Custer[2]; Heather Hopkins[1]. [1]Medicine, Washington DC Veterans Affairs Medical Center, Washington DC, DC; [2]Internal Medicine, Walter Reed National Military Medical Center, Bethesda, MD. (Control ID #3392573)

LEARNING OBJECTIVE #1: Recognize West Nile Virus as a cause of an ALS-like neuropathy

CASE: An undomiciled 63 year-old man with a history of lyme disease-associated facial palsy and tick exposure presented initially for multiple recent falls with progressive fatigue and weakness over the prior two months. At the time of admission he was noted to be hypophonic with tongue fasciculations, bilateral symmetric weakness, truncal ataxia, and hyperreflexia. EMG demonstrated florid abnormal spontaneous activities in the paraspinous muscles (positive sharp waves) and polyphasic large motor units with reduced recruitment in limb muscles and tongue (neuropathic motor recruitment), most consistent with a diagnosis of Amyotropic Lateral Sclerosis (ALS). Interestingly, MRI brain and spine demonstrated no focal lesions or signs of inflammation or edema in the CNS tissue, but did find diffuse T2 hyperintensity in the paraspinous muscles, consistent with myositis. Lumbar puncture (LP) revealed mild pleocytosis and was negative for other infectious or autoimmune causes but eventually demonstrated IgM and IgG positive for West Nile Virus (WNV). The patient was treated conservatively subsequent LP demonstrated a decrease in WNV IgM and an increase in IgG. The patient's weakness and hypophonia gradually improved and he was ultimately discharged to subacute rehab.

IMPACT/DISCUSSION: West Nile Virus is an arbovirus of the flavivirus family that has established endemicity in the US since a 1999 outbreak that signaled its arrival in North America. Here we present a case of WNV presenting as weakness and multiple falls at home with signs of both upper and lower motor neuron injury. Neuromotor manifestations of WNV are well-described and typically present as an acute flaccid paralysis, but are also known to present in a demyelinating pattern similar to Guillain Barre Syndrome (GBS). This case demonstrated neither flaccid paralysis nor signs of demyelination, and instead presented like ALS with evidence of diffuse neuropathic denervation. Additionally, MRI did not show signs of CNS inflammation or lesions, but instead indicated possible inflammation in the paraspinous muscles. This case demonstrates a potentially new type of neurological manifestation of WNV, with signs of upper and lower motor neuron injury.

CONCLUSION: Neurologic presentations of WNV are known to include both an acute flaccid paralysis and a GBS-like demyelinating presentation, but other presentations such as an ALS-like presentation with both upper and lower motor neuron deficits are possible and WNV should be kept in the differential in patients' with the appropriate exposure history.

AN ATYPICAL PRESENTATION OF AMYLOIDOSIS IN THE DIABETIC PATIENT: THE IMPORTANCE OF RECOGNIZING ANCHORING BIAS

Jeffrey Lantz[1]; Steven Delaney[2]. [1]Internal Medicine Residency, Wake Forest Baptist Medical Center, Winston Salem, NC; [2]Internal Medicine, Wake Forest Baptist Health, Winston-Salem, NC. (Control ID #3392144)

LEARNING OBJECTIVE #1: Recognize that signs and symptoms of amyloidosis can mimic autonomic dysfunction frequently seen in diabetes.

CASE: A 71-year-old male with a medical history of hypertension, orthostatic hypotension, and insulin-dependent type two diabetes complicated by peripheral neuropathy, retinopathy, a right foot diabetic ulcer with resultant transmetatarsal amputation, and nephropathy with CKD. The patient's orthostatic hypotension had initially been diagnosed three years prior with 20mmHg systolic decreases when standing. These symptoms were evaluated by multiple providers and felt to be a sequalae of poorly controlled diabetes as his A1C was persistently elevated near 10. While recently establishing care with a new PCP, he reported dizziness, a 25-pound weight loss, and new onset stool incontinence over the last 2-3

months. In clinic, blood pressure sitting was 200/90 mmHg and 135/65 mmHg standing. His labs were notable for an improved A1C of 6.3, creatinine of 1.7 (baseline 1.3), and urine protein creatinine of 3,572.82. Initially, this change in kidney function was thought secondary to dehydration due to recent development of loose stools. His worsened dysautonomia was still believed to be diabetic related. However, repeat creatinine showed no improvement at close follow-up. Perplexed, further studies to rule out other causes were performed including: kappa/lambda ratio of 1.47, beta-2-microglobulin 4.31, SPEP with beta one region M spike of 0.36 and beta two region of 0.36, and immunofixation with IgA kappa x2. A fat pad biopsy was performed with Congo red birefringence consistent with amyloid.

IMPACT/DISCUSSION: Diabetes affects more than 30 million people in America and often has complications involving the nervous system, solid organs, and the vascular system (1). These complications may mimic other underlying pathology, such as amyloidosis. Although moderately rare with only 4,000 new cases of AL amyloidosis diagnosed per year in the USA, a patient's health is dynamic, and a thorough differential should always be implemented to avoid misdiagnosis (2). This is reinforced by a study conducted at Mayo Clinic which showed that 21% of their referrals were misdiagnosed (3). This case presents an atypical presentation of amyloidosis resulting in delayed diagnosis. While there are limited reports of orthostatic hypotension with amyloid, autonomic involvement may be present in up to 15% of cases (4). The presenting autonomic dysfunction of postural hypotension, fecal incontinence, and peripheral neuropathy are similar to those exhibited by diabetic neuropathy (5).

CONCLUSION: ● Diabetic patients who present with new nephrotic range proteinuria or worsened autonomic dysfunction despite well-controlled diabetes should be considered for alternative causes.

● Systemic amyloidosis, while uncommon, should be on the radar in this population. Anchoring bias can result in delayed diagnosis and treatment.

AN ATYPICAL PRESENTATION OF CELIAC DISEASE: ATAXIA CAUSED BY VITAMIN E AND COPPER DEFICIENCY IN THE ABSENCE OF GASTROINTESTINAL SYMPTOMS

Helen Lyo, Charles Milrod, Robert M. Wilechansky. Internal Medicine, Boston Medical Center, Boston, MA. (Control ID #3355650)

LEARNING OBJECTIVE #1: Recognize neurologic symptoms as a potential non-gastrointestinal manifestation of celiac disease.

LEARNING OBJECTIVE #2: Evaluate for nutritional deficiencies associated with celiac disease, which may be present in the absence of gastrointestinal symptoms.

CASE: A 60-year-old man presented with multiple falls over a week. He had a history of remote ischemic stroke and celiac disease, diagnosed 2 years prior when he presented to an outside hospital with ataxia. At that time, MRI brain and spine showed no acute findings; he was found to have copper deficiency and related myelopathy. This admission, he denied abdominal pain and diarrhea but reported weight loss and nonadherence to a gluten-free diet. Exam disclosed temporal wasting, bilateral muscle weakness and hyperreflexia, distal sensory deficits, positive Romberg test, and an ataxic gait. Labs demonstrated tissue transglutaminase IgA >500 CU (normal <20 CU), creatine kinase 8,044 U/L (normal 39-193 U/L), Vitamin A 16 mcg/dL (normal 38-98 mcg/dL), Vitamin E 2.0 mg/L (normal 5.7-19.9 mg/L), Zinc 38 mcg/dL (normal 60-130 mcg/dL), and copper 70 mcg/dL (normal 70-175 mcg/dL). Vitamins B1, B6, B12, and ceruloplasmin were normal. CT head and MRI brain showed no acute changes. Upper endoscopy revealed duodenal mucosal atrophy. Per neurology consultation, symptoms were consistent with myeloneuropathy related to copper and vitamin E deficiency. He was treated with vitamin and trace element supplementation as well as physical therapy and was discharged to an acute rehabilitation facility.

IMPACT/DISCUSSION: This case highlights the importance of recognizing neurologic symptoms as a potential manifestation of celiac disease. In this patient, neurologic symptoms were likely the result of concurrent vitamin E and copper deficiency due to malabsorption. These nutrients are absorbed in the jejunum, an area potentially affected by celiac villous atrophy. Both of these nutrient deficiencies may cause myeloneuropathy with findings such as ataxia and gait instability that can be disabling. Early detection and initiation of supplementation may prevent further neurologic deterioration, but the degree of improvement is variable. Of note, nutritional deficiencies in celiac disease may occur in the absence of gastrointestinal symptoms, and clinicians should have a low threshold to test patients for these abnormalities. This includes fat-soluble vitamins, B12, folate, INR, and micronutrients such as copper, zinc, and iron. Appropriate supplementation should be initiated as soon as these deficiencies are diagnosed.

CONCLUSION: 1. Neurologic symptoms are a potential manifestation of celiac disease and should raise suspicion of nutritional deficiency due to malabsorption

2. Vitamin E and copper deficiency associated with celiac disease can cause a debilitating myeloneuropathy, resulting in muscle weakness and ataxia

3. Nutritional deficiencies in celiac disease may be present in the absence of gastrointestinal symptoms

ANCHORING ON ACETAMINOPHEN – AVOIDING BIAS AND EMPLOYING POCUS IN A CASE OF UNDIFFERENTIATED SHOCK

Matthew N. Metzinger[1]; Michelle Fleshner[2]. [1]Department of Internal Medicine, University of Pittsburgh Medical Center, Pittsburgh, PA; [2]Internal Medicine, UPMC, Pittsburgh, PA. (Control ID #3392021)

LEARNING OBJECTIVE #1: Triage undifferentiated shock using Point of Care Ultrasound (POCUS). **LEARNING OBJECTIVE #2:** Avoid anchoring bias when admitting a patient with a complex past medical history and language barrier.

CASE: A 32-year-old Nepalese female with history of Sjogren's Syndrome and MALT Lymphoma on immunosuppression, who had been taking acetaminophen (1-2 g daily) for recent fever, was transferred to a tertiary care facility for evaluation of hepatocellular liver injury thought to be due to APAP toxicity. She reported one month of sharp chest pain, orthopnea, weight loss of 15 lbs and night sweats. On exam, she was afebrile, tachycardic, hypertensive and saturating 94% on room air. She had an elevated jugular venous pressure, bibasilar crackles and RUQ tenderness with hepatomegaly. Her extremities were cool with 1+ bilateral edema. Labs were notable for leukocytosis of 12.8, AST 415 IU/L, ALT 863 IU/L, ALP 164 IU/L, INR of 2.7 and a negative APAP level. Brain natriuretic peptide was 5000 pg/mL. Creatinine was normal. Lactate rose from 6.2 to 14.7 mMol/L over her first 12 hours of admission. POCUS revealed B-lines in bilateral lung fields, grossly decreased left ventricular function and a dilated IVC without inspiratory collapse. Comprehensive echocardiography confirmed an ejection fraction of 25-35% with global hypokinesis. Right heart catheterization confirmed low output heart failure. No infectious source was found. Given persistent tachycardia, hypertension and fever, a TSH was checked and was 0.16 uIU/mL with a FT4 of 2.78 ng/dL. A cardiac MRI did not show evidence of myocarditis or infiltrative disease. A diagnosis of tachycardia-induced cardiomyopathy due to thyrotoxicosis was made. The patient was treated for cardiogenic shock and thyroid storm before returning home.

IMPACT/DISCUSSION: This case highlights the importance of taking a step back and reframing the differential diagnosis when receiving a patient with a complex history. The team noted several points of

discordant data with her initial diagnosis of APAP toxicity, including non-toxic levels of APAP ingestion (1-2 g/day), AST/ALT only in the hundreds and volume overload with cool extremities. POCUS can play an important role in prioritizing the differential diagnosis in a patient with impending shock. It can answer questions such as, "does this patient have LV dysfunction?" and "does this patient have evidence of pulmonary edema?" In this case, the combination of grossly decreased ventricular function and bilateral B-lines pointed towards the diagnosis and increased the urgency for right heart catheterization, transfer to the cardiac intensive care unit and treatment with inotropes.

CONCLUSION: POCUS is a readily accessible modality to effectively triage undifferentiated shock and pursue appropriate evaluation, especially when resources are limited. Checking our diagnostic reasoning and acknowledging discordant data is fundamental to finding a unifying diagnosis and avoiding anchoring bias, particularly in patients in whom history-taking is challenging.

AND THE RCC SAGA CONTINUES

Irene Rahman. General Internal Medicine, Mount Sinai Hospital, Jersey City, NJ. (Control ID #3374031)

LEARNING OBJECTIVE #1: Identify the metastatic complications of renal cell carcinoma (RCC) in those who are high surgical risk

LEARNING OBJECTIVE #2: Recognize the internist's role to provide support to this population of patients

CASE: My 67 year old female patient with a history of CHF, asthma, OSA, was incidentally found to have a 3.2cm renal mass. CT guided biopsy by interventional radiology (IR) showed that she had renal cell carcinoma (RCC), clear cell type, Fuhrman grade 2. Given co-morbidities, it was felt that the risk/benefit ratio of surgery was high for this patient for a likely slow growing tumor. Over the course of the following year, she sequentially had microwave ablation, cryoablation and embolization performed by IR. In the interim, a known left thyroid nodule of previously benign pathology per FNA was enlarging, causing trouble swallowing and change in voice. Thyroid US confirmed a 4.8cm predominantly solid nodule. Given compressive symptoms, she underwent a left hemithyroidectomy, with final pathology showing...metastatic RCC! Extensive imaging then was performed which showed a 2.7cm left renal mass, a 2cm left adrenal nodule, and subcentimeter nodules in both lungs measuring up to 6 mm in the lingula. A Urologist performed a left robotic/laparoscopic radical nephrectomy/radical adrenalectomy and lymph node dissection. Pathology of the adrenal nodule confirmed...metastatic RCC. For the next three years, continued to monitor the lung nodules, but then CT chest showed increase in size of lingular nodule, and PET scan confirmed hypermetabolic nature. A LUL FNA was non-diagnostic, thus a VATS of the LUL was done, with final pathology again showing...metastatic RCC! The patient is being monitored by serial imaging after the metastasectomy.

IMPACT/DISCUSSION: Approximately one-third of those with RCC are found to have metastatic disease, and one-fifth overall lead to death. Yet, monitoring is the primary option offered to patients incidentally found to have RCC < 4cm in diameter who are high surgical risk, because in this sub-group, the tumor is slow growing and likelihood of death or disability from another medical condition is more likely. The case report of my patient gives a face to someone living with metastatic RCC. In hindsight, the patient felt regret that surgery was not deemed to be the best option initially in her case, given that she eventually had to undergo the surgery anyway, as well as a thyroid surgery, and in addition, years of living in constant worry of another metastatic finding. During this time, my role as her primary care physician was to provide support and reassurance that she was receiving the standard of care based on complex medical decision making.

CONCLUSION: Patients with RCC who are deemed to be poor surgical candidates may be troubled when multiple locations of metastases do develop.

The role of the primary care physician for these patients is to provide ongoing support and explanation of the risk/benefit analysis used in medical decision making.

A NEAR MISS

Mangala Nayak[1]; David Rhee[2]. [1]Internal Medicine, New York School of Medicine, West Orange, NJ; [2]Internal Medicine, New York University School of Medicine, New York, NY. (Control ID #3392004)

LEARNING OBJECTIVE #1: Diagnosing Hypertriglyceridemic Induced Pancreatitis

LEARNING OBJECTIVE #2: Understanding the importance of ordering a lipid panel upon admission when suspecting pancreatitis

CASE: A 48 year old man with a history of hypertension and moderate alcohol use presented with acute abdominal pain after binge drinking with associated anorexia, nausea, and clear/watery emesis. He stated that the abdominal pain began the day prior to admission while eating but resolved without any intervention. Admission labs were notable for Lipase >5400 U/L, Glucose 245 mg/dL, Bicarbonate of 19 mmol/L and an anion gap of 20. Urine studies positive for ketones. Ultrasound of the abdomen showed mild hepatosplenomegaly. Patient was admitted and treated for alcohol-induced acute pancreatitis.

Given his anion gap metabolic acidosis associated with hyperglycemia and ketonuria, a triglyceride level was checked and found to be >4500 mg/dL. With this new diagnosis of hypertriglyceridemia-induced pancreatitis (HTGP), he was started on an insulin intravenous drip and transferred to the Intensive Care Unit for closer monitoring. On insulin, his serum lipase and triglycerides down trended and the patient eventually improved and was discharged with a new diagnosis of diabetes (HbA1C of 10.7%).

IMPACT/DISCUSSION: While gallstones and alcohol abuse are two most common causes of acute pancreatitis, HTGP is an uncommon but well-established cause of acute pancreatitis that typically occurs in patients in the presence of a secondary condition, such as uncontrolled DM, excessive alcohol consumption, or as an adverse effect of medications. Although HGTP symptomatically presents similarly to acute pancreatitis due to other etiologies, HTGP is often associated with greater clinical severity and rate of complications. This diagnosis is often missed or appropriate therapy is often delayed if a lipid panel is not checked shortly after admission. It is therefore crucial to identify hypertriglyceridemia and to target therapy accordingly, including specific therapies to lower serum triglyceride levels.

CONCLUSION: While elevated serum lipase is used commonly as a diagnostic tool for pancreatitis, there are currently no formal guidelines for routine lipid panels in all cases of acute pancreatitis. More concrete guidelines need to be formally available when there is a high suspicion for pancreatitis, arguably more so for first episodes of pancreatitis, that includes a thorough workup for all etiologies of pancreatitis.

AN ELDERLY WOMAN WITH A BONE DESTRUCTING INTRACRANIAL EPIDURAL ABSCESS CAUSED BY APICAL PERIODONTITIS

Mako Koseki[1]; Ivor Cammack[2]; Suguru Matsuzaka[3]. [1]Resident, Teine Keijinkai Hospital, Sapporo, Japan; [2]Resident Supervision, Teine Keijinkai Hospital, Sapporo, Japan; [3]General Internal Medicine and

Infectious Disease Medicine, Teine Keijinkai Hospital, Sapporo, Hokkaido, Japan. (Control ID #3388915)

LEARNING OBJECTIVE #1: Recognize the risk of serious infection in patients with poor oral hygiene

LEARNING OBJECTIVE #2: Recognize the current status and needs for improvement in dental care of the elderly in Japan

CASE: An 80-year-old Japanese woman presented with a 3 day history of left periorbital pain and swelling, dysarthria, and fever followed by right-sided weakness. Her past medical history includes rheumatoid arthritis for which she takes bucillamine. She lives independently.

On physical exam she was febrile, but her vital signs were otherwise normal. She was confused and had slurred speech. There was swelling and redness on the left side of the scalp. Cranial nerves were intact. Barré's sign was positive on the right, and there was reduced muscle strength (4/5) of the right upper and lower limbs.

Blood results showed elevated white blood cell count (1.9x10^4/μL) and CRP (23mg/dL). MRI showed abscess within the temporal bone and epidural and subcutaneous spaces of the left cranium.

Needle aspiration and drainage of the abscess was performed and the patient was started on ceftriaxone and metronidazole. We consulted a maxillofacial surgeon, who discovered apical periodontitis of two left upper molars adjacent to the abscess. *α-Streptococcus* was grown on aspirate, 6 weeks of amoxicillin was prescribed, and the teeth were removed.

On further history, the patient had not seen a dentist for over 20 years and brushed her teeth once daily.

IMPACT/DISCUSSION: This case highlights the risk of cranial epidural abscess due to periodontitis, which can spread into the cranium leading to bone and nerve involvement. More than 90% of epidural abscesses occur in the spine and are considered rare in the cranium but, when seen, are often sub-acute. Previous reports describe that more than 70% of epidural abscesses from oral infection occur due to hematogenous spread in young people under 20 years, with a male to female ratio of 3.6 to 1. In this case, it was unique that there was direct extension from a contiguous focus of ioral nfection to the brain, which we hypothesized to be more common in the elderly, most likely the reason for acute bacterial growth and sudden onset. To date, half of reported epidural abscesses spreading from the oral space were unrelated to dental procedures. A third of them had no prior symptoms. Most of these nonsymptomatic patients, including this case, were immunosuppressed due to diabetes, smoking, or use of immune-modulating medications. This case is a reminder of the importance of oral hygiene, especially in immunocompromised elderly individuals. Finally, our poster will review the evidence of tooth brushing to reduce the risk of dental infection, twice being the average right now, and also summarize the current state of dental care in Japan, where over 30% of the population over 80-year-old have untreated caries.

CONCLUSION: Good oral hygiene is important for elderly patients especially those who have few social supports as deep-seated potentially fatal infections can occur.

ANEMIC 31 YEAR OLD FE-MALE IN A STUDENT-RUN CLINIC: AN IRONIC FINDING

Andzelika Dechnik[1]; Nana Park[1]; Pamela Charney[2,1]. [1]Weill Cornell Community Clinic, Weill Cornell Medicine, New York, NY; [2]Internal Medicine, Weill Cornell Medical College, New York City, NY. (Control ID #3386522)

LEARNING OBJECTIVE #1: Assess persistent iron deficiency anemia in a female

LEARNING OBJECTIVE #2: Recognize dermatitis and iron deficiency anemia as potential signs of celiac disease

CASE: A 31-year-old woman with a 17-year history of iron deficiency anemia without menorrhagia presented to the Weill Cornell Community Clinic (WCCC) for follow-up after an increase in her daily iron (Fe) supplementation from 50 to 150 mg. The patient reported some improvement in her chronic fatigue, but continued to experience an intermittent pruritic rash on her elbows (previously presumed to be eczema), which had been poorly controlled with topical hydrocortisone. She also noted occasional black stool, stomach pain and diarrhea, but denied constipation, fevers, chills, weight loss, shortness of breath, changes in mood, or muscle/joint pain. Patient denied smoking or drug use and reported drinking 1-2 glasses of wine per week.

Her physical exam included normal cardiac and lung exams and a soft, nontender abdomen with normal bowel sounds. A pruritic, papular, non-scaling rash was noted on her bilateral elbow joints. Labs were remarkable for a low hemoglobin and hematocrit (10.4/31.2) with an increased RDW (15.9%). Despite daily Fe supplementation, labs showed a low ferritin (6.8 ng/mL), low Fe (24 ug/dL), elevated Fe binding capacity (413 ug/dL), and a low Fe saturation (6%). Further testing was positive for tissue transglutaminase (>100 U/mL) and endomysial antibody (1:640), highly suggestive of celiac disease.

Following serology results, patient was educated about celiac disease and a volunteer nutritionist provided the patient with in-depth information about a gluten-free diet. Upon follow-up, symptoms of fatigue and rash markedly improved with the restriction of gluten.

IMPACT/DISCUSSION: Iron deficiency is the most common cause of anemia and is prevalent in menstruating women due to blood loss. However, if no improvement of anemia is seen after daily iron supplementation, other sources of iron deficiency anemia must be considered.

Although celiac disease is most often associated with bloating and diarrhea after food consumption (seen in 50% of initial presentations), clinicians should be aware of other nonspecific symptoms. Dermatitis herpetiformis, often misdiagnosed as eczema, affects 10% of patients with celiac disease. Approximately 30% of patients also present with iron deficiency anemia caused by reduced iron absorption in the duodenum, concomitant gastrointestinal bleed, or autoimmune hemolytic anemia. Thus, iron deficiency anemia requires a high index of suspicion for celiac disease. Delayed diagnosis and management can lead to long-term consequences secondary to nutritional deficiencies (iron, folate, vitamin D, vitamin K), which cannot be controlled until the underlying condition is addressed.

CONCLUSION: In patients with chronic intermittent rash and iron-deficiency anemia that is not improving with iron supplementation, clinicians should have a high index of suspicion for celiac disease.

AN EXOTIC CASE OF PROGRESSIVE DYSPNEA

Quint Soto, Michael P. Smith. Internal Medicine, University of Nebraska Medical Center, Omaha, NE. (Control ID #3392387)

LEARNING OBJECTIVE #1: Develop a systematic approach to chronic dyspnea

LEARNING OBJECTIVE #2: Understand the pathophysiology of hypersensitivity pneumonitis and its role in the evaluation and management

CASE: A 44-year-old man presented with three months of progressively worsening dyspnea. He also noted cough productive of white sputum and dyspnea on exertion. He had a history of asthma and followed with a pulmonologist regularly; however, his albuterol no longer provided relief

despite increased use. Oxygen therapy was now required to maintain adequate oxygen saturation. He lived with his parents, as he had cerebral palsy and intellectual disability. He did not smoke nor was he exposed to secondhand smoke. His exam revealed bilateral basilar crackles. There were no abnormal heart sounds and JVP was not elevated, however lower extremity edema was present. Small bilateral pleural effusions with hazy bibasilar pulmonary interstitial and airspace opacities on chest X-ray. Diuresis provided no relief. Chest CT revealed diffuse ground-glass opacification throughout the lungs with areas of superimposed normal-appearing lung with multiple additional bilateral upper lobe nodular opacities that had peripheral ground-glass halos. It was discovered that the patient slept in the same room as a pet cockatoo. He found significant relief after initiation of glucocorticoids. More importantly, removal of the cockatoo from the home as well as deep cleaning of carpets, ducts, and air filters was necessary for continued resolution.

IMPACT/DISCUSSION: Dyspnea is an often-encountered complaint by the general internist. The differential for this problem is broad but most commonly stems from pathology of the cardiac or pulmonary systems. A detail-oriented approach is required to identify rarer causes of dyspnea. It is important to consider environmental exposures as they may precipitate a hypersensitivity pneumonitis.

Hypersensitivity pneumonitis is a diffuse inflammation of lung parenchyma and airways that occurs in response to inhalation of antigens that a patient has become sensitized to. Agricultural dusts, bioaerosols, and various reactive chemical species may all be culprits. There are many degrees of the disease, which depends on the offending antigen and duration of exposure.

Bird fancier's lung is one of the more well-known forms of hypersensitivity pneumonitis. Patients become sensitized to avian proteins present in droppings or feathers. These antigens become aerosolized and are inhaled when patients are in close contact with birds. Glucocorticoids can provide early symptomatic relief. The cornerstone of treatment is strict avoidance of the causative antigens. Patients able to accomplish this tend to have total recovery of lung function, although full recovery may take several years.

CONCLUSION: A thorough history when approaching chronic dyspnea may identify unique exposures and aid in diagnosis. When hypersensitivity pneumonitis is identified, removal of the offending antigen is the most critical aspect of long-term recovery.

AN INTERESTING CASE OF KAPOSI SARCOMA (KS) IN A HIGHLY IMMUNOSUPPRESSED PATIENT WITH CROHN'S DISEASE (CD): EPIDEMIC OR IATROGENIC?

Omar Viramontes, Jennifer Claytor, Stephanie Conner. Medicine, UC-San Francisco, San Francisco, CA. (Control ID #3384501)

LEARNING OBJECTIVE #1: Diagnose and manage a new presentation of KS in a patient newly diagnosed with HIV in the setting of having started a TNF alpha inhibitor (TI) for CD.

CASE: A 32-year-old man with CD presented to the ED with fever and rash. Painful papules arose on his chest 3 weeks prior and spread to his lower extremities. He had diarrhea and abdominal pain despite Prednisone 20 mg and two doses of Infliximab (a TI), but no other symptoms.

Three months earlier, CD had been diagnosed endoscopically, with no dysplasia or infection. He had no prior surgeries or medical problems, family history, recent travel, exposures, or drug use. He was sexually monogamous with his husband.

Exam showed diffuse violaceous plaques and nodules on his face, trunk, and extremities, and one buccal ulcer. Biopsy showed KS. HIV antibody was positive 1 day after discharge, with CD4 count 248 and viral load 3292. He was started on antiretrovirals (ARV). Further doses of Infliximab were held, although Prednisone was continued.

Three weeks later, sigmoidoscopy was positive for HHV-8, CMV, and EBV without lymphoproliferation. He received valgancyclovir for CMV colitis. For extensive visceral and cutaneous KS, he continued on ARVs and initiated Doxorubicin.

IMPACT/DISCUSSION: When approaching fever and rash, gathering a thorough social history is critical. Dermatologic emergencies must be addressed (such as infections and drug eruptions); opportunistic infections and malignancies should be considered in immunocompromised patients. CD-related dermatologic disorders include Pyoderma Gangrenosum and Erythema Nodosum, whereas psoriasis is a common side effect of Tis (0.6-5.3%). Patients on TI are also at higher risk of non-melanoma skin cancers, but KS has not previously been reported.

KS is divided into 4 categories: classic, endemic, iatrogenic, and AIDS-related. The lower extremities are the most common cutaneous site in all types, whereas visceral involvement and aggressive course are typical of iatrogenic and AIDS-related KS. Prognosis for patients with AIDS-related KS is classified by tumor extent, immune status, and systemic illness. For our patient, his KS worsened despite ARV, Doxorubicin is the chemotherapy of choice.

High-dose steroids have been correlated with worsened and incident KS, and 4 cases of KS in HIV-negative patients with CD have been reported in the setting of steroids. However, there are no reports of KS associated with TI. Given our patient's concomitant CMV colitis at higher CD4 count, we hypothesize that the combination of undiagnosed HIV, high-dose prednisone, and TI contributed to his potentially fatal KS presentation. Some countries recommend screening for HIV prior to initiating TI. Such measures may have prevented harm to this patient.

CONCLUSION: ●For rash and fever in an immunocompromised patient, rule out dermatologic emergencies and consider opportunistic infections and malignancies, including KS.

●In addition to TB and Hepatitis B, consider screening high-risk populations for HIV prior to initiating TI.

ANTIPSYCHOTIC MEDICATION EFFECTS MIMICKING MYXEDEMA COMA AND SEVERE SEPSIS

Nisha Soneji, Liwayway R. Andrade, Chukwufumnanya Ikeneme, Jaison John. Internal Medicine, Dell Seton Medical Center at the University of Texas in Austin, Austin, TX. (Control ID #3390432)

LEARNING OBJECTIVE #1: Recognize the adverse reactions of olanzapine confounding clinical picture and mimicking another diagnosis.

CASE: A 64-year-old woman with history of schizophrenia was brought in from jail for bilateral lower extremity edema and hypothermia unrelated to environmental exposure. On arrival to the emergency department, she was agitated, hypotensive (MAP <60), bradycardic (HR in 50s), and hypothermic with a rectal temperature of 90.4°F. Due to the patient's psychotic state, no history could be elicited. Initial differential diagnosis included myxedema coma and severe sepsis. Fluid bolus, antibiotics, intravenous levothyroxine and hydrocortisone were immediately administered. Laboratory findings were significant for neutropenia with an absolute neutrophil count of 984, which was previously normal three weeks earlier. Peripheral smear demonstrated few large granular lymphocytes, which are normal variants. Thyroid studies showed a normal free T4 and mildly elevated TSH with a value of 6.45 mcIU/mL (0.34 – 5.60 mcIU/ml), consistent with subclinical hypothyroidism. Additional laboratory results included a normal lactate, clear urinalysis, unremarkable chest x-ray, and pan-CT non-revealing for an infectious source. Patient had bilateral lower extremity erythema and edema concerning for bilateral lower extremity cellulitis, but this was not significant enough to account for her severe hypothermia, bradycardia, and hemodynamic instability. On further investigation, the

only medication the patient was taking at the time of presentation was olanzapine, a court-ordered medication to be administered for her psychotic symptoms, which was started thirteen days prior to symptoms. During her hospital stay, olanzapine was stopped and switched to aripiprazole (Abilify), which was tolerated well by the patient. Additionally, with active warming and supportive care with fluids and antibiotics, the patient's clinical condition improved. Neutropenia resolved five days after olanzapine was discontinued, and all culture data returned without any sign of infection.

IMPACT/DISCUSSION: Olanzapine (Zyprexa) is an atypical antipsychotic that affects the dopaminergic pathway commonly used in the treatment of schizophrenia and bipolar disorder. Common side effects include extrapyramidal syndrome, akathisia, hyperprolactinemia, weight gain, and transaminitis. Rare adverse effects include hypothermia, bradycardia, and hemodynamic instability, while neutropenia is even more rare. This case illustrates how rare adverse reactions from an antipsychotic medication can confound the clinical picture and mimic another diagnosis, specifically myxedema coma and sepsis. There have been less than a hundred reported cases of antipsychotic-related hypothermia and only two reported cases of olanzapine-related neutropenia in the literature.

CONCLUSION: Awareness of these rare adverse reactions, alongside a thorough investigation and open- minded differential were critical in deciphering this intriguing case.

AN UNCOMMON CAUSE OF CHEST PAIN

Rebecca Green. Medicine, Boston Medical Center, Boston, MA. (Control ID #3391451)

LEARNING OBJECTIVE #1: Broaden the differential diagnosis for acute chest pain to include spontaneous coronary artery dissection (SCAD).

LEARNING OBJECTIVE #2: Recognize SCAD as a cause of myocardial infarction (MI), particularly in women without classic atherosclerotic risk factors.

CASE: 53-year-old woman with hypertension, GERD, and inferior MI 7 years ago caused by a distal PDA lesion unamenable to intervention presented to the ED with chest pain. She reported sudden onset left-sided chest pain preceded by emotional stress. The pain radiated to her jaw and left arm, and was associated with dyspnea. It was unrelieved by sublingual nitroglycerin. She had no smoking history and no family history of cardiovascular disease.

Upon arrival to the ED, patient had BP 171/99, HR 70, RR 16, and was saturating 100% on room air. Exam revealed normal S1S2, and a regular rate and rhythm without murmurs or gallops. Lungs were clear. There was no reproducible chest wall tenderness. ECG showed sinus rhythm with T wave inversions in V5-V6 comparable to prior, and no ST changes. Labs were notable for troponin I of 0.059 which uptrended to 2.718 on repeat.

Patient received full-dose aspirin and was started on a heparin drip and clopidogrel. She underwent cardiac catheterization which showed a spontaneous coronary artery dissection of the left circumflex. Based on this finding, she was managed medically with blood pressure control and one year of dual antiplatelet therapy. She also completed renal and carotid dopplers to assess for fibromuscular dysplasia, both of which were normal.

IMPACT/DISCUSSION: SCAD is a rare cause of MI that disproportionately affects women, often those without atherosclerotic risk factors. While the true incidence is unknown as it is likely underdiagnosed, SCAD is estimated to cause up to 35% of MIs in women under 50. Risk factors include connective tissue disorders and hormonal fluctuations such as those occurring with pregnancy.

Accurately diagnosing SCAD is vital for many reasons. First, as patients with SCAD are often healthy young and middle-aged women, it is important to recognize that they can be having a myocardial infarction despite a lack of cardiac risk factors. Second, management of SCAD differs from that of CAD-related MI. While PCI is a mainstay of management of ACS, it is associated with more complications and worse outcomes in SCAD. Third, diagnosing SCAD helps ensure patients receive appropriate follow-up care including screening for underlying predisposing conditions and counseling regarding future pregnancy and hormone use.

CONCLUSION: SCAD is a rare but underdiagnosed cause of MI, especially in women without classic atherosclerotic risk factors.

Prompt and accurate diagnosis of SCAD can ensure patients get appropriate treatment and follow-up care. Reference: Hayes, SN et al. Spontaneous Coronary Artery Dissection: Current State of the Science: A Scientific Statement From the American Heart Association. Circulation. 2018;137:e523–e557, doi.org/10.1161/CIR.0000000000000564. Accessed January 9, 2020.

AN UNEXPECTED CAUSE OF CUSHING SYNDROME

J. R. Penick. Hospital Medicine, UAB, Birmingham, AL. (Control ID #3391981)

LEARNING OBJECTIVE #1: To discuss a rare instance of an ACTH-producing Pheochromocytoma

CASE: A 41-year-old white female with type 2 diabetes and hypertension presented to emergency department with several week history of weakness, hyperglycemia and hypertension. For 2-3 weeks, her primary care physician had an increasingly difficult time managing her hypertension and diabetes. Family history revealed type 2 diabetes in her father. Pertinent medications included metformin, glimeprimide, irbesartan, and indapamide. Initially, she was afebrile with a blood pressure of 217/112 and heart rate of 111. Physical exam revealed a round face, supraclavicular fat deposition, purple striae along abdomen, and bilateral lower extremity edema. Labs showed a leukocytosis of 16,400, hemoglobin of 16.4 g/dL. BMP was normal except for a potassium of 2.8 and glucose of 214. Random cortisol level was very elevated. Patient failed low dose and high dose dexamethasone suppression tests, with persistently elevated Adrenocorticotropic hormone (ACTH), suspicious for an ectopic source of ACTH. MR brain did not reveal pituitary abnormalities. CT abdomen and pelvis showed a complex 4.2 cm right sided adrenal tumor and bilateral adrenal hyperplasia. Plasma metanephrines and normetanephrines were also elevated, consistent with an ACTH producing pheochromocytoma (pheo). Patient was started on ketoconazole, spironolactone, and doxazosin for alpha. At a later admission, the patient underwent a successful right adrenalectomy. Pathology was consistent with adreno-cortical hyperplasia, ACTH staining pheo. At a PCP follow-up appointment, she was doing well with no further symptoms. She is no longer requiring blood pressure or diabetes medications.

IMPACT/DISCUSSION: Cushing syndrome is rarely caused by a pheo. Cushing syndrome may be either ACTH-dependent or independent, with ACTH-dependent causes being much more common. The majority of these ACTH-dependent causes are a result of pituitary hypersecretion, classically defined as "Cushing disease." Ten to fifteen percent of ACTH-dependent Cushing syndrome are due to ectopic ACTH syndromes. Neuroendocrine tumors of the lungs, pancreas and thymus are among the most common causes, which brings to mind the common association between small cell carcinoma of the lung and ectopic ACTH secretion. ACTH-producing pheos are very rare, and a recent literature search in 2018 from Gabi et al. in the Journal of the Endocrine Society cites fifty-eight total case reports. One of the similarities among cases of ACTH-producing pheos is the rapid onset of symptoms compared to the more subtle onset of most Cushing syndromes. Hypokalemia, in addition to suddenly worsening hyperglycemia and hypertension, were usually seen. The increased intensity of symptoms is thought to be due to the excess of cortisol in addition to excess catecholamines.

CONCLUSION: ACTH-producing pheos are a rare cause of Cushing syndrome but should be considered in all cases of ACTH-dependent Cushing syndrome.

AN UNEXPECTED EPIDEMIC IN YOUNG ADULTS

Lauren K. Michael, Nebil Nuradin. Internal Medicine, Tulane University School of Medicine, New Orleans, LA. (Control ID #3391260)

LEARNING OBJECTIVE #1: Recognize E-cigarette or Vaping Associated Lung Injury (EVALI) as an emerging public health concern

LEARNING OBJECTIVE #2: Assess proposed treatment strategies for EVALI

CASE: A 23-year-old man presented with shortness of breath, nausea, vomiting and epigastric pain following use of illegally sourced tetrahydrocannabinol (THC) electronic vaping cartridges. He had a history of exceedingly heavy THC and had been self-treating anxiety with cannabis. Blood pressure was 126/78 mmHg, pulse 113 bpm, respirations 40 breaths/min and temperature 102.1F. He was anxious, moaning, retching and in respiratory distress. Lab studies were as follows: sodium 147 mmol/L, potassium 3.4 mmol/L, chloride 102, carbon dioxide 18 mm/L, blood urea nitrogen 13 mg/dL, creatinine 0.88 mg/dL white blood cell count 22,400 cells per cubic mm, hemoglobin 14.5 g/dL mL, and platelets 297,000/L, Arterial blood gas demonstrated pH 7.45, CO2 35 mmHg, PaO2 51 mmHg. Chest X-ray revealed patchy interstitial opacities and CT chest revealed bilateral ground glass opacities sparing the apices. Bronchoalveolar lavage had foamy macrophages and lung biopsy pathology returned as acute and organizing lung injury with fibrin exudates. He required high flow oxygen and admission to intensive care. He was unable to be weaned to room air after an extended, complicated hospital stay and treatment included broad-spectrum antibiotics and corticosteroids. No infection was identified, and he was discharged on supplemental oxygen and a steroid taper.

IMPACT/DISCUSSION: EVALI is a serious complication of electronic vaporizer use. In November 2019 the CDC reported 2,172 cases and 42 deaths. 68% were male and 77% were adults younger than 35. Most were associated with informal sources of THC. Vitamin E acetate used in aerosolizing solutions and lipid- laden macrophages have been seen in bronchoalveolar lavage. Respiratory and gastrointestinalsymptoms are most common, a 98% and 90%, respectively. Diffuse ground glass opacities are seen on chest CT. INR elevation can be seen from coagulation pathway disruption from inflammation or vitamin E, which is a vitamin K inhibitor.

Treatment involves high dose steroids with broad coverage antibiotics. Steroid treatment in the inpatient setting is associated with rapid improvement, but a dosing strategy has not been agreed upon. Steroids can increase the chance of an overlying infection and are not recommended in the outpatient setting. Some patients have improved without steroid treatment, but comparative studies have not been done. We recommend broad coverage with antibiotics until infectious sources are ruled out. Counseling on cessation of all inhalants is imperative and prompt reporting of cases to the CDC are essential for further clinical and pathological understanding.

CONCLUSION: With vaping use on the rise, increasing reports of EVALI are noted. Given the advent of this new etiology for lung injury, further investigation is needed to determine appropriate diagnostic and treatment stratgies.

AN UNUSUAL CASE OF A SUPRAGLOTTIC MASS LESION IN A PATIENT WITH AIDS

Katelin Snow[1]; Manasi Tannu[1]; DIVYA BHAMIDIPATI[2]. [1]Internal Medicine, Emory University School of Medicine, Atlanta, GA; [2]Infectious Diseases, Emory University School of Medicine, Atlanta, GA. (Control ID #3390346)

LEARNING OBJECTIVE #1: Recognize CMV as a cause of a neck mass in an immunocompromised patient.

LEARNING OBJECTIVE #2: Treat CMV pseudotumor with medical and surgical management.

CASE: Our patient is a 58-year-old male with a past medical history of HIV, not on antiretrovirals, who presented to the ED with a one-month history of hemoptysis, drooling, decreased oral intake, and progressive dyspnea. On exam, patient was afebrile but tachypneic with excessive drooling. Laboratory evaluation was notable for CD4 count of 10. CT scan of the neck and chest revealed a supraglottic mass causing impending airway obstruction. He was taken to the operating room for emergent tracheostomy tube placement and biopsy of the mass.

Direct laryngoscopic evaluation showed a supraglottic mass with extensive necrosis of surrounding tissues, including the trachea. Biopsy revealed ulcerations with granulation tissue and viral cytopathic inclusions consistent with CMV. Due to the high suspicion for malignancy, repeat biopsy was obtained which confirmed the diagnosis. IV gancyclovir was started and foscarnet was later added.

Unfortunately the patient developed an aspiration pneumonia and septic shock requiring transfer to ICU for mechanical ventilation. Following discussions with multiple care teams regarding the limited surgical and medical options to preserve his airway, the patient decided to pursue palliative care and transfer to hospice.

IMPACT/DISCUSSION: Cytomegalovirus is an important pathogen in immunocompromised patients, including patients with HIV/AIDS. The most well-known manifestations of CMV infections include chorioretinitis, enteritis, and pneumonitis. Less commonly, CMV infection can produce mass lesions, and these have been described in various locations throughout the body. There are few case reports of these "pseudotumors" in the head and neck in immunocompromised patients. Our case is the first that reports a mass causing both airway obstruction and significant ulceration with necrosis of the surrounding soft tissue.

The mainstay of treatment for CMV is IV ganciclovir. However ganciclovir is limited by suboptimal efficacy, toxicity and evolution of resistant strains. Other options for treatment include foscarnet and cidofavir, although use is limited by nephrotoxicity. CMV resistance to antivirals is a major clinical problem in patients with T cell depletion, very high viral loads, recurrent CMV disease, and suboptimal antiviral drug concentrations due to reduced absorption or poor compliance. Some case reports have observed that surgical excision of the mass can be effective in those refractory to medical management.

CONCLUSION: - In immunocompromised patients who present with symptoms of airway obstruction, CMV infection should remain on the list of differential diagnoses.

- Biopsy is necessary to confirm the diagnosis and should show classic viral cytopathic inclusions.

- Typically, CMV infections are treated with IV gancyclovir and mass lesions may be amenable to surgical excision.

AN UNUSUAL CASE OF ASYMPTOMATIC PRESENTATION OF CRYPTOCOCCAL MENINGITIS

Taranika Sarkar. Internal Medicine, Jamaica Hospital Medical Center, Rego Park, NY. (Control ID #3378153)

LEARNING OBJECTIVE #1: Cryptococcal Meningitis is a common opportunistic infection in HIV-AIDS patients with low CD4 count. It has also been reported in immunocompromised patients, like transplant and neutropenic patients. Classically meningitis presents with headache, fever, photophobia and nuchal rigidity. Asymptomatic presentation of meningitis has rarely been reported. We present a case of subacute

cryptococcal meningitis in a kidney transplant patient displaying no typical signs of the disease process.

CASE: A 58-year-old male with past medical history of type 2 diabetes mellitus, kidney transplant on immunosuppressants mycophenolate, prednisone and tacrolimus, presented with low grade fever, productive cough, malaise and anorexia since last two weeks. Physical exam showed stable vitals, temperature of 99.3 F, normal mental status and equally reactive pupils, but diffuse rhonchi on auscultation. Chest X-ray and CT scan showed left perihilar opacities. The patient was admitted for sepsis secondary to community acquired pneumonia.

Two days later, the patient started developing a moderate headache. No photophobia, nuchal rigidity, nausea or vomiting were present. CT scan head showed no abnormalities. Lumbar puncture showed cell count of 27, Neutrophil 1, Lymphocytes 5 and pressure of 26 cm of H20. Due to high suspicion, a cryptococcal panel was sent. Blood culture started growing yeast. Before final cultures were back, the patient was started empirically on Amphotericin B. Latex Agglutination test reported back as Cryptococcal Ag positive (titer 1:1024) and Flucytosine was added. CSF cultures were positive for *Cryptococcus neoformans*. The patient had one session of therapeutic lumbar puncture. He improved clinically. We regularly monitored serum flucytosine levels, serum urea and creatinine and provided aggressive hydration to avoid renal failure.

IMPACT/DISCUSSION: The global burden of Cryptococcosis was recently estimated about ~1 million cases. Cryptococcus has a special tropism for the nervous system, where it can cross to, by paracellular, transcellular and Trojan Horse pathways. Furthermore, different studies have described that diabetic patients have a decreased phagocytic activity and T cells response, which might favor cryptococcal migration to the CNS.

In the background of immunosuppression, a low threshold for suspicion of cryptococcal meningitis is necessary. This will help to avoid the condition, which can lead to permanent sequalae like cranial nerve palsy, or even lead to death. Cryptococcal meningitis, unlike other forms of meningitis, has low cell count in cerebrospinal fluid analysis. But pressure elevation is often dramatic (>250 mm of H20). If left untreated, brain herniation and death may occur. Serial lumbar puncture is therapeutic in this condition.

CONCLUSION: Hence, we emphasize the health care professional to remain vigilant and consider cryptococcal meningitis even when classic symptoms are absent.

AN UNUSUAL CASE OF ATYPICAL DRESS SYNDROME IN A RARELY DESCRIBED AGENT

Ryan J. Fiter, Emily Carroll. Icahn School of Medicine, Mount Sinai Hospital, New York, NY. (Control ID #3392139)

LEARNING OBJECTIVE #1: DRESS can occur in absence of eosinophilia

LEARNING OBJECTIVE #2: Valproic Acid is a rare cause of DRESS

CASE: A 19-year old male presented with 5-10 days of whole-body erythroderma, associated with exfoliative changes, lip swelling, facial edema, and malaise. His past medical history included Intermittent Explosive Disorder, for which he recently had a psychiatric hospitalization 5 weeks prior to admission where he was started on Valproic Acid. He initially presented to his PCP, where he was found to have a leukocytosis of 35 x 10E3/uL WBCs. He presented to the ED for further evaluation, where he was noted to have borderline hypotension. Following fluid resuscitation, he was transferred to the MICU. His labs were significant for a leukocytosis of 34.3 x 10E3/uL WBCs comprised of 33% atypical lymphocytes and no eosinophils, an elevated lactate, and a mixed cholestatic and hepatocellular pattern of liver injury. Over the subsequent days, he developed high-grade fevers, hemodynamic instability, acute liver failure, and acute kidney injury. Further laboratory evaluation revealed hyperuricemia, elevated LDH and D-Dimer, decreased fibrinogen, and notably ferritin >40 000 and IL-2 Receptor Alpha level of 24749 (nl 223-710). Ultimately, peripheral flow cytometry and TCR gene rearrangement studies did not reveal any malignancy, and skin biopsy was significant for erythrodermic drug reaction with lymphomatoid features, consistent with a diagnosis of DRESS syndrome. He was treated with high dose IV steroids, which resulted in improvement of his rash and other symptoms, including his hepatic dysfunction. He was ultimately discharged on an oral steroid taper in stable condition.

IMPACT/DISCUSSION: DRESS is a rare drug reaction that consists of a constellation of symptoms, namely widespread rash, systemic symptoms, and hematologic abnormalities. Eosinophilia classically occurs in DRESS, but in atypical cases, such as ours, atypical lymphocytosis can occur instead. Systemic symptoms most commonly consist of fever, malaise, and lymphadenopathy, and typically multiple organs are involved. Many agents have been associated with DRESS, however Valproic Acid monotherapy has been a very rarely reported cause in the current literature. Furthermore, this case may represent the first case of Valproic Acid induced DRESS syndrome without eosinophilia. DRESS syndrome has a mortality of up to 5-10%, most often due to acute liver failure. Other causes include cardiac, pulmonary, and renal involvement. Hemophagocytic syndrome has also been a reported cause of mortality, which may also have been present in this patient given the very elevated ferritin and IL-2 receptor level.

CONCLUSION: In patients with a new rash 2-8 weeks after initiation of a new medication, DRESS syndrome should be considered as a possible etiology even in the absence of eosinophilia. Although rare, Valproic Acid can cause DRESS syndrome

AN UNUSUAL CASE OF CABG INDUCED MYASTHENIA GRAVIS

Hannah E. Anderson, Rachel A. Ward, Damon Abaray. Internal Medicine, University of Tennessee - Nashville, Nashville, TN. (Control ID #3370065)

LEARNING OBJECTIVE #1: Recognize new onset myasthenia gravis (MG) in patients who are post coronary artery bypass graft (CABG).

LEARNING OBJECTIVE #2: Assess, treat, and manage post CABG myasthenic patients alongside neurology colleagues.

CASE: A 79-year-old male with three vessel CABG performed three weeks prior presented to the hospital with a 2 day history of diplopia, dysarthria, and dysphagia. Physical exam was relevant for bilateral ptosis, bilateral abduction paresis with horizontal nystagmus, and significant dysarthria. MRI of the brain was negative for acute changes. Tensilon test, performed for suspicion of MG, was positive. IV pyridostigmine was initiated, and diagnosis was confirmed with positive acetylcholine receptor (AchR) binding, blocking, and modulating antibodies. High dose steroids were initiated, and CT of the chest ruled out presence of thymoma. With no clinical improvement, a continuous infusion of pyridostigmine and a 5 day course of IVIG were begun. Four days after completing treatment, the patient's diplopia and abduction palsy had improved, but his dysarthria and dysphagia persisted. Over the next week, he underwent 5 sessions of plasmapheresis, resulting in improvement in his dysphagia and dysarthria.

IMPACT/DISCUSSION: Post-CABG myasthenia gravis is an exceedingly rare occurrence. It was first described in a 2003 case series outlining three males with no known autoimmune disorders and no immediate postoperative complications, thereby ruling out previously unidentified MG, who were diagnosed with MG approximately 3-10 weeks after CABG. Though the exact pathophysiology is unclear, it is hypothesized that surgical manipulation of the anterior mediastinum, an area occupied by atrophic thymic tissue, causes release of acetylcholinesterase receptor (AchR) molecules which in turn trigger formation of AchR antibodies.

Treatment modalities are similar to those used in acute crises of idiopathic MG, including acetylcholinesterase (CHE) inhibitors, typically pyridostigmine, followed by glucocorticoids, and, if needed, IVIG and/or plasmapheresis. Long term therapy includes pyridostigmine with possible adjunctive azathioprine or mycophenolate.

In the original case series, one patient responded well to CHE inhibitor, another required adjunctive steroids, and the last required plasmapheresis. All three recovered from acute crisis but continued to have positive antibody titers and chronic disease requiring long-term immunosuppressive medications. Our patient's ultimate clinical course has yet to be determined; however, based on the aforementioned case series and the patient's history of limited response to multiple treatments, he is expected to have ongoing response to therapy followed by chronic MG.

CONCLUSION: New onset MG following CABG is a rare occurrence theoretically due to release of thymic acetylcholinesterase receptors after manipulation of the anterior mediastinum.

Early recognition of the disease and initiation of appropriate treatment is essential to prevent respiratory decompensation.

AN UNUSUAL CASE OF DIPLOPIA: HIDDEN IN THE PLAIN SIGHT

Mallika Velichety[1,2]; Pavan Annamaraju[2,1]. [1]Internal Medicine, Johnston Memorial Hospital -Ballad Health, Abingdon, VA; [2]Nephrology, Johnston Memorial Hospital -Ballad Health, Abingdon, VA. (Control ID #3392064)

LEARNING OBJECTIVE #1: 1. Recognize type 1- diabetes mellitus as an unusual cause of sixth nerve palsy in a young woman

LEARNING OBJECTIVE #2: 2. Evaluate and manage a case of sixth nerve palsy when seen in the clinic.

CASE: A 29-year-old woman was seen in the clinic for sudden onset of diplopia and blurry vision of 10-day duration. Symptoms increased in severity as her gaze turned to the left with both eyes open. There was no associated eye pain, headache, nausea, vomiting, or focal neurological symptoms. Past medical history was notable for type-1 diabetes mellitus (DM), peripheral neuropathy, retinopathy, hypertension, and nephropathy with an eGFR of 25ml/min/1.73^2. She reported quitting intravenous methamphetamine one year ago. On exam, vital signs were stable with BMI 21 kg/m^2. Left 6th cranial nerve palsy was noted. The remainder of the exam was unremarkable. We entertained the possibility of demyelinating or vascular causes. She was hospitalized for further workup. Lab data showed HbA1c 8.1%, LDL 131 mg/dL, HDL 25 mg/dl, and Triglycerides 285 mg/dl, normal thyroid panel. MRI of the brain without contrast showed no acute intracranial pathology. The ophthalmologic evaluation showed bilateral diabetic macular edema. Her symptoms were felt to be from the microvascular complications of type-1DM. On a 3 month follow-up, with strict glycemic control, she had a complete resolution of symptoms reaffirming the diagnosis.

IMPACT/DISCUSSION: Isolated 6th nerve palsy is rare, with an annual incidence of 11.3/100,000. In adults, it is due to microvascular complications noted in 8– 36% of cases. Risk factors include type 2 DM, male sex, age ≧ 50 years, dyslipidemia, and obesity. In this population, expectant management is recommended for 6 months. If symptoms persist MRI brain with gadolinium is performed. Our patient had several interesting features that make the case unique. First, isolated 6th nerve palsy is uncommon in type-1 compared to type 2 DM. Second, atypical demographics (female gender and young age) prompted us to consider demyelinating disorder higher in our differential than vascular causes. Therefore, we performed an MRI of the brain. In a prospective study of isolated 6th nerve palsy, an alternative diagnosis to microvascular palsy was discovered in 17 %- neoplasm, brainstem infarction, demyelinating disease, and pituitary apoplexy. Missing such diagnoses can cause catastrophic outcomes. Third, though the imaging of choice is MRI with gadolinium, the presence of the kidney disease precluded the use of contrast. A standard MRI brain may miss orbital apex lesions or thyroid eye disease. Lastly, we hypothesize that her prior amphetamine abuse could have contributed to vasculopathy.

CONCLUSION: We report an unusual case of isolated 6th nerve palsy in a young type-1 diabetic woman Internists should be aware of this entity giving a growing burden of DM

The decision-approach to perform an MRI for isolated 6th nerve palsy should be individualized. Caution should be taken to avoid missing the many mimics of abducens palsy.

AN UNUSUAL CASE OF HYPOXIA IN AN HIV+ PATIENT

Ravi Jariwala[1]; Sivani Reddy[2]; F. Stanford Massie[3]. [1]Internal Medicine, University of Alabama at Birmingham (UAB), Birmingham, AL; [2]University of Alabama at Birmingham School of Medicine, Birmingham, AL; [3]Medicine, University of Alabama at Birmingham, Birmingham, AL. (Control ID #3388319)

LEARNING OBJECTIVE #1: Diagnose methemoglobinemia

LEARNING OBJECTIVE #2: Treat methemoglobinemia

CASE: A 57-year-old white male with history of HIV presented to the ED with a week of worsening non- productive cough, wheezing, exertional dyspnea. He denied shortness of breath, fever, chills, hemoptysis, recent travel. One month prior, he had an undetectable viral load and a CD4$^+$ count of 210. He was compliant on anti-retroviral therapy (ART) with dapsone Pneumocystis jiroveci pneumonia prophylaxis. Upon arrival, he was afebrile, tachycardic, tachypneic, hypertensive at 170/81, with SpO_2 ranging from 88-90% on 4L nasal cannula. Physical exam with mild respiratory distress, anterior ronchi, subtle bibasilar inspiratory rales. Admission labs with elevated LDH 303, hemoglobin (Hgb) of 11.6, ABG pH 7.47, PCO_2 33, PO_2 79 with an increased A-a gradient, CBC notable for neutrophil predominant leukocytosis. Lactic acid, procalcitonin, and brain natriuretic peptide were within normal limits. Rapid flu was negative. Non-contrast CT chest without consolidation or effusions but with centrilobular nodules on the right lung. He was empirically started on ceftriaxone and azithromycin for community acquired pneumonia coverage and clindamycin, primaquine, and steroids for PJP treatment given elevated LDH, A-a gradient, and his HIV status. One day after admission, he was noted to have SpO_2 in the 80's on 4L nasal cannula with fingernail cyanosis. Labs demonstrated discordance between ABG pulse oximetry, acute on chronic anemia with a decrease in Hgb to 8.1, low haptoglobin (<30), uptrending LDH. Methemoglobin (MetHgb) level was ordered due to discordance between pulse oximetry and ABG with resultant value of 16%. Primaquine was discontinued. He had significant clinical improvement within two days with resolution of his methemoglobinemia. His initial hypoxia was likely due to atypical pneumonia with further exacerbation by methemoglobinemia presumed to be due to addition of primaquine while on chronic dapsone.

IMPACT/DISCUSSION: MetHgb is Hgb with iron in the oxidized state. MetHgb causes a leftward shift in the oxygen-hemoglobin dissociation curve resulting in a reduced ability of the red blood cell to release the oxygen and tissue hypoxia. Iatrogenic causes are most common and include drugs such as dapsone, primaquine, nitrates, and sulfonamides. Several hallmarks of the clinical presentation of methemoglobinemia include: peripheral cyanosis, a low SpO_2 measured by pulse oximetry but a normal PO_2 on arterial blood gas, poor response in the SpO2 to supplemental oxygen, mild hemolysis, and "chocolate-colored" blood that does not change upon exposure to oxygen.

CONCLUSION: Methemoglobinemia should be on the differential in the setting of hypoxia with signs of cyanosis and a drug exposure known to trigger MetHgb formation. Diagnosis is confirmed with co-oximetry

panel. Treatment consists of withdrawing the offending agent and, based on severity of MetHgb levels, administration of IV methylene blue or ascorbic acid.

AN UNUSUAL CAUSE OF ABDOMINAL PAIN: LUPUS ENTERITIS AS THE SOLE PRESENTING FEATURE OF SYSTEMIC LUPUS ERYTHEMATOSUS

Rushi Talati, David Pineles, Mahesh Krishnaiah, Adam Goodman. Medicine, New York University School of Medicine, New York, NY. (Control ID #3392424)

LEARNING OBJECTIVE #1: Recognize the nonspecific clinical features of lupus enteritis as a rare but serious manifestation of SLE

CASE: A 32 year old Asian female presented to clinic complaining of three days of abdominal pain and nausea. Her past medical history was notable for arthritis, H. pylori gastritis, chronic GERD, nephrolithiasis and migraine headaches. She was instructed to continue Nexium for presumptive dyspepsia management. She presented eight days later to the Emergency Room complaining of intractable epigastric abdominal pain. Vital signs were unremarkable. Exam was remarkable for significant lower abdominal tenderness without guarding or rigidity. CT abdomen/pelvis revealed mild right hydronephrosis and hydroureter with surrounding inflammatory changes. A pain regimen was initiated and patient was discharged with a presumptive diagnosis of passed ureteral stone. In the following three weeks she received multiple courses of amoxicillin for positive urine cultures thought to be contributing to abdominal pain without significant response. One month later she began experiencing daily, loose, non-bloody bowel movements. Outpatient EGD was notable only for gastritis. Symptomology persisted and a unifying diagnosis was not retained. Patient re-presented with similar pain three months later and was again admitted. Repeat CT imaging revealed a long segment of small bowel wall thickening not previously present. Infectious work up was unrevealing, however patient improved on a prolonged course of empiric ciprofloxacin/metronidazole. Patient was re-admitted two months later with recurrence of abdominal pain. CT imaging re-demonstrated proximal small bowel wall thickening. Push enteroscopy with biopsy was performed and unremarkable. Index of suspicion at that point prompted rheumatology work up. ANA was positive (>640, speckled). Serum C3 and C4 were low (48; 11 mg/dL), dsDNA and RNP were elevated (12 IU/mL; 1.8 AI). She was started on plaquenil and prednisone as an outpatient with improvement in her symptoms.

IMPACT/DISCUSSION: Lupus enteritis is a rare manifestation of SLE. Few reports describe enteritis as the sole presentation in relapse or active disease, and rarely has it been reported as the initial presentation. This case highlights the challenge in a young, complex female with chronic, intermittent non-specific complaints 20 months after initial symptom onset.

This case also highlights the importance of avoiding anchoring bias. The absence of pathognomonic imaging findings and unremarkable endoscopic biopsy findings led to multiple misdiagnoses and a delayed diagnosis. In this case, nonresolution of symptoms led to additional history and diagnostic evaluation that ultimately led to an accurate assessment.

CONCLUSION: Diagnosis of lupus enteritis requires a high index of suspicion given the low incidence and nonspecific clinical findings

The treatment of lupus enteritis relies on complete bowel rest and steroid treatment, usually with complete remission

AN UNUSUAL CAUSE OF BACTEREMIA AND VERTEBRAL OSTEOMYELITIS WITH CORYNEBACTERIUM DIPHTHERIAE

John Gaudet[1]; Frances V. Ue[1]; Megan Callahan[1]; Amanda Barner[3]; Rebecca Osgood[4]; Eirini Iliaki[2]. [1]Internal Medicine, Cambridge Health Alliance, Cambridge, MA; [2]infectious Diseases, CHA, Cambridge, MA; [3]Pharmacy, Cambridge Health Alliance, Cambridge, MA; [4]Pathology, Cambridge Health Alliance, Cambridge, MA. (Control ID #3391808)

LEARNING OBJECTIVE #1: Become familiar with the differential diagnosis of high grade bacteremia with Gram positive rods (GPRs) and prescribe appropriate empric therapy

LEARNING OBJECTIVE #2: Review *C. diphtheria* as an invasive organism

CASE: A 31 year old male presented to our ED with acute onset back pain. He was well until the night prior when he was awoken by low back pain that was 10/10 in intensity, non-radiating, and worse with movement. He denied recent trauma, lower extremity weakness, numbness, or tingling. He has a chronic non-pruritic rash on his arms and chest. He denied fevers, any new rash, night sweats, weight loss, cough, and sore throat.

His PMH includes a sickle cell variant. He takes no medicines. He is MSM, consumes marijuana, and works in shipping. He recently camped in Massachusetts and has a kitten that scratches but does not bite.

On initial evaluation he was afebrile, non-toxic appearing, and with significant back pain. WBC was 12.5 and 6.5% of the RBCs were nucleated, which prompted a blood smear showing nucleated RBCs, marked acanthocytes, and Pappenheimer bodies. CT abdomen showed an atrophic spleen. The patient was admitted for further workup. MRI of the lumbar spine without contrast was unremarkable. On day 2 of admission he developed a fever to 102.7. WBC at that time was up to 28.6 with 79.3% neutrophils. Blood cultures were drawn and the patient was started on clindamycin and levofloxacin. By 18 hours there was growth of GPRs in 4/4 bottles. The gram stain resembled Chinese letters which is a classic description for *Corynebacteria*. Clindamycin and levofloxacin were switched to vancomycin and zosyn, and there was no further fever. Repeat MRI with contrast the next day showed osteomyelitis in the T12 and L1 vertebral bodies. TTE was negative. The organisms were identified by MALDI-TOF as *C. diptheriae* with high certainty.

IMPACT/DISCUSSION: Bacteremia with GPRs can be *Nocardia, Actinomyces, Listeria*, *Clostridium*, *Corynebacterium*, *Bacillus,* and *Bifidobacterium* species. Gram stain morphology is helpful as *Nocardia* and *Actinomyces* form string-like structures while *Corynebacterium* attach to one another at acute angles in a "Chinese letter" appearance.

Empiric therapy should include penicillin and vancomycin because some GPRs are sensitive to only one of the two. *Clostridium* species can progress rapidly and penicillin is the drug of choice. Most *C. diptheriae* isolates are susceptible to penicillin, but some are resistant.

This case highlighted that *C. diphtheriae* can exist in a non-toxigenic form that does not require the same public health precautions as the classic toxigenic strain that causes life threatening respiratory diphtheria. There are only a few case reports of invasive infections such as endocarditis and osteomyelitis, mostly in immunocompromised patients but there are rare incidents in immunocompetent patients.

CONCLUSION: Clinicians should be vigilant about non-toxigenic but pathogenic *Corynebacterium diphtheriae* as a source of invasive infections and institute appropriate empiric therapy.

AN UNUSUAL CAUSE OF CHEST WALL MASS

Clarissa A. Ramirez[1]; Nandar Mon[2]; tarek mansi[2]; Assad Mohammedzein[3]; James ". Walker[4]. [1]School of Medicine, Texas Tech University Health Sciences Center, Amarillo, TX; [2]Internal Medicine, Texas Tech University Health Sciences Center, Amarillo, TX; [3]Internal Medicine, Texas Tech University Health Science Center, Amarillo, TX; [4]Internal Medicine, Texas Tech, Amarillo, TX. (Control ID #3390683)

LEARNING OBJECTIVE #1: Recognize odontogenic infection as a cause of chest wall abscess

CASE: A 54-year-old male with hypertension and a history of throat cancer treated with chemotherapy and radiation in 2013, presented to the ER with 3 days of painful and rapidly expanding left-sided chest lump, for 2 weeks he had noticed dull sensation across the left chest. He had extensive dental caries with recurrent infection and abscess. He reported no history of trauma or injury. He also denied fever, cough, and dyspnea. Upon admission, vital signs were stable, a 5 cm rounded left infraclavicular lump was identified, the lump was tender and fluctuant without overlying erythema. Labs showed WBC 13.9, neutrophil 11.7. CT of his thorax showed 6.5 x 5.8 x 5.5 cm pleural-based mass-like area in the left upper chest communicating through the left anterior chest with the pectoralis major and minor muscles. There was also a large multiloculated soft tissue mid-neck abscess on the left, extending from thyroid cartilage through the superior submandibular mediastinum. IR needle drainage performed with removal of 80 cc of pus, a drain was placed. Cultures from both blood and fluid grew streptococcus viridans. The patient was started on ceftriaxone 2 g daily for 4 weeks.

IMPACT/DISCUSSION: Odontogenic infections are common in the oral and maxillofacial region which can lead to serious morbidity and mortality if left untreated or delayed diagnosis. It can lead to necrotizing fasciitis, Lemierre's syndrome or cerebral abscess. These Infections can spread by lymphatic, hematogenous dissemination or locally through the fascial planes down to the neck to the mediastinum, axilla or very rarely, as in our patient, to the chest wall. Only a handful number of cases has been reported to extend to the chest wall.

Management of severe odontogenic infections involves early protection of the airway, surgical drainage, early removal of source of infection and microbiological guided antibiotic. Our patient received chemo-radiation for throat cancer which has destroyed his teeth combined with poor dental hygiene causing root canal infection. It descended to involve the soft tissue of the neck and chest and left pectoral region. The growth of *Streptococcus viridans,* an oral pathogen, further supported tooth infection as the primary source. Repeat CT one month after presentation showed minimal residual inflammatory changes. The patient later underwent full mouth extractions.

CONCLUSION: We present an extremely rare case of a chest wall abscess resulting from odontologic *S. viridans* infection tracking across the fascial plane of the neck. It is not clear whether his previous exposure to neck radiotherapy may have predisposed to such dissemination. Early identification and elimination of the source allows for resolution and prevention of recurrence. Clinicians should be aware of such association.

AN UNUSUAL CAUSE OF GASTROINTESTINAL BLEEDING: ACUTE ESOPHAGEAL NECROSIS

Steven Delaney[1]; Jeffrey Lantz[2]; Cambridge Hines[3]; Nyree Thorne[3]. [1]Internal Medicine, Wake Forest Baptist Health, Winston-Salem, NC; [2]Internal Medicine Residency, Wake Forest Baptist Medical Center, Winston Salem, NC; [3]Gastoenterology, Wake Forest Baptist Health, Winston-Salem, NC. (Control ID #3392231)

LEARNING OBJECTIVE #1: Identify acute esophageal necrosis as a rare, but potentially important cause of GI bleeding with high associated mortality.

LEARNING OBJECTIVE #2: Recognize the potential harm associated with the use of NG tubes in undifferentiated suspected upper gastrointestinal bleeding.

CASE: The patient is a 72-year-old male with a 60 pack year smoking history, GERD, BPH, PVD, and HTN. He presented with 5 days of dysphagia, odynophagia, severe epigastric abdominal pain, coffee-ground emesis, and melena. The emesis and melena were each occurring up to 6 times per day. Objectively, he was tachycardic and afebrile. His labs were significant for a hemoglobin decrease from a baseline of 12 to 10g/dL and a leukocytosis of 24k. A CT scan of the abdomen and pelvis showed a moderate sized hiatal hernia, gallstones, nonspecific dilation of the small bowel, and moderate distention of the colon suggestive of possible colitis. An NG tube was considered for management of this suspected upper GI bleed, but deferred. EGD revealed circumferential necrotic mucosa of the distal two thirds of the esophagus (images 1-2). He was made NPO and given IV fluids, a PPI, a H2 blocker, and continued on antibiotics. Further questioning revealed no previous GI bleeding. He had been taking daily naproxen for back pain over the last 6 months and denied any alcohol or drug use. A colonoscopy one-year prior was normal. A repeat CT scan showed colitis, dilated small bowel without obstruction, and circumferential distal esophageal thickening. A repeat EGD two weeks later showed healing esophageal mucosa with ulceration and mild duodenitis (images 3-4). His diet was advanced and he was discharged home.

IMPACT/DISCUSSION: Acute esophageal necrosis is a rare but important cause of gastrointestinal bleeding with less than 100 cases reported and an overall mortality near 30 percent in two studies (1-2). The average age at time of diagnosis is 67 with greater than 80 percent being male (1). The etiology is typically multifactorial and often triggered by hemodynamic compromise (2). Implicated risk factors include: ischemia, gastric outlet obstruction, alcohol, malnutrition, diabetes, infection, and recent surgery among others (1). Patients can experience recovery as soon as one week with 47 percent having full recovery by two months (2). These patients are at high risk of complications including esophageal rupture which occurs in nearly 7 percent and strictures which occur in over 40 percent of cases (2).

CONCLUSION: -Treatment of esophageal necrosis should be directed at the underlying illness, addition of IV fluids even if hemodynamically stable, bowel rest, antacids, and antibiotics if infection is present.

Esophageal necrosis should be considered in upper GI bleeds as management with the use of NG/OG tubes should be avoided due to the increased risk of perforation.

AN UNUSUAL CAUSE OF HYPOXIA: EBSTEIN ANOMALY WITH SECUNDUM ATRIAL SEPTAL DEFECT

Mary Fok[1]; Daniel J. Philipson[2]; Arnold S. Baas[2]. [1]Internal Medicine, University of California, Los Angeles, Los Angeles, CA; [2]Cardiovascular Diseases, University of California, Los Angeles, Los Angeles, CA. (Control ID #3378929)

LEARNING OBJECTIVE #1: Recognize the clinical manifestations of Ebstein anomaly and manage based on defect severity

CASE: A 36-year-old female presented to the emergency room with 3 months of progressive chest pain, palpitations, and hypoxia with a 4 liter oxygen requirement. She denied heart failure symptoms. She has no significant medical, social or family history. Physical exam notable for oxygen saturation of 88% on 4 liters, 10 liters with exertion. Neck veins were flat. Cardiac auscultation revealed a fixed split S2 and a holosystolic murmur loudest over the left sternal border. Clubbing was seen in both hands with trace lower extremity edema. Labs significant for hemoglobin of 17 g/dL and BNP of 28 ng/L. ECG showed right atrial enlargement. Transthoracic echocardiogram (TTE) showed severely enlarged right atrium and right ventricle (RV) size with hyperdynamic systolic function,

15mm diameter ostium secundum atrial septal defect (ASD), severe tricuspid valve regurgitation (TR) with 19mm apical displacement, and a small patent ductus arteriosus (PDA). Right heart catheterization (RHC) revealed normal pulmonary artery and right and left sided filling pressures. Oximetry run confirmed left-to-right shunt. Electrophysiology study (EPS) revealed inducible tricuspid annular atrial tachycardia. Successful catheter ablation was performed. The patient's symptoms improved to baseline with diuresis. She was scheduled for outpatient surgical correction.

IMPACT/DISCUSSION: Ebstein anomaly is a rare congenital heart defect involving the tricuspid valve and right ventricle with a prevalence of 1 in 20,000 live births. Clinical presentation varies ranging from symptomatic neonates to asymptomatic adults depending on severity of anatomic defect. Genetic predisposition has been described and neonatal exposure to lithium is an established risk factor. The most common morphologic feature is apical displacement and dysplasia of the tricuspid valve resulting in "atrialization" of the RV producing a small functional RV and varying degrees of TR. Associated anomalies are patent foramen ovale or ASD, accessory conduction pathways, ventricular septal defect and PDA.

Symptoms result from RV volume overload, cyanosis due to right-to-left shunting, arrhythmia, and paradoxical embolus. Diagnosis involves TTE, cardiac CT or MR, RHC and EPS. Treatment is focused on right heart failure. Surgical repair is indicated with development of heart failure or symptomatic decline. In the case herein, the patient presented with new onset hypoxia. Workup confirmed long-standing disease requiring multidisciplinary management with catheter based and surgical intervention. In patients presenting with new onset hypoxia, it is important to keep a broad differential, including congenital heart disease presenting in adulthood.

CONCLUSION: Ebstein anomaly can have a wide range of clinical presentations.

Treatment involves both pharmacotherapy and appropriately timed surgical and transcatheter intervention.

AN UNUSUAL COMPLICATION OF BENIGN PROSTATIC HYPERPLASIA - PULMONARY EMBOLISM SECONDARY TO AN ENLARGED PROSTATE

ayesha a. khan. Internal Medicine, St Vincent Charity Medical Center, Lakewood, OH. (Control ID #3341934)

LEARNING OBJECTIVE #1:

Recognize potentially rare direct causes of DVT/PE.

CASE: We present a 72 year old man, former smoker, with significant past medical history of hypertension and hyperlipidemia, who presented to the emergency department due to bilateral lower extremity swelling for 1 month, initially starting in the right leg, then slowly progressing to the left leg, associated with some dull, continuous, achy pain of both extremities. On review of systems he also complained of gradually increasing abdominal girth, exertional shortness of breath, urinary frequency and feelings of incomplete voiding for the past month. Physical examination was significant for normal vital signs, distended abdomen with a large, firm, palpable mass at the suprapubic area, and + 2 bipedal pitting edema up to the groin with associated lower extremity erythema, right more than left. He had mildly elevated creatinine of 1.840 mg/dL, mild microcytic anemia of 10 mg/dL and PSA of 41.8 ng/ml. Duplex studies of the lower extremities showed thrombus in the left common femoral vein, deep femoral vein, superficial femoral vein, popliteal vein, and right common femoral vein. CT Abdomen without contrast was significant for a massively distended bladder measuring 27 x 17 x 17 cm with mild symmetrical hydronephrosis causing severe compression of the Inferior vena cava and common iliac veins bilaterally, and prostatomegaly. Due to complaints of shortness of breath, a V/Q scan was also done reporting a high probability of acute pulmonary embolism. A foley catheter was placed in the emergency department draining approximately 9 L of urine on the first day and he received Tamsulosin as well. He was started on heparin drip and eventually transitioned to Rivaroxaban. He was discharged with a foley catheter and was instructed to follow up with urology as an outpatient for further management of his BPH. Patient was not found to have any other risk factors for hypercoagulability. This case represents a rare and unusual complication of Benign Prostatic Hyperplasia and Hydronephrosis.

IMPACT/DISCUSSION: Our patient presented with combined DVT and Pulmonary Embolism secondary to massive bladder distention as a rare complication of BPH. A typical healthy adult human bladder can hold about 300-500mL fluids at a given time [2]. Despite this, there have been cases reported of extreme bladder capacities, with bladder volumes reaching up to 6000mL [3]. Bladder outlet obstruction from BPH causing bladder enlargement and subsequent compression of the venous system followed by formation of DVTs have been reported in the past, [4][5][6][7], with at least one other case reporting subsequent PE related to bladder distention [8]. In one report, increased venous pressure from BPH alone was enough to cause DVT [7]. Despite such evidence, BPH is still not recognized as a risk factor for DVT and PEs.

CONCLUSION: We believe it is important for clinicians to recognize the relationship of BPH and DVT/PE as these can have fatal consequences for our patients.

AN UNUSUAL PRESENTATION OF DISSEMINATED CRYPTOCOCCUS IN AN AIDS PATIENT

Ramandeep Dhillon[1]; Aalam Sohal[2]; Lu Zhao[2]; Lin Li[2]. [1]UC Davis School of Medicine, Sacramento, CA; [2]Department of Internal Medicine, University of California, San Francisco-Fresno (UCSF-Fresno), Fresno, CA. (Control ID #3390125)

LEARNING OBJECTIVE #1: Recognize the clinical features of thyroid cryptococcal infection

CASE: A 30 year-old female with AIDS presented with three weeks of headache, dry cough, odynophagia, emesis, fatigue and weight loss. She had a history of cryptococcal meningitis requiring lumbo-peritoneal drain four years prior but was lost to follow up, with non-adherence to maintenance and antiretroviral therapy. She appeared cachectic with oropharyngeal candidiasis and a tender, palpable left thyroid nodule. Laboratory evaluation revealed CD4 count < 20 cells/mm3 and HIV viral load of 33,600 copies/mL, serum cryptococcus antigen titer of 1:65500 and TSH of 4.0. Lumbar puncture revealed positive cryptococcus cerebrospinal fluid titer of 1:32768 with equivocal culture. CT of the chest showed miliary pattern micronodularity of the lungs with positive culture for cryptococcus made by bronchoscopy. To evaluate the odynophagia, a CT of the soft tissue neck and esophagram revealed a para-esophageal 0.9cm rim-enhancing fluid collection with adjacent walled-off lumen, an enlarged thyroid gland and a left thyroid nodule. An endoscopy ruled out an esophageal perforation but incidentally revealed a 12mm cratered ulcer in the gastric body with fundus biopsy revealing cryptococcus. A thyroid ultrasound revealed a heterogeneous nodule measuring 3.8 x 2.4 x 1.6cm with hyperemia and calcifications. Fine needle aspiration (FNA) biopsy revealed thyroid cryptococcus. We initiated induction therapy with amphotericin B and flucytosine. Amoxicillin- clavulonic acid treated the para-esophageal abscess with resolution confirmed by CT of the neck.

IMPACT/DISCUSSION: Disseminated C. neoformans infection commonly involves the CNS and lungs as an AIDS-defining condition with a CD4 count <200 cells/mm3. Gastric and notably, the thyroid gland are rarely described. Gastric cryptococcus has been found in postmortem autopsies and clinically as abdominal distension, melena, and odynophagia with diagnosis made by endoscopy. The few reported cases of thyroid cryptococcal infection

have presented in postmortem autopsies and patients with subacute thyroiditis, goiter, abscess and enlarged thyroid. We report an unusual case of disseminated cryptococcal infection in an AIDS patient with odynophagia and vomiting found to have a para-esophageal abscess, infectious thyroiditis with normal thyroid function tests and gastric cryptococcus. In this case, endoscopy confirmed the presence of cryptococcus in the gastric fundus and FNA biopsy uncovered cryptococcal organisms in the thyroid. The diagnosis of disseminated cryptococcus with gastric and thyroid involvement led to treatment with amphotericin B and flucytosine.

CONCLUSION: We conclude that gastric and thyroid involvement is an under-recognized phenomenon of disseminated cryptococcus and may be overlooked if infectious etiologies are not considered. Suspicion must be high in an AIDS patient with odynophagia and a thyroid nodule and warrants further investigation by endoscopy and fine needle aspiration biopsy.

AN UNUSUAL PRESENTATION OF HODGKIN LYMPHOMA

Cindrel Tharumia Jagadeesan[1]; Sreeja Biswas Roy[1]; Nathan Dennison[1]; Sabyasachi Roy[1]; Jaya Raj[2]. [1]Internal Medicine, St.Joseph's Hospital and Medical Center, Phoenix, AZ; [2]Internal Medicine, St. Joseph's Hospital, Phoenix, AZ. (Control ID #3379121)

LEARNING OBJECTIVE #1: Recognize febrile cholestatic jaundice as an uncommon presentation of Hodgkin lymphoma.

CASE: : A 47-year-old woman with no significant past history presented with fever, nightsweats, abdominal pain, nausea, vomiting, and dark urine for 4 days. She also reported one episode of non-bloody diarrhea. Review of systems was otherwise negative. On admission, vitals were: T 39.9 C, HR 142/min, RR 28/min, BP 126/58 mmHg. Physical exam showed hepatomegaly and tenderness in the RUQ, LUQ, and epigastric regions without palpable masses. Labs: WBC 2.5 $x10^3/\mu L$ with lymphopenia (100 cells/μL), hemoglobin 9.3 gm/dL, platelet count 130 $x10^3/\mu L$, Na 128 mmol/L, HCO3 18 mmol/L, albumin 3.1 gm/dL, total bilirubin 1.8 gm/dL, direct bilirubin 1.2 gm/dL, ALT 51 units/L, AST 138 units/L, alkaline phosphatase 578 Units/L, PT 14.8 sec, and LDH 578 units/L. Peripheral blood smear showed pancytopenia, normocytic anemia with teardrop cells and circulating nucleated red cells, and granulocytic left shift. Nasopharyngeal and stool PCR, viral hepatitis panel, and HIV test were negative. Abdominal ultrasound showed gallstones, gall bladder thickening, negative Murphy's sign, and no biliary ductal dilation. Abdominal CT additionally showed hepatosplenomegaly and enlarged (1.2 cm) para-aortic lymph nodes. HIDA scan showed slightly delayed biliary to bowel transit time but no scintigraphic evidence of acute cholecystitis. The patient underwent endoscopic ultrasound, in which no biliary dilation, masses, or gallbladder thickening were seen; however, the liver parenchyma was diffusely hyperechoic, and biopsies were taken. Pathology revealed necrotizing granulomatous hepatitis. Empiric antibiotics were discontinued, as all cultures were negative. However, the patient continued to spike high-grade fevers and remained pancytopenic. Bone marrow biopsy was performed and showed 70% cellular marrow involvement with nodular foci of intermediate to large cells with lobulated nucleoli and peri-nucleolar clearing, consistent with Reed-Sternberg cells. Immunohistochemical (IHC) studies were positive for CD30, PAX5, MUM1, CD15 and negative for CD20. IHC studies were subsequently performed on the liver biopsy specimens, which confirmed hepatic parenchymal involvement with classic Hodgkin lymphoma.

IMPACT/DISCUSSION: Febrile cholestatic jaundice is an uncommon initial presentation of HL, reported in only 1.4% of HL cases. Jaundice in HL can be due to intrahepatic cholestasis, extrahepatic biliary tract compression, paraneoplastic effect, or the rare vanishing bile-duct syndrome. Our patient had a non-dilated biliary tree and EUS suggesting intrahepatic cholestasis. Liver biopsy confirmed the diagnosis of hepatic HL.

CONCLUSION: Our case illustrates a rare presentation of Hodgkin lymphoma with febrile cholestasis and unexplained pancytopenia.

AN UNUSUAL SOURCE FOR A PYOGENIC LIVER ABSCESS

Chelsea F. Dahl, Rebecca Vento. Internal Medicine, University of Pittsburgh, Pittsburgh, PA. (Control ID #3392043)

LEARNING OBJECTIVE #1: Recognize asymptomatic sigmoid diverticulitis as a source for pyogenic liver abscess

CASE: A 56-year-old male with a medical history significant for diverticulitis presented with fever of unknown origin. Four weeks prior to presentation, he saw his PCP for symptoms of fatigue and malaise without localizing symptoms. He was prescribed a course of oral steroids for "pulmonary wheezing" but subsequently developed daily fevers to 104 F with chills and night sweats. He was prescribed azithromycin and then levofloxacin for presumed CAP but continued to be febrile every 6-8 hours. Studies were notable for persistent leukocytosis but his infectious evaluation was unrevealing, including urinalysis, blood cultures, throat culture, Lyme disease EIA, and CXR. CT imaging revealed a multilocular rim-enhancing fluid collection replacing hepatic segments 7 and 8 most compatible with pyogenic abscess and diverticulosis of the sigmoid colon without inflammation. No other intraabdominal infectious sources were identified. He underwent US guided drainage, and cultures grew *Prevotella oris* and *Streptococcus intermedius.* Blood cultures and TTE were unremarkable. Repeat imaging during his hospitalization revealed acute diverticulitis with a 5.2 x 4.8 cm pericolonic abscess near the rectosigmoid junction and decreasing size of the hepatic abscess. He underwent CT guided drainage of the pericolonic abscess, but cultures were negative likely due to prolonged antibiotic exposure. He completed an eight-week course of IV ceftriaxone and oral metronidazole. Interval CT imaging revealed residual hepatic microabscesses and resolution of the pericolonic abscess.

IMPACT/DISCUSSION: Pyogenic liver abscess (PLA) is the most common type of intraabdominal abscess. The pathogenesis of PLA is due to one of three mechanisms. The most common source of PLA is direct spread from an infectious biliary source; underlying biliary tract disease is present in 40-60% of cases. PLA may also develop following hematogenous seeding from systemic bacteremia, such as in endocarditis. Many PLAs, such as this one, result from portal vein pyemia – infectious spread through the portal venous system from any tributary of the portal venous system. Sigmoid diverticulitis is an uncommon cause of PLA, with less than 100 cases reported in the literature. A nationwide cohort study in Taiwan[1] found that the incidence of PLA was 2.44-fold higher in patients with diverticular diseases with an adjusted hazard ratio of 2.11 (95% CI, 1.81-2.44). Patients should be evaluated for asymptomatic diverticulitis when the evaluation for other infectious sources is unrevealing, or if there is no interval resolution after appropriate antimicrobial treatment.

[1]M. Tsai *et al., Medicine* 94 (2015), doi:10.1097/MD.0000000000002210

CONCLUSION: Asymptomatic sigmoid diverticulitis is a rare source for pyogenic liver abscess and thus important to consider in patients without localizing symptoms and an otherwise unremarkable infectious evaluation.

AORTOENTERIC FISTULA: A PERIAORTIC MASS-QUERADE

Luke T. Baldelli[1]; Christopher Walker[4]; Destiny Folk[3]; Eduardo Borja-Lascurain[2]. [1] Internal Medicine Residency Program, UNC Hospitals - UNC Chapel Hill, Chapel Hill, NC; [2]Internal Medicine, WakeMed, Raleigh, NC; [3]School of Medicine, UNC, Raleigh, NC; [4]Medicine, Campbell University, Raleigh, NC. (Control ID #3391116)

LEARNING OBJECTIVE #1: Diagnose Secondary Aortoenteric Fistula (AEF) with atypical features on CT imaging.

LEARNING OBJECTIVE #2: Manage AEFs using a multi-modal diagnostic and multi-disciplinary approach.

CASE: A 59-year-old woman presented with two days of hematochezia, fevers and chills. She reported a month of worsening back pain, weight loss, and poor appetite. She has a PMHx of HTN, COPD, CAD, and aortoiliac vascular disease with aortobifemoral bypass graft surgery, complicated by pseudoaneurysms. On presentation, she was hemodynamically stable with lower abdominal tenderness, WBC of 18, Hgb of 14, CRP of 23, and heme positive stool test. CT abdomen revealed a new periaortic mass. The patient reported spontaneous resolution of her symptoms within 48 hours, was discharged, and scheduled for outpatient endoscopy. Within 3 days, she returned with fevers, chills, and hematochezia. Repeat abdominal CT showed no change. EGD revealed an ulcerated area in the third part of the duodenum, with white exudate and visible aortic graft confirming secondary AEF. Urgent graft excision, duodenal resection and repair was performed. Graft cultures were positive for anaerobes and Streptococcus anginosus. She was discharged on six weeks of ceftriaxone and metronidazole without complication.

IMPACT/DISCUSSION: Secondary AEFs are a rare condition resulting from inflammation of an aortic graft near a section of bowel, and are fatal if untreated. This case is an informative teaching example of several classic signs of AEF, while also highlighting how atypical imaging findings can create diagnostic ambiguity. While CT and EGD have now emerged as first line diagnostic tests, sensitivities vary. Specifically, the stable "mass" in this case lacked common CT features associated with secondary AEF, including contrast extravasation, ectopic gas, focal bowel wall thickening, or mass progression. Thus, clinicians must remember to rule out AEF in any patient with prior aortic surgery and suggestive symptoms, which include GI bleeding, abdominal pulsatile mass, sepsis, and abdominal pain. In regard to management, this case emphasizes that early surgical and gastroenterological (GI) consultation with intervention is imperative, as mortality increases in patients that require more emergent surgery. Polymicrobial infection and sepsis is not uncommon. If present, antibiotics to cover gram positive, gram negative and anaerobes should be started, and generally continued for 4-6 weeks. Ultimately antibiotics were tailored based on culture data in this case. The pathogens grown in culture were consistent with organisms identified in prior studies and case reports.

CONCLUSION: Secondary AEFs are rare, life threatening, and require prompt diagnosis. CT and EGD are first line, though negative results do not rule out AEF. Suspicion for secondary AEFs must remain high in any patient with a history of aortic surgery and GI bleeding. Early consultation with surgery and GI is critical for diagnosis, intervention, and patient survival.

A PAINFUL JAW: UNUSUAL DISEASE AT AN UNUSUAL SITE

Mariol Garcia Cunillera[1]; Ana M. Garcia Payano[2]; Tingyin Chee[1]. [1]Internal Medicine, St. Barnabas Hospital, Bronx, NY; [2]Internal Medicine, St. Barnabas Hospital, Bronx, NY. (Control ID #3367789)

LEARNING OBJECTIVE #1: To explore the differentials for jaw pain

LEARNING OBJECTIVE #2: To review treatment for Paget's

CASE: An 84 years old female with hypertension and depression presented to primary care for left ear and jaw pain of a few weeks. She was seen by ENT prior; suspected for temporomandibular joint (TMJ) dysfunction and treated with naproxen and muscle relaxants. She reported worse pain, impaired mastication, without headache or vision changes. Exam showed left TMJ tenderness and lack of dentition. Recent labs were normal for calcium, alkaline phosphatase, and vitamin D. X-ray showed lytic lesions of Paget's disease in the mandibula. The skeletal bone survey showed thickening of the skull from the sclerotic phase of osteitis deformans. DEXA scan showed mild osteopenia. She started treatment - alendronate with vitamin D and calcium. After initial improvement, she developed severe dyspepsia and switched to Zoledronic acid, which she tolerated and improved her pain.

IMPACT/DISCUSSION: The most common causes of acute jaw pain are dental related (caries, abscess, wisdom teeth) followed by TMJ or masticatory muscle disorders. The differential for chronic jaw pain should include neuropathy (trigeminal, hypoglossus, post-herpetic, burning mouth syndrome, cluster headache), giant cell arteritis, post-stroke, osteonecrosis, osteosarcomas, metastasis, chronic osteomyelitis, and fibrous dysplasia.

Paget's disease, or osteitis deformans, is the most common metabolic bone disorder after osteoporosis. The prevalence in the United States is 1-2%, higher in the northeast. It is caused by accelerated bone remodeling, resulting in bone overgrowth at single or multiple sites, most commonly in the lumbar spine, proximal femur, skull, or pelvis. Progression can cause fractures, nerve entrapment, deafness, malignant conversion to osteosarcoma.

Most patients are asymptomatic and diagnosed incidentally on imaging. Monostotic Paget's disease of the jaw is rare. Disease activity can be measured by bone turnover markers: total alkaline phosphatase, serum procollagen type 1 N terminal propeptide (PINP) and bone-specific alkaline phosphatase. However, these can be normal when skeletal involvement is limited.

Treatment goals for Paget's are to ease pain and normalize the rate of bone remodeling. Oral nitrogen-based bisphosphonates are first-line; they suppress biomarkers and heal lesions on X rays and should be started with Vitamin D and Calcium to prevent hypocalcemia and impaired bone mineralization. Zoledronic acid is suggested for those with more extensive disease or older as even a single infusion has improved quality of life scores. If intolerant to both, calcitonin can be an alternative and Denosumab has been anecdotally reported.

CONCLUSION: Consider a broad differential for patients presenting with jaw pain. Patients with Paget's should be treated with bisphosphonates and monitored for clinical and biomarker improvements.

A PAIN IN MY SIDE: FIBROMUSCULAR DYSPLASIA PRESENTING AS FLANK PAIN WITH RENAL INFARCTION

Justin Nichols. Medicine/Pediatrics Residency Program, Christiana Care Health System, Philadelphia, PA. (Control ID #3391954)

LEARNING OBJECTIVE #1: Distinguish renal infarct as a presenting feature of fibromuscular dysplasia.

LEARNING OBJECTIVE #2: Recognize the workup and treatment for fibromuscular dysplasia.

CASE: A 44 year old female with a past medical history of Graves' disease presented to the emergency department with a chief complaint of six days of epigastric pain radiating to her right flank. She was treated with famotidine and sucralfate without relief. She was mildly hypertensive but hemodynamically stable. Physical exam was positive for mild tenderness to epigastric palpation and negative for costovertebral angle tenderness. Renal function was within normal limits.

CT angiography of the abdomen unexpectedly showed multiple wedge-shaped areas of right renal infarct and small splenic artery aneurysms. No atrial fibrillation was noted on telemetry during admission and transesophageal echocardiography showed no intracardiac thrombus. Hypercoagulability workup was unrevealing. MRA of the head and neck ultimately showed diffuse beading of the bilateral vertebral arteries with mild stenosis and subtle beading of the right and left cervical internal carotid arteries consistent with fibromuscular dysplasia (FMD).

The patient was treated on a heparin drip and transitioned to rivaroxaban. Renal function remained stable. One year imaging follow up was recommended with continued anticoagulation as an outpatient.

IMPACT/DISCUSSION: Fibromuscular dysplasia (FMD) is a non-inflammatory process largely affecting medium-sized arteries. The classic presentation typically involves renal artery stenosis leading to hypertension; however, renal infarct without renal arterial stenosis is an unusual presentation. It is unclear if this patient's infarct was a local thrombotic event from small, non-visualized aneurysm or dissection versus an embolic event. Once FMD is suspected, workup includes imaging of head, neck, chest and abdominal vessels with CTA or MRA to examine for arterial anomalies in other vascular beds. Medical therapy typically focuses on antiplatelet versus anticoagulation therapy for secondary prevention of thromboembolic events, especially in patients with cerebrovascular FMD. However, more severe, symptomatic stenotic lesions may require percutaneous angioplasty or stent and large aneurysms may require endovascular or surgical repair. This unusual presentation of multifocal FMD presenting as flank pain with renal infarction highlights the need for a high index of suspicion to avoid delay in appropriate care.

CONCLUSION: Fibromuscular dysplasia can present in unusual ways, such as renal infarction. Workup involves cross sectional arterial imaging to examine vascular bed anomalies. Medical treatment includes antiplatelet versus anticoagulation therapy followed by annual reimaging.

A PAIN IN THE NECK: BACTEREMIA AND NATIVE CERVICAL OSTEOMYELITIS DUE TO CORYNEBACTERIUM STRIATUM

Nicholas M. McDonald, Gina Suh. Infectious Diseases, Mayo Clinic, Rochester, MN. (Control ID #3358011)

LEARNING OBJECTIVE #1: Recognize that indolent gram positive bacteremia with Corynebacterium may be confused with contamination.

CASE: Positive blood cultures are often encountered in the hospital setting. The clinical significance depends on the syndrome, host and organism identified. The implications of positive cultures range from life- threatening to a simple contaminant. It is critical to maintain a degree of suspicion, particularly in certain clinical settings. Here we present a case of bacteremia and invasive disease with *Corynebacterium striatum*, initially considered a contaminant.

An 80-year-old man with a past medical history of type 2 diabetes mellitus presented to the Emergency Department with two days of left subscapular pain. He reported engaging in extensive gardening the day prior to presentation and feeling like he "pulled a muscle."

He was initially treated with analegsics for muscle sprain, but did not improve as expected. After administration of one dose of cefepime, blood cultures performed in the emergency department returned positive in two of two bottles from one set for gram-positive bacilli at 57 hours and was reported as a possible contaminant. Despite this, empiric broad-spectrum antibiotics were started and repeat blood cultures obtained. The gram-positive bacilli from the initial blood cultures was identified as *Corynebacterium striatum*. His CRP returned elevated at 135.2 mg/L (reference range < 8.0 mg/L). Repeat blood cultures remained positive for *Corynebacterium striatum* and the patient developed pain in his cervical spine near the C6-C7 level. MRI demonstrated mild enhancement within the C6-C7 vertebral bodies with adjacent edema, consistent with developing osteomyelitis-discitis. Aspiration was recommended, but could not initially be obtained given the patient had been taking Apixaban.

The patient remained persistently bacteremic with *Corynebacterium striatum* for seven days. Positron emission tomography was obtained to rule-out alternative causes of infection and demonstrated increased FDG activity in the C6-C7 interspace, further raising suspicion for osteomyelitis. He was treated with vancomycin for a planned 6 week duration. His pain and inflammatory markers were improving at his most recent follow-up.

IMPACT/DISCUSSION: While positive blood cultures due to contamination can occur, it can also represent true bacteremia causing invasive disease. In this case, a patient developed bacteremia with *Corynebacterium striatum*, an organism which is a known skin colonizer and common contaminant. *Corynebacterium striatum* is increasingly being recognized as an emerging, multidrug-resistant pathogen and has been reported to cause vertebral osteomyelitis/discitis. Due to persistent growth of this organism in the absence of growth of others, *Corynebacterium striatum* was felt to be pathogenic in this case. More broadly, this case highlights the importance of maintaining suspicion in the face of low-grade bacteremia with a gram positive bacillus.

CONCLUSION: See discussion above.

A PANCREATIC NEUROENDOCRINE TUMOR PRESENTING WITH SECONDARY HYPERTENSION

Rosemina Patel[1]; Karam Khaddour[2]. [1]Internal Medicine, Rosalind Franklin University, Mchenry, IL; [2]Internal Medicine, Rosalind Franklin University of Medicine and Science- Chicago Medical School, McHenry, IL. (Control ID #3370291)

LEARNING OBJECTIVE #1: Recognizing clues to secondary hypertension while evaluating patients with resistant hypertension.

CASE: A 54-year-old Caucasian male with a history of poorly controlled hypertension, presented to the emergency room with abdominal distension and epigastric pain radiating to the back and leg swelling of eight weeks duration. A review of systems was positive for intermittent bouts of watery diarrhea, easy bruising and a significant 40 lbs. weight gain over the past six months. Physical examination was significant for elevated blood pressure, facial and supraclavicular fullness with central adiposity. The hospital course was complicated by resistant hypertension and hypokalemia. A thorough hormonal workup was done for evaluation of resistant hypertension, with increased suspicion for hypercortisolism given the examination findings. The patient had elevated ACTH, cortisol, and chromogranin A (CgA), confirming ACTH dependent hypercortisolism. To evaluate abdominal pain, a CT scan of the abdomen and pelvis was performed which showed a 4.6x3.8 cm hyper-enhancing mass arising from the head of the pancreas, with features suggestive of neuroendocrine tumor (NET). At this point, ectopic ACTH production from the pancreatic tumor was suspected. An endoscopic ultrasound-guided aspiration of the pancreatic mass confirmed a well-differentiated NET. One month later, he underwent a Whipple's procedure and multiple liver masses were discovered on intraoperative ultrasound, confirmed to be NET on the frozen section, without any lymph node metastasis. Post-operative follow-up showed a decrease in CgA and ACTH levels and a decrease in the need for antihypertensive medications. Subsequently, the patient was started on a somatostatin analog, Lanreotide with normalization of ACTH levels and no evidence of recurrence at eight months follow-up.

IMPACT/DISCUSSION: Endocrine etiology of secondary hypertension should be considered in patients with resistant hypertension associated with unexplained hypokalemia or features of Cushing's syndrome (CS). Ectopic ACTH secretion from a pancreatic NET (PNET) is very rare with few cases reported in the literature. Most are diagnosed at an advanced stage and guidelines regarding management are lacking. Complete resection is the only curative treatment, but it's often complicated by the presence of liver metastasis. In advanced cases, resection of the primary tumor is done for symptom control as demonstrated in our case with a significant drop in ACTH level immediately after resection. Medical treatment with Lanreotide has shown to have an important role in

achieving and maintaining symptom control and increasing progression-free survival in patients with PNET.

CONCLUSION: Treatment of the cause of secondary hypertension can result in normalization of blood pressure. This report highlights the importance of appropriate evaluation of secondary hypertension and presents a rare case of ectopic ACTH secretion by a metastatic PNET with good disease control post- resection.

A PATIENT WITH A SILVER COLORED STOOL

Malik Shehadeh[1]; JALAL EL-AKAWI[2]; Emil Oweis[3]. [1]Internal Medicine, Medstar Washington Hospital Center, Washington, DC; [2]Internal Medicine, Medstar Washington Hospital Center, Washington, DC; [3]Pulmonary and Intensive Care Medicine, Medstar Washington Hospital Center, Washington, DC. (Control ID #3392442)

LEARNING OBJECTIVE #1: Recognize silver stool sign and looking for underlying pathology.

CASE: A 69-year-old female patient with a medical history significant for hypertension, diabetes and paroxysmal atrial fibrillation presented to our hospital with silver colored stool.

Upon arrival to the hospital, her vitals showed blood pressure 95/69 and heart rate of 105 beats per minute. Her labs were remarkable for hemoglobin 7.5 g/dl (normal 11-14.5 g/dl). Liver panel showed cholestatic pattern with elevated aspartate transaminase, alanine transaminase, alkaline phosphatase and conjugated hyperbilirubinemia. Her rectal exam showed silver colored stool that was positive for occult blood.

She was given volume resuscitation with improvement in her hemodynamics. Chest X ray, urinalysis and blood cultures were not suspicious of any infection. A computerized tomography of abdomen/pelvis with contrast showed evidence of cecal neoplasm with multiple metastases scattered throughout the liver, largest measuring 5.4 cm.

The patient underwent ultrasound guided core biopsy of the liver which confirmed the presence of metastatic colorectal adenocarcinoma. Given multiple liver metastasis, she was not a candidate for transhepatic biliary drain placement. Her source of bleeding was expected to be from the cecal neoplasm. After a discussion of treatment options with the patient and her family, the decision was made not to pursue surgery. Goals of care were transitioned to focus on the patient's comfort.

IMPACT/DISCUSSION: Dr. A. M. Thomas, a British pathologist, has pointed out in 1955 that in cancer involving the ampulla of vater the patient sometimes passes silver stools. She explained the silver colored stool as a combination of the white stool of obstructive jaundice and the black stool of melena. This silver stool sign was named as Thomas's sign.

Here we are reporting a case of a patient with Thomas's sign which is the third reported case in the literature up to our knowledge.

It is highly important to keep in mind that any cause of biliary obstruction will result in pale colored stool. Such a stool may contain a blood from many sources. If that stool was black tarry stool, then a silver colored stool will be noticed.

CONCLUSION: Silver stool sign might reflect a serious underlying pathology such as cancer. Such sign needs further investigations and workup to look for underlying pathology.

A PECULIAR CASE OF DRY BERIBERI IN THE CONTINENTAL UNITED STATES

Shivam Thakur, William White. Internal Medicine, Christiana Care Health System, Newark, DE. (Control ID #3387825)

LEARNING OBJECTIVE #1: Recognizing the risk factors and clinical situations that put patients at increased risk for developing thiamine deficiency.

CASE: Beriberi is an ancient disease spanning as far back as 300 A.D. The name itself is a Sinhalese phrase meaning "weak, weak", an adept description of the devastating natural history of this disease. In the 21st century, Beriberi is rarely encountered in developed countries. However, in certain patient populations and clinical presentations the diagnosis should be considered and treatment initiated immediately as misdiagnosis can have grave consequences.

Our case describes a 32-year-old male with a past medical history of alcohol abuse who presented with a 10 day history of leg weakness and falls. History revealed recurrent falls and a sensation of bilateral lower extremity weakness that was progressively worsening. He denied any acute focal weakness, facial droop, or dysarthria. The falls were described as mechanical in nature. Other review of systems was negative. Social history was significant for 5-6 alcoholic beverages daily. Physical exam revealed diffuse weakness of the bilateral lower extremities, along with mild deficits in light touch and proprioception primarily in the distal aspects of the lower extremities. His exam was otherwise unremarkable including a normal cardiovascular and pulmonary exam. He had an MRI of his spine which showed chronic degenerative changes and mild cord compression. Neurosurgery was consulted and determined his exam findings were inconsistent with imaging findings and other etiologies should be considered. Further labs were ordered and a B12 was normal. As the patient's clinical condition was not improving, a blood thiamine level was ordered. However given his progressively worsening ataxia, heavy alcohol use, and poor nutritional intake, high-dose thiamine was started empirically. Blood thiamine levels eventually came back markedly decreased and the diagnosis of dry Beriberi was confirmed. The patient was continued on high dose IV thiamine. His clinical condition showed slow but steady improvement and he was eventually discharged to an acute rehabilitation facility.

IMPACT/DISCUSSION: The diagnosis of dry beriberi is rare in the United States, as many foods are fortified with thiamine. In developed countries, patients with anorexia, severe alcoholism, or a history of bariatric surgery are at highest risk for developing thiamine deficiency. Thiamine is absorbed into the small intestines, and phosphorylated into its active compound thiamine pyrophosphate. Its deficiency can cause decreased ATP production due to its integral role in dehydrogenase catalyzed reactions involved in energy production. Neuronal cells are initially uniquely susceptible to this, but deficiencies that go undiagnosed can cause degeneration into multi-organ involvement and failure.

CONCLUSION: In patients with specific risk factors and a constellation of signs and symptoms, Beriberi should be strongly considered and treatment initiated immediately.

A POSSIBLE CASE OF T-CELL LARGE GRANULAR LYMPHOCYTE LEUKEMIA WITH LYMPHOPENIA

Poy Theprungsirikul. Internal Medicine, New York University School of Medicine, New York, NY. (Control ID #3391665)

LEARNING OBJECTIVE #1: Recognize a broad differential diagnosis and workup of diffuse lymphadenopathy, T-cell lymphopenia, neutropenia and recurrent infections

CASE: A 40-year-old woman with a history of chronic pancreatitis, Crohn's, T-cell lymphopenia, diffuse lymphadenopathy, and recurrent infections presented with a 4-day history of fever, chills, sore throat, abdominal pain and diarrhea. Prior workup included hypermetabolic

lymph nodes seen on a PET scan and reactive changes noted on a left cervical lymph node core needle biopsy. There was no evidence by either flow cytometry or immunohistochemistry of a hematologic malignancy. Immunologic workup was also negative.

Laboratory findings were notable for neutropenia, thrombocytopenia, normal quantitative immunoglobulins, normal triglycerides, normal fibrinogen, normal ferritin, mildly elevated LDH, elevated ESR/CRP, low CD3, and low CD4. Infectious workup, including CMV, EBV, HIV, Legionella, Mycoplasma, GI stool pathogen, ova & parasytes, blood/stool/sputum/urine cultures, was negative. CT of the chest, abdomen and pelvis showed no evidence of Crohn's flare, but revealed diffuse lymphadenopathy in the axillary, supraclavicular, and lower neck regions. A bone marrow aspirate and biopsy was performed which showed a depressed CD4:CD8 ratio and a mild relative increase in CD57(+) gamma-delta T lymphocytes, raising a concern for T-cell large granular lymphocyte leukemia (T-LGL).

IMPACT/DISCUSSION: The differential of diffuse lymphadenopathy, T-cell lymphopenia, neutropenia and recurrent infections is broad. Though suspicion for T-LGL was initially raised based on neutropenia and recurrent infections, other etiologies were favored given the absence of peripheral blood lymphocytosis which is a common characteristic of T-LGL. IgG4-related disease was ruled out by the absence of an increase in IgG4+ cells in the lymph node biopsy. There was no evidence by either flow cytometry or immunohistochemistry of a T or B cell lymphoma. Histiocytic disorders including Rosai-Dorfman, Kikuchi, and hemophagocytic lymphohistiocytosis (HLH) were also considered. However, the lymph node biopsy neither showed extensive necrosis typically found in Kikuchi, nor granuloma and abnormal histiocytic proliferation typically noted in Rosai-Dorfman. HLH was unlikely given no splenomegaly, normal triglycerides, normal fibrinogen, normal ferritin and no hemophagocytosis on the bone marrow biopsy. Normal level of immunoglobulins was not consistent with common variable immunodeficiency. While PCR studies for T-cell clonality are still in process, a diagnosis of T-LGL should not be excluded because of lymphopenia.

CONCLUSION: We report an interesting case of a middle-aged woman with diffuse lymphadenopathy, T-cell lymphopenia, neutropenia and recurrent infections with the bone marrow biopsy findings concerning for T-LGL. This case emphasizes the importance of maintaining a broad differential diagnosis and a high clinical suspicion for T-LGL even in the absence of peripheral blood lymphocytosis.

A POTENTIALLY FATAL DISEASE IN A REFUGEE PATIENT WITH HIV

Katie Kozacka, Deepa Ramadurai. Internal Medicine, University of Colorado, Denver, CO. (Control ID #3366509)

LEARNING OBJECTIVE #1: Recognize the presentation of systemic histoplasmosis in an immunocompromised patient.

LEARNING OBJECTIVE #2: Identify social determinants that impact prevention of opportunistic infection (OI) in patients with human immunodeficiency virus (HIV).

CASE: A 42-year-old Honduran refugee with HIV presented to the emergency room with headache and fever (38.1 C). The patient had been off anti-retroviral therapy for 4 months after fleeing from domestic violence. Physical examination and other vitals were unremarkable. Labs were notable for pancytopenia (WBC 2.3 k/ul, HGB 9.9 g/dL, PLT 70 k/ul), CD4 count of 18 cells/μL, AST of 219 U/L, ALT of 109 U/L, and ferritin 1542 ng/mL. Computed tomography (CT) of the brain and cerebrospinal fluid analysis were unrevealing. Chest CT demonstrated subtle, diffuse, upper lobe predominant interstitial opacities while abdominal CT demonstrated hepatosplenomegaly and para-aortic lymph node enlargement. Sputum was negative for acid- fast bacilli. She was initiated on vancomycin, cefepime, acyclovir, and metronidazole. On day two of hospitalization, she developed signs of hypotension and fevers to 40 C. Empiric amphotericin B was initiated, after which, her hemodynamics stabilized. Histoplasma urine antigen was positive on day 7. She completed 14 days of intravenous amphotericin B, transitioned to oral itraconazole. She was discharged to stay with family in-state; however, she has not followed up in clinic nor has she responded to outreach.

IMPACT/DISCUSSION: Histoplasmosis is a fungal infection that presents asymptomatically in immunocompetent hosts. When infecting a patient with advanced HIV, histoplasmosis can cause life- threatening disseminated disease with 100% mortality if left untreated. Little is known about the epidemiology of Histoplasmosis, in immigrants or refugees in the United States (US) as it may be under- diagnosed and confused with other illnesses such as tuberculosis.

Beyond the diagnostic challenges around histoplasmosis in the immunocompromised are the dilemmas that arise with HIV care in refugee patients. In this case, the patient's priority was safety amidst an acute crisis. Discrimination, religion, family responsibility, social isolation, mental health, and financial insecurity are among reasons cited for not receiving HIV care in Latino immigrants[1]. Social determinants including limited access to care and prior trauma compound the burden of disease in patients with chronic conditions such as HIV.

1. Levison, et al. "Where It Falls Apart": Barriers to Retention in HIV Care in Latino Immigrants and Migrants. AIDS Patient Care STDS. 2017;31(9):394–405.

CONCLUSION: Disseminated histoplasmosis must be considered in a patient with CD4 <100 cells/μL, fevers, and weight loss when pancytopenia, acute hepatocellular injury, and significantly elevated ferritin are present.

Social risk assessments of non-US citizens with a new diagnosis of HIV is paramount and can facilitate safe transitions of care in order to help prevent the development of other life-threatening illnesses.

A PRECOCIOUS DIAGNOSIS

Elaine Buckholtz, Michael P. Smith. Internal Medicine, University of Nebraska Medical Center, Omaha, NE. (Control ID #3392372)

LEARNING OBJECTIVE #1: Understand the most recent colon cancer screening guidelines for average- risk patients

LEARNING OBJECTIVE #2: Consider causes for the rise in incidence of colon cancer in young adults and its impact

CASE: A 34 year-old woman presented with ongoing epigastric fullness and discomfort. Her symptoms were associated with a several week history of decreased appetite and mild weight loss. She also reported smaller, more infrequent bowel movements over the same time period. She had no known chronic medical conditions and an insignificant social history. Her physical exam was notable for a palpable liver slightly below the costal margin. She had slightly abnormal liver function tests and suspicious appearing liver masses on ultrasound. The abdominal CT showed a large colonic mass with widespread lesions concerning for metastasis. She underwent a colonoscopy with biopsy of the near-obstructing left-sided mass. Serum CEA was greatly elevated at >10,000 ng/mL. Pathology confirmed the diagnosis of colon adenocarcinoma. Further testing on tissue samples was negative for BRAF mutations which is associated with poorer prognosis in colorectal cancers. Immunohistochemical stains also indicated intact DNA mismatch repair within the tumor cells. She had no significant personal or family history to suggest a hereditary syndrome or increased risk for colon cancer.

IMPACT/DISCUSSION: Colorectal cancer (CRC) remains amongst one of the most common and lethal cancers despite an overall decline in incidence and mortality presumably due to improved colon cancer screening and awareness. Unfortunately, over the past decade, there has been a

significant rise in CRC in young adults. In recent years, a review of existing data and the Microsimulation Screening Analysis-Colon (MISCAN-Colon) model were used to determine whether earlier screening for average-risk patients would be more of a burden or a benefit over their lifetime. The data suggested that the due to an increase of CRC incidence in younger adults, it may be more of a benefit to initiate cancer screening earlier than the age of 50. This led to the American Cancer Society updating its recommendation to start colon cancer screening at the age of 45 for average-risk groups, though the US Preventative Task Force has not. Research suggests that low physical activity, obesity and poor dietary choices may be driving the increased incidence, though the data is still lacking. Regardless of environmental factors, certain hereditary syndromes put younger patients at a higher risk for CRC, the most common being Lynch Syndrome (hereditary non-polyposis colon cancer) and familial adenomatous polyposis.

CONCLUSION: Over the past decade, there has been an increasing incidence of colon cancer in young adults, often at a late stage. Current colon cancer screening guidelines for average-risk patients vary amongst expert groups, so it is essential that the general internist understand the data in order to help patients make informed decisions.

A PRESSURED SYSTEM: HOW LACK OF ACCESS TO ANTI-HYPERTENSIVES CAUSED A PERINEPHRIC HEMATOMA

Mali Jurkowski[1]; Jill Allenbaugh[2]. [1]Internal Medicine, Temple University Hospital, Philadelphia, PA; [2]Medicine, Lewis Katz School of Medicine at Temple University, Philadelphia, PA. (Control ID #3387872)

LEARNING OBJECTIVE #1: Identify perinephric hematoma as a rare complication of uncontrolled hypertension

LEARNING OBJECTIVE #2: Cite social determinants of health as a cause of morbidity and mortality in underserved populations

CASE: A 53-year-old woman with a past medical history of hypertension and type 2 diabetes presented with a two-day history of sharp, severe, LLQ abdominal pain radiating to the back. On arrival to the ED, she was hypertensive to 200/106, appeared diaphoretic, and exhibited abdominal guarding. Her UA showed large blood. A CT abdomen and pelvis revealed a large perinephric hematoma, measuring 15 cm and compressing the left kidney. She denied any trauma, recent anticoagulation use, or history of renal cancers. She denied any other changes to her health, but noted she had run out of all of her medications, including her anti- hypertensives, for the past two weeks because she could not afford them. Given the uncertainty of catastrophic rupture, the patient remained hospitalized for four days for monitoring of her hemodynamics and titration of blood pressure medications. Repeat scans looking for anatomic abnormalities or malignancy were negative. The hematoma was deemed to be spontaneous and attributed to uncontrolled hypertension. Upon discharge, she was given a voucher for medication payment, and connected to a free clinic for continued care.

IMPACT/DISCUSSION: Spontaneous perinephric hematomas typically occur in the setting of underlying anatomic abnormalities or renal cell carcinoma. However, they have been described as a rare consequence of uncontrolled hypertension. This case represents the downstream and often severe effects of inability to afford medical care. The patient had multiple social barriers to appropriate care including lack of insurance, inability to afford medications, residing in an underserved area, and overall low socioeconomic status. Once a diagnosis was made, her team shifted the focus of her care to fully address her social determinants of health and facilitate a safe discharge. Ensuring access to healthcare should be a priority for safe hospital discharges in underserved communities, as doing so can prevent harmful and rare consequences of common medical conditions.

CONCLUSION: Uncontrolled hypertension is a widespread problem in underserved communities, contributing to significant morbidity and mortality. Prioritizing social determinants of health ensures that care teams provide more effective treatment, while preventing devastating complications of easily controllable medical conditions.

A PROLONGED DIAGNOSIS

Andrew I. Kim[2]; Katie Raffel[2]; Andrew Leavitt[1]; Brad Sharpe[2]; Andrew Lai[2]. [1]Hematology/Oncology, University of California San Francisco, San Francisco, CA; [2]Medicine, UCSF Medical Center, San Francisco, CA. (Control ID #3386662)

LEARNING OBJECTIVE #1: Recognize a focused differential diagnosis for isolated PTT elevation

LEARNING OBJECTIVE #2: Manage acute blood loss from acquired coagulopathies

CASE: An 80-year-old man with prostate cancer requiring an indwelling Foley catheter presented with three days of hematuria and a hemoglobin of 5.2 mg/dL.

Exam was significant for normal vital signs, pink urine, melena, and no abdominal pain. A repeat hemoglobin was 3.8 mg/dL. INR was 1.5 and PTT was 70.5 seconds. Bilirubin, reticulocyte count, and fibrinogen were normal, and no schistocytes were seen on blood smear.

Hematology-recommended evaluation revealed low factor VIII activity and a mixing study positive for an inhibitor. Factor II, IX, X, and XI activities were normal. A Russell's Viper Venom Test was negative for lupus anticoagulant. The patient was diagnosed with an acquired factor VIII inhibitor, and initial assessment for hematologic malignancies and autoimmune disorders was negative.

He was treated with prednisone and factor VIII inhibitor bypass activity. The hemoglobin stabilized with red blood cell transfusions; the hematuria and melena resolved. An upper endoscopy and colonoscopy revealed no bleeding source. Over two weeks, the PTT decreased to 44 seconds and factor VIII inhibitor titers declined.

On chart review, the INR elevation had been present for a year and attributed to malnutrition. The PTT elevation manifested five months prior to admission but was never evaluated despite presentations for hematuria and a retroperitoneal hematoma. The failure to further evaluate led to preventable adverse events.

IMPACT/DISCUSSION: General internists frequently encounter laboratory abnormalities that can be easily overlooked. This patient's unexplained elevated PTT persisted until it manifested as a life-threatening bleeding episode. The failure to assess the elevated PTT was an error, possibly due to lack of knowledge, distraction by other acute medical issues, and/or cognitive bias (i.e. attribution to malnutrition).

PT and PTT elevations each have limited differential diagnoses. An isolated PTT elevation poses the most concerning diagnoses, including acquired factor VIII deficiency, acquired von Willebrand disease, and antiphospholipid antibody syndrome. The first two have serious bleeding consequences, but antiphospholipid antibodies are associated with thrombosis. While PT elevations proportionally increase bleeding risk, PTT elevations can cause bleeding at any level. Treatment with coagulation factors alone is ineffective with an acquired inhibitor. Mainstay therapies include glucocorticoids and factor bypass agents. In rare cases, inhibitors can spontaneously resolve.

CONCLUSION: A new isolated or disproportionate PTT elevation without a clear medication culprit is a potential medical emergency. While lupus anticoagulant is the most common explanation, an acquired factor VIII or von Willebrand factor inhibitor must be entertained. Catastrophic bleeds can happen at any level of PTT elevation and require immediate diagnostic and therapeutic intervention.

A RARE CASE OF ACQUIRED FACTOR VIII DEFICIENCY IN PATIENT WITH HEPATITIS C

Anuja A. Kamat[1]; Faiza Mubeen[1]; Jankikeerthika M. Dharmarpandi[2]; Praveen Tumula[3]. [1]internal medicine, Texas Tech University Health Sciences Center- Amarillo, Amarillo, TX; [2]Internal Medicine, Texas Tech University Health Sciences Center School of Medicine Amarillo, Amarillo, TX; [3]Hematology Oncology, Texas Oncology, Amarillo, TX. (Control ID #3388465)

LEARNING OBJECTIVE #1: Recognize association of acquired factor VIII inhibitor with hepatitis C infection

CASE: 65 years old male with history of hepatitis C presented with severe symptomatic anemia. He had sudden onset back pain with dizziness and generalized weakness. He was tachycardic and hypotensive in the ER. CBC was significant for Hb 5.8gm/dl, normal MCV and platelet count. CT showed diffuse anasarca and hematoma formation in multiple muscles including right paraspinal muscles, left psoas muscle and posterior chest wall. No history of bleeding disorder. The coagulation panel showed normal PT/INR, fibrinogen levels with prolonged PTT 92sec and high d-dimer. A month ago, he had spontaneous iliopsoas hemorrhage, for which unsuccessful embolization was performed leading to complications at right femoral access site including pseudoaneurysm formation, infection and thrombosis of right femoral vein. Patient was discharged on apixaban for the DVT in femoral vein. Apixaban was stopped 3 weeks before the he developed spontaneous bleeding. The mixing study showed no correction with addition of normal plasma. Factor VIII(FVIII)activity was found to be low <1% and FVIII inhibitor titer 239.3 Bethesda units was significantly elevated. The diagnosis of acquired hemophilia A(AHA) was made. He was treated for hemorrhagic shock with blood transfusion and FFPs. He was then started on steroids and steady improvement was noted. He was discharged with stable Hb and was asked to follow-up with gastroenterologist for treatment of Hepatitis C and with hematologist.

IMPACT/DISCUSSION: Hepatitis C(Hep C) infection is associated with a variety of autoantibody formation but its association with anti-FVIII autoantibodies(AHA) is rare and only been reported in a handful of cases. The first reported case was in 63 year Japanese male by Sugishita et al. Similar case is reported by Shredi et al, in a 61 year old woman with chronic untreated Hep C. Another case was reported, where development of AHA was seen in 81 year old women with acute Hep C infection. In all these cases the final outcome was fatal. The diagnosis of AHA is made with combination of isolated prolongation of APTT which cannot be corrected by mixing it with normal plasma(mixing study) and subsequent identification of a reduced FVIII level with evidence of FVIII inhibitor activity; as was made in our patient. The management is primarily based on controlling and preventing bleeding, eradicating the inhibitor and treatment of underlying disease. The resolution of AHA was seen with treatment of Hep C with direct antiviral agent in a patient with co-infection with HIV; in a case reported by Maugi et al.

CONCLUSION: The bleeding in AHA mostly is severe and fatal, hence it is important to recognize its association with Hep C early as prompt diagnosis with early treatment can be life saving in theses patients. Treatment of Hep C has been noted to resolve the inhibitor previously and should be done in a timely manner.

A RARE CASE OF ACUTE PANCREATITIS DUE TO VERY SEVERE HYPERTRIGLYCERIDEMIA SUCCESSFULLY TREATED BY LONG-ACTING INSULIN

Sourabh Sourabh, Ankita Aggarwal, Mishita Goel, Padmini Giri, Anubhav Jain. Internal Medicine, Wayne state university school of medicine, Rochester, MI. (Control ID #3392344)

LEARNING OBJECTIVE #1: Management of HTG induced Acute pancreatitis with long-acting insulin (Lantus) alone

CASE: A 35-year-old obese male with no past medical history presented to the hospital with upper epigastric pain of one-day duration. He denied any history of diabetes or prediabetes, obesity, binge drinking, abdominal trauma, any offending drugs, and any procedures including endoscopic retrograde cholangiopancreatography. Family history was not significant for coronary artery disease, cerebrovascular accident, diabetes, dyslipidemia, pancreatitis, or gallstone. His lab work revealed Lipase 1174 U/dl (13-60), Triglyceride >4425 mg/dl (0-190), non-ketotic hyperglycemia with HbA1C-10. USG showed acute pancreatitis, confirmed on MRCP with the edematous pancreas and peripancreatic fluid without evidence of necrosis/duct dilation/ gall stones. Based on the laboratory findings and imaging, we diagnosed acute pancreatitis (AP) secondary to hypertriglyceridemia. The patient was initiated on intravenous fluids and long- acting insulin to help decrease the triglyceride level with the plan to initiate apheresis if needed. However, the patient improved on sc insulin therapy alone with triglyceride level < 500 mg/dl by Day 3, which negated the need for apheresis, and the patient was discharged within a week with fenofibrate, metformin with no further complications.

IMPACT/DISCUSSION: HTG, although rare, is the third leading cause of AP after gallstones and alcohol use, and it can cause up to 7% AP cases. HTG induced AP commonly occurs in patients with prior lipid disorders or abnormalities precipitated by a secondary factor such as the use of alcohol, medication, or poorly controlled diabetes. The pathogenesis of HTG-induced pancreatitis is thought to result from the hydrolysis of TGs by pancreatic lipase and the release of free fatty acids inducing free radical damage. It is essential to bring the TG level down aggressively to 500 mg/dl in the initial stage with either IV insulin or plasmapheresis. Plasmapheresis may be particularly important for the treatment of hypertriglyceridemic necrotizing pancreatitis immediately after its onset. The goal of insulin therapy here is to reverse the stress- associated release of fatty acids from adipocytes, to promote intracellular TG generation within adipocytes, and to promote fatty acid metabolism in insulin-sensitive cells. We follow IV insulin with DKA protocol usually, but sc insulin can be tried to the same effect as it provides sustained insulin supply to the body.

CONCLUSION: There are no current established guidelines for the treatment of very severe HTG-induced AP, although insulin, heparin, and plasmapheresis have all been used in the literature. The unique feature of our case can be emphasized with a quick and effective response to long-acting insulin therapy alone. Additionally, the cost-effectiveness of plasmapheresis remains uncertain, and further investigations are warranted to establish best care practices.

A RARE CASE OF ANEMIA FROM AZATHIOPRINE-INDUCED RED BLOOD CELL APLASIA

Jeremy I. Sullivan, David Rhee. Internal Medicine, New York University School of Medicine, Brooklyn, NY. (Control ID #3392447)

LEARNING OBJECTIVE #1: Recognize the presentation of pure red cell aplasia caused from Azathioprine

LEARNING OBJECTIVE #2: Distinguish key parts of history and lab findings that help diagnose pure red cell aplasia

CASE: A 42-year-old female with a medical history of Crohn's disease, mixed connective tissue disease (MCTD), hypertension, and stage 3 chronic kidney disease, presented to the hospital with a complaint of fatigue and weakness for the previous two weeks. She was taking azathioprine, vedolizumab, and prednisone 5 mg for her Crohn's disease and MCTD. In addition, allopurinol was added 1.5 months prior. Initial lab workup revealed a macrocytic anemia with a hemoglobin of 7.5 mg/dl and a mean corpuscular volume of 100.9 fl. Previous CBCs showed a

hemoglobin around 14 mg/dl with normal mean corpuscular volume. She reported no history concerning for bleed. She had normal ESR and CRP levels and an unremarkable CT abdomen. Folate and B12 levels were normal. She had a haptoglobin of 152 mg/dl, an LDH of 218 units/liter, and total bilirubin of .3 mg/dL, inconsistent with hemolysis. A peripheral smear did not reveal hypersegmented neutrophils. Her reticulocyte count was 0.58%, and absolute count of 0.013, which suggested bone marrow suppression. Her white blood cell count and platelets were both normal. A 6-thioguanine nucleotides RBC level was elevated at 559 pmol/8x10(8)RBC (normal 235-400). Her azathioprine was subsequently discontinued, and her symptoms improved. A CBC on follow up visit approximately 3.5 months after discharge showed a hemoglobin of 13 mg/dl.

IMPACT/DISCUSSION: Azathioprine is a purine analogue that interferes with DNA synthesis and inhibits proliferation of rapidly growing cells. 6-mercaptopurine (6-MP) is a drug metabolite of azathioprine that is used in the treatment of autoimmune diseases such as Crohn's disease. This occurs in part by the active metabolite, 6-Thioguanine nucleotide (6-TGN). Bone marrow suppression has been documented as a possible adverse effect of azathioprine, which is thought to occur via 6-TGN. Rarely, the suppression can be specific for erythrocyte generation and lead to a pure red cell aplasia (PRCA).

Of note, our patient recently began allopurinol treatment to attempt to increase efficacy of the azathioprine. This occurs in part due to the inhibition of one of the metabolic pathways of 6-MP via Xanthine oxidase which will lead to increased therapeutically active 6-TGN. This simultaneous use likely contributed to the elevated 6-TGN metabolites and myelosuppression. This occurs more commonly in patients with low levels of Thiopurine methyl transferase (TPMT), however, aplastic anemia secondary to azathioprine can occur in patients with normal TPMT activity.

CONCLUSION: Allopurinol is often added in combination with azathioprine in the treatment for Crohn's disease. If these patients present with fatigue and macrocytic anemia, drug induced pure red cell anemia must be considered.

A RARE CASE OF APICAL HYPERTROPHIC OBSTRUCTIVE CARDIOMYOPATHY

Marc Zughaib[1,2]; Marcel LeTourneau[1]. [1]Heart Institute, Ascension Providence Hospital, Howell, MI; [2]Michigan State University College of Osteopathic Medicine, East Lansing, MI. (Control ID #3392459)

LEARNING OBJECTIVE #1: Recognize clinical presentation, ECG, echocardiogram, and cardiac catheterization results of Apical Hypertrophic Cardiomyopathy

LEARNING OBJECTIVE #2: Review management of Apical Hypertrophic Cardiomyopathy compared to typical HOCM

2**CASE:** T.M. is a 60 year old Caucasian male with a past medical history of hypertension, hyperlipidemia, and COPD who presented to our outpatient office with a chief complaint of chest pain. The pain started about 6 months ago, and is located substernally. Episodes are reproduced upon moderate exertion, last a few minutes at a time, and are relieved by rest. He described this chest pain as an ache with radiation to the right side of his neck. Episodes occur daily, and are associated with dyspnea and diaphoresis. He is a former smoker, and denies current alcohol use. His medications include atorvastatin 40mg, metoprolol tartrate 25mg, and albuterol sulfate. He had a cardiac catheterization in 2014 that was reportedly normal.

His examination revealed a BMI of 30.7, pulse of 48, and blood pressure of 135/75. There was laterally displaced point of maximal impulse. Cardiac, pulmonary, and all remaining systems upon examination were otherwise within normal limits.

ECG revealed sinus bradycardia, ST segment depression in leads V3-V6, "giant" T-wave inversions in leads V3-V6, and criteria for left ventricular hypertrophy by the Cornell criteria. Echocardiogram demonstrated apical left ventricular hypertrophy, normal ejection fraction, and no significant valvular abnormalities. Coronary angiography revealed mild coronary disease with a large left dominant circulation system, and the left ventricle was described as "spade-like."

The combination of history, physical examination, ECG, echocardiogram, and cardiac catheterization led to the diagnosis of a rare apical variant of hypertrophic cardiomyopathy (HOCM), also known as Yamaguchi Syndrome.

IMPACT/DISCUSSION: This case highlights a rare variant of the typical HOCM. The hypertrophy is typically localized to the left ventricular apex with or without midsegment involvement. A study from the Journal of American College of Cardiology in 2017 demonstrated the prevalence of Apical HOCM in Japanese and Caucasian populations as 0.21% and 0.05%, respectively. Typically, HOCM patients are treated medically and advised to receive an implantable cardiac defibrillator (ICD) to prevent sudden cardiac death. Additional genetic testing and cardiac MRI are recommended. Patients with the apical variant have a 15 year survival of 95% with medical therapy alone. Therefore, management only requires medical therapy without extensive genetic family testing or the need for ICD.

CONCLUSION: - Not all HOCM patients are created equal, and not all variants have the same prognosis or require genetic screening or advanced therapies.

Apical HOCM has characteristic ECG, echocardiogram, and catheterization findings that are important to recognize.

A RARE CASE OF CEREBRAL VENOUS SINUS THROMBOSIS IN A PATIENT WITH AMPHETAMINE ABUSE

john kimbugwe, randa hazam, moutasim souliman, hina yousuf, Nicoleta Rus, Manish Patel. internal medicine, texas tech university health science center, Amarillo, TX. (Control ID #3387552)

LEARNING OBJECTIVE #1: Amphetamine abuse can have an association with Cerebral Venous Sinus Thrombosis

LEARNING OBJECTIVE #2: Physician should be aware of such association

CASE: A 20 year old female with no past medical history presented to the emergency department with severe right sided throbbing, constant headache of sudden onset for one hour before arrival. She was nauseated and vomiting. Medication history was negative for contraceptive use. Family history was negative for coagulation disorders. On exam, vital signs were normal except bradycardia. She was fully conscious, neck soft, pupils were equal and reactive, normal extra ocular eye movement, fundus was unremarkable. Motor, sensory exams were within normal limits. Lab workup was unremarkable except for Urine toxicology that was positive for methamphetamine. CT head showed a hyperdense lesion adjacent to the right tentorium with a suspicion of right transverse sinus thrombosis. Magnetic resonance venography confirmed the presence of right transverse sinus thrombosis and possible sagittal sinus thrombosis. She was started on anticoagulation. Workup for lupus anticoagulant, anticardiolipin antibodies, factor V Leiden and antithrombin III deficiency were negative. Patient's headache improved and she was discharged on apixaban.

IMPACT/DISCUSSION: Amphetamine abuse can cause convulsions and sudden cardiac death, hyperpyrexia, acute renal failure, psychosis and cerebral hemorrhage. Although disseminated intravascular coagulation is recognized in amphetamine toxicity, cerebral venous sinus thrombosis (CVT) is not well known to be associated with amphetamine abuse.

To our knowledge there are only 2 cases in the literature were documented association between amphetamine abuse and CVT. However the mechanism that predisposes to CVT is not known. Amphetamines cause increased heat production and sweating and this leads to dehydration which is a recognized. The combination of volume depletion and thermogenic effect of amphetamines could result in hypercoagulability state leading to CVT.

CONCLUSION: As cerebral venous sinus thrombosis is rare, it is not feasible to conduct larger studies to find causations with Amphetamines. But we propose that more case reports and case series should be reported as a starting point to find common patterns.

A RARE CASE OF CHRONIC ABDOMINAL PAIN

Khaing Khaing Htwe[1]; THANDAR AYE[2]. [1]Internal Medicine, Kingsbrook Jewish Medical Center, Brooklyn, NY; [2]Cardiology, Sakura Hospital, Virginia beach, VA. (Control ID #3391965)

LEARNING OBJECTIVE #1: Chronic abdominal pain can be a challenging complaint for every clinician. We present a patient with nonspecific abdominal pain in whom the etiology was determined to be median arcuate ligament syndrome (MALS). This case helps clinicians to recognize this rare syndrome which is usually low on the differential diagnosis.

CASE: A 65-year-old man with past medical history of hypertension presented with intermittent, non- radiating, postprandial epigastric pain for 3 weeks. Fasting and leaning forward relieved the pain to a certain degree. He also had symptom of nausea. Weight loss of 18 pounds was documented within 3 weeks. There was no history of fever, vomiting, diarrhea, constipation and melena. He had the similar episode 3 months ago and was admitted to the hospital with the suspicion of cardiac cause. Cardiac work-up including left heart catheterization was normal. He denied any smoking, alcohol or drug use. His physical examination was insignificant except mild epigastric tenderness to palpation. His laboratory studies including liver function tests and serum lipase were normal. Electrocardiogram, Chest X-ray, Ultrasound and computed tomography (CT) of abdomen were negative. Esophagogastroduodenoscopy and colonoscopy failed to reveal any abnormality. CT angiography of abdominal aorta revealed severe stenosis of the proximal celiac axis, near its origin, and post-stenotic dilatation. These findings were consistent with MALS. He was presented the options of surgical treatment. After the detailed discussion, he opted for conservative management through small frequent meals and weight gain approach. There was no recurrence of symptoms after two years elapse.

IMPACT/DISCUSSION: MALS, known as celiac axis compression syndrome is a rare condition with the incidence of 2 per 100,000 populations. It is more common in young females with a thin body habitus between the ages of 40 and 60 years. Patients report symptoms of postprandial abdominal pain, weight loss and occasional abdominal bruit. The diagnosis is one of exclusion. The mechanism of chronic abdominal pain is not fully understood. It may be related to compression of the celiac artery by the median arcuate ligament or mediated by the celiac plexus. Various surgical approaches have been reported in the literature, however, outcomes are varied. Contrarily, there were two cases from Japan whose symptoms were relieved through conservative management with weight gain approach and pharmacological therapy to facilitate gastrointestinal motility respectively.

CONCLUSION: The diagnosis of MALS is challenging and easy to miss because of its rarity and lack of specificity of symptoms. Hence, clinicians should always be aware of the possibility of MALS in patients with postprandial pain and weight loss. More studies are required to better define the pathophysiology and explore further into various management approaches including conservative vs. surgery that can lead to the definite algorithm.

A RARE CASE OF CLADOPHIALOPHORA BANTIANA INTRACEREBRAL ABSCESS IN AN IMMUNOCOMPETENT PATIENT

Arya Mariam Roy[1]; Joyce Johnsrud[2]; Atul Kothari[2]. [1]Internal Medicine, University of Arkansas for Medical Sciences, Little Rock, AR; [2]Division of Infectious Disease, University of Arkansas for Medical Sciences, Little Rock, AR. (Control ID #3390132)

LEARNING OBJECTIVE #1: Cerebral phaeohyphomycosis is a very rare infection of the central nervous system (CNS) caused by dematiaceous fungi. It is commonly a disease of immunocompromised patients.

LEARNING OBJECTIVE #2: Cladophialophora bantiana is the most common agent identified with this disease, which has found to have a predilection for the CNS in immunocompetent individuals.

CASE: A 65-year-old patient with poorly controlled diabetes, hypertension presented to the hospital with a chief complaint of blurry vision for 3 weeks, worsening left frontal headache for 2 weeks and difficulty with learned motor skills such as walking and driving. He denied seizures, focal weakness, weight loss, night sweats, recent travel history. He has a past history of significant for Nocardia asteroides gluteal abscess 7 years ago which was treated with trimethoprim-sulfamethoxazole. On examination, he was afebrile and his vital signs were normal. Neurological exam was unremarkable except for right visual field defects and gross confrontation abnormalities bilaterally despite corrective lenses. Laboratory studies were negative for leukocytosis. Liver function and renal function were normal. CT head followed by MRI brain showed multiple irregular thin-walled ring-enhancing lesions in bilateral occipital lobes and left frontal lobe, the largest lesion measuring 3.2 x 2.2 cm, with vasogenic edema and 3 mm midline shift concerning for abscess or solid tumor. Treatment was initiated with vancomycin, ceftriaxone, metronidazole, and dexamethasone.

HIV test and blood cultures were negative. Beta-glucan was elevated to 100 pg/ml. Histoplasma and Blastomyces urine antigens were negative. Neurosurgery performed drainage of occipital abscess and the smear from the fluid showed fungal hyphae on direct smear. As the MRI showed bilateral maxillary sinusitis, endoscopic sinus surgery was performed which was negative for invasive fungal sinusitis. The patient was started on liposomal amphotericin B; which was continued as monotherapy. Fungal cultures from surgery grew a black mold, which was identified as Cladophialophora bantiana. Antifungals were changed to voriconazole based on sensitivities. Patient had resolution of his visual field defects after surgery. He was discharged and currently being treated with voriconazole for 10 months.

IMPACT/DISCUSSION: The treatment is not standardized for cerebral phaeohyphomycosis and it has very high mortality even in immunocompetent patients. Amphotericin B is the most commonly used agent for treatment. Itraconazole and voriconazole have broad activity against dematiaceous fungi and are often used for these infections. Voriconazole has good CNS penetration and has been used in several case reports; however, failures have been reported.

CONCLUSION: Complete surgical resection appears to be necessary for an optimal outcome. Prolonged follow up is also necessary as relapses are also not uncommon.

A RARE CASE OF DIFFUSE ALVEOLAR HEMORRHAGE AS THE PRESENTING PHENOMENON OF SYSTEMIC LUPUS ERYTHEMATOSUS

Jamie Yao, I. Obi Emeruwa, Nida Qadir. University of California, Los Angeles, Los Angeles, CA. (Control ID #3375680)

LEARNING OBJECTIVE #1: To recognize and treat DAH as a complication of SLE

CASE: Ms. K is a 24-year-old woman with no past medical history who presented with three months of progressive fatigue, loss of appetite, and pain on ambulation rendering her bedbound. One month prior, she had developed fevers and sore throat. On outpatient visits, she was prescribed antibiotics for bronchitis without improvement.

On presentation to the referring hospital, vital signs were: temperature 38.3 degrees Celsius, heart rate 102, blood pressure 82/50, respiratory rate 16, oxygen saturation 97% on room air. Physical exam was remarkable for cachectic appearance and a gluteal pressure ulcer. Laboratory evaluation was notable for white blood cell count 9700/uL with 6% lymphocytes, hemoglobin 9 g/dL, platelet 211/uL, sodium 139 mmol/L, potassium 4.1 mmol/L, chloride 109 mmol/L, BUN 65 mg/dL, creatinine 2.2 mg/dL, bicarbonate 15 mmol/L, AST 105 IU/L, ALT 53 IU/L, and alkaline phosphatase of 120 IU/L. She was treated for sepsis with intravenous fluids, vancomycin, and cefepime.

Her course was complicated by an aspiration event leading to cardiopulmonary arrest, with return of spontaneous circulation after five minutes of ACLS, during which she was intubated. She was then transferred to our institution, where she was noted to have worsening hypoxia and progressive bilateral hazy opacities on chest radiograph. She underwent bronchoscopy with sequential bronchoalveolar lavage (BAL) with return of increasingly hemorrhagic lavage aliquots.

Evaluation for infectious etiologies was negative. Rheumatologic evaluation was notable for ANA with a titer of greater than 1:1280, with positive dsDNA, SS-A, and SS-B antibodies. Based on her serologies and clinical manifestations, the patient was diagnosed with systemic lupus erythematosus (SLE) complicated by diffuse alveolar hemorrhage (DAH) and suspected lupus nephritis. She was treated with pulse dose methylprednisolone for three days, underwent five rounds of plasmapheresis, and given cyclophosphamide. Her bloody secretions resolved and oxygenation improved, her kidney function improved, and she was successfully extubated.

IMPACT/DISCUSSION: This case illustrates a rare but severe clinical presentation of SLE. DAH occurs in 4% of SLE patients who are hospitalized and presents with fever, cough, dyspnea, hemoptysis, anemia, and diffuse radiographic opacities. Mortality may be as high as 50%, though reduced with treatment. The return of increasingly bloody fluid on sequential BAL is diagnostic. SLE patients with DAH have a higher incidence of nephritis compared to SLE patients without DAH. Treatment includes supportive ventilation, antibiotics for possible infectious triggers, high-dose glucocorticoids, and additional immunosuppression if indicated. Cyclophosphamide is often started in conjunction with steroids.

CONCLUSION: If the DAH is not responsive, azathioprine, intravenous gamma globulin, and plasmapheresis are next steps to consider. The clinical course is often paved with recurrences.

A RARE CASE OF EVANS SYNDROME AFTER MALIGNANT THYMOMA TREATMENT

John Xie, Gerard Chaaya, Thomas Atkinson. Internal Medicine, Tulane, New Orleans, LA. (Control ID #3372753)

LEARNING OBJECTIVE #1: Demonstrate the evaluation for severe anemia

LEARNING OBJECTIVE #2: Review the diagnostic criteria for Evans syndrome

CASE: A 39-year-old man with a history of thymoma presented with syncope, fatigue and exertional dyspnea for 3 days. Eight months prior, he presented similarly and the thymoma was diagnosed at that time. He completed chemotherapy and radiation and symptoms resolved at that time.

Hemoglobin level returned at 2.9 mg/dL and platelet count of 166,000/microL which later dropped to 89,000/microL. The reticulocyte count was low (0.01), elevated lactate dehydrogenase (LDH) of 497 IU/L, and low haptoglobin of less than 30 mg/dL. He also had a positive direct antiglobulin test (DAT) for IgG. HIV and hepatitis panel were negative. Peripheral blood smear revealed spherocytes and normal platelets.

A bone marrow biopsy revealed erythroid hyperplasia and had a negative stain for parvovirus B19. He was treated with packed RBCs and IV solumedrol 250mg daily for 4 days. His hemoglobin rose appropriately following transfusion and continued to rise until discharge.

IMPACT/DISCUSSION: In this patient with severe anemia, work-up begins with a reticulocyte count and examination of the peripheral blood smear. The low reticulocyte count indicates insufficient erythropoiesis in the bone marrow. However, the peripheral blood smear revealed spherocytes, consistent with intravascular hemolysis. With high LDH, low haptoglobin, and positive IgG direct antiglobulin test (DAT) a diagnosis of warm agglutinin autoimmune hemolytic anemia (AIHA) was made. However, hemolytic anemia is generally associated with reticulocytosis. This discrepancy raised our concern for a separate process in the bone marrow causing the decreased reticulocytes, such as aplastic crisis and prompted further investigation with a bone marrow biopsy, which did not indicate aplastic crisis. Low reticulocyte counts can occur in severe AIHA cases when the bone marrow does not have time to respond appropriately, which is most likely what happened in this case.

General guidelines for AIHA with adequate bone marrow response do not typically involve a bone marrow biopsy or transfusion of packed RBCs. A bone marrow biopsy was done in this case to rule out a concurrent aplastic crisis. RBC transfusion is warranted in AIHA with severe anemia and a low reticulocyte count, which can be life-threatening due to insufficient bone marrow response.

Our patient had a concurrent thrombocytopenia without abnormality on the smear and bone marrow biopsy revealed adequate megakaryocytes, indicating adequate platelet production. This biopsy was consistent with idiopathic thrombocytopenic purpura (ITP). The combination of AIHA and ITP in this patient therefore led us to the diagnosis of Evans syndrome. The subsequent improvement in with steroids further solidified this diagnosis.

CONCLUSION: This case demonstrates the use of systematic approaches to anemia and thrombocytopenia, leading to discovery of AIHA and ITP and underlying accurate diagnosis of Evans syndrome.

A RARE CASE OF INTRACARDIAC RECURRENCE OF NON-HODGKIN LYMPHOMA.

ayesha shaik[1]; Steven Bleich[2]; Jeffrey Hirst[2]; Bakhsh Muhammad[2]. [1]Internal Medicine, university of connecticut, Hartford, CT; [2]Cardiology, Hartford Hospital, HARTFORD, CT. (Control ID #3391927)

LEARNING OBJECTIVE #1: Incidence, manifestations, diagnosis and management of cardiac lymphoma.

CASE: 59 yr old with medical history of Chronic Lymphocytic Lymphoma (CLL) diagnosed 20 years ago and received chemotherapy and allogeneic stem cell transplant, presented with complaints of shortness of breath, burning non-radiating substernal chest pain for the past 1 month. Mentioned she had “no signs of lymphoma” for 16 years. Initial EKG showed sinus tachycardia without acute ST or T wave abnormalities. CTA chest revealed subsegmental right pulmonary embolism, moderate pericardial effusion, large right ventricular (RV) masslike filling defect and enlarged mediastinal and supra-clavicular lymphadenopathy. Transthoracic echocardiogram showed large complex echogenic mass 8.1x2.9 cm

extending from distal aspect of right atrium extending through the tricuspid valve into the right ventricle and its outflow tract (RVOT)with EF of 48%, medium sized pericardial effusion without tamponade. Cardiac MR showed bulky tumor burdern along RV and RVOT. Right heart catheterization with ultrasound guided pericardial drainage was done with 400 cc of bloody fluid removed, right atrial pressure dropped from 21 to 14 mm of Hg. No effusion was noted on repeat echocardiogram. Left supraclavicluar lymph node and pericardial cell block biopsy revealed transformed low to high grade agressive B cell lymphoma with positive CD 19,20,22,23 markers. Surgical intervention was declined due to high risk. She was started on salvage RICE which consists of rituxan, ifosfamide(with Mesna), carboplatinum, and etoposide. She developed worsening dypnea with frequent arrhythmias and was made comfort measures only by family.

IMPACT/DISCUSSION: Cardiac malignancies are rare with secondary tumors more common than the primary ranging from 0.05 % to 0.48% in prevalence. Lung, breast and hematological malignancies in this order are the most common causes of secondary malignancies. Non-Hodgkin lymphomas (NHL) are one of the common hematological malignancies and present as heart failure, pericardial effusion, arrhythmias, cardiac arrest. Intracardiac involvement in NHL is extremely rare and usually is an autopsy finding. We reported a cardiac recurrence of NHL after 16 years of remission.

Imaging modalities like echocardiogram, cardiac CT, MRI, PET CT help in characterizing mass size, location, extent, valvular involvement, flow obstruction, regional contractility, pericardial metastasis and effusion. Definitive diagnosis is by histopathological and immunohistochemical staining of pericardial fluid or tissue biopsy. Treatment modalities for cardiac secondaries is still debatable with no clear data. It includes isolated radiation, chemotherapy. Based on retrospective study of 94 cases of primary and secondary cardiac lymphomas, median survival is 3 months.

CONCLUSION: Highlight the rare delayed recurrence of NHL as transformed high grade B cell lymphoma in heart.

A RARE CASE OF LEUKOPENIA IN ADULT STILL'S DISEASE

Poy Theprungsirikul, David Rhee. Internal Medicine, New York University School of Medicine, New York, NY. (Control ID #3391110)

LEARNING OBJECTIVE #1: Recognize that leukopenia does not exclude Adult Still's Disease

CASE: A 44-year-old male with a history of treated hepatitis C infection presented with a 3-week history of quotidian high grade fevers (103 F), chills, night sweats, nonproductive cough, malaise, 25-lb weight loss, and erythematous rashes on face, chest and bilateral shins. There was no recent travel, sick contacts, animal exposure, outdoor activities or recent dental procedure.

Laboratory findings were notable for pancytopenia (WBC 1.9 10^3/uL, HGB 9.7 g/dL and PLT 148 10^3/uL), mild transaminitis, mild coagulopathy, elevated LDH, markedly elevated ferritin (9770 ng/mL), elevated d-dimer, elevated ESR/CRP, normal triglycerides, normal fibrinogen, normal haptoglobin, and normal soluble CD25. A rheumatologic workup including ANA, anti-dsDNA antibody, anti-Smith antibody, C3 and C4 was unrevealing. Infectious workup, including blood cultures, AFB culture, Histoplasma, Syphilis, Legionella, Ehrlichia chaffeensis, Anaplasma phagocytophilum, Leptospira, Rickettsia rickettsii, Rocky Mountain spotted fever, CMV, EBV, HIV, Hepatitis, Adenovirus, Coronavirus, Human metapneumovirus, Rhinovirus, Influenza, Parainfluenza, Respiratory syncytial virus, Bordetella pertussis, Chlamydophila pneumoniae, and Mycoplasma pneumoniae, was negative. Transthoracic echocardiogram showed no valvular vegetations. CT of the chest, abdomen and pelvis showed mediastinal lymphadenopathy and splenomegaly. A bone marrow aspirate and biopsy showed no evidence of leukemia, lymphoma, or hemophagocytosis. With no other alternative unifying diagnosis, the patient met the Yamaguchi criteria for Adult Still's Disease (ASD).

IMPACT/DISCUSSION: To date, there are only two published case reports of ASD with leukopenia, both were men in their 20's [1,2]. This is an exceptionally rare case of a middle-aged man with ASD who presented with leukopenia rather than leukocytosis. Although suspicion for ASD was initially raised based on the patient meeting the Yamaguchi criteria with quotidian fevers, maculopapular rash, splenomegaly, lymphadenopathy, and transaminitis, other infectious and hematologic etiologies were favored given the marked pancytopenia but eventually ruled out. While different diagnostic criteria have been proposed for ASD, the Yamaguchi criteria was found to be the most sensitive (96.2% sensitivity, 92.1% specificity) [3]. Although leukocytosis is a major criteria and a hallmark characteristic of ASD, a diagnosis of ASD should not be excluded because of leukopenia.

CONCLUSION: We report an exceptionally rare case of a middle-aged man who underwent a negative rheumatologic, hematologic, and infectious workup, and met the Yamaguchi criteria for ASD despite the presence of pancytopenia. This case emphasizes the importance of maintaining a high clinical suspicion for ASD even in the absence of leukocytosis.

A RARE CASE OF PELVIC LEIOMYOSARCOMA AFTER 4 YEARS OF TOTAL ABDOMINAL HYSTERECTOMY WITH BILATERAL SALPINGECTOMY

Sabrina Matosz[1]; Ali Hachem[2]; Farrah Ibrahim[1]. [1]Internal Medicine, UAB-Huntsville, Huntsville, AL; [2]Hematology/Oncology, The Cancer Center of Huntsville, Huntsville, AL. (Control ID #3391748)

LEARNING OBJECTIVE #1: Recognize that although rare and unexpected years after a hysterectomy with no characteristics for malignancy, a leiomyosarcoma has to be considered in case of a tumor in the lower abdomen.

CASE: We present a 47-year-old female with a history of benign uterine fibroids and menometrorrhagia. She failed conservative management so she underwent a total abdominal hysterectomy with bilateral salpingectomy (TAH-BSO). She has been following up with her gynecologist that involves yearly mammograms starting before the age of 40 as her mother died of breast cancer at the age of 35.

Four years later, her yearly mammogram revealed asymmetric foci of her left breast. PET scan showed multiple FDG-PET positive lymph nodes and abnormal increased activity within the pelvis with CT revealing a heterogeneous mass. Surgical removal of the pelvic mass revealed a cellular, mitotically active smooth muscle neoplasm of 9 cm involving the ovarian parenchyma and pathology confirmed leiomyosarcoma.

The patient underwent left lumpectomy with axillary lymph node dissection which confirmed a 1.9 cm invasive ductal carcinoma, poorly differentiated grade 3, ER+ 70%, PR+ 70%, HER-2/neu negative, with 3/9 lymph nodes positive. The leiomyosarcoma was also surgically excised. She did undergo genetic testing for a multi gene panel which showed a variant of unknown significance involving MSH2 and PALB2.

IMPACT/DISCUSSION: We present a woman diagnosed with leiomyosarcoma concurrently with invasive ductal carcinoma of the breast years after an uncomplicated TAH-BSO through a vertical midline incision with no characteristics for malignancy in previous histological analysis. In literature review, cases were recognized that the use of power morcellation during a laparoscopic hysterectomy caused an increased risk

of dissemination even if the specimen tissue initially was benign. However, power morcellation was not performed in this case. Alternative options and considering the risk of dissemination and occult malignancy should be taken into consideration in every hysterectomy performed. Minimally invasive surgery has dramatically improved in recent years; however, complications are still occurring. The way of specimen retrieval should be discussed after complete investigation, appropriate patient selection, and informed consent. Although minimally invasive surgery is used more frequently rather than an abdominal incision, it still poses a risk of spreading malignant tissue that may worsen patients' long-term survival.

CONCLUSION: We encountered a case of leiomyosarcoma that occurred after TAH-BSO. Although unexpected after a hysterectomy, a leiomyosarcoma has to be considered in a pelvic mass. In addition to the startling diagnosis, these rare tumors only account for about 2-5% of all uterine malignancies. We need to be aware that minimally invasive surgery may not prevent dissemination of specimens into the abdominal cavity and other modalities may need to be discovered.

A RARE CAUSE OF LIVER LESIONS; A CASE OF PRIMARY HEPATIC CHORIOCARCINOMA IN A 37 YEAR OLD MALE

Anna A. Artymowicz[1]; Michael Castellarian[1]; Deepa Mittal[3]; Om Pandey[1,2]. [1]Internal Medicine, Dell Seton Medical Center at The University of Texas, Austin, TX; [2]Hematology/Oncology, Dell Seton Medical Center at The University of Texas, Austin, TX; [3]Internal Medicine, Dell Medical School, Austin, TX. (Control ID #3392089)

LEARNING OBJECTIVE #1: Recognize liver tumors as a rare but important presentation of non- gestational primary choriocarcinoma.

CASE: A 37-year old previously healthy male with no family history of cancer underwent an outpatient biopsy of a liver mass found on work-up of his progressive abdominal pain and nausea. The biopsy revealed poorly differentiated adenocarcinoma. The patient was uninsured and presented to the emergency department for care. Imaging showed the mass had doubled in size since his initial scan. CA 19-9, AFP, CEA, MRI, and EGD were negative. The tumor was diagnosed as primary cholangiocarcinoma and the patient was started on Gemcitabine-Cisplatin therapy. Further testing revealed a markedly elevated B-hCG. As this is rare in cholangiocarcinoma, the liver biopsy was re-evaluated. On re-evaluation, the working diagnosis changed to primary choriocarcinoma. Scrotal ultrasound was negative. The patient completed two rounds Bleomycin, Etoposide and Platinum (BEP) therapy with a downtrending Beta HCG initially suggestive of a positive therapeutic response. Unfortunately, the patient's poor clinical condition necessitated suspension of chemotherapy. A later interval check found the bhCG re-elevated and a subsequent CT-scan revealed continued enlargement in liver tumors. The patient passed away five weeks after his second BEP round.

IMPACT/DISCUSSION: Choriocarcinoma (CC) is a germ-cell tumor characterized by an abnormal proliferation of trophoblastic cells. Gestational choriocarcinomas originate from fetal trophoblasts. Non- gestational choriocarcinomas (NGCC) are very rare but have been reported in various tissues, primarily in pelvic and abdominal organs. The pathogenesis of NGCC remains controversial. Some hypothesize they arise from ectopic cells, while others argue they metastasize from unidentified germ cell tumors. Some NGCC cases have been considered examples of retrodifferentiation from a pre-existing adenocarcinoma. Primary Hepatic Choriocarcinoma (PHC) is particularly rare, with only 11 cases reported in the literature to date. Clinical diagnosis of PHC is difficult. There are no specific cell markers for choriocarcinoma. Although elevated serum hCG levels have been found in all patients with PHC, hCG levels are not routinely measured when working up liver tumors unless choriocarcinoma is suspected. Lastly, choriocarcinoma shares histopathological features with several other cancer types. These factors can contribute to missed or delayed diagnoses. Outcomes could potentially be improved by avoiding delays in diagnosis. Consequently, screening of serum hCG is reasonable in liver tumor cases with an unusual clinical presentation or indeterminate histopathological analysis.

CONCLUSION: This case illustrates a rare presentation of choriocarcinoma as primary hepatic tumors. Clinicians should consider checking a quantitative B-hCG in clinically atypical or histopathologically uncertain tumors. This may prevent delayed diagnosis of an atypical choriocarcinoma.

A RARE CAUSE OF STROKE IN IMMUNOCOMPROMISED PATIENT

JALAL EL-AKAWI[1]; Malik Shehadeh[1]; Hussam Ammar[2]. [1]Internal Medicine, Medstar Washington Hospital Center, Washington, DC; [2]Medicine, Medstar, Washington, DC. (Control ID #3392039)

LEARNING OBJECTIVE #1: To recognize cryptococcal vasculitis as a potential cause of stroke in immunocompromised patients.

CASE: A 47-year-old male patient with a medical history significant for multiple sclerosis for which he has been on fingolimod. He presented to our hospital with a one-month history of fever, confusion and generalized weakness.

Upon arrival to the hospital, vitals were unremarkable except for temperature of 38.9 Celsius. Laboratory investigations were significant for a white blood count of 10.2 K/microL (normal 4 -10.8 k/microL). Human immunodeficiency virus (HIV) test was negative. Chest X ray and urinalysis were unremarkable. Blood cultures and cerebrospinal fluid cultures were positive for Cryptococcus neoformans. Patient was started on intravenous amphotericin and flucytosine.

While in the hospital, he developed a new left upper extremity weakness that was highly concerning for a stroke. Brain magnetic resonance imaging revealed a focus of early subacute ischemia within the posterior limb of the right internal capsule along with subacute infarcts in bilateral cerebelli.

Head and neck computed tomography angiography didn't show any evidence of carotid artery disease. An echocardiogram was performed and showed normal left ventricular function without left ventricular thrombus or evidence of valvular disease. Lipid profile and hemoglobin A1c were within normal. Etiology of multiple strokes was attributed to cryptococcal small vessel vasculitis.

The patient improved and was transferred to a rehabilitation facility after 4 weeks of induction therapy with amphotericin and flucytosine.

IMPACT/DISCUSSION: Cryptococcus neoformans is an opportunistic yeast that causes life-threatening meningoencephalitis in patients with advanced HIV infection with CD4 counts usually below 200/μL. It can also be seen in other immunocompromised states such as in patients on immunosuppressive medications. Our patient has multiple sclerosis and was on Fingolimod which is an immunosuppressive medication that was FDA approved in 2010 for the treatment of multiple sclerosis. In the years following approval of this medication, several cases of cryptococcal meningitis in patients undergoing treatment with Fingolimod have been reported in the literature.

Vascular involvement in cryptococcal meningitis is rare and only few reports have described this association.

It primarily causes infarcts in the basal ganglia, internal capsule and cerebellum. Interestingly, some reports showed that patients with Cryptococcus vasculitis and cerebral infarcts have worse prognosis than those without cerebral infarcts.

CONCLUSION: Cryptococcus meningitis is common in immunocompromised individuals including patients with multiple sclerosis who are on Fingolimod. Small vessel vasculitis is an exceedingly rare complication that

can be seen in patients with Cryptococcus meningitis and almost always manifests as a stroke involving basal ganglia, internal capsule and cerebellum.

A RARE DIAGNOSIS PRESENTING AS PERICARDIAL EFFUSION

Malik Shehadeh[1]; Ramez M. Halaseh[2]; Meghan Connelly[1]. [1]Internal Medicine, Medstar Washington Hospital Center, Washington, DC; [2]Internal Medicine, Medstar Washington Hospital Center, Washington, DC. (Control ID #3392428)

LEARNING OBJECTIVE #1: To recognize primary cardiac malignancies as potential cause of pericardial effusion.

CASE: A 44-year-old male patient without significant medical history presented to our hospital with progressive shortness of breath of 3 days duration. He also reported subjective fevers, night sweats and weight loss over the prior several months.

Upon arrival to the hospital, his vitals were unremarkable. His labs showed normal white blood count. Two assays of troponin were performed 6 hours apart and were negative. His electrocardiogram (ECG) had no ST-T wave changes suggestive of ischemia. Chest X ray was unremarkable and had no signs of infection. A computed tomography pulmonary angiography was negative for pulmonary embolism but showed moderate to large pericardial effusion with mass-like lesion surrounding the heart.

Transthoracic echocardiogram (TTE) subsequently revealed a large pericardial effusion with evidence of right ventricular diastolic collapse. The patient underwent pericardiocentesis with successful removal of 1350 ml of bloody fluid. Pericardial fluid studies were negative for bacterial cultures, acid-fast bacilli or fungi and no malignant cells were seen on cytology. Rheumatological work-up including anti-nuclear antibodies and rheumatoid factor was negative. His human immunodeficiency virus (HIV) test was also negative.

Cardiac magnetic resonance imaging (MRI) was obtained and revealed an intrapericardial mass measuring 55 x 31mm located within the right atrioventricular groove. Patient underwent excisional biopsy of the intrapericardial mass. Pathology was consistent with high grade pericardial angiosarcoma. He was started on doxorubicin and ifosfamide and was monitored closely for improvement in right heart function.

IMPACT/DISCUSSION: Angiosarcoma of the heart is an uncommon malignancy with a very poor prognosis. It most commonly presents as a blood-stained pericardial effusion, fever, weight loss and night sweats. This type of malignancy tends to occur in the 3rd to 5th decade of life and is more common in males. To date, no risk factors have been linked to the development of this malignancy.

Primary cardiac tumors are often first detected by TTE. Computed tomography (CT) and cardiac MRI have excellent diagnostic advantages in that they can provide information regarding tumor delineation, tissue characterization and degree of spread. In general, the information obtained from noninvasive imaging is enough to determine the need for surgery/transvenous biopsy, where a definitive histologic diagnosis can be established.

The median survival time following diagnosis is typically 6 to 12 months, although long-term survival has been reported with complete resection.

CONCLUSION: Cardiac malignancies represent 13-38 % of cases of patients presenting with moderate to large pericardial effusions. Initial evaluation should include an echocardiogram, followed by cardiac CT and cardiac MRI to further characterize the tumor and then tissue sampling by biopsy for definitive pathologic diagnosis.

A RARE PRESENTATION OF CALCIPHYLAXIS

Stacy M. Yanofsky[1]; John Xie[2]; Jacqueline Witt[2]; Geraldine E. Menard[3]. [1]Internal Medicine, Tulane University School of Medicine, New Orleans, LA; [2]Internal Medicine, Tulane, New Orleans, LA; [3]Medicine, Tulane University School of Medicine, New Orleans, LA. (Control ID #3392489)

LEARNING OBJECTIVE #1: Recognize rare causes of calciphylaxis and its management

LEARNING OBJECTIVE #2: Diagnose Antiphospholipid Syndrome and assess when to begin treatment

CASE: A 34-year-old Caucasian woman with no chronic medical conditions presented with a painful rash over her abdomen, flanks, and thighs. The rash began as an urticarial eruption, which quickly progressed to firm, ecchymotic and retiform plaques. Punch biopsy was consistent with small vessel vasculitis. Two weeks prior, the patient was diagnosed with ischemic heart failure and unprovoked DVT. She was treated with enoxaparin, and briefly bridged to warfarin, but only received two doses due to hematuria. Workup was positive for lupus anticoagulant, along with elevated inflammatory markers (ESR >120 mm/hr and CRP 37 mg/dL). Infectious and autoimmune vasculitis workups were non-revealing. The small vessel vasculitis was attributed to thrombotic events in the microvasculature.

One month later, she was admitted with expanded skin lesions now with central necrosis and black eschar. Repeat punch biopsy showed focal calcium deposits in the subcutaneous fat with vascular wall involvement, consistent with calciphylaxis. Relevant labs included serum creatinine of 0.81 mg/dL, calcium 9.4 mg/dL, and parathyroid hormone 46 pg/mL. She was treated with solumedrol 1g for 3 days followed by a steroid taper, Intravenous Immune Globulin (IVIG) for 4 days, and sodium thiosulfate 25 g 3 times weekly. She received complicated wound debridement of her eschars, requiring wound vacuum-assisted closures and subsequent skin resections to fascial depth. During her hospital stay, she was treated with IV heparin and transitioned to fondaparinux following surgery for presumed antiphospholipid syndrome (APLS).

IMPACT/DISCUSSION: Calciphylaxis has a survival rate of 57% at six months with sepsis being the most frequent cause of death. ESRD patients are most commonly affected, but rare non-uremic causes include primary hyperparathyroidism, malignancy, alcoholic liver disease, connective tissue disease, and warfarin. Relevant workup was negative for these causes in our case with the exception of warfarin use, although less likely as our patient only received two doses. Mainstays of treatment focus on wound care, management of secondary infections, pain, and identifiable inciting factors. Additionally, a trial of sodium thiosulfate is recommended.

Autoimmune disorders in non-uremic patients have been associated with calciphylaxis. APLS is characterized by antibodies formed against phospholipid-binding proteins, such as lupus anticoagulant. Laboratory criteria include detection of lupus anticoagulant on two occasions, 12 or more weeks apart, although some reports suggest a 6-week interval is more feasible and may be as equally clinically useful. Although our patient did not technically meet criteria for APLS, given the rapid progression of her disease, it was imperative that we met a diagnosis quickly and began treatment.

CONCLUSION: APLS is a rare cause of calciphylaxis.

A RETAINED INTRAUTERINE DEVICE IN AN ELDERLY WOMAN CAUSING MULTIPLE HEPATIC ABSCESSES

Christopher Valente[1]; Andrew Canakis[1]; Karim G. Khan[2]. [1]Internal Medicine, Boston University Medical Center, Boston, MA; [2]Infectious Disease, Boston University Medical Center, Boston, MA. (Control ID #3390998)

LEARNING OBJECTIVE #1: 1. Identify uncommon sources of liver abscess.

CASE: An 86-year old woman with chronic kidney disease and type 2 diabetes mellitus was brought in after her family found her lethargic and vomiting.

In the emergency department, she was febrile, tachypneic, and had diffuse abdominal tenderness. Labs revealed a mild leukocytosis, elevated lactate, and mild transaminitis. Computed tomography (CT) noted multiple lobulated hypodensities in the liver concerning for abscesses, as well as a retained intrauterine device (IUD). She was admitted to the medical intensive care unit for septic shock where she was started on broad-spectrum antibiotics and vasopressors.

Her course was complicated by respiratory failure requiring intubation and acute renal failure requiring continuous hemofiltration. Blood cultures grew *K. oxytoca*, *S. constellatus*, and *B. fragilis*. The liver abscesses were aspirated and cultures grew *K. oxytoca, S. constellatus, E. coli*, *O. splanchnicus,* and *A. turicensis*. Given their multifocality, the liver abscesses were presumed to be secondary infections. The IUD was removed and cultured *B. cenocepacia*.

After removal of the IUD, the patient's clinical status improved significantly. She was extubated and transitioned to intermittent hemodialysis. She continued an extended course of antibiotics with the plan to continue until radiologic resolution.

IMPACT/DISCUSSION: In the U.S. there are 2.3 cases of hepatic abscesses per 100,000 admissions. They are often caused by direct extension of neighboring infected tissue or by hematogenous spread from intra-abdominal sources, such as inflammatory bowel disease, diverticulitis, and appendicitis. Up to this point, there have only been 2 case reports of infected IUD as the source of a hepatic abscess. In one case, a 20-year old IUD caused a tubo-ovarian abscess with *S. milleri* bacteremia and hepatic abscesses. The other reported a newly-placed IUD that led to septic pelvic thrombophlebitis resulting in *F. necrophorum* bacteremia and multiple liver abscesses.

In our case, the IUD culture grew different species than were found in the hepatic abscesses. However, the species found in the hepatic abscesses, such as *Actinomyces, Streptococcus, Bacteroides* and *E. coli* are commonly found in reproductive tract infections. *Actinomyces* is classically associated with IUDs, and though her IUD did not grow the organism, she had received cephalosporins prior to its removal, which likely altered its culture yield. Sputum cultures grew *Burkholderia*, matching the speciation found on the IUD, suggesting its hematogenous spread from the reproductive tract. As no other acute abdominal process was identified, and given her clinical improvement following its removal, the IUD was the suspected source of her hepatic abscesses.

CONCLUSION: 1. Regardless of age, in women with hepatic abscesses without a source, consider the presence of a retained IUD.

2. Long-term IUDs increase risk for infection and should likely be removed unless indicated.

A SILENT WOLF IN THE ROOM

Kenneth N. John[1]; Ian Ross[1]; Simran Grewal[1]; Elliot Martin[1]; Anuj Mehta[2]. [1]Internal Medicine, Penn State Hershey Medical Center, Lancaster, PA; [2]Penn State College of Medicine, Milton Hershey Medical Center, Allentown, PA. (Control ID #3390772)

LEARNING OBJECTIVE #1: Assess a fever of unknown origin

LEARNING OBJECTIVE #2: Recognize the utility of the SLICC criteria

CASE: A 59-year-old white male presented to the emergency department for one week of confusion, weakness, weight loss, fevers, cough, and dyspnea. On admission, his vital signs were T 38.7C, HR 120, BP 109/91. Initial labs notable for WBC 4.3 (4.0-10.4 K/μL), Hg 11.0 (13.0-17.0 g/dL), PLT 250 (150-350 K/μL). A respiratory virus panel was positive for coronavirus. A chest X-ray showed bilateral pleural effusions and a left lower lobe consolidation. A lumbar puncture resulted as follows: cell count 1, glucose 52 (40-70 mmol/L), protein 64 (15-45 g/L). Urinalysis revealed proteinuria. Blood cultures and viral studies (HSV, EBV, CMV) were negative. Brain MRI showed bifrontal subdural hygromas with mild reactive dural enhancement. Despite various broad spectrum antibiotics for 8 days, he continued to be encephalopathic with fevers. On day 9, he was intubated for progressive respiratory failure. That same day, an ANA titer resulted at 1:2560. Rheumatology was consulted and were concerned for systemic lupus erythematosus (SLE) as he met SLICC criteria: ANA 1:2560, lymphopenia (WBC 2.87, lymphocytes 0.07), urine protein/Cr 0.62, and serositis (CRP 12.2, ESR 62, ferritin 984). Solumedrol 1000mg daily was administered for 3 days. He was extubated on day 10. He was started on a prednisone taper and hydroxychloroquine and was discharged on day 15.

IMPACT/DISCUSSION: The routine thought process for a presentation of fever, encephalopathy, and unstable vital signs is to find an infectious source. In our patient, we had evidence of a pneumonia that did not improve with antibiotics. As no alternative infection was apparent, we found ourselves dealing with a fever of unknown origin (FUO). FUO is defined as an illness of more than three weeks' duration, fever higher than 38.3C on several occasions, and diagnosis uncertain after one week of investigation in the hospital. The causes of FUO are typically familiar diseases with uncommon presentations. Due to encephalopathy, a thorough history was unattainable. However, on exam we were able to elicit diffuse joint pain. This, along with an elevated ANA, led us to consider a rheumatologic etiology.

The SLICC criteria is used to diagnose SLE. Requirements for diagnosis are > 4 criteria met (at least 1 clinical, 1 immunologic) OR biopsy-proven lupus nephritis with positive ANA or Anti-DNA. The SLICC criteria is more sensitive but as specific as the American College of Rheumatology SLE classification criteria. Our patient met the criteria with a history of arthritis, serositis, neurologic symptoms, lymphopenia, and positive ANA and Anti-DNA antibody testing. Here, we initiated steroids which ultimately helped the patient recover.

CONCLUSION: This case reinforces the concept that if a treatment regimen is not improving the patient's clinical status, it is beneficial to broaden your differential and implore the aid of consultants to help guide the management of a complex patient.

A SPOONFUL OF THYROID HELPS THE SUGAR STAY UP

Muhammad Ibrar Islam, Aaron Mills. Internal Medicine, Eastern Virginia Medical School, Norfolk, VA. (Control ID #3392174)

LEARNING OBJECTIVE #1: Recognize that hypothyroidism can be a potential etiology in cases of nonresponsive hypoglycemia in Insulin-dependent Diabetics.

CASE: A 41 y/o AAF with H/O HTN, Insulin-dependent DM, CKD, Post-Surgical hypothyroidism admitted for workup of atypical chest pain that was deemed muscular after workup. She was on 350 mcg of Synthroid for her hypothyroidism. Her diabetes was well managed on insulin glargine 65 units and Insulin Lispro 15 units with meals. She had a history of hypoglycemic episodes at home. Her hypoglycemic episodes were initially considered secondary to a higher dosage of insulin regimen. During hospitalization, she was started on Insulin Lantus 45 units and insulin lispro 10 units with meals. She had an episode of hypoglycemia with a glucose level of 46mg/dl, her insulin regimen was decreased to insulin lantus 20 units and sliding scale correctional insulin with meals. Despite changing the insulin regimen, she continued to have episodes of hypoglycemia with episodes ~50. She was taken off insulin and observed. Despite being off insulin she continued to have episodes of hypoglycemia as low as 42. Hypoglycemia workup was started, there was no use of oral

hypoglycemic agents per history, renal functions were stable at baseline during these episodes.

Her lab work showed normal values of insulin, c peptide, proinsulin, beta-hydroxybutyrate. Her AM cortisol was borderline at 6.79 (6.02-18.4) with an ACTH level of 75.1 (7.2-63.3). She had a TSH level of 86.31 mcU/ml (0.27-4.2) and a free T4 of 0.2 ng/dl (0.9-1.8). Based on hypoglycemic episodes, significant hypothyroidism and concern for depression of pituitary, hypothalamic adrenal axis due to hypothyroidism and some element of suboptimal absorption of levothyroxine she was stated on a higher dose of IV Levothyroxine. After the start of IV Levothyroxine, episodes of hypoglycemia subsided. Her repeated thyroid profile at that point showed a free T4 of 1.1 ng/dl (0.9-1.8) and a free T3 level of 2.3 pg/ml (2.3-4.2). There were no more episodes of hypoglycemia.

IMPACT/DISCUSSION: The resolution of hypoglycemic episodes along with improvement in thyroid function correlates that hypoglycemia was secondary to hypothyroidism. it has also been reported in couple of other case reports before. Hypoglycemia in Hypothyroidism is due to multiple mechanisms proposed blunted growth hormone and cortisol to insulin-related hypoglycemia, reduced glucagon, glycogenolysis as well as gluconeogenesis. Blunting of the hypothalamic-pituitary-adrenal axis also leads to hypoglycemia in hypothyroid patients and treating hypothyroidism, improves hypoglycemia and axis as well. As an internist, while dealing with hypoglycemia above pathophysiology should be taken into account.

CONCLUSION: Hypothyroidism can be a potential cause of hypoglycemia in insulin-dependent diabetics and treating it can result in quick correction of hypoglycemia.

Thyroid Profile should be a part of work up in nonresponsive hypoglycemia in insulin-dependent diabetics.

ASSOCIATION OF PULMONARY LYMPHOMATOID GRANULOMATOSIS WITH NEWLY- DIAGNOSED HIV INFECTION

Doyoung Kim[1]; Alexander Ostrovsky[1,2]. [1]Internal Medicine, St. Mary Medical Center, Langhorne, PA; [2]Alliance Cancer Specialists, Langhorne, PA. (Control ID #3379411)

LEARNING OBJECTIVE #1: Diagnose and treat Pulmonary Lymphomatoid Granulomatosis, a rare B-cell lymphoproliferative disorder associated with Epstein-Barr virus (EBV) infection

CASE: 49-year-old male presented to our hospital with a two-day history of fever, chills, cough, respiratory distress, and 20-pound unintentional weight loss over the past two months. PMH includes multiple bilateral pulmonary nodules up to 2.5cm. A transbronchial biopsy two months ago only showed nonspecific inflammation. Prior to admission, he denied any respiratory complaints. On evaluation, the patient was found to be profoundly neutropenic and thrombocytopenic. A CT chest showed a notable progression of diffuse micro-nodularity. His physical exam was unremarkable.

A transbronchial biopsy on the right lobes was repeated because of his worsening respiratory status. The biopsy result was again non-diagnostic, and testing for mycobacterium and a rheumatological workup was also unremarkable. Given his nonspecific symptoms and negative workup, he was screened for HIV and was consistent with AIDS. Meanwhile, the patient developed recurrent neutropenia despite GCS-F support. Thus, a bone marrow biopsy was ordered to further investigate potential etiologies.

VATS was then performed for surgical biopsies, which established the diagnosis of PLG. Interestingly, EBV in situ hybridization was negative, and the prior bone marrow biopsy showed no evidence of hematologic malignancies. A staging CT abdomen revealed prominent bilateral inguinal lymph nodes.

Once the diagnosis was established, R-CHOP was initiated as an inpatient due to his immunosuppressed status. ART was started simultaneously, and a course of broad-spectrum antibiotics was completed. After discharge, he completed 4 cycles of chemotherapy without significant side effects. A 6 month follow-up CT scan showed a marked improvement of diffuse lung pathology and resolution of prior lymphadenopathy.

IMPACT/DISCUSSION: Though rare, PLG should be considered in the differential diagnosis of pulmonary lesions with nonspecific presentations in immunocompromised populations. Common chest radiographic findings include diffuse ill-defined nodules. As untreated PLG has a high mortality rate (40-70%), early open lung biopsy should be done to establish the diagnosis. Histological findings typically consist of angiitis, polymorphic lymphoid infiltrates, and focal necrosis. The clinical course varies, but PLG often progresses to large B-cell lymphoma. A three-tiered system, according to the number of EBV-positive B-cells, guides the treatment strategy: grade I-II-III. It is debatable whether truly EBV-negative PLG exists. Grade I lesions are often EBV-negative. Sampling error may account for EBV-negative cases, or HIV itself may have caused cellular transformation as recent literature and this case illustrates.

CONCLUSION: In practice, the treatment strategy depends on the clinical status and the extent of extrapulmonary involvement and is similar to treating aggressive lymphoma with R-CHOP.

ASSOCIATION OF RECURRENT THROMBOEMBOLISM FROM MARANTIC ENDOCARDITIS IN A PATIENT WITH METASTATIC PROSTATE CANCER

Doyoung Kim[1]; Ahmad Jarrar[1]; Charles Nicholson[1]; Muhammad Z. Khan[1]; Carlin McLaughlin[1,2]. [1]Internal Medicine, St. Mary Medical Center, Langhorne, PA; [2]Penn Hematology/Oncology, Langhorne, PA. (Control ID #3390816)

LEARNING OBJECTIVE #1: Diagnose marantic endocarditis, a rare nonbacterial bacterial thrombotic endocarditis associated with advanced malignancy

CASE: 61-year-old male presented to our hospital with a sudden onset right-sided weakness and slurred speech. He also endorsed chronic headaches with varying locations. PMH includes paroxysmal AF, recurrent TIA, PFO, acute ischemic colitis, and prostate cancer. His brain MRI/MRA 2 years ago for TIA was unremarkable. TTE at that time demonstrated a large PFO without evidence of intracardiac thrombus. Given his history of paroxysmal AF, he has been treated with apixaban and aspirin since the diagnosis.

On neurological examination, his right-sided weakness resolved, but his facial numbness and headache were persistent. Radiographic evaluation again demonstrated no evidence of acute stroke or vascular stenosis. However, it showed disease in the clivus that was consistent with metastatic disease. Regarding his prostate cancer, he received radiotherapy 6 years ago and Lupron for 2 years following the diagnosis. His previous PSA was undetectable. Concerned for recurring disease, PSA was obtained with a level of 364ng/mL. A bone scan confirmed metastasis.

A repeated TTE showed no evidence of intracardiac thrombus. TEE was then ordered, which demonstrated a small, highly mobile echodensity on the aortic and mitral valve. Subsequent evaluation for bacterial endocarditis was negative, including four sterile blood cultures. Rheumatological and hypercoagulable studies were also unremarkable. Based on the clinical presentation, metastatic prostate cancer, and TEE findings, marantic endocarditis was diagnosed. On discharge, he was continued on both apixaban and aspirin. GnRH-analogue was given to treat his metastatic prostate cancer.

IMPACT/DISCUSSION: Marantic endocarditis is defined as the deposition of sterile platelet aggregates commonly on the aortic and mitral

valve. Though uncommon, it should be considered in the differential diagnosis of CVA with a background of advanced malignancy. Evaluation should also consider SLE, as it is another highly associated condition. Antiphospholipid syndrome and rheumatoid arthritis also show an association, however less commonly. It is mostly associated with the lungs, colon, and ovarian malignancies. Our case is unique, as marantic endocarditis is uncommon with advanced prostate cancer. It is almost certain that his recurrent TIA and acute ischemic colitis were secondary to previously undiagnosed marantic endocarditis, as a consequence of his prostate cancer, and that he may be in chronic DIC.

CONCLUSION: Vegetations on marantic endocarditis tend to more easily embolize then infective endocarditis due to less severe inflammation at the site of attachment. These conditions together significantly increase the risk of extensive infarction; that the patient here has been on both apixaban and aspirin worked favorably. As our case demonstrates, treatment options consist of indefinite anticoagulation and the treatment of the underlying malignancy.

ASYMMETRIC WEAKNESS SECONDARY TO GUILLAIN-BARRE SYNDROME – AN UNUSUAL CASE.

Muqsita Nashat[1]; Amanullah Rana[1]; M.Azam Mohiuddin[2]. [1]Internal Medicine, Nazareth Hospital, Hamilton, NJ; [2]Neurology, Nazareth Hospital, Philadelphia, PA. (Control ID #3392293)

LEARNING OBJECTIVE #1: Recognize that a negative cerebrospinal fluid (CSF) analysis does not rule out Guillain-Barre Syndrome (GBS) in a patient with asymmetric weakness.

CASE: A 37-year old female with a history of depression presented to the hospital with complaints of six-day history of weakness and numbness in the bilateral lower extremities associated with numbness and tingling of her left hand. She denied facial weakness, trouble swallowing, visual symptoms, numbness or weakness of right arm. There was no bladder or bowel incontinence. She had sore throat two months ago. She denied fever, rash or tick bite. She drank 3-4 bottles of alcohol every day. Physical exam revealed normal vital signs and cranial nerve exam. Muscle power grade was 4/5 for proximal muscles of left leg and right leg, 2/5 for dorsal and plantar flexion of the left foot, 4/5 for right foot and 5/5 for bilateral upper extremities. Sensory exam showed decreased pinprick on the dorsum of left foot medially, decreased vibration in toes bilaterally. Reflexes were absent throughout and her plantar reflex was normal. CT scan of brain was negative for acute stroke. Blood work showed normal serum TSH, aldolase, B12. Her AST was 57 u/L. RPR and Lyme's serology were negative. MRI of thoracic, cervical and lumbar spine were unremarkable. Her CSF analysis showed normal protein, glucose and WBC. Her Nerve Conduction Study (NCS) showed sensory motor demyelinating peripheral polyneuropathy with axonal changes in bilateral lower extremities left more than right. Based on the NCS, she was treated for Guillain-Barre syndrome (GBS) with I.V immunoglobulin; she improved and was transferred to acute rehabilitation unit.

IMPACT/DISCUSSION: GBS is an autoimmune monophasic acquired poly radiculoneuropathy, often provoked by a preceding viral infection. The most common variants are acute inflammatory demyelinating polyneuropathy (AIDP 60-80%) and acute motor axonal neuropathy (AMAN 7-30%). GBS has an incidence of 1-2 cases per 100,000 people. Usually, the patient presents with an acute onset of rapidly progressing symmetrical ascending flaccid paralysis with absent or diminished reflexes, often associated with sensory symptoms as well as cranial nerve involvement. This progressive symmetrical paralysis in the legs and arms occurs over hours to days and often plateaus in 1-4 weeks. Asymmetric weakness is secondary to CNS involvement. Cerebrospinal fluid (CSF) analysis is done to support the clinical diagnosis of GBS and reveals elevated CSF proteins with normal white blood cell counts. This is known as albuminocytologic dissociation, seen in up to 75% of patients within the first 3 weeks, but normal CSF profile can be found in 10 % of GBS patients throughout the disease as seen in our patient. The mainstay of treatment consists of plasma exchange versus I.V immunoglobulin, which is mostly of equal efficacy.

CONCLUSION: This is an unusual case of GBS and emphasizes that GBS should be considered in patients presenting with asymmetric weakness with a normal CSF.

A TALE OF COMPETING PATHOLOGIES: FINDING OPTIMAL BALANCE IN VENOUS THROMBOEMBOLISM PREVENTION IN THE SURGICAL PATIENT

Erik Johnsen. Medicine, Tulane University School of Medicine, New Orleans, LA. (Control ID #3391253)

LEARNING OBJECTIVE #1: Review current guidelines for perioperative deep venous thrombosis prophylaxis in the orthopedic patient

LEARNING OBJECTIVE #2: Discuss management of retroperitoneal hematoma

CASE: A 68-year-old man presented after a mechanical fall. Imaging revealed a left distal femur and left scapular fracture. He required PRBC transfusion on arrival for a hemoglobin of 5.9, down from baseline of 8-10. He underwent open reduction internal fixation surgery for the femur fracture. Post-operatively, he developed hypotension and respiratory failure requiring bilevel positive airway pressure. Electrocardiogram demonstrated an S1Q3T3 pattern and transthoracic echocardiogram showed right sided heart failure suspicious for pulmonary embolus (PE). CT of the chest with contrast could not be performed due to acute kidney injury. Heparin infusion was initiated. Hemoglobin level again declined requiring repeat transfusion. With improvement of creatinine, CT was obtained and revealed a right pulmonary artery filling deficit suspicious for PE as well as left retroperitoneal and adductor compartment hematomas. After initial stabilization, he again became hypotensive with development of a new left thigh firmness and ecchymosis. The left leg was also cool to palpation. Point of care ultrasound was concerning for an expanding hematoma. Both interventional radiology and surgery evaluated patient for embolization vs evacuation though risk was deemed too high. Shortly thereafter, bleeding into hematoma had ceased. An inferior vena cava filter was placed for prevention of further PE.

IMPACT/DISCUSSION: Anticoagulation in the perioperative orthopedic patient is needed to reduce risk of venous thromboembolim (VTE) and PE. In our patient, rivaroxaban was held postoperatively which led to potential development of VTE. VTE risk is higher in Total Hip Replacement [THR], Total Knee Replacement [TKR] and Hip Fracture Repair [HFR]. Anticoagulation is typically held 12 hours pre and post operatively per ACCP guidelines. Duration of therapy depends on procedure: TKR 10-14 days, THR/HFR 30 days. Low Molecular Weight Heparin has traditionally been the agent of choice though recent meta-analyses have shown that direct oral anticoagulants have been more effective with improved safety profile and reduced bleeding risk. Intermittent Pneumatic Compression devices can be used in patients with high bleeding risk.

Signs of a retroperitoneal hematoma are represented by Lenk's triad: acute flank pain, symptoms of internal bleeding such as hemodynamic instability and abdominal tenderness. Treatment involves halting anticoagulation, pRBC and either surgical or interventional radiology intervention. If hematoma is small with mild symptoms, it can be treated conservatively although surgery would be indicated in hemodynamic instability or acute nerve damage.

CONCLUSION: Anticoagulation in the post-operative setting is often a delicate balance. Internists will need to consider the patient's injury, comorbidities, and acute illnesses to determine the best course of action.

A TALE OF TWO STENTS : REFLECTING ON COGNITIVE AND IMPLICIT BIAS

Frank Cacace, Jason Ehrlich, Joseph Conigliaro. Internal Medicine, Zucker School of Medicine, New Hyde Park, NY. (Control ID #3392060)

LEARNING OBJECTIVE #1: To recognize the cognitive biases present while evaluating a patient's symptoms in a compressed setting

LEARNING OBJECTIVE #2: To reflect on how diagnostic errors can be made in women with coronary artery disease

CASE: We are vulnerable to cognitive biases. These can walk in tandem with implicit bias that inexorably shapes our thinking. Add compressed time and the clinician may fail to appreciate important diagnostic possibilities.

First vignette - I was seeing my last patient in a morning session and was very behind. I noticed an e mail and phone message from the same patient, thought it odd, and decided to respond then. The patient was a 72 year old man with mild hyperlipidemia, bronchiectasis and reflux. He reported anorexia that morning, with left neck pressure and sweatiness three hours prior, now resolved. He was most concerned with his appetite.

When asked to go to the emergency room to evaluate, he balked at first, then relented. In the ER, he was hemodynamically stable, but had ST wave elevations inferiorly and very high troponins. In the catheterization lab, he required an RCA stent to halt any further infarct.

Second vignette - I was again behind seeing morning patients; there was a knock on the door. Our nurses were triaging, answering a call from a 62 year old retired RN with HTN, dyslipidemia, and active tobacco use. She was having severe gastric upset. She was on d14 of doxycycline for Lyme disease. I spoke to our nurses in the hallway and thought quickly. The doxycycline must be turning her stomach upside down. "Have her take some ranitidine and TUMS, and take her next dose of doxycycline with a large meal". After we hung up, the patient's gastric pain became intolerable even with these interventions. She went to the ER. There she had inferior wall ST elevations and very high troponins. In the catheterization lab, she required the same RCA stent.

IMPACT/DISCUSSION: Reflecting on these cases, the man, with less risk factors and a less convincing story, was diagnosed correctly. The woman with clear risk factors was not - with her, I anchored on her Lyme disease and the doxycycline. The same humility and respect for gastric symptoms experienced with inferior wall ischemia did not surface. She fortunately had a crescendo in her pain and went to the ER.

With these cases, one should recognize availability bias, the 'within case' momentum bias, a bit of overconfidence bias and the type 1 thinking I engaged in with fast self confirmatory dialogue. My heuristics helped the patient in one case, but almost hurt the other. The larger concern, however, is that an implicit bias toward women who experience coronary disease differently was also at play. Somewhere in my rushed metacognition, I believe it contributed to my premature closure.

CONCLUSION: The tale of these two stents underscores that as we evaluate patients we should:

- Take time outs, ask what doesn't fit
- Name the cognitive biases out loud and ask which may be at play
- Customize illness scripts to women who may have coronary disease

ATRIAL FIBRILLATION IN DURHAM VA HOME BASED PRIMARY CARE PATIENTS AND IMPLEMENTATION OF ANTICOAGULATION THERAPY GUIDELINES

Jeannette F. Stein[1,2]; Radhika Kothapalli[2]; Jonathan Hale[2]. [1]Department of Internal Medicine, Duke University Medical Center, Durham, NC; [2]Durham VA Medical Center, Durham, NC. (Control ID #3391472)

LEARNING OBJECTIVE #1: Recognize the importance of anticoagulation therapy among those with nonvalvular atrial fibrillation (AF) with prior stroke, TIA, or a CHA2DS2-VASc score of > 2, given that anticoagulation among elders reduces stroke risk.

LEARNING OBJECTIVE #2: Identify elements of home-based patient support that may improve the implementation of anticoagulation therapy

CASE: HPI: 69 yo male Veteran with HTN, HF with EF 45%, joint pain, lymphedema, obesity, AF, with CHA2DS2-VASc score 4 on rivaroxaban. The patient was referred to the Durham VA HBPC in 2/2017 due to his debility, poor mobility, wheelchair-bound status and numerous missed appointments.

ROS notable for weakness, chronic low back, hip and bilateral knee pain.

PE pertinent for BP 130/78, obesity, irregularly irregular rhythm, normal S1/S2 and pedal edema.

Pill boxes were filled by the PA making monthly home visits, resulting in compliance. The patient continued to receive home-based care and received oral anticoagulants until Nov 2019 when he moved away.

IMPACT/DISCUSSION: There are three steps to anticoagulation prescribing: identification of the appropriate patient, risk vs benefit discussion in which the patient /family agrees to the medication, and patient adherence to the medication. This discussion pertains to implementation of anticoagulation therapy once the appropriate patient is identified and once the patient agrees. Since questionable medication adherence is the reason for many referrals to Home Based Primary Care (HBPC), the implementation of anticoagulation therapy was assessed among HBPC patients with AF. To determine if chronically-ill Veteran patients with AF receiving HBPC are receiving guideline-consistent anticoagulation therapy, a chart review of all HBPC patients was undertaken in 2019. Of these 210 patients, 46 had AF (22%). Among the 46 patients with AF, 70% were prescribed anticoagulation therapy, including 13% of those on warfarin and 57% on direct oral anticoagulants. Explanations of failure to receive anticoagulation therapy included palliative care status, a history of hemorrhagic complications, and patient/ family refusal. Hernandez I, et al. identified patients newly diagnosed with AF in 2014–2015 using Medicare claims data, and collected prescriptions filled for anticoagulants in the 12 months after AF diagnosis, finding that only 35% of Medicare recipients received anticoagulation therapy. Our sample of complex, elderly patients receiving HBPC support achieved 70%. This is likely related to the close follow-up and medication management by the clinical team in the home. Elements of HPBC care that could be provided in a less resource- intensive manner include tools such as medication boxes (either simple pill boxes or second-generation electronic pill boxes with audible reminders) which family can fill.

CONCLUSION: In order to improve the implementation of anticoagulation therapy in veteran patients with AF, consider patient enhanced support in the form of a home-based team. Hernandez I, et al. Am J Cardiovasc Drugs. 2019

ATTENTION TO PREVENTION: WE CAN'T AFFORD TO CHICKEN OUT

Anupama M. Kapadia, Meera Bhakta, Joseph H. Joo, Ciaura Brown, Sherine Salib. Internal Medicine, Dell Medical School, University of Texas at Austin, Austin, TX. (Control ID #3391539)

LEARNING OBJECTIVE #1: Recognize that vaccine preventable diseases (VPDs) should remain on the differential diagnosis, even in immunocompetent patients.

LEARNING OBJECTIVE #2: Recognize the societal factors associated with VPDs, including social inequities and costs of care.

CASE: A 51-year-old man with no past medical history presented with a painful and pruritic rash. His symptoms began six days prior with sore throat, odynophagia, fever, nausea, and poor oral intake. The rash began on his scalp and spread to his entire body. He denied sick contacts and travel since moving from El Salvador to the U.S. nine years ago and reported to be in a monogamous relationship.

On physical exam, he had a temperature of 103.9°F, blood pressure of 99/57, and heart rate of 139 beats/min. He had a diffuse vesicular rash with an erythematous base on his head and neck, oral cavity, trunk, and extremities including the palms and soles.

Labs were significant for thrombocytopenia, transaminitis, acute kidney injury, and lactic acidosis. A punch biopsy revealed a highly positive Tzanck smear. He was admitted to the ICU for complicated primary varicella zoster virus (VZV) infection with possible superimposed bacterial infection and septic shock given multiorgan involvement. He was given IV fluids, IV acyclovir, vancomycin and cefepime. Additional testing for HIV, syphilis, and HSV was negative. The patient's family members were vaccinated. He was discharged home on day six with valacyclovir.

IMPACT/DISCUSSION: There are few recently documented adult cases of primary VZV, particularly complicated VZV infection in immunocompetent adults. Involvement of the palms and soles, as in our patient, is exceedingly rare. To our knowledge, only four cases involving palms and soles have been reported outside of regions with endemic monkey pox. Three of these were in children.

For several reasons, there has been a resurgence of VPDs in the U.S. According to the Texas Department of State Health Services, varicella was the second highest cause of reported VPDs in 2019.

There is a significant societal impact of VPDs, including the cost that our patients and healthcare system bear.

One estimate of the direct costs of VPDs annually is $9 billion. Moreover, a large burden of disease falls on vulnerable populations such as immigrant and incarcerated/detained patients. Although neighboring Latin American countries have high vaccination rates, those most likely to seek refuge in the U.S. tend to be from rural areas with lower vaccination rates.

CONCLUSION: 1. VPDs, which can present both typically and atypically in immunocompetent adults, should remain on the differential diagnosis.

2. The societal impact of VPDs, including costs of care, is high.

3. Understanding the inequities leading to VPDs allows us to evaluate and implement opportunities for prevention.

ATYPICAL PRESENTATION OF AORTIC DISSECTION AND DIAGNOSTIC DILEMMA

Mishita Goel, Danyal Taheri, Sourabh Fnu, Radha Kishan Adusumilli, Kristen Hughes, Vesna Tegeltija. Internal medicine, wayne state university school of medicine/ascension providence rochester hospital, Rochester, MI. (Control ID #3390782)

LEARNING OBJECTIVE #1: Recognize atypical presentations of aortic dissection

LEARNING OBJECTIVE #2: Diagnose aortic dissection when AKI precludes CT angiography

CASE: 38-year-old morbidly obese male with history of uncontrolled hypertension and a known thoracic aortic aneurysm presented with diffuse upper abdominal pain associated with diarrhea and an episode of vomiting. He was slightly hypertensive on admission with BP of 168/91 in both arms and labs showed leukocytosis and elevated creatinine. CT abdomen showed mild thickening of the wall of the ascending and proximal transverse colon. However, his pain progressively worsened overnight and abdomen became tense, prompting a repeat CT scan (without contrast due to AKI) that showed air in mesenteric veins and intrahepatic portal veins. Surgery was consulted and patient underwent open exploratory laparotomy with resection of small bowel due to infarcted small bowel from mid jejunum until the beginning of terminal ileum. Post operatively, the patient remained hypertensive despite nicardipine drip and had worsening renal failure. In view of persistent hypertension and worsening renal failure, possibility of dissection was discussed. Patient underwent an IVUS interrogation of the aorta since CT angiography could not be done due to renal failure. The results revealed a large Type B aortic dissection. The right renal artery was not visualized but the left renal artery was seen coming off the true lumen. The right iliac segment was patent and the dissection flap appeared to end in the common iliac. To confirm the anatomic extent of the lesion, CTA with arrangement for emergent dialysis was done which showed type A dissection of the entire aorta with slightly poor opacification of left subclavian artery, hypoperfusion of entire right kidney and acute infarct of anterior half of the lower two thirds of the left kidney. Complete blockage of the left external iliac artery from its origin for a length of about 7.5 cm, with normal opacification of the distal left external iliac artery, left common femoral artery and its bifurcation was also seen. Patient was taken to OR for aortic dissection repair.

IMPACT/DISCUSSION: Acute mesenteric ischemia is an ominous but rare complication with reported incidence of 3-4% in association with acute aortic dissection. Diagnostic techniques include CTA, aortography, TTE and TEE. In our patient, CTA could not be done initially due to AKI, and TTE was unremarkable. IVUS was used to diagnose aortic dissection as other imaging was contraindicated. This is an expedient method that allows visualization of vessel wall and lumen without any need for IV contrast. This case highlights the unique potential of this modality in diagnosing aortic dissection when other modalities cannot be performed.

CONCLUSION: Although rare, suspect aortic dissection as a cause in patients with mesenteric ischemia and utilize IVUS as a diagnostic modality for suspected cases of aortic dissection when other imaging cannot be performed.

ATYPICAL PRESENTATION OF A SYSTEMIC DISEASE WITH HIGH MORTALITY: A CASE REPORT

Ecem Sevim[1]; Hanan Lodhi[1]; Pardeep Kaur[1]; Andrea Porrovecchio[2]. [1]Medicine, Montefiore Medical Center - Wakefield Campus, Bronx, NY; [2]Medicine, Montefiore Medical Center, Bronx, NY. (Control ID #3392665)

LEARNING OBJECTIVE #1: Acute rheumatic fever can present with atypical clinical manifestations.

LEARNING OBJECTIVE #2: We should consider checking for anti-streptolysin O (ASO) titers in patients with atypical clinical presentations of ARF; even with no history of preceding streptococcal infection

CASE: A 29-year-old woman with morbid obesity and uncontrolled hypertension presents a few days of upper respiratory tract infection symptoms followed by acute onset of dyspnea and productive cough. She denied fevers, rash or arthralgias. Her physical exam was notable for scattered wheeze. Labs remarkable for creatinine: 2.90 mg/dL (baseline 1.2 mg/dL), albumin: 3.2 g/dL. Total protein: 6.7 g/dL and. 1.7 gr / d of proteinuria. Chest x-ray revealed mild pulmonary vascular congestion and cardiomegaly. Transthoracic echocardiogram had moderate, diffuse left ventricular hypo-kinesis and moderately decreased left ventricular (LV) ejection fraction of 37%. Exercise sestamibi perfusion scan revealed no signs of ischemia but global hypo kinesis and dilation of LV, compatible with myocarditis without valvular involvement. ANA, ds-DNA, complement 3 and 4, Ro/LA, Anti-GBM, p-ANCA, PR3, MPO were negative. ESR and CRP were found to be elevated (40 and 0.9, respectively). Anti-

streptolysin O (ASO) titer was (924 IU/mL) and patient was diagnosed with acute rheumatic fever (ARF); falling under the category of `Possible/ Uncertain Rheumatic Fever`.[1] Patient was started on Benzathine Penicillin 600,000 units IM monthly for 1 year for secondary prevention per revised Jones criteria.[1] Kidney biopsy planned as outpatient for interstitial nephritis.

IMPACT/DISCUSSION: Even though the incidence of ARF has significantly declined in North America and Europe, it is of high importance to be aware of the persisting high cardiovascular mortality and morbidity, especially among populations with poor socioeconomic resources worldwide; more prominently in developing countries. The diagnosis of initial or recurrent ARF relies on patients fulfilling a set of clinical criteria. Typical manifestation of carditis in ARF is valvulitis (involvement of the endocardium), especially of the mitral and aortic valves. However, myocarditis and pericarditis may occur as well. The 2015 Jones revision provides the diagnosis of "possible ARF" for cases with a high clinical suspicion of ARF but incomplete fulfillment of the criteria in the setting of lack of criteria secondary to the unavailability of laboratory or echocardiographic testing, poor clinical history, and/or late presentation. In these circumstances, it is recommended to offer secondary prophylaxis with clinical and echocardiographic re-evaluation in one year. [1]

CONCLUSION: Diagnosis of ARF might be challenging especially in patients with atypical presentations; and should be included in differential diagnosis of patients with cardiomyopathy.

Our case is a good example to remind general internist to check for ASO titer in patients even with no prior infection history and/or atypical cardiac presentations of ARF.

A UNIQUE COMBINATION OF UNILATERAL BELL'S PALSY, BILATERAL ANTERIOR UVEITIS, AND RASH AFTER CHECKPOINT INHIBITOR TREATMENT OF METASTATIC MELANOMA

Siamak Kohan, Soniya Rabadia, Aleksandr Gorin, Magdalena Ptaszny. Internal Medicine, UCLA, Los Angeles, CA. (Control ID #3390805)

LEARNING OBJECTIVE #1: Recognize checkpoint inhibitor toxicity.

CASE: A 62-year-old male with stage IV BRAF+ metastatic melanoma to the brain and lungs presented to the hospital with a 2-day history of right-sided facial weakness, dysarthria, bilateral purulent eye discharge, bilateral leg rash, and fevers. He denied eye pain, headaches, and confusion. The patient had been receiving immune checkpoint inhibitor (ICI) therapy with Nivolumab and Ipilimumab within 3 months of presentation.

Neurological exam was notable for right-sided facial droop and decreased taste on the left, rear tongue, and dysarthria. Brain MRI was significant for hyperenhancement of bilateral facial nerves and geniculate ganglia, which was consistent with bilateral facial nerve palsy. There was no evidence of new brain metastasis on imaging or CSF cytology. There was pitting edema through both his calves, more significant on his left leg, associated with significant erythema, warmth, and tenderness. Ultrasound imaging was negative for deep vein thrombosis. Ophthalmic exam was notable for poor visual acuity, irregular and sluggish pupils, corneal dusting, and keratic precipitates which was consistent with bilateral anterior uveitis. Infectious work-up for uveitis was negative.

His constellation of symptoms was consistent with checkpoint inhibitor toxicity, thus, he was started on high dose glucocorticoids for his facial nerve palsy and steroid eye drops for his uveitis with significant improvement in his symptoms.

IMPACT/DISCUSSION: Ipilimumab, an anti-CTLA-4 agent, and Nivolumab, an anti-PD-1 agent, are both associated with immune-related adverse events (irAE). These irAE typically occur within 3 months of starting therapy, and are more common with combination therapy versus monotherapy with either class. Most commonly, these irAE include diarrhea, colitis, pruritus, rash, and endocrinopathies. Peripheral neuropathy involving cranial nerves is treated with prednisone. Anterior uveitis is treated with topical steroids, systemic steroids, and cycloplegic agents. ICI therapy may be resumed once systemic steroids are tapered down and symptoms improve.

While neurologic and ocular toxicities are associated with checkpoint inhibitors, both are exceedingly uncommon and occur in <1% of cases. Our patient had a unique combination of symptoms from these agents which have only rarely been described in the literature. Individually, cases with uveitis or Bell's palsy develop within weeks after administration of Ipilimumab, not Nivolumab. In cases where patients were on both Ipilimumab and Nivolumab, the irAE resolved with a steroid course and discontinuation of Ipilimumab.

CONCLUSION: ICI can cause neurologic and ocular irAE which may present months after treatment.

ICI may be continued after irAE depending on the severity of symptoms and response to treatment.

A UNIQUE PRESENTATION OF CARDIOGENIC SHOCK IN THE SETTING OF TYPE 2 AMIODARONE-INDUCED THYROTOXICOSIS

Joseph Kaplan[1]; Evelina Grayver[2]. [1]Internal Medicine, Hofstra Northwell Health, Manhasset, NY; [2]Cardiology, Hofstra Northwell NSLIJ, Manhasset, NY. (Control ID #3352605)

LEARNING OBJECTIVE #1: Recognize the clinical features and course associated with Type 2 Amiodarone-Induced Thyrotoxicosis (AIT).

LEARNING OBJECTIVE #2: Understand proper treatment for Type 2 AIT.

CASE: A 59 year old female with a history of atrial fibrillation, cardiac arrest from presumed contrast allergy, unspecified arrhythmias and heart failure (EF 40%) presented as a transfer from an outside hospital (OSH). She was admitted 5 days prior for palpitations and was found to be in atrial fibrillation with a heart rate up to 220. She was intubated for respiratory distress and had intermittent ventricular tachycardia for which amiodarone was started. A TTE was grossly abnormal with an EF of 20%. The patient continued to decompensate and was transferred to our CCU.

Surgical history included pacemaker placement. Home medications were entresto, metoprolol, coumadin and aspirin. While in China for the past month she developed worsening cough, diarrhea and weight loss. Months ago she was found to have low TSH but free T4 was normal. On transfer, the patient was intubated, had an audible S3 and S4 with +JVD and had 3+ pitting edema of all extremities. Her acute decompensated heart failure required lasix drip, Swan-Ganz Catheter placement and pressors. For recurrent tachyarrhythmias amiodarone and esmolol drips were started. TSH was found to be <0.01. Steroids were started for possible Graves vs Type 2 AIT. Cholestyramine was also started. An AST of 359 U/L and ALT of 738 prevented propylthiouracil/methimazole use. Thyroid US and TSH receptor antibody were normal. The free T4 was elevated to 4.1 ng/dl. Given known amiodarone use during prior hospitalizations, Type 2 AIT was diagnosed. After initiating treatment, esmolol and pressors were weaned off, the Swan-Ganz was removed and extubation was successfully performed. The patient left the CCU 2 days later. She was discharged on oral steroids and amiodarone. At the time of discharge her free T4 was 3.3 and her heart rate stabilized in the 60s.

IMPACT/DISCUSSION: Type 2 AIT is a destructive thyroiditis resulting from intrinsic toxic effects of amiodarone. It can develop

months to years after use and causes excess follicular cell T3/T4 release without increased synthesis. Steroids are the primary treatment while cholestyramine is also used to aid enterohepatic clearance. With treatment, lab abnormalities may take months to normalize. For Type 2 AIT, amiodarone does not require immediate discontinuation. There is no benefit in doing so given its mean 58 day half-life. Additionally, amiodarone appears to ameliorate hyperthyroidism by blocking T4 to T3 conversion and beta-adrenergic receptors, along with possibly T3 receptors. Stopping amiodarone may actually worsen symptoms.

CONCLUSION: Patients with a history of amiodarone use require long-term thyroid function monitoring given its toxic effects can take years to develop. If any concern for type 2 AIT arises, urgent initiation of steroids is imperative. Immediate discontinuation of amiodarone, however, is unnecessary and potentially detrimental.

AUTOIMMUNE GASTRITIS INDUCED VITAMIN B12 DEFICIENCY AND RBC HEMOLYSIS

Nihal Patel, Johnny Cai, Thomas Deloughery. Internal Medicine, Oregon Health and Science University, Portland, OR. (Control ID #3391596)

LEARNING OBJECTIVE #1: Recognize the clinical signs/symptoms of severe anemia

LEARNING OBJECTIVE #2: Recognize the association between Vitamin B12 deficiency and hemolytic anemia

CASE: A 65 year old male with a history of hepatitis C status treated with sustained viral response and COPD who presented with subacute, progressive chest pain, dyspnea on exertion, and lower extremity numbness/tingling. Review of systems was notable for muscle aches, loose stools, and fifteen pound unintentional weight loss over the last 2-3 months. Vitals and physical exam were notable for tachycardia and pallor. Preliminary labs revealed pancytopenia with WBC of 2.7, Hb of 4.6 and platelets of 107. Further labwork revealed a low corrected reticulocyte count, MCV of 112.8, and 1+ schistocytes on peripheral smear.

Given his clinical history, pancytopenia, and schistocytes, we pursued work up for a possible hemolytic process. Haptoglobin was below detectable limit, while lactate dehydrogenase was above the detectable limit with normal total bilirubin (0.8). Devastating causes of hemolytic anemia such as thrombotic thrombocytopenic purpura, disseminated intravascular coagulopathy, hemolytic uremic syndrome, and autoimmune hemolytic anemia were considered but deemed unlikely given the absence of renal dysfunction, unremarkable INR (1.23), negative Coomb's test, ANA, and protein electrophoresis. Although worrisome for myelodysplastic syndrome, there were no atypical features on peripheral smear. Work-up for megaloblastic anemia was notable for a vitamin B12 level below the detectable lower limit with elevation in homocysteine and methylmalonic acid. Subsequent work-up revealed elevated intrinsic factor antibody (159.0) and antiparietal cell antibody (29.7) diagnostic of pernicious anemia.

IMPACT/DISCUSSION: Vitamin B12 deficiency is a common finding with readily available confirmatory testing and treatment strategies. However, when untreated, patients can develop severe hematologic complications including intramedullary hemolysis. Although the exact mechanism is not fully understood, in vitro studies suggest that oxidative stress from a buildup of homocysteine is an important factor. Despite the commonness of vitamin B12 deficiency, hemolytic anemia remains a rare complication, occurring in only 1.5% of B12 deficient patients. Our case highlights the many varied presentations B12 deficiency takes while emphasizing the need to evaluate the causes of B12 deficiency.

CONCLUSION: B12 deficiency has nonspecific symptoms but can have severe neurologic and hematologic complications if untreated.

B12 deficiency should be considered as a cause of hemolysis in the right clinical setting. Further studies to determine the cause of vitamin B12 deficiency should be conducted.

AUTOIMMUNE HEPATITIS AS AN UNDER-RECOGNIZED RISK FACTOR FOR HEPATOCELLULAR CARCINOMA

Jellyana Peraza[1]; Rachel Levy[1]; Darlene LeFrancois[2]. [1]Internal Medicine, Montefiore Medical Center, Bronx, NY; [2]Medicine, Montefiore Medical Center, Bronx, NY. (Control ID #3392187)

LEARNING OBJECTIVE #1: Describe the clinical presentation of autoimmune hepatitis

LEARNING OBJECTIVE #2: Recognize the risk of progression of autoimmune hepatitis to cirrhosis and hepatocellular carcinoma

CASE: A 62-year-old woman with a history of well-controlled diabetes and hypothyroidism presented with one month of worsening epigastric pain radiating to her back. She had a history of 6 years of intermittent epigastric pain and more than 14 years of intermittently mildly-elevated aminotransferases (AST 60, ALT 50). Abdominal US done 10 years prior to presentation showed mild hepatomegaly and parenchymal disease with fatty infiltration. CT abdomen performed six years before presentation showed hepato-splenomegaly and perisplenic varices suggestive of cirrhosis. Hepatitis serologies were positive for HBsAb, anti-HBc and anti-smooth muscle antibody and negative for HBsAg and HCV Ab, suggestive of immunity due to past hepatitis B infection. On presentation, she had ascites. Alpha-fetoprotein was elevated. CT abdomen revealed cirrhotic liver, multiple small liver and pancreatic masses, and peripancreatic lymphadenopathy. Fine needle aspiration of the liver revealed metastatic hepatocellular carcinoma (HCC). The patient started chemotherapy, but her course was complicated by large volume ascites, acute renal failure, and severe anemia leading to the patient's death.

IMPACT/DISCUSSION: Abnormal liver enzymes are frequently detected in asymptomatic patients, as they are often included in routine blood test panels. Mild elevation (less than 15 times the upper limit of normal) is seen with chronic liver disease and reflects ongoing liver injury. Further evaluation should include a detailed review of medications, screening for alcohol use, viral and autoimmune hepatitis serologies, and workup for hemochromatosis and nonalcoholic fatty liver disease.

Autoimmune hepatitis (AIH) is a chronic inflammatory disease whose etiology is unknown but is thought to involve environmental triggers, in genetically susceptible individuals. It is often seen in women with other autoimmune disorders. Many patients are asymptomatic while others present with non-specific symptoms such as fatigue, weight loss, and anorexia. More rarely, patients present with evidence of acute liver failure. The diagnosis is made by a combination of elevated aminotransferases, increased gamma-globulin levels, serologic markers (e.g. ANA, anti-smooth muscle antibodies), and liver biopsy.

The incidence of HCC in patients with AIH is thought to be 3 per 1000 patient-years, but it increases to 10 per 1000 patient-years in patients with AIH-related cirrhosis. In a systematic review, patients with cirrhosis and AIH had a 20-year probability of 23% of developing HCC. However, AIH with cirrhosis has not been identified as a high-risk group requiring increased surveillance for HCC.

CONCLUSION: Recognition of the clinical and often subtle manifestations of chronic liver disease can yield a timely diagnosis of cirrhosis and treatment of underlying etiology can prevent the development of HCC

A VERY CHEEZY MASQUERADE

Laya Reddy. Internal Medicine, Scripps Clinic, San Diego, CA. (Control ID #3378841)

LEARNING OBJECTIVE #1: Identify mimics of peritoneal carcinomatosis

LEARNING OBJECTIVE #2: Recognize those at risk for peritoneal tuberculosis

CASE: This is a 57-year-old Hispanic woman who presented with 3-weeks of abdominal distention and weight loss. She denied fever, chills, night sweats, cough, shortness of breath, leg swelling, vaginal bleeding or discharge. Past medical history included rheumatoid arthritis and latent tuberculosis (status post isoniazid x 6 months). Medications included adalimumab (recently started 3 months prior to admission) and hydroxychloroquine. Patient's mother passed away from cervical cancer at age 34. Patient originally from Mexico and has lived in San Diego for 15 years. She is up-to-date with age appropriate screenings and vaccinations.

Physical exam significant for moderately distended, non-tender abdomen with shifting dullness. Initial basic labs unremarkable. CT abdomen pelvis with large volume ascites and increased nodularity of omentum concerning for peritoneal carcinomatosis. Serum level of CA-125 elevated at 220. Ascitic fluid revealed cell count of 832 with lymphocytic predominance, serum-ascites albumin gradient of less than 1.1, and negative cytology.

After discharge, she followed with Oncology – repeat imaging revealed right adnexal mass. Biopsy of mass revealed granulomas with focal central necrosis. She was then referred to Gynecology Oncology – laparoscopy with necrotizing granulomas and no positive organism stains. Infectious disease consulted and further history obtained in terms of patient's dietary intake. Patient noted frequent ingestion of soft cheese from unpasteurized cow's milk from roadside markets in Mexico. There was then suspicion for Mycobacterium bovis (M. bovis). She was started on empiric treatment for possible M. bovis versus M. tuberculosis given recent initiation of adalimumab in setting of latent tuberculosis. Acid fast bacilli (AFB) culture returned positive for M. bovis and pyrazinamide discontinued. Ethambutol stopped after 2 months. Rifampin and isoniazid continued for a total 9-month treatment course. Patient's symptoms resolved and she was not restarted on adalimumab.

IMPACT/DISCUSSION: M. bovis is part of the M. tuberculosis complex and accounts for less than two percent of cases of disease in the United States. However, in certain regions along the border with Mexico, incidence is higher given more access to unpasteurized milk products. M. bovis is a zoonotic disease and involvement is most commonly extrapulmonary. Tuberculosis due to M. bovis is clinically and radiographically indistinguishable from tuberculosis due to M. tuberculosis. Difficulties lie in diagnosis given it is frequently mistaken for a gynecological malignancy. In our patient, initiation of adalimumab was a significant factor in either rupture of an existing M. bovis granuloma as well as in prevention of initial granuloma formation.

CONCLUSION: Keep in mind a patient's cultural background and nutritional intake when forming the differential diagnosis of new-onset ascites.

A WEAK SUSPICION REVEALED THE REASON FOR A PATIENT'S WEAKNESS: AN ATYPICAL PRESENTATION OF MYASTHENIA GRAVIS.

Mihaela F. Missel, Joie Young. Internal Medicine, University of Mississippi Medical Center, Jackson, MS. (Control ID #3391413)

LEARNING OBJECTIVE #1: Recognize an atypical presentation of Myasthenia gravis in a male.

LEARNING OBJECTIVE #2: Recognize the importance of accuracy and precision in taking the history of present illness.

CASE: Mr N is a 33 yo black male with no known past medical history, other than being previously told that he had a "problem with his eye nerves", who presented with progressive generalized weakness for five months, as well as significant weight loss. He is an immigrant from Cameroon who has been residing in an ICE detention center for several months. His weakness began in his lower extremities, then progressed to involve upper extremities, muscles of the neck, and face. He became unable to walk or eat solids, thus adopted a liquid diet. He denied having any sensory changes, numbness or tingling, but endorsed diplopia.

Upon examination, patient appeared expressionless. His strength was 2/5 throughout, also manifesting lid lag, ophthalmoplegia, hypophonia, and dysarthria. Patient was diagnosed with oropharyngeal dysphagia by SLP, confirmed with an MBS study, and was declared unsafe for PO intake. Following a PEG tube placement, feeds and vitamin B1 replacement were initiated. Neurology team anticipated improvement of his neurological symptoms, as thiamine deficiency was their primary working diagnosis. However, there was no marked improvement, and an EMG was pursued. Its findings revealed postsynaptic neuromuscular junction disorder, and the diagnosis of Myasthenia gravis was confirmed by a positive AchR binding antibody titer. Patient was given five sessions of IVIG infusions, Pyridostigmine was initiated, and Prednisone was up- titrated to 40mg by the time of discharge. Mr N is scheduled to follow up with Neurology at John Hopkins.

IMPACT/DISCUSSION: This case portrays an atypical presentation of Myasthenia gravis in a male. Lower extremity weakness as the initial symptom is known to be very rare. Ocular symptoms, on the other hand, are the most common presentation, found in 50% of patients later diagnosed with MG. If his "eye nerve disease" previously mentioned in his home country was truly his initial presentation, he is among the half whose disease progressed to the generalized form. The specificity of AchR binding Ab's in Myasthenia gravis is 99%. Although I previously resorted to Guillan-Barre and its variants when evaluating ascending weakness, I am now aware that MG is a potential diagnosis as well. This encounter also underscored the importance of precision in obtaining the history of present illness. Noticing that the patient's weakness preceded his dysphagia prevented us from attributing his symptoms to malnutrition alone and missing or delaying the diagnosis.

CONCLUSION: The initial presentation of Myasthenia gravis can be isolated lower extremity weakness. Ocular symptoms are the most common initial presentation, with progression to generalized disease in 50% of patients.

Demonstrating AchR binding Ab's provides the laboratory confirmation of myasthenia gravis, as they are 99% specific for the disease.

A YOUNG WOMAN SUFFERING FROM LOWER BACK PAIN WITHOUT ANY HISTORIES OF CANCERS: CAN YOU SUSPECT THE DIAGNOSIS OF DISSEMINATED CARCINOMATOSIS OF BONE MARROW ONLY WITH THE FINDINGS OF PLAIN X-RAYS OF BONES?

Satsuki. Oie, Yoshinori Tokushima, Naoko E. Katsuki, Masaki Tago, Shu-ichi Yamashita. General Medicine, Saga University Hospital, Saga, Japan. (Control ID #3386125)

LEARNING OBJECTIVE #1: Recognize that slight brightness and osteosclerotic changes of bones on plain X-ray can be clues to the correct diagnosis of disseminated carcinomatosis of bone marrow (DCBM).

CASE: A 34–year–old woman without a history of cancer visited our hospital because of lower back pain. Physical examination showed no

abnormalities including breast masses or lymphadenopathy. The laboratory examination showed WBC count of 2.9 × 10^9 cells/L without erythroleukoblastosis, hemoglobin of 9.4 g/dL, platelet count of 136 ×10^9/L, ALP concentration of 3,196 IU/L (isozyme type 2 plus 3, 91%), LDH of 169 U/L, serum calcium concentration of 8.9 mg/dL, and inorganic phosphorus concentration of 3.8 mg/dL. Diffuse hyperdense areas were found in the lumbar spine and bilateral alae of the ilium on plain X–rays. Enlarged views of lateral lumbar spine revealed disappearance of vertical lines of bone trabeculae and unclear endplates of vertebral body as findings of osteosclerosis. Bone scintigraphy showed beautiful bone sign and absent kidney sign, suggesting diffuse bone metastatic lesions. We suspected disseminated carcinomatosis of the bone marrow caused by gastric or breast cancer; however, upper gastrointestinal endoscopy revealed Borrmann 4 type cancer on the anterior wall of the gastric angle. We finally diagnosed DCBM due to poorly differentiated gastric adenocarcinoma by histopathological findings of gastric tumor.

IMPACT/DISCUSSION: It could be difficult to make a diagnosis of diffuse bone metastasis of a solid cancer by findings of plain X–ray, because they might apparently look normal. Although osteosclerotic changes such as sandwich sign or rugger jersey vertebrae are well known, these signs could become less prominent when cancer cells invade the bone marrow, making the transparency of whole vertebrae low. To notice the presence of slightly bright spines and disappearance of normally translucent lines of endplates are the keys to making a correct diagnosis. Disappearance of translucent lines of endplates was confirmed in the present case as well as previously reported cases of diffuse bone metastasis.

The only useful so-called red flag sign of low back pain concerning metastatic cancers of bones, which suggests the importance of careful interpretation of plain X-rays of bones, is a past history of a cancer. However, approximately 40% of DCBM cases did not have the history of cancer. It is essential to carefully interpret the findings of plain X-ray of bones with suspecting the presence of bone metastasis when they are examined due to lower back pain.

CONCLUSION: Clinicians should be alert to the presence of slight brightness and osteosclerotic changes of bones on plain X–rays, especially in patients without a history of gastric, colon, breast, lung, or prostate cancers, which could lead to the diagnosis of DCBM.

A 'STROKE' OF FUNGAL FATE

Rebecca K. Tsevat[1]; Rachel Brook[2]. [1]Internal Medicine and Pediatrics, UCLA, Los Angeles, CA; [2]Internal Medicine, UCLA, Los Angeles, CA. (Control ID #3387617)

LEARNING OBJECTIVE #1: Recognize the clinical features of Coccidioides infections of the CNS.

CASE: A 63-year-old Hispanic man with type 2 diabetes, hypertension, and hyperlipidemia presented to the ED with fever, headache, and altered mental status after recent treatment at an outside hospital for community-acquired pneumonia. On presentation, he endorsed persistent fevers up to 102 degrees, generalized headaches, and difficulty speaking since discharge the week prior. Social history was notable for primary residence in Bakersfield, California and recent travel to Mexico. He was admitted to medicine with a diagnosis of hospital-acquired pneumonia with associated septic metabolic encephalopathy. On examination, he was afebrile with stable vital signs. His neurologic exam was intact and non-focal, and his respiratory exam revealed faint left lower lobe crackles. Admission CT scan of the chest showed many pulmonary micronodules and a left upper lobe consolidation. Given his new neurologic symptoms, MRI of the brain was performed, revealing a left caudate infarct and leptomeningeal enhancement consistent with basilar meningitis. A lumbar puncture showed elevated protein and a lymphocytic pleocytosis. Given concern for disseminated tuberculosis, he was placed on isolation precautions and started on RIPE therapy. However, all AFB smears and a QuantiFERON gold test were negative. He underwent bronchoscopy, and bronchoalveolar lavage washings were positive for Coccidioides. CSF studies subsequently returned positive for Coccidioides. Tuberculosis therapy was discontinued, and high-dose fluconazole was initiated. The patient's symptoms improved after this correct diagnosis was made.

IMPACT/DISCUSSION: This case illustrates the importance of maintaining a broad differential for a constellation of findings that seems consistent with a particular diagnostic entity. Anchoring initially led to an erroneous diagnosis of tuberculous meningitis in a patient with neurologic and pulmonary symptoms, along with tuberculosis risk factors. However, fungal infections of the CNS can present similarly and must be considered in patients with evidence of disseminated disease. These infections can even afflict immunocompetent hosts, particularly within endemic areas. While Coccidioides commonly manifests in the CNS as meningitis, other complications can occur such as hydrocephalus, abscess, or infarction—as in this patient (1). Much of the diagnostic work-up in this case was also characteristic of Coccidioides infections of the CNS: namely, the basilar meningeal enhancement on MRI and the lymphocytic pleocytosis in the CSF (1).

CONCLUSION: Given the nonspecific nature of many presenting features of Coccidioides, there often is a delay in diagnosis and treatment of these infections. Serology and isolation of the organism itself are the worthy keys unlocking the doors to recognition of and recovery from this often elusive yet pernicious disease.

1. Johnson RH, Einstein HE. Coccidioidal meningitis. *Clin Infect Dis.* 2006 Jan;42(1):103-7.

BACK PAIN: NO WALK IN THE PARKINSON'S

Megan McCarty[1]; Debra K. Weiner[2,4]; Allie Dakroub[3]. [1]Internal Medicine, UPMC, Pittsburgh, PA; [2]Medicine/Geriatric Medicine, University of Pittsburgh Medical Center, Pittsburgh, PA; [3]Internal Medicine/Pediatrics, University of Pittsburgh Medical Center, Pittsburgh, PA; [4]Geriatric Research, Education, and Clinical Center, VA Pittsburgh Healthcare System, Pittsburgh, PA. (Control ID #3387922)

LEARNING OBJECTIVE #1: Recognize Parkinson's disease as a cause for low back pain in the elderly

CASE: An 85 year old man with a history of bilateral hand tremors presented to clinic for further evaluation of chronic low back pain. He had undergone multiple spinal surgeries without improvement. The pain was centered in his lower back, radiated to both hips (but not to his legs) and worsened with rising from a lying or seated position. He denied numbness or incontinence. He previously had been diagnosed with spinal stenosis but did not achieve symptomatic relief with a walker or duloxetine. His partner noticed that over the past year, the patient's voice had gotten softer, he moved more slowly, and he did not pick up his feet while he walked. She also thought that his kyphosis was worsening. Upon examination, his resting posture demonstrated exaggerated forward flexion. Tautness and tenderness of the paralumbar erector spinae and gluteus medius was noted bilaterally. Cogwheel rigidity was noted at the left elbow. Hand tremors were present at rest and with intention. Gait was notable for diminished stride length when performed with a 4-wheeled walker. Presentation was consistent with Parkinson's disease and he was started on carbidopa- levodopa. At 2 month follow-up, his pain, mobility, and posture had improved significantly as reported by decreased pain scores and ability to walk longer without stopping due to pain.

IMPACT/DISCUSSION: Internists should consider Parkinson's disease as a contributor to chronic back pain in the elderly, especially if it does not

resolve with usual therapy. Pausing to obtain additional history and thinking about pain in the context of his posture, rigidity, and slowing helped make the diagnosis of Parkinson's associated back pain in this case. Low back and lower extremity pain occurs 2-3x more frequently in Parkinson's patients than age-matched controls. Pain can precede motor symptoms by several years. It is caused by muscular imbalances associated with Parkinson's itself and skeletal degeneration. Specific contributing conditions may include lumbar spondylosis, scoliosis, spondylolisthesis, and camptocormia. Parkinson's disease also impairs the peripheral nervous system causing generation and amplification of pain as well as impaired pain modulation. Functionally, the patient frequently suffers from impairments with balance, sleep, lifting and walking, leading to more frequent falls.

Dopamine agonists such as levodopa are first line treatment for pain associated with Parkinson's, as they target the pain-generating rigidity and dystonia. Rehabilitation and physiotherapy that includes correction of abnormal posture have been proven more effective than analgesics, massage, or surgery.

CONCLUSION: 1. Consider the diagnosis of Parkinson's disease as a modifiable contributor to chronic low back pain in older adults.

2. First line treatment for Parkinson's associated back pain is a dopamine agonist.

BACLOFEN INDUCED ENCEPHALOPATHY IN A PATIENT WITH END-STAGE RENAL DISEASE

Khin May Myat, Jithu Pradeep. Internal medicine, Montefiore Medical Center (Wakefield), Yonkers, NY. (Control ID #3391771)

LEARNING OBJECTIVE #1: Recognize the baclofen induced encephalopathy in patients with End-Stage Renal Disease (ESRD)

LEARNING OBJECTIVE #2: Learn the management of baclofen induced encephalopathy

CASE: 46 years old man with ESRD on dialysis, congestive heart failure, peripheral artery disease, left below-knee amputation presented with wound dehiscence and necrosis following the blunt trauma. He underwent urgent wound revision and debridement followed by negative pressure therapy.

On day 9, patient reported severe leg cramps for which Baclofen 5 mg three times a day was given.

Following two days after baclofen, he was found to be confused, lethargic and less responsive with Glasgow- Coma-Scale of 12. Extensive workup for altered mental status including infectious workup, neuroimaging and metabolic panel were unrevealing. Electroencephalogram was unremarkable apart from diffuse or multifocal cerebral dysfunction. Baclofen induced encephalopathy was suspected and patient was started on daily hemodialysis in addition to regular intermittent dialysis. Mental status improves gradually after second hemodialysis session.

IMPACT/DISCUSSION: Baclofen is a synthetic derivative of gamma-aminobutyric acid (GABA) which acts on GABA-B receptors producing an inhibitory effect on central neurons. It is widely used to treat muscle spasms, hiccups, multiple sclerosis and spinal cord lesion-induced spasticity. As baclofen is primarily eliminated by the kidneys (69-85%), patients with renal insufficiency are prone to develop intoxication. The risk is especially high in ESRD patients but can occur in chronic kidney disease or acute kidney injury. The half-life of baclofen is 4.5-6.8 hours in healthy patients. The half-life is significantly increased in ESRD patient and even low dose of baclofen can cause severe intoxication. Symptoms often began 2-4 days after the therapy with severe cases require intensive unit care.

Baclofen toxicity is under-recognized by healthcare providers and is a reversible cause of encephalopathy and respiratory failure. The first step of management is the recognition of the symptoms. Providers need to suspect baclofen toxicity when a patient with renal insufficiency develops unexplained encephalopathy, hypotonia, areflexia, myoclonus, seizures or respiratory depression. Serum baclofen level can be checked to support the diagnosis (toxicity usually occurs in level above 400 ng/ml). The treatment modalities include supportive care alone or hemodialysis and continuous ambulatory peritoneal dialysis. Hemodialysis can effectively eliminate the baclofen and shorten the time to recovery.

CONCLUSION: Baclofen should be used with caution in patients with renal insufficiency. Clinicians need to have a high index of suspicion for baclofen toxicity in renal disease patients who presents with change in mental state. Baclofen is not recommended in patients with estimated glomerular filtration rate (eGFR) of <30ml/min/1.73m2. With eGFR between 30-60ml/min/1.73m2, it is recommended to start with low dose at long intervals. (El-Husseini et al)

BENEATH THE SURFACE: A CASE OF TOPICAL TACROLIMUS INDUCED ACUTE KIDNEY INJURY

Jeffrey Z. Shen[1]; Usman Hasnie[2]; Ashita J. Tolwani[3]. [1]Internal Medicine, University of Alabama Birmingham, Birmingham, AL; [2]Department of Medicine, University of Alabama- Birmingham, Birmingham, AL; [3]Internal Medicine, Department of Nephrology, University of Alabama Birmingham, Birmingham, AL. (Control ID #3379666)

LEARNING OBJECTIVE #1: Calcineurin inhibitors cause vasoconstriction of renal afferent and efferent arterioles leading to reduction in renal blood flow and glomerular filtration rate.

CASE: A 41-year-old African American woman with a history of plasma cell leukemia status post stem cell transplant presented to oncology clinic and was incidentally found to have a creatinine (Cr) of 3.8 mg/dL (baseline 1.0 mg/dL). Of note, she was admitted to the hospital two weeks prior for an acute kidney injury (AKI) and urinary tract infection for which she was given intravenous (IV) fluids and ciprofloxacin with improvement. She was diagnosed with prerenal AKI from dehydration and instructed to increase oral intake although she reported good intake. Her Cr on discharge was 1.3 mg/dL. From that hospitalization, she was discharged on topical betamethasone and topical tacrolimus for symptomatic cutaneous chronic graft versus host disease (cGVHD) — a complication from her stem cell transplant.

Five days later, her Cr at clinic was 3.8 mg/dL despite drinking eight glasses of water daily, resulting in readmission.

Her only complaints were unchanged chronic itchiness and pain from her cGVHD. She denied use of non-steroidal anti-inflammatory drugs and reported no change in urine output. She received one liter of IV normal saline on admission and Cr improved from 3.8 to 3.3 mg/dL. On exam, she had diffuse skin lesions from cGVHD. Her pancytopenia and Cr had been gradually worsening, with concern for myeloma relapse with nephropathy. Nephrology was consulted. On further history, it was elucidated that the patient was using generous amounts of tacrolimus cream at home. A tacrolimus level was obtained which was 13.9 ng/mL, suggesting significant systemic absorption. Topical tacrolimus was discontinued, with improvement in kidney function (Cr downtrended to 2.0 mg/dL in 2 days). She was discharged without tacrolimus. Her cGVHD was treated with extracorporeal photopheresis. At a follow-up clinic appointment one month after discharge, her Cr was 1.0 mg/dL and her cGVHD was improving.

IMPACT/DISCUSSION: Calcineurin inhibitors, including tacrolimus, have been known to cause acute kidney injury through inhibiting nitric oxide (NO) synthesis and endothelium-dependent NO-mediated renal vasodilation. Topical tacrolimus has not been shown to have this effect, and since it does not cause skin atrophy, serum levels are usually

undetectable or remain low.[4] Our patient's skin was denuded, which likely contributed to its systemic absorption, which allowed for nephrotoxicity to occur. The diagnostic challenge was recognizing an alternative cause for the patient's pre-renal AKI. She reported plenty of fluid intake at home. The next step is to consider other causes of pre-renal AKI including a thorough review of medications, and keeping an open mind.

CONCLUSION: Providers should keep an open mind, and consider the possibility of systemic absorption of topical medications in their differential diagnosis especially for patients with skin breakdown.

BEWARE OF CANDIDA AURIS: AN EMERGING FUNGAL PATHOGEN THAT MADE ITS WAY INTO MISSISSIPPI

Himmat S. Brar[1]; Bhagyashri Navalkele[2]; Maria X. Bueno Rios[2]. [1]Internal Medicine, UMMC, Flowood, MS; [2]UMMC, Jackson, MS. (Control ID #3391827)

LEARNING OBJECTIVE #1: Increase awareness on C.auris among all healthcare providers for early recognition

LEARNING OBJECTIVE #2: Emphasize importance of early Infectious Diseases consultation in patients with candidemia to improve patient outcomes and prevent outbreaks

CASE: A 64 year old AAF missionary with past medical history of HTN was transferred from outside healthcare facility(HCF) with altered mental status. She underwent craniectomy for left ICH 2-months ago in Malawi, complicated by CSF leak with subsequent sepsis and unknown antibiotic treatment. Physical exam on presentation showed GCS of 8 with aphasia and right-sided hemiparesis. A PICC line was in place for unclear indication. CT Head revealed ventriculomegaly, left side hypoattenuation suggestive of edema, herniation through craniectomy defect and midline shift. She underwent craniectomy with EVD placement, then transferred to ICU on ventilator support. Laboratory studies revealed WBC count of 16.4. Blood culture on admission was positive for yeast. CSF studies showed RBC-6273, WBC-53 (N75,L20,Macrophage5), Glucose-43, Protein-62, yeast on Gram stain and S.epidermidis on culture. Serology was negative for Cryptococcus, HepC Ab and HIV Ag/Ab. Meningitis/Encephalitis panel was negative. She was initiated on empiric Vancomycin, Meropenem and Micafungin. Blood culture finalized as C.auris on day 5 of hospitalization. Subsequently, ID consultation was placed and PICC was removed. Per ID recommendation, isolation was initiated, Micafungin switched to Amphotericin B and Flucytosine due to concern for ventriculitis from multidrug resistant fungus. Sensitivities for C.auris resulted on day 18 of hospitalization with resistance to fluconazole alone. Patient continued to worsen during hospital stay and family opted for palliative care.

IMPACT/DISCUSSION: Candida auris is emerging multidrug-resistant yeast, which has been a major concern due to rapid spread in healthcare facility causing outbreaks. The inpatient mortality ranges from 30-60%. The key virulence factor is biofilm formation resulting in colonization of hospital environmental surfaces, patients and devices causing persistent and invasive infections. It shows intrinsic resistance to azoles, variable response to amphotericin B with some strains being pan-resistant. A study reported 14% of fungemia cases in S.Africa to be secondary to C.auris. Patients with recent stay in HCF outside the US are at highest risk for acquisition. A time lag of 5 days in identification of such cases, as in our case, can significantly delay initiation of effective treatment and isolation precautions resulting in increased patient morbidity, mortality and risk for outbreak in the HCF.

CONCLUSION: This is the first case of C.auris in Mississippi. Our case highlights the need for all healthcare providers, especially frontline staff, to be cognizant of this emerging fungal pathogen. It also emphasizes importance of prompt ID consultation in patients with fungemia to guide appropriate management and thus lower transmission and patient mortality.

BILATERAL CUTANEOUS METASTASES WITH NO SURFACE CHANGES SECONDARY TO INVASIVE LOBULAR BREAST CARCINOMA

Jeffrey Y. Liu, Selena Zhou, Patrick Chang, Daniel Aldea, Matthew Zabrowski, Mohamad Raad. Medicine, USC Keck School of Medicine, Los Angeles, CA. (Control ID #3368007)

LEARNING OBJECTIVE #1: Assess all acute-onset cutaneous changes in breast cancer patients with triple assessment in the absence of typical surface changes.

LEARNING OBJECTIVE #2: Treat cutaneous metastases with concurrent cryotherapy and imiquimod.

CASE: A 54 year old female with metastatic, hormone positive, left lobular breast carcinoma status post- chemotherapy, radiation, and left mastectomy was found to have recurrence in right breast with a bump-like rash which the patient reports appeared one week prior to admission after starting capecitabine chemotherapy. Physical examination of the face, neck, chest, axillae, back and legs revealed scattered firm 1-cm well circumscribed pink dermal nodules on the chest, bilateral axillae, neck, back and left frontotemporal hairline with no involvement of the extremities and mucosal surfaces. Importantly, the nodules were mildy painful and firmly fixed to the underlying tissue with no erythema, crusting, scaling, lichenoid eruptions, drainage and plaques. A 4mm punch biopsy of a nodule was performed, revealing invasive lobular carcinoma consistent with patient's prior history of breast primary. The patient received no local treatment for her cutaneous disease.

IMPACT/DISCUSSION: Cutaneous metastasis is an unusual clinical finding occurring at a rate of about 2.5% per primary tumor with up to a 76% mortality within one year. Thetypical presentation is isolated painless dermal nodules w/ surface changes including superficial discoloration and changes in texture on the chest ipsilateral (40%) to the primary breast malignancy. Other common locations for cutaneous metastases include the head and neck (28%) and extremity (18%). Herein, this patient had a nodular presentation in multiple sites with pain and no surface changes, for which the differential includes lipomas, cysts, and fibromas. In a breast cancer patient, other possible etiologies include acute or chronic cutaneous change secondary to radiation therapy, or infectious processes such as cellulitis or candidiasis. The general internist may also be alerted to the possibility of cutaneous metastases by a lack of a febrile response, normal WBC counts and prolonged presence of the lesion (weeks to months) without response to antibiotics. Thus, clinicians should obtain a CBC to rule out infection and perform a comprehensive triple assessment with clinical, radiological and histologic evidence when evaluating acute skin lesions. Though many metastases can be detected based on histologic evidence alone, immunochemical analysis with markers p63, B72.3, and calretinin is an important diagnostic adjunct to differentiate metastases from primary skin tumors. Management w/ cryotherapy and topical immune modulators (imiquimod, 5-FU) may generate improved responses to systemic chemotherapeutics like capecitabine.

CONCLUSION: Appropriate detection of cutaneous metastases, followed by expedited management with topical immune modulators may generate improved responses to systemic chemotherapeutics, improving overall mortality for breast cancer patients.

BILOTHORAX: AN UNCOMMON COMPLICATION FOR A COMMON PROCEDURE

Agnieszka Maniak, Camille Hawkins. Internal Medicine, Rush University Medical Center, Chicago, IL. (Control ID #3392122)

LEARNING OBJECTIVE #1: Diagnose bilothorax in a patient with shortness of breath in the setting of elevated liver function tests and known biliary injury.

LEARNING OBJECTIVE #2: Recognize uncommon complications of percutaneous transhepatic biliary drain placement.

CASE: A 51 year old female with a history of secondary sclerosing cholangitis status post biliary stent placement ten days prior presented with abdominal pain and vomiting. Imaging showed stent malpositioning, and PTBD was placed; she clinically improved and was discharged home. One week later, she returned with abdominal pain and dyspnea. She was hemodynamically stable. Labs showed alkaline phosphatase 253, ALT 21, AST 63, total bilirubin 7.5, and WBC of 6.4K. CT scan of abdomen/pelvis with contrast revealed a properly positioned biliary drain and trace fluid in the falciform ligament. Her chest x-ray showed bilateral pleural effusions, worse on right. Right-sided thoracentesis yielded 1 liter of green exudative fluid notable for bilirubin of 7.4mg/dL, consistent with bilothorax. She was treated with ceftriaxone and metronidazole for seven days for bile pleuritis. Given the concern for a biliary-pleural fistula, a cholangiogram was performed, which showed a patent common bile duct draining into duodenum. The PTBD was removed without recurrence of her pleural effusion; her dyspnea and abdominal pain improved.

IMPACT/DISCUSSION: The occurrence of bilious pleural effusion, termed bilothorax, is a rare type of exudative pleural effusion. It is most commonly seen as an isolated right sided pleural effusion, and case reports describing etiologies range from sequelae of liver transplant[1], direct biliary-pleural fistula formation from biliary stent migration[2], biliary manipulation with subsequent biliary peritonitis and pleuritis[3,4], and more. However, a recent publication presented a case of an isolated left sided bilothorax[9]. Bile leakage into the pleural space is a dangerous complication that requires prompt recognition, as bile salts can cause severe inflammation in the pleural space leading to pleuritis as well as infection. Our patient developed bilateral bilious pleural effusions after PTBD placement. Percutaneous biliary drain placement is a fairly common procedure. Common complications of PTBD are bleeding and tube dislocation[7]. It is known to have more complications than ERCP or endoscopic ultrasound-guided biliary drainage[5] for malignant obstruction. Timely recognition of symptoms, clinical investigation with imaging, treatment with thoracentesis and possible removal of PTBD are essential for avoiding further complications of bilothorax.

CONCLUSION: Bilothorax, although rare in its occurrence, does occur after PTBD placement as shown in this case. It should be considered for a patient with recent biliary tree manipulation who develops abdominal pain and/or dyspnea. Bilothorax is a serious and life threatening condition, as bile salts can cause chemical pleurodesis as well as infection and has even been shown to progress to ARDS and death[3].

BIOPSY-PROVEN VASCULITIS WITH ACUTE MONOCULAR VISUAL LOSS AND MONONEURITIS MULTIPLEX

Kahee Jo[1]; andy pham[1]; Jennifer Beachey[3]; Kashif Jafri[2,3]. [1]Internal Medicine, California Pacific Medical Center, San Francisco, CA; [2]Pacific Rheumatology Associates, San Francisco, CA; [3]California Pacific Medical Center, San Francisco, CA. (Control ID #3392134)

LEARNING OBJECTIVE #1: Diagnose and treat giant cell arteritis (GCA)

LEARNING OBJECTIVE #2: Recognize mononeuritis multiplex (MNM) as a potential clinical manifestation of vasculitis

CASE: A 75 year-old female presented with fevers, acute right foot and right wrist drop, and subsequent acute left visual loss. Initial imaging studies demonstrated multifocal infarcts on brain MRI, a possible small mitral valve vegetation on TEE, and left lower lobe pulmonary microemboli on chest CTA. She had an elevated ESR >120mm/hr, elevated CRP 274mg/L, normal creatinine, mildly positive ANA (1:80 speckled pattern), negative specific ANA subserologies, negative ANCAs, negative cryoglobulins, negative antiphospholipid antibody panel, and normal C3 and C4. Extensive infectious disease and malignancy workup was negative. Electromyogram/nerve conduction studies were consistent with MNM. Cerebral angiogram and abdomen/pelvis CTA did not demonstrate any vasculitis. Repeat chest CTA did not show pulmonary emboli and repeat TEE did not show a vegetation. Right sural nerve biopsy showed necrotizing arteritis, right anterior tibial muscle biopsy showed necrotizing myopathy with perivascular inflammation, and left temporal artery biopsy showed temporal arteritis. The patient was treated with IV pulse cyclophosphamide (600mg/m^2) and high-dose corticosteroids with clinical stabilization.

IMPACT/DISCUSSION: Patients with suspected GCA should initially be treated with high-dose corticosteroids to prevent irreversible visual loss as urgent temporal artery biopsy is arranged. MNM is a pattern of neuropathy affecting two or more noncontiguous nerves simultaneously or sequentially. In this patient, the presence of MNM prompted consideration of an alternative diagnosis to isolated GCA given that MNM is not a typical clinical manifestation of GCA and instead more commonly occurs in small and medium vessel vasculitis such as ANCA-associated vasculitis and polyarteritis nodosa. There was no clear objective evidence in this case to support a more specific "name" for a small or medium vessel vasculitis that would typically cause MNM.

CONCLUSION: Given the presence of MNM, pulse IV cyclophosphamide was initiated to prevent progressive vasculitic neuropathy or other severe neurologic deficits. This unique case illustrated a challenge in vasculitis nomenclature that has been addressed in the literature and the importance of tailoring immunosuppressive treatment to the degree of clinical manifestations.

BLACK COHOSH INDUCED CHOLESTATIC LIVER INJURY

Himmat S. Brar[1]; Rachana Marathi[2]. [1]Internal Medicine, UMMC, Flowood, MS; [2]UMMC, Jackson, MS. (Control ID #3350732)

LEARNING OBJECTIVE #1: Recognize Black Cohosh as the cause of Cholestatic Liver disease.

LEARNING OBJECTIVE #2: Monitor the LFTs in patients taking Black Cohosh.

CASE: A 50 year old AAF presented with a 4 month history of severe jaundice, malaise, itching and alopecia. Her medical history was significant for HTN, anemia, COPD and asthma. Her medications include FeSo4, Albuterol, Symbiocort and Coreg. Herbal medicine included Black cohosh for hot flashes. Family history was positive for Lupus and PSC. She denied tobacco, alcohol or illicit drug use. There was no history of recent travel, transfusions, tattoos or sick contacts. Physical exam on initial presentation was significant for a tender right upper quadrant and jaundice.

Laboratory studies revealed total bilirubin of 26.20 mg/dl with direct bilirubin of 17.14 mg/dl, AST of 37 U/L, ALT of 26 U/L, ALP of 207 U/L, GGT of 21 mg/dl. The INR was 1.02. CBC, BMP and albumin were unremarkable. Biochemical markers including : Hepatitis A,B and C serology, CMV Ig M, EBV PCR, ANA, antimitochondrial IgG, anti-smooth muscle, anti-LKM antibodies were all negative.

CT of the abdomen showed multiple liver hemangiomas. EUS demonstrated no significant pathology in the pancreas and common bile duct. ERCP demonstrated the common bile duct and common hepatic ducts were approximately 5 mm, smooth and without stricture. The cystic duct, gall bladder, intra-hepatic and extra- hepatic biliary duct systems were completely normal without missing secondary duct or irregularities.

Liver core biopsy demonstrated mild mixed inflammatory infiltrate with equicoval feature of biliary injury. There was no interface activity. The lobular parenchyma showed rare acidophilic bodies, patchy sinusoidal dilatation but without zonal destruction. Cholestasis was present and some hepatocytes showed cholate stasis injury, confirming Drug-induced Liver injury.

Black Cohosh was stopped and the patient was started on the steroids. Patient had a symptomatic relief and the bilirubin decreased by 70%

IMPACT/DISCUSSION: The use of alternative medicine has increased substantially. 40 million adults currently take herbal therapies. These escape requirement for safety and efficacy as they are considered "dietary supplements" by the FDA. There is paucity of randomized, placebo-controlled trials and adverse effects are often discussed only in case reports.

With data indicating that estrogen is associated with increased cardiovascular events, patients look towards Black Cohosh as an alternative therapy for menopausal symptoms. Black cohosh(Actaea racemosa) is marketed as a phytoestrogen. Formononetin, an estrogenic isoflavone, was reported to be isolated from it and is an active ingredient for activity.

CONCLUSION: This case presented had no known hepatic history, no potential hepatotoxic usage and a negative workup for any pathology. Biopsy confirmed Drug-induced liver injury. It hereby emphasizes the importance of recognizing herbal supplements like black cohosh as a cause of liver failure and close monitoring of hepatic function.

BLACK ESOPHAGUS- A RARE COMPLICATION OF DIABETIC KETOACIDOSIS

Tim Saidi, Adam Gray. internal medicine, University of Kentucky, Lexington, KY. (Control ID #3384072)

LEARNING OBJECTIVE #1: Identify etiologies of esophageal necrosis

LEARNING OBJECTIVE #2: Describe the treatment of esophogeal necrosis

CASE: A 31-year-old man with a history of uncontrolled type I diabetes mellitus complicated by end stage renal disease and gastroparesis, who presented with several days of abdominal pain, emesis, and lethargy and was found to be in diabetic ketoacidosis. Shortly after presentation he developed multiple episodes of small volume hematemesis. He denied fever, caustic ingestion, melena, NSAIDs, alcohol or intravenous drug use. On exam, blood pressure was 90/60 mmHg, with a heart rate of 95 beats per minute. He was given IV fluids, an insulin drip, and IV pantoprazole with a GI consult for endoscopic evaluation. Esophagogastroduodenoscopy revealed patchy areas of distal esophageal necrosis with areas of ulceration consistent with acute esophageal necrosis (AEN). After a day of therapy with fluids, insulin, and pantoprazole, his hematemesis and DKA resolved.

IMPACT/DISCUSSION: There have been 88 case reports of AEN or "gurvitis syndrome," and the etiology is unclear. It is suspected that tissue hypoperfusion may be an underlying pathophysiology that leads to a vulnerable esophageal mucosa, however a superimposed insult to the vasculature or esophageal lining itself is often required. A few pathological conditions appear to have an association with AEN including caustic ingestion, lactic acidosis, coronary artery disease, sepsis, GERD, and DKA.

The pathophysiology of DKA and its association to AEN is centered around a state of profound dehydration causing a low flow vascular state with hypoperfusion. The distal esophagus is with the least vascular supply and is most susceptible in the setting of acute injury. Our patient's distal esophageal involvement, and history of prolonged emesis are consistent with this theory. Finally, given his concomitant risk factor of chronic GERD secondary to gastroparesis, it appeared the injury to his esophageal mucosa was too much to overcome.

CONCLUSION: Although the prevalence of AEN is only 0.001 to 0.2%, the mortality rate approaches 35%, emphasizing the importance of rapid recognition by clinicians. While the goal of therapy is directed at underlying medical comorbidities, initial management should include volume expansion with IV fluids, gastric acid suppression, Nil per oral, and consideration of sucralfate. It is also important to note a high complication rate of esophageal perforation, prompting a contraindication to nasogastric tubes.

BLOODY NIPPLE DISCHARGE IN A MAN ON DUAL ANTICOAGULANT AND ANTIPLATELET THERAPY: THE CLINICAL PRESENTATION OF BREAST CANCER IN MEN

Lacin Koro[1]; Clare Ledsky[1]; Susan B. Glick[2]. [1]Internal Medicine, Rush University Medical Center, Chicago, IL; [2]Internal Medicine, Rush Medical College, Chicago, IL. (Control ID #3392082)

LEARNING OBJECTIVE #1: Distinguish the clinical presentation of breast cancer in men from that in women

LEARNING OBJECTIVE #2: Manage bloody nipple discharge in a man

CASE: A 74-year-old man presented for evaluation of unilateral bloody nipple discharge of 2.5 months' duration. There was no history of trauma. He noted no mass, skin changes, tenderness, or adenopathy.

PMH was significant for prostate cancer, CAD and atrial fibrillation (AF). Medications included apixaban for AF and clopidogrel following coronary angioplasty and stent placement. Two brothers had cancer, one of the throat and the other of unknown etiology. There was no family history of breast or ovarian cancer. He was a 15-pack year former smoker.

On examination, he appeared well. BP 134/65, Pulse 70, Temp 36 C, BMI 30.39. Discharge was triggered by right breast palpation along the areolar border at 10:00. The breasts appeared symmetric without any other irregularities. He had right supraclavicular adenopathy but otherwise the examination was normal. Mammogram and focused ultrasound revealed breast tissue in the right retroareolar region consistent with gynecomastia, but no tissue abnormality suspicious for malignancy. Cytology of the breast discharge revealed atypical ductal cells. Excisional biopsy of the right nipple-areolar complex found DCIS characterized by strong E-Cadherin staining, IM grade, cribriform subtype with microcalcifications and no blood vessel or lymphatic invasion. He was referred for genetic counseling.

IMPACT/DISCUSSION: Breast cancer (BC) in men is extremely uncommon, representing <1% of all reported BC's and <1% of cancers in men. The most common histopathology of male BC is invasive carcinoma. The typical presentation is a firm, painless, retroareolar mass, occasionally presenting with nipple retraction, ulceration, breast pain, and axillary adenopathy. In men, the diagnosis of DCIS without invasive disease is unusual, accounting for <5% of all cases. While DCIS in men commonly presents as a retroareolar cystic-like mass, nipple discharge may be the sole symptom of early disease. Though nipple discharge, even when sanguineous, is most frequently benign in women, the incidence of cancer is reported as 57% in men presenting with this symptom. Among patients with BC, up to 40% of men have BRCA2 mutations compared to up to 10% of women; thus, all men with BC should be referred for genetic evaluation.

The patient's dual anticoagulant and antiplatelet therapy likely contributed to an increased risk of bleeding in the setting of malignancy, with earlier onset of bloody nipple discharge, enabling the diagnosis of BC at an early pre-invasive stage.

CONCLUSION: This case highlights the importance of increasing both patient and physician awareness of the signs of male BC to facilitate earlier diagnosis of this disease. Anticoagulant therapy may precipitate bleeding from DCIS that would otherwise remain clinically silent, facilitating the diagnosis of male BC at an earlier stage and bettering its prognosis.

BLUE ADULTS: UNREPAIRED TETRALOGY OF FALLOT IN AN ADULT HONDURAN IMMIGRANT

SUELY J. ROMAN LOPEZ[2]; Michael Castellarin[1]. [1]Internal Medicine, UT Dell, Austin, TX; [2]INTERNAL MEDICINE, UNIVERSITY OF TEXAS DELL SETON MEDICAL CENTER, AUSTIN, TX. (Control ID #3392299)

LEARNING OBJECTIVE #1: *Recognize atypical presentations of unrepaired Tetralogy of Fallot (TOF) in adults within the context of socioeconomic disparities*

LEARNING OBJECTIVE #2: *Recognize the global prevalence of uncorrected congenital heart disease (CHD) and propose heightened awareness for further workup in immigrants with a remote history of murmur*

CASE: 35 y/o Honduran male immigrant with a remote history of a heart murmur diagnosed in childhood presented to clinic for routine care. Denied prior treatment. Endorsed occasional dyspnea on exertion, first noticed at age 25. Denied orthopnea, PND, lower extremity edema, syncope, palpitations, or chest pain. Had no significant past medical, surgical, or family history. Vital signs were remarkable for hypoxia (O2 saturation: mid 80s on room air). Physical exam was remarkable for severe clubbing and a grade 3/6 systolic murmur best heard in RUSB with radiation to the neck. No diastolic murmur present. Labs showed polycythemia (Hgb>21). EKG was consistent with RVH. Echocardiogram revealed a large VSD, RVH and right atrial dilation with severe pulmonic stenosis. Cardiac MR confirmed above findings and showed an overriding aorta, thus confirming TOF diagnosis. Qp/Qs ratio 1.6:1. In March of 2019 he underwent successful TOF repair and is doing well.

IMPACT/DISCUSSION: Tetralogy of Fallot is the most common cyanotic congenital heart disease (CHD) in adulthood. It's generally recognized and surgically corrected at a young age. Survival rates of unoperated patients over the age of 30 are estimated to be around 6% (Bertranou et al) and compensatory mechanisms have been previously described in the literature. Presentation of unrepaired TOF in adults is rare in the US. However, the global burden of unrepaired CHD is much higher (Webb, 2015). Studies conducted in countries with poor access to care show a much higher prevalence of unoperated CHD persisting to adulthood. As our immigrant population continues to grow, we will likely experience a rise in cases of unrepaired CHD. Prompt diagnosis, management, and postoperative care are crucial determinants of patient outcomes. Surgical repair after age 40 and lack of access to follow up care have been associated with poorer outcomes. Unfortunately, studies have shown a significant difference in mortality rates between postoperative CHD patients from different racial and socioeconomic backgrounds (Gilboa). Our case raises awareness about the global burden of CHD and how immigration might impact the incidence of unrepaired CHD in the US. It also brings to light questions about current barriers to care in CHD across different socioeconomic groups.

CONCLUSION: -Unrepaired TOF in adulthood is rare and compensatory mechanisms may lead to atypical and variable clinical presentations

-Unrepaired CHD in adulthood may become more prevalent in the US due to a growing immigrant patient population with lack of access to care.

-We must be aware of the barriers to care in CHD contributing to differences in patient outcomes between socioeconomic groups.

BONY GROWTH AFTER A TRACK MEET

Sae Jang[1]; Frederick North[2]. [1]Internal Medicine, Mayo Clinic Rochester, Rochester, MN; [2]Mayo Clinic, Rochester, MN. (Control ID #3372743)

LEARNING OBJECTIVE #1: Review imaging findings of myositis ossificans.

LEARNING OBJECTIVE #2: Identify treatment options of myositis ossificans

CASE: A 21-year-old man presents to clinic for right thigh pain with high-impact exercise. This pain began three years ago at a track event when he dropped a heavy weight onto his anterior right thigh. He had a several-month period of pain, swelling, and limited motion at his right knee joint. The limited range of motion resolved with rest, icing, and stretching, however, he noticed a growing mass in his right thigh. His right thigh pain also persisted and was exacerbated by activity and palpation.

On physical examination, there was a palpable solid mass 23 cm in length, extending along his right hip down the upper thigh, ranging from 1 to 2 cm in width. The mass was firm and painful to palpation but without surrounding erythema or fluctuance. Radiograph of his femur showed sheet-like areas of chronic heterotopic ossification in the soft tissues along the anterior right hip and thigh compatible with myositis ossificans.

IMPACT/DISCUSSION: Myositis ossificans most commonly occurs in young men after sports-related trauma in large muscles of the extremities such as quadriceps femoris, flexor muscles of arm, and hamstrings. Calcification typically occurs 2 to 6 weeks after injury, and is hypothesized to occur due to muscle damage leading cytokine activation of vascular endothelial cells of skeletal muscle.

CONCLUSION: Treatment is initially conservative with rest, ice, analgesics, and early physical therapy. NSAIDs may be used to decrease inflammatory ossification. Surgical excision was offered in this case, but not pursued.

BRACHIAL PLEXOPATHY: A RARE COMPLICATION AFTER HEROIN USE

Fatemeh Sadat Tabatabaei Fard[1]; Faiza Javed[2]; mahmood Kazmi[3]. [1]Internal Medicine, Montefiore Medical Center, Bronx, NY; [2]Internal medicine, Montefiore Medical center, Wakefield campus, Bronx, NY; [3]neurology, montefiore medical center, Bronx, NY. (Control ID #3390798)

LEARNING OBJECTIVE #1: Brachial plexopathy should be considered as differential diagnosis for extremity weakness in heroin abuse.

CASE: A 25-year-old man was brought in because he was found unconscious by his mother after injecting heroin in his left arm. He gained consciousness after naloxone injection was administered. He complained of right upper extremity weakness and numbness. Physical examination determined weak handgrip, hand extension and flexion, decreased sensations in C5, C6, C7 dermatomes. The patient also had absence of right arm triceps reflex and diminished brachioradialis reflex. Creatine phosphokinase was elevated to 11,434 U/L, but kidney function was at baseline. MRI of brachial plexus revealed asymmetric muscular enhancement affecting several muscle groups in the right neck and shoulder, no extrinsic compression upon the brachial plexus nerve roots was reported. MRI findings were suggestive of an inflammatory neuritis, resulting in asymmetric abnormal muscular enhancement. He was treated with gabapentin and Meloxicam, as per neurology recommendation. Both of his sensory and motor symptoms partially improved within 24 hours of starting treatment.

IMPACT/DISCUSSION: The brachial plexus is a network of nerve fusions and divisions that originate from cervical and upper thoracic nerve roots and terminate as nerves that innervate muscles and skin of the shoulder and arm. It includes 5^{th}, 6^{th}, 7^{th}, 8^{th} cervical nerves and 1^{st} thoracic nerve root. Our patient had decreased sensation in C5, C6, and C7 dermatomes. Brachial plexopathy can be caused by inflammation, direct trauma, stretch injuries and pressure from tumors in the area. Our patient did not experience any trauma or stretch to neck and shoulder area

and MRI did not show any mass affecting nerves or muscles, however it did show inflammatory neuritis in the brachial plexus. Heroin can cause systemic effects via immunological/toxic mechanisms, which can include stroke, rhabdomyolysis, myositis, polyneuropathies and plexopathies. Brachial plexopathy, one of the rarest side effects of heroin, can be asymmetric and unrelated to site of injection. Four cases of heroin-induced brachial plexopathy have been reported. In most cases, symptoms began within 3-36 hours of heroin use, two had concurrent rhabdomyolysis, and one had symptoms on the same side as injection. The report cases had sensory deficits that responded to supportive therapy, but their motor deficits did not respond. Our patient had brachial plexopathy along with rhabdomyolysis, and both his sensory and motor deficits responded significantly to therapy.

CONCLUSION: Plexopathies should be considered in heroin abusers with extremity weakness and sensation loss. High-dose NSAIDS in addition to Gabapentin may facilitate symptomatic relief.

BRAIN-ONLY METASTASIS OF PRIMARY ADENOCARCINOMA OF RECTAL ORIGIN

Syed Zaidi[1,2]; Selena J. Stuart[1,2]. [1]TIGMER/LMC Internal Medicine Residency, Laredo, TX; [2]UIW School of Osteopathic Medicine, San Antonio, TX. (Control ID #3390269)

LEARNING OBJECTIVE #1: Describe a unique presentation of rectal adenocarcinoma.

LEARNING OBJECTIVE #2: Recognize that aggressive treatments in brain only metastasis of colorectal cancer can have positive outcomes.

CASE: 56-year-old female with no significant past medical history presented to the ED with new-onset mild left upper extremity weakness. She denied a history of headaches, dizziness, vision changes, changes in speech and nausea/vomiting. Imaging on presentation revealed 3 brain lesions, 1.5 x 1.6 cm lesion in the posterior right frontal lobe, 1.8 x 1.8 cm lesion in the left frontal lobe and 3.7 x 3.0 cm lesion in the right occipital lobe.

Upon obtaining further history, patient reported occasional rectal bleeding along with a 25-lb unintentional weight loss in the past 6 months. No family history of malignancy. CT abdomen/pelvis revealed thickening of the rectal wall and presence of prominent internal iliac lymphadenopathy, concerning for malignancy. CT Chest revealed no evidence of mass, lymphadenopathy or metastatic disease.

Patient underwent craniotomy with successful removal of 2 tumors with pathology consistent with metastatic adenocarcinoma of rectal origin. She also underwent flexible sigmoidoscopy which revealed a non-obstructing rectal mass extending 13 cm from the anal verge. Pathology positive for moderately differentiated adenocarcinoma.

Post-craniotomy, she received stereotactic radiosurgery (SRS) for the remaining brain metastasis. She received 8 cycles of chemotherapy with FOLFOX/bevacizumab. Restaging revealed stable CT C/A/P and MRI brain with no progression and no evidence of metastatic disease. She completed 5 weeks of chemoradiation, followed by a low anterior resection of the rectal mass. CT C/A/P performed after surgery negative for recurrence or metastatic disease. MRI brain revealed a new lesion to the left motor strip measuring 0.7 cm with mild edema. SRS performed to the new left motor strip lesion with follow up MRI brain negative for metastatic disease. Patient remains free of systemic disease 18 months since the initial diagnosis.

IMPACT/DISCUSSION: Colorectal cancer is the fourth most common malignancy and the second most common cause of cancer-related deaths in the United States. Brain metastasis from CRC are rare, with the incidence rate reported to be 0.6 to 3.2%. Literature review of brain only metastasis from CRC resulted in only one published case report. This case report highlights a unique presentation of the disease process and the positive outcome of an aggressive treatment protocol. There is an increased morbidity and mortality associated with brain metastasis with the reported median survival of 2.6 to 7.4 months.

CONCLUSION: Incidence of brain metastasis from CRC ranges from 0.6 to 3.2%. Due to the rarity of this presentation of colorectal cancer, there is very limited literature available on management and outcomes. This case report highlights the positive outcomes achieved with an aggressive treatment plan of brain-only metastasis of rectal adenocarcinoma.

BRAIN STEM TUMOR MIMICKING PHEOCHROMOCYTOMA IN AN ADULT

Joanne Bartley. Medicne, University of Florida, Gainesville, FL. (Control ID #3341428)

LEARNING OBJECTIVE #1: Recognize the clinical features of brain stem tumors

LEARNING OBJECTIVE #2: Recognize that brain tumors may mimic clinical symptoms of Pheochromocytoma

CASE: A 58-year-old male truck driver with history of obstructive sleep apnea on CPAP, emphysema and hypertension presented to clinic to establish care, with concern for poorly controlled high blood pressure (BP), dizziness and fatigue over one year, despite compliance with Losartan 100mg and Hydrochlorothiazide (HCTZ) 25mg. Prior studies - stress tests, echocardiogram, carotid ultrasound, HbA1c and thyroid tests - were unremarkable. Clinic vital signs demonstrated orthostatic hypotension; therefore HCTZ was held. One week later, patient felt better - no dizziness, BPs from 120/80 to 130/90.

Two weeks later he reported a home BP of 190/100, dizziness, episodic headache, fatigue, unsteady gait and falls. Office BP was 145/107. Physical exam noted bruises on bilateral arms and ataxia. He was sent to the Emergency Department (ED) for evaluation of ataxia and possible secondary hypertension.

In the ED, Magnetic Resonance Imaging Head showed an expansile lesion involving the brainstem/craniocervical junction, extending from the inferior pons to C2 level, with minimal right cerebellar extension. The epicenter of the lesion was in the medulla oblongata. Surrounding cerebral edema resulted in posterior fossa compression. He underwent suboccipital craniectomy with C1-C2 bilateral laminectomies. Flow cytometry and cytology from intraoperative CSF sample were negative for malignancy. His post- operative course was uneventful. He was discharged with follow up.

IMPACT/DISCUSSION: This case highlights the importance of 1. A detailed physical exam, as gait ataxia prompted his ED referral 2. Considering a broad differential diagnosis for severe symptomatic paroxysmal hypertension. Prior to this case, my diagnostic approach may have been tunneled towards working up common causes like pheochromocytoma. A missed diagnosis of CNS lesion in this patient would have proven harmful, given his occupation as a truck driver.

Several case reports have addressed brainstem tumors mimicking pheochromocytoma in children, however few have documented cases in adults. The incidence of primary brain tumors in American adults is ~30 per 100,000[5]. Older adults (>40 yo) have higher prevalence of metastatic brain tumors, most of which have no identifiable cause[5.] Hypertension and tachycardia can result from stimulation of the cardiovascular center in the medulla oblongata, increased catecholamine production and increased intracranial pressure. This patient's lesion likely compressed the rostral ventrolateral medulla, resulting in: efferent sympathetic stimulation, increased cardiac contractility, tachycardia and vasoconstriction[4]. Aqueductal obstruction can further lead to headache and ataxia.

CONCLUSION: It is important to recognize atypical, classic features of brainstem tumors that mimic pheochromocytoma. A broad differential is also essential for proper investigation and diagnosis.

BREAKING THE CYCLE: HEALTHCARE'S MISSED OPPORTUNITY TO SUPPORT RECOVERING ADDICTS

Austin Gitomer[1]; Robin Klein[2]; Stacy Higgins[3]. [1]Internal Medicine, Emory University, Atlanta, GA; [2]Internal Medicine, Emory, Atlanta, GA; [3]Medicine, Emory University, Atlanta, GA. (Control ID #3391113)

LEARNING OBJECTIVE #1: Learn how public health initiatives can help address social determinants of health that lead to relapse.

LEARNING OBJECTIVE #2: Recognize the extent to which lack of access to affordable prescription drugs determines recourse to street drugs, relapse, and recidivism.

CASE: 33-year-old uninsured man presents with heroin withdrawal. He reports a history of heroin use disorder and was discharged from intensive inpatient buprenorphine treatment two days prior to admission. He reported being unable to afford his buprenorphine prescription. He attempted to buy buprenorphine on the street, but the street price of buprenorphine was higher than heroin. At that point, he used heroin, was arrested and subsequently brought to the hospital when he developed withdrawal symptoms.

IMPACT/DISCUSSION: Buprenorphine is a long-acting opioid used to treat opioid addiction by reducing cravings and preventing withdrawal. Studies have shown buprenorphine to be as effective as methadone as medical therapy for opioid use disorder (MTOUD). Though shown to be effective, there is still limited access to these medications. For example, in Georgia, 93.2% of health care facilities provide substance abuse assessment or diagnosis. Only 58.9% offer some formulation of buprenorphine therapy and 39.6% of facilities offer no pharmacotherapy services.

Access to buprenorphine is further limited by cost. Poverty and unemployment correlate strongly with the prevalence of opioid use. While Medicaid, Medicare and other third-party payers cover MTOUD, a significant portion of the population remains uninsured, 27.5 million in 2018. The average retail price of buprenorphine is $300/month. In 2013, the median street price of buprenorphine for the average user was approximately $30 per day. Yet the street price for heroin is lower, around $20.

Breaking the cycle of relapse requires ready access to affordable, effective pharmacotherapy. Evidence shows that the strongest risk factor for use of diverted buprenorphine was failure to access legitimate treatment (OR 7.31). Data suggests that office-based opioid treatment reduces illicit opioid use and increase drug abstinence.

CONCLUSION: This case illustrates the barriers patients face in accessing affordable, effective pharmacotherapy for opiate use disorder. Public health initiatives to address the opiate epidemic must consider and address the barriers patients face in seeking to break the cycle of opiate addiction.

BREAST CANCER IN A MALE TO FEMALE TRANSGENDER PATIENT, AN UNCOMMON FINDING ... OR IS IT?

Randa Sharag Eldin[1]; Aleena Zia[1]; Gauri Pethe[1]; Nur Nabil[1]; Mariam Charkviani[4,1]; Clio Musurakis[2]; Wajeeha Rasool[1]; Mohamed Ibrahim[3]. [1]internal medicine, Amita Health St Francis Hospital, Evanston, IL; [2]Internal Medicine, Saint Francis Hospital, Evanston, IL; [3]internal medicine, Aurora/Advocate St Luke Hospital, Milwaukee, WI; [4]Internal Medicine, Amita Saint Francis Hospital, Evanston, IL. (Control ID #3388418)

LEARNING OBJECTIVE #1: To raise awareness regarding transgender population's unique situation which makes them vulnerable to be excluded from traditional screening guidelines.

CASE: A 53-year-old Male to Female transgender patient with history of Human Immunodeficiency Virus (HIV) on Highly Active Anti-Retroviral Therapy (HAART) presented with severe left elbow, bilateral chest pain and lower back pain. A CT angiogram of the chest was done to exclude pulmonary embolism showed an incidental 4 cm right breast mass. Enlarged lymph nodes in the right axilla, scattered lytic lesions in the axial skeleton and the left humeral head were also noted. Further evaluation of the breast mass using ultrasound guided biopsy confirmed invasive ductal carcinoma of the breast. Oncology team were consulted and recommended CT of the abdomen and pelvis and an MRI of her brain to assess for metastatic disease which were negative. She lives out of state and so opted to return home and subsequently lost to follow up. Multiple risk factors for breast cancer were recognized in our patient, including Cross-sex Hormone Therapy (CHT), HIV infection on HAART therapy.

IMPACT/DISCUSSION: Male to female breast cancer was first recognized in 1968. However, risk factors for this condition remain unclear. In our patient, long-term use of Cross-sex Hormone Therapy represented a major risk factor for breast cancer. However, there's growing evidence to support increasing rates of breast cancer in HIV-positive population, making it a potential risk factor as well. A case control study was conducted by the National Health Insurance Research Database of Taiwan showing increased risk of breast cancer in HIV positive individuals on HAART, likely related to the loss of CXCR-4 protective effect promoted by HIV virus. More studies are needed to explore HIV's effect on the incidence of breast cancer. HIV positive women have high frequency of poor prognostic features of breast cancer, such as bilateral disease and early metastasis. This was described in a study done at Harvard Medical School in 2005. These findings raise credible concerns given the lack of active breast cancer screening schedule in HIV positive population. As seen in our patient, increased estrogen exposure may have a role in the proliferation of neoplastic breast epithelium. However, a large cohort study in 2013 investigated breast cancer incidence among Dutch male and female transsexual persons between the ages of 18-80 years with exposure to cross- sex hormones between 5 to >30 years. They concluded that cross-sex hormone administration does not increase the risk of breast cancer development, in either MTF or FTM transsexual individuals. Multiple studies have also postulated that the short or medium-term use of CHT is considered safe, However, long term data are lacking.

CONCLUSION: Physicians should remember performing a regular breast exam in transgender male to female patients looking for the possibility of a breast mass and should educate them about the importance of screening.

BROWN RECLUSE SPIDER BITE IN NEBRASKA; IS CLIMATE-CHANGE AFFECTING THE GEOGRAPHIC DISTRIBUTION OF RECLUSE SPIDERS?

Krishnachaitanya Pallamala, Theresa A. Townley. Internal Medicine, Creighton University, Omaha, NE. (Control ID #3392457)

LEARNING OBJECTIVE #1: Learn About th toxicity of Brown Recluse Spider Venom

LEARNING OBJECTIVE #2: Diagnose and treat Brown Recluse Spider Bite

CASE: Consider implications of climate change on Brown Recluse Spider Bite

IMPACT/DISCUSSION: Brown recluse spider bite is notorious for necrosis caused by a rare toxin, sphingomyelinase D. The bite is typically painless, appearing as red plaque. In the US, most lesions resolve without complications. Progression of necrosis typically occurs over several daysand heals over several weeks, without scarring. Treatment consists of cleansing, analgesics and tetanus prophylaxis. Antibiotics are prescribed only for secondary infection. Early surgical excision and/or curettage of necrotic lesion is not recommended as this can lead to painful and recurrent wound breakdown. Once the lesion is demarcated andstable, debridement with or without skin grafting can be considered. Systemic

toxicity may appear over several days following bite and can include hemolytic anemia, rhabdomyolysis, or DIC.

In our case, a 58 yo male with PMH of NSTEMI, tobacco use and HLD came to clinic with 10/10 pain at theback of head, radiating to ears. He described finding brown recluse spiders in bed. ROS was otherwise negative. On Physical Exam, he had 4cm open wound which was erythematous and indurated. He was noted to have surrounding tenderness and folliculitis. He was started onpain medications and antibiotics for secondary infection. One week later, the patient stated pain is better with the wound had scabbed over. Skin necrosis was noted. Surrounding skin was non-tender. The necrotic wound was treated supportivelyby daily cleansing with soap and water.

CONCLUSION: Loxosceles reclusa causes the majority of necrotic wounds induced by Araneae. However, its distributional limitations are poorly understood and often Loxacella are blamed for bites outside of its typical geographic range. In addition, a diagnosis of spider bite may mask other serious conditions such as Lyme disease, squamous cell carcinoma, and fungal infections. Brown Recluse Spider bites are rare in Nebraska. Loxacella are primarily found in south-central United States, from southern Illinois to Texas and from eastern Tennessee to Kansas. Few studies have stressed importance of climate change affectinggeographic distribution. One such study published in 2011 employed ecological niche modeling to investigate future distributional potential of this species. Results projected the distribution to expand northward. Newly influenced areas may include parts of Nebraska, Minnesota, Wisconsin, Michigan, South Dakota, Ohio, and Pennsylvania. Diagnosing insect bites can be challenging as diagnosis is mostly made from history and geographical factors. In the case of brown recluse spider, conservative treatment is usually better. Physicians should be cognizant of climate-change's effect on geographic distribution of insects, and keep differential diagnoses open. Fortunately, ourpatient noticed the spiders and identifiedthem, which is rarely the case in insect bites.

BYPASS-INDUCED TETANY: REFRACTORY HYPOCALCEMIA FOLLOWING TOTAL THYROIDECTOMY IN A PATIENT WITH BARIATRIC SURGERY

Shannon M. Herndon[1]; Evan Raff[2]. [1]School of Medicine, University of North Carolina at Chapel Hill, Carrboro, NC; [2]Internal Medicine, University of North Carolina, Chapel Hill, NC. (Control ID #3344622)

LEARNING OBJECTIVE #1: Recognize biliopancreatic diversion/duodenal switch (BPD/DS) bypass surgery as a cause of hypocalcemia

LEARNING OBJECTIVE #2: Identify novel treatment options for bypass-related hypocalcemia

CASE: A 35-year-old woman presented with a 1-day history of bilateral hand spasms, paresthesia and diffuse pain. Her history is notable for BPD/DS surgery four years prior and total thyroidectomy complicated by symptomatic iatrogenic hypoparathyroidism two years prior. Two months prior to her current presentation, she developed severe refractory hypocalcemia and was hospitalized numerous times for calcium infusions.

On exam, her temperature was 37.4^{o} C, blood pressure 122/83 mmHg, and pulse 70 bpm. Gentle tapping of the facial nerve elicited tetany. Labs revealed hypocalcemia (6.5 mg/dL), hyperphosphatemia (5.3 mg/dL), low parathyroid hormone (11.4 pg/mL), low vitamin A (28.8 mcg/dL) and low zinc level (0.59 mcg/mL), but otherwise normal serum creatinine, albumin, magnesium, potassium, vitamin D 25-hydroxy, and vitamins E and K. Two months prior, she had a normal 24-hour urine calcium. During the hospitalization she required daily intravenous calcium despite maximum titration of oral calcium regimen. Therefore, she underwent conversion of BPD/DS to Roux-en-Y gastric bypass (RYGB) with functional return of 300 cm of small bowel. Post-operatively, her serum calcium normalized to 8.4 mg/dL and she was discharged home on oral supplementation. A repeat serum calcium at five days post-discharge was stable.

IMPACT/DISCUSSION: Given the risk for profound hypocalcemia following bariatric surgery and associated morbidity, the general internist must assess additional patient risk factors for hypocalcemia prior to surgery referral. This includes history of hypoparathyroidism or personal or family history of thyroid goiter that may predispose to future iatrogenic hypoparathyroidism. The prevalence of hypocalcemia following BPD/DS (10% to 48%) is higher than the prevalence of hypocalcemia following RYGB (1-3%). In RYGB, the gastric pouch is anastomosed to the distal jejunum, whereas in BPD/DS it is anastomosed to the distal ileum. The majority of dietary calcium is absorbed by paracellular diffusion in the lower small intestine; therefore, the additional small bowel bypassed in the latter explains increased hypocalcemia in this population. There have been few case reports on management of refractory hypocalcemia following total thyroidectomy in bariatric surgery patients. Of note, these reports were in patients with RYGB rather than BPD/DS, likely owing to the lower prevalence of the latter. In this case, surgical conversion from BPD/DS to RYGB led to the resolution of refractory hypocalcemia and serves as a guide for treatment in future cases.

CONCLUSION: - BPD/DS followed by iatrogenic hypoparathyroidism can lead to profound hypocalcemia

- Conversion of BPD/DS to RYGB is a novel treatment for refractory hypocalcemia in this population

CACHEXIA, PANCYTOPENIA AND VOMITING: AN UNUSUAL CASE OF VITAMIN B12 DEFICIENCY

Pardeep Gondal. Internal Medicine, Montefiore Medical Center (Wakefield), Bronx, NY. (Control ID #3392394)

LEARNING OBJECTIVE #1: Recognize pancytopenia and dyspepsia as a presentation of vitamin B12 deficiency and autoimmune metaplastic atrophic gastritis (AMAG)

LEARNING OBJECTIVE #2: Discuss management of pernicious anemia and AMAG

CASE: 59-year old man presented with anorexia, vomiting, epigastric pain and progressively worsening fatigue. He had a 20 lb weight loss in the past three months along with chills and night sweats. He denied medical or surgical history and was not on medications. On physical exam, he appeared cachectic. Laboratory tests were significant for hemoglobin 5.4 g/dl, with mean corpuscular volume (MCV) 102 fL, white blood cell count 2,900/ml, and platelet count 57,000/mL. Peripheral smear showed macrocytosis, hyper segmented neutrophils, which was suspicious for vitamin B12 deficiency. B12 level was undetectable with normal folate level. Anti-intrinsic factor antibodies (AIFA) testing was positive, confirming pernicious anemia. In view of cachexia, flow cytometry and CT chest/abdomen were done but found to be normal. Upper GI endoscopy revealed diffusely atrophic gastric fundal mucosa with biopsy confirming chronic atrophic gastritis in fundus, corpus and antral mucosa with intestinal metaplasia which met the criteria for AMAG. He was treated with weekly B12 shots with improvement in pancytopenia and symptoms.

IMPACT/DISCUSSION: This case illustrates a dramatic presentation of B12 deficiency caused by AIFA in setting of AMAG. B12 is required for optimal hematopoiesis and neurologic function. B12 deficiency is either due to decreased intake (e.g. with veganism) or malabsorption. Deficiency arises when hepatic stores are depleted, which takes many years. While macrocytic anemia, neuropsychiatric symptoms and diarrhea are more common presentations, it can rarely manifest with gastric cancer and osteoporosis.

On laboratory evaluation of anemia, suspicion for vitamin B12 deficiency arises when MCV greater than 100 fL, low reticulocyte count, and hyper segmented neutrophils on peripheral smear. Methylmalonic acid levels are elevated in B12 deficiency. B12, folate and iron panel are essential. If B12 levels are low then AIFA should be checked, which if present indicates auto-immune nature of B12 deficiency. With presence of AMAG, Gastrin levels are elevated and anti-parietal cell antibodies are positive. No treatment is available for AMAG, but it requires lifelong B12 supplementation and H. pylori eradication is important as atrophic gastritis confers a higher risk of gastric malignancy by itself.

CONCLUSION: B12 deficiency should prompt testing for pernicious anemia with anti-intrinsic factor antibodies. Evaluation of pernicious anemia should include testing for AMAG.

CAINE YOU SPOT NON-ALCOHOLIC WERNICKE ENCEPHALOPATHY?

Shalini Vadalia[1]; Justin Nichols[2]; Michaela Seigo[3]. [1]Internal Medicine - Pediatrics, Christiana Care Health System, North Potomac, MD; [2]Medicine/Pediatrics Residency Program, Christiana Care Health System, Philadelphia, PA; [3]Internal Medicine, Christiana Care Health System, Delaware, DE. (Control ID #3390309)

LEARNING OBJECTIVE #1: Recognize the risk factors for developing non-alcoholic Wernicke encephalopathy

LEARNING OBJECTIVE #2: Describe appropriate diagnostic workup and treatment of Wernicke encephalopathy

CASE: Patient 1 was a 43-year-old female with a history of small bowel resection and recent pancreatitis who presented with confusion, weakness, and ataxia. She denied excessive alcohol intake. Exam revealed diplopia, horizontal and vertical nystagmus, lateral gaze palsy, and ataxia. She was oriented only to self with tangential speech and confabulations. Labs revealed lactic acidosis and hyperglycemia. MRI brain was notable for hyperintense signals in the periaqueductal gray area and medial thalami with enhancement in the mammillary bodies and inferior colliculi. Due to concern for Wernicke encephalopathy, the patient was started on IV thiamine. Her mental status and nystagmus improved, but her ataxia persisted at discharge. Patient 2 was a 42-year-old female with recent salpingo-oopherectomy complicated by ileus and poor oral intake who presented with altered mental status. She had no history of alcohol intake. Exam showed hypothermia, tachycardia, horizontal nystagmus, and profound lethargy. Labs were significant for leukocytosis and a low thiamine level of 16. MRI brain showed bilateral thalamic restricted diffusion. She was started on IV thiamine. Her clinical course was complicated by new-onset heart failure (wet beriberi) and autonomic dysfunction. Despite improvement in her confusion, she exhibited significant cognitive deficits at discharge.

IMPACT/DISCUSSION: Wernicke encephalopathy (WE) is a life-threatening condition caused by thiamine (vitamin B1) deficiency. Thiamine, a water-soluble vitamin stored in the liver with an 18-day half-life, is an imperative cofactor for metabolic reactions. WE is exhibited by the triad of oculomotor dysfunction, ataxia, and confusion which can progress to lethargy, coma, hypotension, hypothermia, vestibular dysfunction, peripheral neuropathy, and tachycardia. WE is commonly associated with chronic alcoholism but is underdiagnosed in patients without alcohol use. Other conditions associated with WE include hyperemesis gravidarum, starvation, gastrointestinal surgery, malignancy, dialysis, and HIV. Diagnosis is made by meeting two of the four Caine criteria: dietary deficiency, oculomotor abnormalities, cerebellar dysfunction and altered mental status. Labs are not required for diagnosis, though direct thiamine blood level or erythrocyte thiamine transketolase can be measured. MRI can show abnormalities in diencephalon, midbrain, mamillary bodies, or periventricular regions. Treatment of WE involves parenteral thiamine replacement. Ocular manifestations subside over hours to days, but improvement in confusion and ataxia is variable.

CONCLUSION: Non-alcoholic Wernicke's encephalopathy is an often missed diagnosis in patients with poor oral intake presenting with altered mental status. Clinical diagnosis using the Caine criteria should evoke prompt initiation of IV thiamine replacement.

CANDIDA LAMBICA; AN EXCEPTIONAL AND RARE FUNGAL INFECTION

Nadia Aslam, Muhammad Usman Ali, Maitreyee Rai. internal medicine, Crozerchester medical center, Secane, PA. (Control ID #3391455)

LEARNING OBJECTIVE #1: Candida lambica was first described by Linder and Genoud in 1913 as mycoderma lambica. In 1970, Mycoderma lambica was recognised as distinct species within candida genus. It is commonly found in belgian beer, milk products, water and fruits and rarely causes infection in humans. It is frequently misidentified as candida krusei due to their similar appearance on candida culture plate. In literature review, so far there have been only four reported cases of C. lambica infections.

CASE: A 72 year old female presented to the emergency room with altered mental status and fever. Her medical history is significant for uterine cancer treated with chemotherapy and radiotherapy, end stage renal disease on hemodialysis, ischemic colitis status post exploratory laparotomy with colectomy complicated by enterocutaneous fistula requiring total parenteral nutrition. The patient recently had prolonged hospitalization due to sepsis and was treated with meropenem for Klebsiella bacteremia and micafungin for candida parapsilosis fungemia. On physical examination, the patient appears cachetic with a temperature of 102F°, blood pressure of 124/40mmHg and a heart rate of 87/min. Rest of the examination was unremarkable. Blood analysis showed an elevated white cell count of 18,000/mm3. A chest x-ray showed consolidation. A CT abdomen and pelvis was reportedly unremarkable. Blood cultures were ordered and the patient was started on broad spectrum antibiotics (meropenem) and antifungal (micafungin). Blood culture came back positive for candida parapsilosis and yeast. Dialysis catheter and PICC line was exchanged and tips was sent for culture.

A fundoscopy examination did not reveal any signs of hematogenous dissemination of the yeast in eye. A transesophageal echocardiography was done that ruled out infective endocarditis. The culture later came back positive for candida lambica and antifungal treatment was switched to fluconazole. The patient started to improve and blood culture came back negative. The patient was sent to nursing home and recommended to complete the course of treatment.

IMPACT/DISCUSSION: Our patient was immunocompromised due to malignancy, chemotherapy and ESRD, leading to recurrent fungemia which later on found to be candida lambica. Our patient was initially treated with micafungin without improvement. The key tests to differentiate C.lambica from C.krusei are assimilation of xylose(positive for candida lambica and negative for candida krusei) and growth at 42C° (positive for candida krusei only) but definite identification is possible using molecular techniques. It is critical to differentiate between candida lambica and candida krusei since it has therapeutic implications with C. krusei being inherently resistant to fluconazole and C. lambica can be potentially treated with Fluconazole.

CONCLUSION: Candida Lambica rarely causes infection in humans and clinician should be aware of this organism as treatment differs and early recognition is decisive to decrease morbidity and mortality.

CAN MAGNESIUM CITRATE CAUSE PARADOXICAL CONSTIPATION?

Anchit Bharat[1]; Sudarsana Srivangipuram[1]; Nikita Jain[2]. [1]Internal Medicine, IU Health Ball Memorial Hospital, Muncie, IN; [2]Internal Medicine, Chicago Medical School, RFUMS, Northwestern Medicine, McHenry, McHenry, IL. (Control ID #3367271)

LEARNING OBJECTIVE #1: Prior to surgical interventions, it is imperative to correct all electrolyte abnormalities including hypermagnesemia, providing high value care to the patient.

LEARNING OBJECTIVE #2: Cautious use of magnesium citrate laxatives is emphasized. Importance to proper patient education should be given, as this can prevent patients from using higher doses than prescribed.

CASE: A 71 year old male presented with delirium, abdominal pain and distention. He had intermittent constipation for the last 1 year which was refractory to multiple medications. Clinical findings included diffuse abdominal distention with tenderness on palpation without guarding or rigidity and absent bowel sounds. CT abdomen and pelvis with IV contrast on admission showed right colonic dilatation with a diameter of 15 cm in the absence of a structural lesion. A diagnosis of ACPO was made. Decompressive colonoscopy was attempted, but the gastroenterologist was unable to pass the scope beyond sigmoid colon. General surgery recommended exploratory laparotomy, which the patient refused. We proceeded with conservative management. All electrolytes were optimized. IV fluids and furosemide were administered to correct hypermagnesemia (6.2 to 2.1). 2 days after correction of hypermagnesemia, patient had 2 large bowel movements. His mentation improved; WBC decreased from 34.1 to 11.1 k/cumm. A comparison of the CT abdomen and pelvis on admission and 1 week after our interventions showed marked reduction in colonic diameter (15 to 10 cm).

IMPACT/DISCUSSION: Acute colonic pseudoobstruction (ACPO) refers to acute dilatation of the colon in the absence of an anatomic lesion that obstructs the flow of intestinal contents. It has been reported in patients with preeclampsia/ eclampsia, multiple pregnancies and patients undergoing caesarian section [1]. Hypermagnesemia may decrease bowel motility by blocking the myenteric neurons [2]. However, the precise mechanism remains unknown.

Our Proposed Mehanism:

Chronic slow transit constipation > Magnesium citrate ingestion > Magnesium citrate retention and increased absorption > Hypermagnesemia > Worsened motility and progressive colonic dilatation > ACPO

CONCLUSION: Patient's remarkable improvement in mentation, GI motility, WBC and CT scan findings led us to hypothesize that hypermagnesemia had a significant role in the development of ACPO. The patient had consumed magnesium citrate in much higher doses than he was prescribed; exact cumulative dose could not be quantified. Due to preexisting slow-transit constipation, prolonged intestinal retention of the ingested Mg might have enhanced its absorption. The resulting hypermagnesemia might have slowed his transit time even more. A vicious cycle might have ensued, eventually leading to massive colonic dilation. In the current literature, no direct association has been made between ACPO and hypermagnesemia. More studies need to be done to explore the underlying pathophysiology.

CAN ONE KNOW WHAT RESIDES IN THE HEART OF ANOTHER?

Alexandra Barger[1]; Hannah Oakland[2]. [1]Internal Medicine, Tulane Unversity School of Medicine, New Orleans, LA; [2]Medicine, Yale School of Medicine, New Haven, CT. (Control ID #3391191)

LEARNING OBJECTIVE #1: Apply specificity and positive predictive value (PPV) to echocardiography in diagnosis of infective endocarditis (IE).

LEARNING OBJECTIVE #2: Demonstrate the utility of pre-test probability in echocardiography interpretation

CASE: A 36-year-old man with AIDS and current IV drug use presented with right-sided facial swelling and fever. He had a temperature of 101F and heart rate of 117bpm. A soft tissue facial abscess was incised and drained. No murmurs were appreciated, and rhythm was regular. Laboratory studies revealed a WBC count of 5.6 x 10 9 /L, and a CD4 count of 25 cells/mm3. EKG returned normal sinus rhythm. A transthoracic echocardiogram (TTE) ordered to evaluate for IE revealed a 10x9 mm structure attached to the tricuspid papillary muscle, and a small mass on the lateral tricuspid annulus. Treatment for presumed IE was initiated.

Due to the unusual location of the 10x9mm structure (on papillary muscle) a transesophageal echocardiogram (TEE) was performed and returned with no evidence of vegetation and identified the 10x9mm "structure" as papillary muscle. The patient was transitioned to oral antibiotics for soft tissue infection and discharged. Blood cultures at 5 days remained negative.

IMPACT/DISCUSSION: The patient narrowly avoided prolonged hospitalization with the attendant risks of nosocomial infection, drug adverse effects, cost, and the inconvenience. His case raises questions about use of echocardiography in the diagnosis of endocarditis. A 2015 AHA Scientific Statement recommends obtaining a TTE for patients in whom IE is suspected. In hindsight, the presentation of this patient may not have warranted a TTE. Though he was a current IV drug user with AIDS presenting with sepsis, he did not have prior endocarditis, a murmur, or EKG abnormalities, and he had another source of infection. He also had negative blood cultures.

A 1994 article reports the specificity of both TTE and TEE in diagnosing endocarditis as 91%. This means that if TTE is positive, TEE is not indicated as the false positive rate would be the same. In patients with a "high risk" presentation and blood cultures growing an organism commonly causing endocarditis, the PPV of a positive echocardiogram is 79%. In patients with a low-risk clinical picture, even when blood cultures are positive, the PPV can be as low as 50%. Both TTE and TEE can incorrectly identify noninfectious valve abnormalities as vegetations. Intuitively, the PPV of TTE and TEE is lower in patients with low clinical probability of IE than in patients with high pre-test probability. However, there is not a consensus on what defines high- vs low-risk presentation.

CONCLUSION: This case demonstrates that the decision to obtain echocardiography is driven by physicians' clinical judgment and should not be reflexive. A low-risk presentation is not defined, but this patient could conceivably have been considered low-risk. In low-risk patients, the positive predictive value of TTE is reduced enough that the risk of obtaining the study may outweigh the benefit.

CAPTURING THE OVERALL PICTURE OF A POST-GASTRECTOMY PATIENT IN THE JAPANESE HEALTHCARE SYSTEM

Mariko Morioka[1]; Suguru Matsuzaka[2]; Ivor Cammack[3]. [1]Residency, Teine Keijinkai Hospital, Sapporo-shi, Hokkaido, Japan; [2]General Internal Medicine and Infectious Disease Medicine, Teine Keijinkai Hospital, Sapporo, Hokkaido, Japan; [3]Resident Supervision, Teine Keijinkai Hospital, Yoichi, Hokkaido, Japan. (Control ID #3388241)

LEARNING OBJECTIVE #1: Assess unavoidable complications that occur years after surgery

LEARNING OBJECTIVE #2: Recognize potential pitfalls in follow up of postoperative patients in the Japanese healthcare system

CASE: A 74-year-old frail man had a surgical history of total gastrectomy in 2004 for gastric cancer. He presented with a three-month history of general fatigue and numbness in both feet. He described the sensation as if he was walking on gravel. He also described a tendency to fall backward especially at night over the previous year. It was initially thought that the patient was suffering from peripheral vascular disease, and he was referred to the vascular team. However, the ankle-brachial blood pressure index was normal in both legs, and upon consultation to general medicine, neurology examination revealed reduced vibration sensation and proprioception in both feet. Laboratory data showed macrocytic anemia with a severely low vitamin B12 (68 pg/mL). Our working diagnosis was subacute combined degeneration of the spinal cord due to vitamin B12 deficiency after gastrectomy. He was commenced on weekly intramuscular vitamin B12 supplementation and he was transferred to a community hospital.

Although he had been receiving weekly parenteral nutrition via a central line for the last nine years to manage the malnutrition due to his gastrectomy, monitoring of vitamin B12 was lacking.

IMPACT/DISCUSSION: Vitamin B12 deficiency is inevitable in post-gastrectomy patients. This can lead to macrocytic anemia and peripheral neuropathy. The Japanese Gastric Cancer Association guideline for gastric cancer treatment does not discuss vitamin B12 supplementation but focuses on detecting cancer recurrence. The National Comprehensive Cancer Network guideline for gastric cancer treatment recommends follow-up of vitamin B12 and iron levels after gastrectomy of T1a tumors, but there is no established protocol for postoperative care.

This case illustrates the clinical importance of vitamin B12 and the potential flaws of an overly specialized Japanese health service. Open access enables citizens to easily receive specialist care, but the lack of a family physician for most patients hampers overall management. Although this patient had regular surgical appointments, follow-up focused on detecting recurrent cancer and treating malnutrition.

CONCLUSION: Peripheral neuropathy may originate from postoperative vitamin B12 deficiency. Focused specialist care can ignore elements of the patient's overall health management.

CARDIAC-PRECIPITATED PRE-SYNCOPE

Morgan Lamberg, Amy H. Farkas. General Internal Medicine, Medical College of Wiscponsin, Milwaukee, WI. (Control ID #3373625)

LEARNING OBJECTIVE #1: Recognize the clinical features and cardiac exam findings of aortic stenosis

LEARNING OBJECTIVE #2: Understand criteria for valve replacement in aortic stenosis

CASE: A 62 yo female with a PMH of DMII and HTN presents to clinic with several episodes of lightheadedness. Her symptoms last for a few seconds and are exacerbated by positional changes. On physical exam, patient has sinus tachycardia and a new systolic ejection murmur heard best at the aortic position. Her orthostatic vitals are negative but patient is symptomatic when transitioning from laying to sitting position. Of note, review of TTE from ten years prior shows no signs of stenosis or outflow obstruction Patient was referred for a TTE that was significant for severe aortic stenosis (AS) (aortic valve area of 0.84 cm2 and mean gradient 48mmHg). During follow up with cardiology, patient presented with DOE, edema, paroxysmal nocturnal dyspnea, and weight gain. Cardiology recommended aortic valve replacement (AVR). Patient successfully underwent tissue AVR three months after her initial presentation. Postoperatively, patient's symptoms resolved.

IMPACT/DISCUSSION: This case highlights the progressive clinical manifestations of AS. Our patient's severe AS began with pre-syncopal symptoms but in a few short months, advanced to include symptoms consistent of heart failure. Other classic symptoms include decreased exercise tolerance and exertional angina. These vague symptoms are common and clinicians should include AS on their differentials.

While a late-peaking, loud systolic murmur in the aortic position (often radiating to the carotids) and a single second heart sound (S2) are sensitive for AS, a carotid upstroke delay and decrease in amplitude of the carotid pulse are the findings that most closely correlate with the severity of AS. Additionally, a normally split S2 is the only physical exam finding that can dependably exclude severe AS. Physical exam findings must be confirmed with a TTE.

AVR is recommended in patients with severe AS (stage D1). This is defined as a decreased systolic opening of the valve, a Vmax of 4.0m/sec or a mean pressure gradient of 40 mm Hg or greater and symptoms of heart failure, syncope, exertional dyspnea, angina or presyncope. Our patient's symptoms, combined with a mean pressure gradient of 48mm Hg, classified her as stage D1 AS,. Also, an AVA less than or equal to 1.0 cm2 is usually seen in severe AS. Our patient's valve area was 0.84 cm2, consistent with severe AS.

CONCLUSION: Physical exam findings, especially a new systolic heart murmur, should increase your suspicion for AS and further evaluation with TTE Knowledge about the indications for AVR will help the internist make appropriate referrals and streamline the patient's path to surgery

CARPHOLOGIA AND FLOCCILLATION

Rahul R. Bollam[1]; Amitha Avasarala[2]; Miguel Mamauag[1]; Hiran Patel[1]. [1]Department of Internal Medicine, UPMC Mercy, Pittsburgh, PA; [2]Internal Medicine, UPMC Mercy, Pittsburgh, PA. (Control ID #3392106)

LEARNING OBJECTIVE #1: Recognition of the abnormal hand movements specific for delirium and their clinical significance.

CASE: A 52-year-old Caucasian male with a past medical history significant for chronic alcohol use and mild intellectual disability presented to the emergency department with confusion and visual hallucinations. The patient was a poor historian and no further history could be obtained. Physical examination was prominent for cachexic state with global muscle loss and altered mental status. Initial labs and neuroimaging were unremarkable. Patient was started on high dose IV thiamine with no improvement. Four days after initial presentation he was transferred to a tertiary care center for further workup including a lumbar puncture. On subsequent physical examination, the patient appeared to be reaching for imaginary objects and attempting to talk to "some who was not present". Extremities were tremulous with increased tone and primitive reflexes(suckling reflex and palmar grasp) were also evokable.

Repeat labs obtained the following day showed elevated alkaline phosphatase, AST and ALT consistent with biliary disease. CT Abdomen done showed findings consistent with acute cholecystitis and laparoscopic cholecystectomy was performed. Patient's mental status gradually improved during the postoperative period and his abnormal movements resolved. Remaining hospitalization was uneventful and the patient was discharged to a skilled nursing facility for continuing physical therapy and safety.

IMPACT/DISCUSSION: Delirium is the acute change in brain function that affects nearly 30% of older medical patients while hospitalised. It can present as hyperactive, hypoactive or a combination of both. Delirium is heavily under-diagnosed with the majority of hypoactive delirium presenting unnoticed. Herein we discussed the case of a patient who presented in a delirious state with a highly specific but uncommon presentation.

Carphology(lint-picking behavior) and floccillations(plucking at the air) are uncommon physical signs but are highly suggestive of delirium. In a study out of 110 patients who experienced an episode of delirium, 21 exhibited carphology and/or floccilations.

The sensitivity and specificity of these findings were 14 and 98%, respectively. These behaviours tend to occur early in the delirium episode. The inpatient mortality rate of patients exhibiting these movements was double the rate of patients without them, although these did not reach statistical significance. These findings were present in both hypoactive and hyperactive delirium.

CONCLUSION: Although uncommon, floccillations and carphology can be easily recognised at bedside prompting investigation of delirium and its cause. If absent, delirium cannot be ruled out but if present then there should be a high suspicion for a delirious state

These movements are unrelated to delirium subtypes and can aide in the diagnosis of overlooked hypoactive delirium.

CASE OF CANDIDA GLABRATA BLADDER FUNGAL BEZOAR

Thomas Moffitt. Internal medicine, DDEAMC, Grovetown, GA. (Control ID #3384633)

LEARNING OBJECTIVE #1: Recognize Fungal Bezoar as rare cause for renal failure in immunosuppressed patient

LEARNING OBJECTIVE #2: Treatment of Obstructive fungal Bezoars

CASE: Our Patient is a 66yo woman with history of uncontrolled diabetes mellitus type II who was initially admitted to our Intensive care unit for diabetic ketoacidosis and acute renal failure. She had presented with nausea/vomiting and diarrhea and had been non-adherent to anti-hyperglycemic therapy.

Initial CT scan of her abdomen demonstrated mild unilateral hydronephrosis and bladder wall inflammation without evidence of nephrolithiasis. Urine Culture on admission along with blood cultures grew Candida glabrata.

Due to continued fevers and non-improving renal function, it was believed that she may have fungal ball in her bladder. A percutaneous nephroureteral tube was placed to allow for decompression of the right collecting system and a cystoscopy was performed.

Cystoscopy revealed a mass in her bladder consistent with fungal Bezoar. Bladder irrigation was performed and this mass was removed. She was started on amphotericin B irrigation through her nephroureteral tube.

She received ten days of this antifungal as bladder irrigation in addition to her IV therapy. After a month in the hospital She was discharged to a rehab facility, however, she eventually required placement of a percutaneous urinary catheter.

IMPACT/DISCUSSION: Fungal infections are a common complication in the immunocompromised, especially diabetics. Obstructive nephropathy from a fungal Bezoar is a rare complication of renal failure.

This patient was found to have nephropathy due to fungal bezoar with only mild evidence of obstruction on imaging.

Candida albicans is the most likely cause of fungal bezoars with candida glabrata being very rare with few cases reported in medical literature. Initial therapy choices should consider coverage for glabrata since this agent is usually resistant to azoles antifungals.

CONCLUSION: Bladder fungal infections can uncommonly present as renal failure due to obstructive bezoars. Providers should have a high index of suspicion for a mass when patients do not improve with adequate antimicrobial coverage and any evidence of obstruction on imaging.

Advanced fungal infections such as fungal Bezoars should especially be considered in the immunocompromised such as uncontrolled diabetes. Treatment may require surgical intervention as well as percutaneous antifungals in addition to intravenous/oral therapy.

CASE OF UNILATERAL HEMIPLEGIA ASSOCIATED WITH VARICELLA ZOSTER VIRUS INFECTION

Thomas Moffitt. Internal medicine, DDEAMC, Grovetown, GA. (Control ID #3384662)

LEARNING OBJECTIVE #1: Recognize and evaluate CNS complications of Varicella Zoster Virus (VZV) infection

LEARNING OBJECTIVE #2: Manage Disseminated VZV in a complicated patient

CASE: Our patient is a 73yo male with history of HTN and CKD V, currently on prophylactic antibiotics and high-dose steroid for contrast-induced nephropathy who presented with sudden onset of a large and painless vesicular rash on left upper extremity extending from hand to shoulder in a poly-dermatomal distribution. Initial ROS was positive for dyspnea, fatigue, cough. Vitals were within normal limits and exam demonstrated volume overload and a rash consistent with herpes zoster. Rapid flu testing was positive for Influenza type A.

Following admission, he was continued on his steroid taper and started on oral oseltamivir and acyclovir. PCR of skin lesions were positive for varicella Zoster virus.

His course was complicated by acute lower GI bleeding due to ischemic colitis. His oseltamivir was discontinued at this time due to rare associations with colitis and no other appreciable causes. In addition to GI issues, approximately 48 hours into admission he endorsed left sided weakness. These were consistent on physical examination.

MRI/MRA was obtained which revealed an acute left sided occipital lobe lacunar stroke but nothing to explain this acute change. Due to concern for disseminated infection, a lumbar puncture was performed which demonstrated elevated CSF protein. A bacterial/viral meningitis PCR panel was positive for VZV.

He was transitioned to IV acyclovir for 14 days and discharged with some improvement in his symptoms.

IMPACT/DISCUSSION: CNS complications are a rare but known issue from VZV reactivation. They range from post-herpetic neuralgia to meningoencephalitis, CVA or hemiplegia/paresis.

This case highlights an atypical presentation of VZV. Despite large surface area of zoster rash our patient remained without pain during his hospital course and presented with disseminated infection.

This patient also presented with influenza infection, renal failure and ischemic colitis. None of these explain his neurologic symptoms found during his hospital stay. While Influenza infection also has rare neurologic complications, our patient did not have a clinical syndrome of severe infection and CSF was positive for VZV.

While CNS complications from VZV are usually delayed, our patient's hemiparesis occurred relatively suddenly from onset of zoster rash.

CONCLUSION: Neurologic complications from common and otherwise benign viral infections should be considered when patients present with neurologic deficits and there is no evidence of other central nervous involvement such as acute stroke or seizure.

Disseminated VZV should be considered in anyone with zoster rash and other neurologic findings.

Diagnostic testing such as lumbar puncture should be performed. Patients should be rapidly transitioned to IV therapy when disseminated VZV is suspected.

CASE REPORT: A RARE CAUSE OF DRUG-INDUCED PSORIASIFORM DERMATITIS

Franck H. Azobou Tonleu[1]; Marissa Baranowski[1]; CAITLIN ANDERSON[2]; John P. Haydek[3]. [1]Internal Medicine, Emory University, Atlanta,

GA; [2]Internal Medicine, Emory University School of Medicine, Atlanta, GA; [3]Department of Internal Medicine, Emory University School of Medicine, Atlanta, GA. (Control ID #3343026)

LEARNING OBJECTIVE #1: Consider the potential harms before prescribing PPIs

LEARNING OBJECTIVE #2: Take a thorough drug history when assessing rashes in the primary care setting

CASE: A 48-year-old female with a history of eczema, gastric ulcers, and seizure disorder presented with bilateral hand rash for one week. She described the rash as pruritic, burning, and not responding to Neosporin cream. She reported that her symptoms started two weeks after taking esomeprazole. Her other medications included citalopram, valproate, and levetiracetam. Her exam was notable for desquamating rash of bilateral palms. Initial labs were remarkable for elevated liver enzymes (Aspartate aminotransferase 158 U/L, alanine aminotransferase 69 U/L, alkaline phosphatase 300 U/L) and thrombocytopenia (platelets 134 x 10E3 U/L), which had previously been normal. Her valproate level was low. She was diagnosed with eczema, prescribed triamcinolone 0.1% cream, and esomeprazole was discontinued. A few days later, the patient presented to the emergency department complaining of worsening rash, with new erythema and spread to the elbows and axillae. She was discharged with hydroxyzine 10 mg and an oral prednisone taper.

A week later, the patient presented to clinic complaining of rash spreading to the buttocks, legs, and feet as well as daily emesis related to pain. She also noted fatigue, diarrhea, diffuse arthralgias, and pain with walking due to plaques on the soles of her feet. She reported not taking prednisone. Dermatology was consulted and noted erythematous to violaceous papulosquamous thin plaques of the arms, upper legs, hands, and feet with scattered violaceous papules with dusky centers on the abdomen and back. They recommended switching triamcinolone to betamethasone 0.05% ointment BID.

She presented to dermatology clinic shortly after and a biopsy was performed, showing subacute spongiotic dermatitis–consistent with drug-induced psoriasiform dermatitis. They recommended a course of oral prednisone while continuing betamethasone 0.05% ointment. The patient's rash improved within two weeks with resolution of erythema in axillary region, and improvement in itching of palms and soles. However, she continued to report burning of her palms and soles. Betamethasone was stopped, and the patient was started fluocinonide 0.05% ointment for maintenance therapy.

IMPACT/DISCUSSION: Proton pump inhibitors (PPIs) are among the most frequently prescribed medications in the primary care setting. PPIs have been identified as the offending agent in multiple cutaneous manifestations associated with hypersensitivity reactions.[1-9]This is the first case described in the literature of PPI-induced psoriasiform dermatitis.

CONCLUSION: Although PPIs are generally well tolerated, providers should remember to discuss possible adverse effects, including uncommon ones, with the patient.

When assessing a rash ash, we encourage internists to take a thorough drug history as medications have been implicated as etiologies for a variety of rashes.

CASE REPORT ON THE DIAGNOSTIC APPROACH AND MANAGEMENT OF E-CIGARETTE OR VAPING ASSOCIATED LUNG INJURY (EVALI)

Branavan Ragunanthan[1]; Apoorv Deotare[1]; Basem Rashwan[1]; Joseph P. Myers[1,3]; Rami Abboud[1,2]. [1]Internal Medicine, Summa Akron City Hospital, Akron, OH; [2]Pulmonology/Critical Care Medicine, Summa Akron City Hospital, Akron, OH; [3]Infectious Disease, Summa Akron City Hospital, Akron, OH. (Control ID #3389668)

LEARNING OBJECTIVE #1: Recognize the clinical features and association of EVALI among young adults

LEARNING OBJECTIVE #2: Diagnose EVALI as a diagnosis of exclusion

CASE: A 19 y.o. female with a history of hourly smoking abuse with vape and dab pens for 2 years presented to the ED with a chief complaint of progressive dyspnea, rhinorrhea, nausea, and vomiting one day after failed outpatient management of suspected community acquired pneumonia (CAP) with oral doxycycline. Physical exam in the ED demonstrated VS of BP at 126/72, temperature at 37.3C, HR at 135, RR at 18, SpO2 at 100%, right-sided inspiratory rhonchi and chest wall tenderness to palpation. CXR showed consolidative opacities in the right lung and trace opacities in the left lung and CBC demonstrated a WBC of 15.4 x 103/μL. She was admitted for CAP and treated with IV vancomycin + ceftriaxone + azithromycin, levalbuterol nebulizer, IV methylprednisolone and IV fluids. Initial workup including BNP, liver enzymes, urinalysis, BioFire™ nasopharyngeal respiratory viral panel, urine pneumococcal antigen, blood cultures, urinary Legionella antigen, procalcitonin level, toxicology screen, and EKG were normal/negative. Chest CTA demonstrated diffuse bilateral patchy ground-glass lung opacities/infiltrates with subpleural sparing with bilateral hilar and mediastinal lymphadenopathy and multiple small foci of pneumomediastinum within the upper lobes. CT chest with oral contrast obtained was unremarkable and antibiotics were changed to vancomycin + piperacillin/tazobactam. Allergen panel, ANA, HIV screen, and TTE were normal. However, pro-BNP was elevated at 1,399 pmol/L, ESR elevated at 99 mm/hr, CRP elevated at 241 mg/L, and bronchoscopy incidentally positive for CMV (felt NOT to be a pathogen). Her leukocytosis and symptoms improved on therapy and she was discharged on a prednisone taper and oral levofloxacin. Outpatient PFTs were unremarkable, and she reported resolution of symptoms.

IMPACT/DISCUSSION: Clinical Impact: EVALI should be a differential in vaping patients that present with respiratory and gastrointestinal symptoms with opacities on CT or infiltrates on CXR. Treatment includes antibiotics and steroids.

Teaching Points: EVALI is a diagnosis of exclusion that can be ruled in if a patient has vaped prior to pulmonary symptoms, opacities are discovered on CT, and there is an absence of significant infection on workup.

Impact on Healthcare Provider: Providers should expand their assessment of a social history by questioning e-cigarette/vaping in addition to other substance abuse.

How Case Adds to Current Literature: E-cigarettes were only introduced in the U.S. circa 2006. According to the CDC, as of 2020, only 2,600 cases of EVALI have been reported within the U.S. This case aims to expand the limited literature on a modern-day pathology.

CONCLUSION: ●EVALI can present with respiratory and gastrointestinal symptoms with findings similar to other infectious pulmonary processes

●A comprehensive workup must be done to diagnose EVALI

CATASTROPHIC ANTIPHOSPHOLIPID ANTIBODY SYNDROME

Sumaira Zareef[1]; Abeer Zeeshan[1]; Asli S. Sucu[2,1]. [1]Internal medicine, Montefiore Medical Centre, Bronx, NY; [2]Internal Medicine, Montefiore Medical Center, Bronx, NY. (Control ID #3388473)

LEARNING OBJECTIVE #1: The unique characteristics of Catastrophic antiphospholipid syndrome (CAPS) are rapid onset thrombosis resulting in multiple organ dysfunction, common association with other thrombotic microangipathies, high risk of systemic inflammatory

response syndrome, unusual organ involvement, and high mortality rate despite optimal therapy

CASE: Our patient was a 44 year old man with known history of hypertension, diabetes mellitus, chronic thrombocytopenia, and autism, admitted for right sided weakness. He was diagnosed with acute ischemic stroke, treated for it, and transferred to acute rehabilitation facility. He developed abdominal pain and distention during the rehabilitation facility stay. Imaging of the abdomen revealed emboli in pulmonary arteries, superior mesenteric artery, splenic artery, and he was started on unfractionated heparin. Repeat abdominal imaging showed thickening of small bowel in right abdomen concerning for intramural hemorrhage and large territory splenic infarction. He underwent exploratory laparotomy for bowel ischemia secondary to thrombosis. He further developed lower extremity venous thrombus as well. Transthoracic echocardiogram revealed a patent foramen ovale. He tested positive for anticardiolipin antibodies and was started on plasma exchange along with Solumedrol for CAPS. The anticoagulation therapy was transitioned from intravenous heparin to warfarin, with a goal INR of 2-3 and intravenous heparin was later discontinued. He was switched to oral prednisone and placed on an appropriately scheduled steroid taper. He was discharged once medically stable and was planned to follow up with hematology, Coumadin clinic, and general surgery for appropriate continuation of care.

IMPACT/DISCUSSION: Antiphospholipid syndrome (APS) is a multisystem autoimmune condition that is characterized by vascular thrombosis and, or pregnancy loss associated with persistently positive antiphospholipid antibodies (APLA). Catastrophic antiphospholipid syndrome (CAPS) also known as Asherson's syndrome is the most severe form of APS with acute multiorgan involvement and is usually associated with micro thrombosis. CAPS has been defined as thrombosis in three or more organs developing in less than a week, micro thrombosis in at least one organ and persistent APLA positivity. If a patient has three out of four abovementioned criteria then they are probable CAPS as opposed to definite CAPS. Previous diagnosis of APS and persistently positive APLA is of significance for APS diagnosis but almost half of the patients with CAPS have no history of APLA positivity. All patients should be treated with anticoagulants, corticosteroids, and possibly plasma exchange. Newer therapies as rituximab and eculizumab may be options but need further study.

CONCLUSION: CAPS should be considered as a diagnostic possibility in patients with rapid onset thrombosis involving multiple organs and unusual organ involvement.

CAUTION WITH THAT TURTLE! SALMONELLA OSTEOMYELITIS IN THE SETTING OF ANTI-TNF TREATMENT

Victoria Garland[1]; Amira Elshikh[1]; Adrienne N. Poon[2]. [1]Internal Medicine, George Washington University School of Medicine & Health Sciences, Washington, DC; [2]Department of Internal Medicine, George Washington School of Medicine and Health Sciences, Clifton, NJ. (Control ID #3347550)

LEARNING OBJECTIVE #1: Identify patients at risk for disseminated salmonella

LEARNING OBJECTIVE #2: What is a strategy to prevent harm in patients on anti-TNF therapy

CASE: A 70 year old man with psoriatic arthritis on infliximab, hypertension, and chronic low back pain complained of three weeks of intermittent fevers, headaches and worsening back pain after returning from the Dominican Republic. He reported contact with a box turtle and a nontraumatic bird bite but denied sick contacts. He was originally treated for sinusitis with no relief; back pain was thought chronic. Symptoms acutely worsened after infliximab infusion. He was promptly sent to the Emergency Department for MRI spine that showed nonspecific edema. He was admitted for severe back pain preventing his ability to move. He was hemodynamically stable with white blood cell count 17, erythrocyte sedimentation rate 109, C-reactive protein 230. Urinalysis and chest x-ray were normal. He was started on broad spectrum antibiotics but continued to spike fevers to 39 degrees Celsius. Blood cultures grew salmonella sensitive to Ceftriaxone.

MRI lumbar spine 1 week later showed discitis and osteomyelitis at L2-L3 and septic facet arthritis and myositis at L3-L4. Neurosurgery was consulted for spinal involvement. Decision was made to forgo surgery. At two months, he had improvement in pain and mobility but repeat MRI showed continued infection. He underwent biopsy and aspirate grew salmonella. At that time, antibiotic course was extended to a 96 day course of ceftriaxone plus oral azithromycin, which he remains on at present day.

IMPACT/DISCUSSION: This case demonstrates the rare risk of disseminated salmonella infection in patients, such as ours, on infliximab, an anti-tumor necrosis factor (TNF) agent. The medication inhibits TLR-4 expression on dendritic cells, leading to decreased activation of interferon gamma which defends against intracellular and fungal pathogens. This pathway is also involved in bacterial adherence in the gut, affecting bacterial migration across the intestinal epithelium. Case reports describe unusual salmonella soft tissue and joint infections in this population. Spinal osteomyelitis and discitis are uncommon manifestations, associated with sickle cell disease or an immunocompromised state, as our patient.

Anti-TNF drugs are now one of the best-selling pharmaceutical drugs. Over 1 million people are prescribed anti-TNF medications to treat chronic inflammatory conditions. These patients should be counseled to avoid risk factors. Reptiles are known to carry salmonella; turtles, birds, raw egg consumption should be avoided. Salmonella should be considered in these patients with persistent fevers, pain, travel to endemic regions, and no clear infectious source.

CONCLUSION: Understanding of susceptibility to disseminated salmonella infection with spinal involvement in patients on anti TNF medications is essential as these drugs become more widespread. Awareness can lead to timely diagnosis and treatment and may have mitigated complications in our patient.

CAVITARY LUNG LESION AND ERYTHEMA NODOSUM: A CASE OF SYSTEMIC COCCIDIOIDOMYCOSIS

Jared A. Geibig, Sonia Lin. Internal Medicine, LAC+USC, Los Angeles, CA. (Control ID #3390900)

LEARNING OBJECTIVE #1: Recognize the epidemiological factors and clinical features of systemic Coccidioidomycosis

LEARNING OBJECTIVE #2: Create a differential for Erythema Nodosum

CASE: A 38 year-old male with a living donor renal transplant in 2016 in El Salvador with 2 months of fevers, chills, dry cough, and fatigue along with 2 weeks of polyarticular pain and swelling with associated tender subcutaneous nodules. Of note patient was on vacation in Los Angeles and had been residing in Utah prior to his arrival. Upon presentation he was found to be afebrile, normotensive, tachycardic to 120, and sating 100% on room air. Exam was notable for swelling of his left wrist and a few scattered, tender, slightly indurated subcutaneous nodules distributed over the lower and upper extremities consistent with erythema nodosum. Labs were significant for a leukocytosis to 12 with neutrophil predominance along with a creatinine of 2.20 which was near baseline. Chest X-ray and CT-thorax were remarkable for a right upper lobe cavitary lesion. The patient was ruled out for active tuberculosis infection and then underwent a

rheumatologic workup with no significant findings including normal complement, ANCA, and ANA levels. Biopsy of his rash was then performed and found to be consistent with systemic Coccidioidomycosis. The diagnosis was also supported with positive Coccidioidomycosis serum serologies. The patient was started on fluconazole with significant symptomatic improvement and discharged.

IMPACT/DISCUSSION: This case highlights the epidemiological and unique clinical features of a patient with systemic coccidioidomycosis. His immunosuppressed status as a solid organ transplant patient placed him at significant risk for developing systemic infection. In addition his relocation to Utah predisposed him to exposure to coccidioidomycosis. Most patients typically present with acute pulmonary symptoms even in patients with systemic infection. However it is also common, with one case series finding up to 75% of transplant patients to have extrapulmonary dissemination which often includes skin, bone, and joint involvement. A unique aspect of this case was the presence of a cavity lesion as there have only been case reports of patients presenting with cavitary lesions as a result of systemic infection. An additional unique aspect of this case was the presence of erythema nodosum. Causes of erythema nodosum include medications, infections, rheumatologic conditions, and idiopathic. Given the presentation this finding was helpful in narrowing the differential. Systemic coccidioidomyocisis is a rare occurance however in the immunocompromised namely solid organ transplant recipients it is quite common and can present with various extrapulmonary findings.

CONCLUSION: - Coccidioidomycosis is a common infection endemic to the Pacific Southwest that in solid organ transplant patients will often present with systemic findings

- The causes of erythema nodosum is varied however in the correct clinical context can greatly assist in narrowing differntials.

CHAGASIC MEGAESOPHAGUS IN A CENTRAL-AMERICAN PATIENT IN LOS ANGELES CLINIC

Salvador Hernandez[1,2]; Kirsten Kaldas[1]; Colin Forsyth[2]; Lourdes Concepcion Martinez Cartagena[2]; Celena Carolina Guevara Flores[2]; Sheba Meymandi[2,1]. [1]Internal Medicine, Olive View-UCLA Medical Center, Sylmar, CA; [2]Internal Medicine, Center of Excellence for Chagas Disease, Sylmar, CA. (Control ID #3392732)

LEARNING OBJECTIVE #1: Diagnose Chagasic Achalasia

LEARNING OBJECTIVE #2: Early diagnosis and treatment for chagasic achalasia

CASE: A 59- year -old female, originally from Sonsonate, a rural area in El Salvador with medical history of hypothyroidism, prediabetes, and worsening progressive dysphagia of 1 year. She recalls exposure to kissing bugs. She reported one year of worsening progressive dysphagia solids to liquids, eating 6 meals a day due to food getting stuck in her chest and regurgitating whole food particles, vomiting, no nausea, 10 pound weight loss in one month, odynophagia. She tried omeprazole but stopped four months before presentation due to no relief. Anamnesis positive for tobacco use in her youth, chronic constipation. Father and grandfather died of cardiac disease. Positive serology for *T. cruzi* at a commercial lab, confirmed by CDC TESA blot. An XR esophagram in 10/2018 showed a dilated esophagus with distal tapering concerning for achalasia vs megaesophagus from Chagas disease. Esophagogastroduodenoscopy found the middle third of the esophagus with mild dilation consistent with achalasia. A chest X-ray showed borderline widening of the mediastinum. Cardiac MRI indicated delayed enhancement of mid myocardium of basolateral wall. Normal echocardiogram, electrophysiology study and Holter. Manometry diagnosis of Type 2 achalasia. She underwent antitrypanosomal treatment and Heller myotomy. Patient reported complete remission of dysphagia after Heller myotomy,

IMPACT/DISCUSSION: Chagas Disease (CD), caused by the protozoan *Trypanosoma cruzi* affects approximately 6-7 million people, mostly in Latin America. CD's acute phase, lasting 4-8 weeks, is typically asymptomatic or may present with self-limited febrile illness. Irreversible cardiac, gastrointestinal, and/or neuronal damage appears in 30-40% of those in the chronic phase. In some regions, 15-20% have digestive alterations. CD digestive involvement has usually been characterized in South America and rarely seen in Mexico and Central America (CA), as it is thought that different regional *T. cruzi* strains produce different pathogenesis. We describe the first case of a chagasic achalasia (megaesophagus) reported in California and to the best of our knowledge the first in an individual from CA. Dysphagia is the major symptom of esophageal involvement in CD. In a 2014 study by Pinazo et al, they found a prevalence of 21.1% of chronic gastrointestinal manifestations in patients with *T. cruzi* infection. This report is important because dysphagia is not a pathognomonic symptom of CD, but, is a relevant factor that needs to prompt providers to test for *T. cruzi* in at-risk patients.

CONCLUSION: Chagasic achalasia should be suspected in patients from endemic countries or risk factors (i.e. travel to endemic areas, transfusion of contaminated blood, etc). Diagnosis is made by radiologic examination and manometry. Given the possibility of chagasic achalasia in the at-risk population, this condition should be part of U.S. clinicians' differential diagnosis.

CHALLENGES OF GUARDIANSHIP: EXTENDED INPATIENT LENGTH OF STAY IN A PATIENT WITH SCHIZOPHRENIA

Ethan M. Cohen[1]; Siri S. Sarvepalli[1]; Diane L. Levine[2]. [1]Medical Student, Wayne State University School of Medicine, Detroit, MI; [2]Internal Medicine, Wayne State University, Detroit, MI. (Control ID #3361492)

LEARNING OBJECTIVE #1: Recognize the challenges in treating non-decisional schizophrenic patients on the medicine inpatient service.

LEARNING OBJECTIVE #2: Emphasize the need for advocacy to improve establishment of guardianship.

CASE: A 71-year-old woman with schizophrenia, personality disorder, and multiple medical problems including pulmonary sarcoidosis was brought to the Emergency Department with acute psychosis and suicidal ideations. She was found non-decisional by psychiatry and, because she required chronic oxygen supplementation, was admitted to the medical service. She was treated with haloperidol for schizophrenia and oxygen, lisinopril, atorvastatin, aspirin, and levothyroxine for her other diagnoses. On psychiatric evaluation, the patient was not suicidal and was able to answer questions appropriately but displayed no insight into her condition. It was recommended she be discharged to a facility with supervised care. She remained on the medical service waiting for a guardianship hearing to allow placement post discharge. The patient attempted to leave on her own, and a sitter was provided. None of her comorbidities were medically problematic. After 39 days, guardianship still had not been established; the patient missed her appointment in the sarcoidosis clinic. Medications were adjusted by the pulmonary service. Guardianship was obtained on day 44, and she was discharged to a nursing home with continued outpatient psychiatric care.

IMPACT/DISCUSSION: Schizophrenia is a chronic disorder that causes a complex array of manifestations including disordered speech, hallucinations, and social dysfunction and often presents with a range of comorbidities. Treatment consists of medication and psychosocial interventions which can be carried out in in- or outpatient settings. In the US, significant acute changes in mental status are addressed primarily in inpatient facilities. Although this has the benefit of constant supervision, there are problems including increased cost and exposure to nosocomial

infections. Our patient was initially admitted with an acute psychiatric crisis and should have received an emergency guardian within 48 hours after appropriate parties were notified and filings submitted. However, she stayed on a medical ward for 44 days even though crisis

symptoms resolved and she was clinically stable. Inpatient hospital care is far more expensive than any other healthcare setting. Had timely guardianship been established, we could have greatly saved on costs as well as treated our patient more effectively.

CONCLUSION: All systems are interconnected. As we focus on training physicians to care for complex patients, we need to advocate for systems that are safe, timely, equitable, efficient, and patient centered. This includes advocating within our court systems to facilitate timely guardianship to avoid inappropriate and extended hospital stays, which unnecessarily expose patients to risk and increase healthcare costs.

CHOLANGIOCARCINOMA MASQUERADING AS HEPATIC ABSCESSES

Meghana Singh, Anantha Sriharsha Madgula, Dominique Feterman. Internal Medicine, UConn school of medicine, Hartford, CT. (Control ID #3392235)

LEARNING OBJECTIVE #1: Understand that the incidence of cholangiocarcinoma is increasing in young adults.

LEARNING OBJECTIVE #2: Identify the risk factors associated with cholangiocarcinoma in young adults.

CASE: A 21-year-old female with no significant past medical history presented to her OB/GYN with the chief complaint of fever and diffuse abdominal pain starting 3 days earlier. On pelvic examination, she was noted to have white-colored discharge. Due to concern for pelvic inflammatory disease, she was given one dose of ceftriaxone and discharged on doxycycline and metronidazole. However, the patient could not tolerate oral medications due to severe nausea, prompting her visit to the emergency department (ED). In the ED, she was febrile, with an elevated white blood cell count to 12,800, transaminitis with AST 106, ALT 43, ALP 149. CT abdomen pelvis was done showing innumerable hypodense lesions throughout the liver, concerning for infectious process versus metastatic disease. She denied any sick contacts, recent travel, personal or family history of malignancy, inflammatory bowel disease. She was started on broad spectrum antibiotics with vancomycin and piperacillin-tazobactam for treatment of hepatic abscesses. Further work up including Echinococcus IgG, Giardia stool antigen, Entamoeba histolytica studies, stool O&P, blood cultures were negative. She then underwent ultrasound-guided biopsy of the liver lesion; the results were consistent with poorly differentiated adenocarcinoma, most likely cholangiocarcinoma (CCA).

She was then discharged with outpatient follow up with hematology-oncology to discuss treatment options. However, she was readmitted to the hospital due to persistent fevers and hyperbilirubinemia. Her labs were then significant for spontaneous tumor lysis syndrome. She, unfortunately, passed away shortly despite prompt hemodialysis.

IMPACT/DISCUSSION: Cholangiocarcinoma is the second most common liver malignancy (10-15%). The usual age at diagnosis is around 50 years. The incidence In young patients(<30 years age) is rising. In a few studies, primary sclerosing cholangitis (PSC) has been reported as the most common risk factor with as high as half the patients having a history of PSC. The other risk factors include inflammatory bowel disease, hepatitis B, hepatitis C, genetic polymorphisms. Our patient did not have any of the known risk factors.

CCA in the young is highly aggressive, and most commonly present at an advanced stage with a high histologic grade and is associated with poor survival. The treatment options may be limited to hepatectomy, adjuvant, or neoadjuvant chemotherapy, liver transplantation. The median survival is less than two years in unresectable patients.

CONCLUSION: It is important for clinicians to be aware of the rising incidence of CCA in young adults and opt for prompt biopsy of the lesions, especially in patients with known risk factors. Further research is warranted to better understand the risk factors and the need for surveillance in younger patients.

CHRONIC STRESS AND THE BROKEN HEART: TAKOTSUBO WITHOUT AN ACUTE TRIGGER

Mateen Saffarian. Internal Medicine, LAC USC Medical Center, Los Angeles, CA. (Control ID #3341397)

LEARNING OBJECTIVE #1: Recognize atypical presentations of Takotsubo Cardiomyopathy.

LEARNING OBJECTIVE #2: Recognize possible underlying risk factors for Takotsubo Cardiomyopathy.

CASE: A 70 year-old female visiting from Mexico with a past medical history of hypertension and chronic anxiety presented with one day of acute onset substernal chest pain and shortness of breath. On arrival, the patient was hypertensive with systolic blood pressures above 200 mmHg, EKG was significant for ST elevations in leads I and AVL, and troponin T was elevated to 0.15 ng/ml. Given the high concern for ACS, the patient was taken directly to the catheterization lab. She was found to have non obstructive coronary artery disease and the ventriculogram showed apical ballooning with hyperdynamic basal wall motion. Subsequent TTE showed severe hypokinesis of the anterior apical, mid anteroseptal, and apical myocardium. A diagnosis of Takotsubo Cardiomyopathy was made.

2**IMPACT/DISCUSSION:** Takotsubo Cardiomyopathy characteristically presents with symptoms, EKG findings, and biomarker elevations consistent with acute coronary syndrome. The classic findings on subsequent cardiac catherization are non-obstructed coronary arteries and LV dysfunction with apical hypokinesis. Takotsubo myopathy is typically seen in postmenopausal females (~90%) with a preceding emotional or physical stress event (85%). While recognition of Takotsubo has increased greatly over the years, the syndrome remains relatively rare and poorly understood. New studies and case reports are illustrating atypical presentations, identifying possible underlying risk factors, and revealing long-term outcomes. This case illustrates how in a subset of patients, there is no identifiable stress event preceding Takotsubo Cardiomyopathy. Additionally, the case highlights chronic stress as a possible risk factor for Takotsubo. Whether chronic stress can predispose someone to develop Takotsubo cardiomyopathy remains largely unknown. However, several studies show that chronic anxiety and stress disorders are significantly more common in Takotsubo patients than in ACS patients. Additionally, while patients are typically thought to have improvement of LV function in the weeks to months following Takotsubo Cardiomyopathy, new data shows that long-term outcomes can be poor. Studies have shown that outcomes can be similar to patients with acute coronary syndrome, and the rate of major adverse cardiac and cerebrovascular events is around 9.9% per patient-year.

CONCLUSION: ● Takotsubo Cardiomyopathy is classically thought to be triggered by an acute stress event. However, in a small proportion of cases, there is no identifiably stressor.

● Though data is currently limited, several studies and case reports hypothesize that chronic stress may be an underlying risk factor for Takotsubo Cardiomyopathy.

● Patients must have good follow up as long term outcomes can be poor.

CHRONIC URTICARIA: A HINT TOWARDS SOMETHING MORE

Andy Wu, Tanya Nikiforova. Internal Medicine, University Of Pittsburgh Medical Center, Pittsburgh, PA. (Control ID #3391846)

LEARNING OBJECTIVE #1: Describe the clinical presentation and natural history of chronic spontaneous urticaria

LEARNING OBJECTIVE #2: Review the initial diagnostic testing and management of chronic spontaneous urticaria

CASE: A 39-year-old man presented with a pruritic diffuse rash which has been recurring over the past two years, and getting worse in frequency over the past month. The rash occasionally develops after eating spicy foods, with stress, or when changing from a hot to cold environment, but often occurs without a clear preceding trigger. He had no personal or family history of thyroid or autoimmune disease, and took no medications. Exam was negative for thyromegaly and notable for scattered well-circumscribed oval plaques over the upper arms, chest, and flanks in a wheal and flare pattern. Laboratory studies including CBC, TSH, ESR, and CRP were all normal. He was diagnosed with chronic spontaneous urticaria based on the clinical appearance and chronicity of the rash. He was started on a daily second-generation anti-histamine and the frequency of the rash improved significantly.

IMPACT/DISCUSSION: In contrast to acute urticaria, chronic spontaneous urticaria (CSU) is a condition affecting only 1% of the population in the United States, and is defined as the presence of urticaria for a period of six weeks or longer. Although classic triggers of urticaria may be present, the absence of a clear trigger during the majority of occurrences satisfies the diagnostic criteria of spontaneous urticaria. CSU presents as a self-limited disease in most patients, with spontaneous remission rates between 30 to 50% within the first year. CSU has been shown to be associated with thyroid disorders, as well as autoimmune conditions such as rheumatoid arthritis, Sjogren's syndrome, and systemic lupus erythematosus. As such, the initial evaluation of patients presenting with CSU includes a careful history, exam, and screening tests to evaluate for thyroid and autoimmune etiologies. However, no specific cause can be identified in 80 to 90% of individuals with CSU. There are several established guidelines on treatment of CSU, with the consensus first-line agent being a second-generation anti-histamine. About 20% of individuals with CSU may experience symptoms beyond 5 years, and in these cases escalation to dual anti-histamine regiments, H2-antagonists, leukotriene receptor antagonists, and ultimately omalizumab or cyclosporine may be warranted.

CONCLUSION: This case reviews the presentation of a commonly recognized condition in urticaria, and explores how the initial diagnostic testing and management of this condition changes when patients present with a chronic course of symptoms.

CLOPIDOGREL-INDUCED THROMBOTIC THROMBOCYTOPENIC PURPURA SUCCESSFULLY TREATED WITHOUT PLASMA EXCHANGE

Chiraag Kapadia[2]; Courtney N. Miller-Chism[1]. [1]Hematology/Oncology, Internal Medicine, Baylor College of Medicine, Houston, TX; [2]Baylor College of Medicine, Houston, TX. (Control ID #3343094)

LEARNING OBJECTIVE #1: Recognize thrombotic thrombocytopenic purpura (TTP) in patients treated with thienopyridine anti-platelet agents.

LEARNING OBJECTIVE #2: Acknowledge that a subset of patients with TTP may respond to steroids alone, while recognizing that plasma exchange remains the standard of care.

CASE: A 54-year-old male with history of peripheral artery disease and recent popliteal artery stent placement presented with acute right middle cerebral artery stroke. Platelet count was 22 K/μL at admission and normal one month ago at clopidogrel initiation. Peripheral blood smear displayed schistocytes, indicating microangiopathic hemolytic anemia (MAHA). Fresh frozen plasma and prednisone were initiated. Plasma exchange (PLEX) was initially scheduled, but ultimately deferred due to 1) uncertainty about the TTP diagnosis, and 2) concerns that PLEX would induce transient hypotension and exacerbate ischemic neurological damage.

Briefly after the start of steroids, platelet count began to rise with stabilization of neurological symptoms. Six days after admission, ADAMTS-13 activity evaluated on admission was reported to be $\leq 2\%$, confirming diagnosis of TTP. By this time, the platelet count had normalized and thus PLEX was not initiated. An alternative anti-platelet agent for thromboprophylaxis was administered and the patient was discharged in good condition with no further relapse.

IMPACT/DISCUSSION: Thienopyridine anti-platelet agents such as ticlopidine and clopidogrel are prescribed to prevent thrombosis after peripheral vascular or coronary stent placement. Ironically, microvascular thrombosis is a rare adverse event of thienopyridines, manifesting as TTP. Patients with TTP present with MAHA, schistocytosis, and thrombocytopenia and may display neurological and renal deterioration. The mainstay of treatment for thienopyridine-induced TTP is emergent plasma exchange, which eliminates circulating niduses of thrombosis formation. Glucocorticoids are often administered acutely in conjunction to PLEX therapy to mitigate any autoimmune etiology.

Prior to the era of PLEX, TTP was associated with a 90% mortality rate due to systemic infarcts. Our patient's recovery indicates not all patients necessitate emergent PLEX administration in cases of clopidogrel-induced TTP. Further investigation must determine which patients may benefit from glucocorticoid treatment alone and if glucocorticoid bridging to PLEX initiation for initial poor responders provides outcomes equivalent to immediate plasma exchange in a select TTP population.

CONCLUSION: Induced thrombotic thrombocytopenic purpura (TTP) is a rare but potentially adverse effect of clopidogrel treatment and presents as MAHA, thrombocytopenia, and schistocytosis, often in the context of neurological and/or renal impairment. Emergent plasma exchange is standard-of-care for TTP treatment but not always required for TTP resolution. Further study must determine if glucocorticoid treatment is as efficacious as immediate plasma exchange in a subset of TTP patients.

CLOSTRIDIUM SEPTICUM-INFECTED AORTIC ANEURYSM: A RARE INDICATION FOR SCREENING COLONOSCOPY

Matthew C. McCullough. Internal Medicine, Baylor College of Medicine, Overland Park, KS. (Control ID #3392265)

LEARNING OBJECTIVE #1: Diagnosis and treatment of mycotic aortic aneurysm

LEARNING OBJECTIVE #2: Recognize *C. Septicum* is associated with GI malignancy

CASE: A 70-year-old woman presented with 4 weeks of progressively worsening abdominal and lower back pain. Accompanied by nausea, retching, non-bloody emesis, & subjective fevers. 1 week prior went to an urgent care where she received fluids and a course of oral metronidazole for presumed gastritis without clinical improvement. Her past medical history is otherwise uneventful.

On exam vitals are normal. She is in pain and retching. Abdominal exam with tenderness to deep palpation throughout all quadrants without

guarding. No point tenderness of spine on palpation. Exam otherwise unremarkable.

Initial laboratory investigations with a leukocytosis of 23,000 WBC and elevated CRP 19 mg/dl. A CT abdomen shows a saccular infra-renal aortic aneurysm measuring 4.2x5.4x7.2 centimeters with surrounding soft tissue stranding along with nodularity and inflammation adjacent to the cecum. MRI of the spine is negative for osteomyelitis.

Broad spectrum antibiotics were started on admission. A TEE was performed to rule-out endocarditis, but with preliminary findings concerning for possible aortic dissection. Emergent CTA was negative for dissection, but did show a second aneurysm measuring 3.0x3.0x2.2 centimeters arising distal to the left subclavian artery. Infectious work-up remained negative, including several blood cultures and a DNA-PCR sequencing assay for microbial cell-free DNA.

Vascular Surgery performed an open infra-renal abdominal aortic aneurysm repair using an aorto-iliac graft on hospital day 5. Anaerobic surgical tissue cultures were positive for *Clostridium Septicum*. Uneventful post-operative course and discharged on indefinite suppressive amoxicillin therapy. Colonoscopy as outpatient was negative for malignancy. Vascular surgery is planning for close outpatient follow-up with serial imaging for the second thoracic aortic aneurysm,

IMPACT/DISCUSSION: This case demonstrates the diagnosis and management of mycotic aortic aneurysm. Diagnosis should be established with CT, and antibiotics should be tailored to cover Staph and Salmonella spp. the most common pathogens. Chronic suppressive antibiotics should be considered if poor source control.

A literature search reveals this diagnosis to be a rare and lethal combination. Diagnosis is often challenging as *C. Septicum* is an obligate anaerobe. Several case-series report a nearly 100% mortality for untreated patients. The literature also reveals a strong link between *C. Septicum* infection & primary GI malignancy in well over 50% of patients. For our case, the cecal lesion gains added importance as a potential primary malignancy. Despite the negative colonoscopy, suspicion of malignancy for our patient remains high and brings into consideration the possibility of appendiceal etiologies as well.

CONCLUSION: The imaging modality of choice for the diagnosis of mycotic aneurysms is CT *C. Septicum* Infection should prompt screeing colonoscopy

CMV COLITIS IN AN IMMUNOCOMPETENT PATIENT

Alexandria Lucas. Internal Medicine, University of Kentucky, Lexington, KY. (Control ID #3391983)

LEARNING OBJECTIVE #1: Differentiate CMV colitis from inflammatory bowel disease and other causes of severe colitis.

LEARNING OBJECTIVE #2: Recognize CMV as a possible diagnosis in a healthy patient with severe colitis.

CASE: A 34 year old male with no significant past medical history presented to the hospital with a five day history of fever, chills, diffuse abdominal pain, and hematochezia. The patient endorsed two similar episodes of self-resolving hematochezia in the past that lasted for three weeks. His family's medical history was significant for a mother who was diagnosed with colon cancer at 55 years old. A CT of the abdomen showed severe colitis from the right colon to the rectum. Infectious colitis and IBD were considered in the differential diagnosis, thus a colonoscopy with a biopsy was performed. The colonoscopy showed moderate inflammation from the anus to the hepatic flexure that was concerning for either ulcerative colitis or CMV colitis. The biopsy confirmed CMV colitis and an infectious workup showed CMV IgM with >10,000 IU/mL on a quantitative CMV PCR. Since CMV colitis is so rare in immunocompetent individuals, tests for immunosuppression were conducted. However, no sources of immunosuppression could be identified. Four days of ganciclovir were given in the hospital and the patient's fever, abdominal pain, frequency of bowel movements, and hematochezia improved significantly. He was discharged with valganciclovir 450mg 2 tablets BID for twenty-one days to treat his CMV colitis.

IMPACT/DISCUSSION: Cytomegalovirus (CMV) is a common virus that is typically asymptomatic or causes a mild mononucleosis syndrome in healthy adults. Severe manifestations of the virus, such as CMV colitis, are rarely seen in immunocompetent patients, especially those who are young, healthy, and without comorbidities. CMV colitis can be difficult to differentiate from other forms of colitis such as inflammatory bowel disease, thus a biopsy can confirm the diagnosis. CMV colitis should be a part of the differential for severe colitis when other sources have been ruled out, even in those who are young and healthy.

CONCLUSION: -CMV should remain in the differential for a patient with severe colitis, even in healthy individuals.

-CMV colitis can be confirmed and distinguished from other forms of colitis via biopsy of the colon.

CNS RING ENHANCING LESIONS AFTER SOLID ORGAN TRANSPLANTATION: A LATE COMPLICATION

Belicia Ding[1]; Luke Andrea[2]; Scott Schafler[2]. [1]Internal Medicine, Montefiore, The Bronx, NY; [2]Internal Medicine, Montefiore Medical Center, Bronx, NY. (Control ID #3392037)

LEARNING OBJECTIVE #1: Distinguish between CNS toxoplasmosis and CNS lymphoma in immunocompromised patients

LEARNING OBJECTIVE #2: Assess utility of serum and CSF markers for central brain lesions

CASE: A 60 year-old man with a history of deceased donor renal transplant with thymocyte induction 5 years ago that was complicated by acute t-cell mediated rejection requiring three additional rounds of thymoglobulin post-transplant, presented with 8 months of progressive focal neurologic deficits and paranoid delusions. Brain imaging revealed ring enhancing lesions. CNS fluid had WBC of 13, high protein, normal glucose, and no organisms. Further CNS studies were pertinent for a positive PCR for Epstein-Barr virus, a negative PCR for Toxoplasma gondii, a negative cryptococcal antigen, and a negative PCR for JC virus. Serum Toxoplasma IgG antibody was positive with no past Toxoplasma levels for comparison, a SPECT/CT scan of the brain showed no increased uptake in the lesions, which is more consistent with an infectious process rather than lymphoma. The patient was treated with Bactrim for several weeks, and serial MRIs showed decreasing lesion size and resolution of enhancement.

IMPACT/DISCUSSION: The differential for multiple enhancing brain lesions in immunocompromised patients, such as transplant patients, is broad, including Toxoplasma gondii, Aspergillus, Nocardia asteroides, EBV, Listeria monocytogenes, Mucorales, Tuberculosis, Coccidioides, and less commonly Cryptococcus. Although data on transplant populations is limited, the two most commonly reported causes of brain lesions with mass effect are Toxoplasma and lymphoma. In most patients with Toxoplasma reactivation, serology IgM is absent with positive IgG antibodies, but serum IgG cannot distinguish between active and past infection. PCR for Toxoplasma in CSF is not always helpful, with a sensitivity of only about 50%. And unfortunately, sensitivity and specificity for EBV in CSF varies widely. SPECT/CT scan can be helpful in distinguishing between toxoplasma and CNS lymphoma. Thallium, a potassium analog, will be taken up more by hypermetabolic tumor cells, such as in lymphoma as compared with toxoplasma with no cellular component. It has a sensitivity and specificity of 100% and 93%, respectively. Nevertheless, brain biopsy is still the gold standard. In cases where a biopsy would put

the patient as significant risk, patients are sometimes empirically treated with follow up imaging to assess for response. Finally, Toxoplasma should be always be considered on the differential in this type of patient, as the 60 day mortality is reported to be up to 82%.

CONCLUSION: - Toxoplasma remains rare in patients with renal transplant after 3 months, but needs to be on differential with CNS process work-ups

- While serology testing and lumbar puncture is helpful for ruling out many other etiologies, a negative result for toxoplasma cannot rule out toxoplasmosis

- Advanced imaging can help to distinguish between toxoplasma and lymphoma

COAGULATION SYSTEM GONE ROGUE: CATASTROPHIC ANTIPHOSPHOLIPID SYNDROME

Samiullah Arshad. Internal Medicine, Montefiore Medical Center, Wakefield, Bronx, NY. (Control ID #3392073)

LEARNING OBJECTIVE #1: Identifying the thromboembolic events involving three or more organs as a presentation of Catastrophic Antiphospholipid Syndrome (CAPS)

LEARNING OBJECTIVE #2: Role of Plasmapharesis and IVIG in the management of CAPS

CASE: 43 year old gentleman presented with right hemiparesis found to have acute left pontine infarct with pure motor deficit. In the initial acute rehabilitation course, patient developed fever of 101 F and abdominal pain. A CT scan abdomen with IV contrast showed multiple emboli in the Pulmonary arteries, SMA, splenic artery and veins with splenic infarction. There was also evidence of small bowel edema resulting from ischemia. Patient was started on a heparin drip. Patient underwent exploratory laparotomy with 20 cm of ischemic bowel resected. Lupus anticoagulant screen returned positive. Hematology was consulted and a diagnosis of the Catastrophic Antiphospholipid Syndrome (CAPS) was made. Patient then underwent plasmapharesis thrice followed by a course of IVIG for 5 days. Histopathology of the small bowel showed hemorrhage and vascular congestion and was interpreted to be consistent with thromboembolic disorders. Patient was then started on IV methylprednisolone and transitioned to prednisone and tapered off after 1 month. Patient was discharged on long term anticoagulation with warfarin with a goal of INR 2-3.

IMPACT/DISCUSSION: Catastrophic Antiphospholipid Syndrome (CAPS) is the unusual but severe form of antiphospholipid antibody syndrome and is characterized by arterial and venous thrombosis involving 3 or more organs with characteristic microvascular thrombosis. Early diagnosis and management of CAPS is essential as the mortality can be as high as 30% based on initial reports. Triggers for thrombosis may include infection, medications, surgery, lupus flare and obstetric complications must be appropriately managed. Treatment is focused at managing the hypercoagulable state with anticoagulation and the suppression of the inflammatory cascade and reducing the antibody burden. Plasmapharesis helps with removal of the Antiphospholipid antibodies. A systemic review of 342 CAPS cases showed patients who underwent therapy with anticoagulation, glucocorticoids and combination of plasmapharesis and IVIG had better outcomes. In patients resistant to the initial therapy, Rituximab and eculizumab have been found to be effective. Long term anticoagulation is of utmost importance to prevent recurrence of the thromboembolic events.

CONCLUSION: Timely management of CAPS with IVIG and plasmapharesis after identification of acute thrombosis with involvement of 3 or more organ systems can be lifesaving in this nearly fatal condition.

COCAINE INDUCED PSEUDO WELLENS SYNDROME

Ellen Nein[1]; Aseel A. Dweik[3]; Sujata Bhushan[2]. [1]Internal Medicine, University of Texas Southwestern Medical Schhol, Dallas, TX; [2]-Section of General Internal Medicine, Dallas VA Medical Center, Dallas, TX; [3]Internal Medicine, University of Texas at Southwestern, Allen, TX. (Control ID #3390736)

LEARNING OBJECTIVE #1: Recognize Wellens' syndrome on an electrocardiogram (ECG).

LEARNING OBJECTIVE #2: Distinguish pseudo-Wellens' syndrome from true Wellens' syndrome.

CASE: A 59-year old male with a past medical history of hypertension presented with shortness of breath and dyspnea on exertion. He used marijuana daily and denied any additional recreational drugs. The physical examination showed a heart rate of 79 beats per minute, blood pressure of 158/102 mm Hg, jugular venous pressure of 12 cm, left parasternal heave, and displaced point of maximal impulse.

Laboratory workup was notable for an elevated creatinine, troponin, and brain natriuretic peptide. Chest radiograph showed new cardiomegaly. ECG showed left ventricular hypertrophy; T wave inversions in leads I, II, III, and aVF; and biphasic T waves in leads V4 – V6. Repeat ECG showed new biphasic T waves in V3 and V4. Transthoracic echocardiogram showed moderate left ventricular hypertrophy, severe global hypokinesis, and left ventricular systolic function of 20%. The patient was started on aspirin, heparin, and furosemide for new onset systolic heart failure and non-ST segment elevation myocardial infarction (NSTEMI). He urgently underwent left heart catheterization for his ECG pattern concerning for Wellens' syndrome. Coronary angiography showed normal coronary arteries. He was diagnosed with pseudo-Wellens' syndrome. His urinary toxicology screen returned positive for cocaine and his diagnosis was attributed to cocaine use.

IMPACT/DISCUSSION: Wellens' syndrome was first described in 1982 as an ECG finding observed in patients with unstable angina and critical stenosis of the proximal left anterior descending (LAD) artery. It is a precursor to a potentially fatal extensive anterior myocardial infarction, implying that the ECG pattern should be treated as a STEMI equivalent. The Wellens' ECG pattern is characterized by symmetric, deeply inverted T waves (Type A) or biphasic T waves (Type B) in the precordial leads along with the following criteria: normal or minimally elevated ST segments, no Q waves, and normal to slightly elevated troponin. Characteristic T wave changes are classically seen in leads V2 - V3 with normal precordial R wave progression and often occur when patients are free of chest pain. The pathophysiology of Wellens' syndrome is unknown. Pseudo-Wellens' syndrome is described in several case reports of patients with ECG findings of Wellens' syndrome but with normal coronary angiography. The condition has been documented in patients with cocaine use, marijuana use, immune checkpoint inhibitor use, hypertension, pulmonary embolism, acute cholecystitis, takotsubo syndrome, and intracranial hemorrhage.

CONCLUSION: (1) Wellens' pattern on ECG requires urgent cardiac consultation for evaluation of critical proximal LAD stenosis.

(2) Pseudo-Wellens' syndrome is a condition characterized by Wellens' pattern on ECG in patients with normal coronary angiography. It can be seen in a variety of clinical scenarios including cocaine-induced coronary artery vasospasm.

COGNITIVE BIASES ARE ESSENTIAL TOOLS IN DIAGNOSIS, BUT CAN ALSO LEAD TO SERIOUS ERRORS!

Kashif Khan[1]; Hiba Mazhar[2]. [1]Hospital Medicine, Ohio State University Wexner Medical Center, Columbus, OH; [2]Internal Medicine, University Hospitals/ Case Western Reserve University, Cleveland, OH. (Control ID #3342489)

LEARNING OBJECTIVE #1: Recognize cognitive biases in clinical medicine.

LEARNING OBJECTIVE #2: Strategies to reduce diagnostic errors.

CASE: A 62-year-old male presents to the hospital with numbness of arms, thigh pain and difficulty walking for 2 weeks. His symptoms started at work after a prolonged extension of his back. A spinal MRI showed severe cervical stenosis. Neurosurgery team advised no surgical intervention with out-patient physical therapy. Three days later, he presented to another hospital with persistent symptoms. These were again attributed to cervical stenosis with recommendations for outpatient neuro-surgery follow up and continued physical therapy. Five days later, he presented to a third hospital with progressive symptoms. History revealed a recent respiratory tract infection. Physical examination was remarkable for equally diminished power in both lower extremities with absent ankle and knee reflexes as well as decreased sensation in feet.

MRI spine from the previous hospitalization showed severe cervical stenosis without cord compression. Electromyography showed sensory-otor neuropathy with early demyelination. Lumbar puncture revealed elevated proteins. A presumptive diagnosis of Guillain- Barré syndrome was made and he was started on high dose IVIG. Within two weeks he was asymptomatic and walking independently.

IMPACT/DISCUSSION: Relying too heavily on the initial piece of information to formulate a diagnosis can lead to premature closure of cases resulting in diagnostic inaccuracies and harm to our patients. In this case, multiple providers succumbed to common cognitive biases by attributing the patient's symptoms to cervical stenosis, even without a history of back pain or evidence of cord compression on imaging. None of the previous notes documented a sensory exam or deep tendon reflexes, nor a history of respiratory tract infection which assisted in arriving at the accurate diagnosis. Easy availability of advanced imaging has led us away from the basics of practicing medicine - history and a complete physical examination.

CONCLUSION: Identification and increasing awareness of cognitive biases in clinical practice can help reduce medical errors. A few strategies include:

Re-visiting history and examination when the diagnosis is not forthcoming. Formulating a differential diagnosis independent of the labels applied by others. Using a diagnostic "time-out" for difficult clinical problems.

COLD AGGLUTININ DISEASE IN THE SETTING OF MYCOPLASMA PNEUMONIAE INFECTION AND CHRONIC MYELOGENOUS LEUKEMIA

Aditi Jani[1]; Olivia T. Van Gerwen[2]. [1]Medicine, University of Alabama at Birmingham, Birmingham, AL; [2]Infectious Diseases, University of Alabama at Birmingham, Birmingham, AL. (Control ID #3391493)

LEARNING OBJECTIVE #1: Recognize the classical association of cold agglutinins with *M. pneumoniae* and hematologic malignancies.

LEARNING OBJECTIVE #2: Avoid premature closure when evaluating complex clinical cases, especially when multiple etiologies can explain one clinical finding.

CASE: A 60 year-old woman with bronchiectasis presented to care with 2 weeks of dyspnea, fever, and productive cough. On admission, she was intubated for acute hypoxemic respiratory failure. Exam revealed fever to 100.6 F, scleral icterus, wheezing, and jaundice. Laboratory workup revealed leukocytosis of 79,000/mm^3, hemoglobin of 6.7g/dL, total bilirubin of 28 mg/dL (direct 22 mg/dL). CT chest revealed multi- lobar pneumonia. She underwent bronchoscopy which detected *M. pneumoniae* via PCR. Given her anemia and hyperbilirubinemia, an autoimmune hemolytic anemia work-up was initiated. Direct antiglobulin testing was positive for C3, suggesting cold agglutinin disease (CAD) or paroxysmal cold hemoglobinuria.

Peripheral smear showed erythrocyte clumping and cold agglutinin titer was 1:640, consistent with CAD. Her pneumonia was treated with moxifloxacin and her respiratory status and laboratory abnormalities improved. Her leukocytosis persisted, peaking at 96,000/mm^3. Peripheral smear showed precursor cell forms, initially thought to be due to steroids and critical illness. Thus BCR-ABL testing and bone marrow biopsy were pursued and revealed chronic myelogenous leukemia (CML). Dasatinib was initiated and she achieved a major molecular response.

IMPACT/DISCUSSION: CAD is an autoimmune hemolytic anemia in which circulating autoantibodies bind to erythrocyte antigens at low temperatures, causing erythrocyte agglutination and extravascular hemolysis. CAD can be primary (i.e. idiopathic) or secondary to an underlying infectious (e.g. *M. pneumoniae*, EBV), autoimmune, or lymphoproliferative disorder (e.g. lymphoma, lymphocytic leukemia). Although many patients are asymptomatic, some present with hemolytic anemia or cold-induced symptoms such as Raynaud phenomenon. Diagnosis requires clinical and laboratory evidence of hemolysis, positive direct antiglobulin test for C3, and a cold agglutinin titer of ≥1:64. Evaluation for underlying etiology is appropriate. Management includes cold avoidance, supportive transfusions, and treatment of the underlying disorder. There is also a role for rituximab-based therapy to target antibody production. While this patient had an underlying infection contributing to her CAD, her relentless leukocytosis was not fully explained by this alone. She was ultimately found to have CML as well, underscoring the importance of avoiding premature diagnostic closure.

CONCLUSION: CAD is an autoimmune hemolytic anemia in which cold agglutinins bind erythrocytes, causing clumping and hemolysis.

Infectious and lymphoproliferative conditions can be associated with CAD.

Premature diagnostic closure in complex clinical cases may cause critical concurrent differential diagnoses to be missed.

COMMON SYMPTOMS WITH AN UNCOMMON CAUSE: A RARE COMPLICATION OF PEPTIC ULCER DISEASE

Lavanya Dharmarajan[1]; Jennifer Lom[2]. [1]Internal Medicine, Emory University, Atlanta, GA; [2]General Medicine, Emory University, Atlanta, GA. (Control ID #3391951)

LEARNING OBJECTIVE #1: Recognize rare complications of peptic ulcer disease (PUD)

LEARNING OBJECTIVE #2: Review management of gastric outlet obstruction due to PUD

CASE: A 45 year old male presented with severe nausea, vomiting, and abdominal pain for one month. He noted symptoms were worse after meals and reported a 40 pound weight loss. His social history was remarkable for heavy marijuana use.

On admission, the patient's vital signs were within normal limits. Physical exam was notable for tenderness to palpation in the epigastric area. Laboratory evaluation revealed a creatinine of 1.6 from a baseline of 1.0 and metabolic alkalosis. CT Abdomen/Pelvis revealed a distended, fluid-filled stomach, concerning for gastroparesis. Given his cannabis use, age, and lack of other risk factors, the initial working diagnosis was cannabinoid hyperemesis syndrome.

An esophagogastroduodenoscopy (EGD) was attempted, which revealed an edematous pylorus and erosions of the antrum with inability to pass the endoscope through the pylorus. Subsequent upper GI series showed a gastric outlet obstruction with stricture at the gastric antrum, concerning for malignancy. A repeat EGD with balloon dilation was attempted, but still with inability to advance past the stricture. Biopsies

were positive for *H. pylori* and negative for malignancy. The patient was started on 4-drug therapy for *H. Pylori* in hopes this would relieve his symptoms. However, his symptoms recurred following his treatment and he required laparoscopic pyloroplasty for gastric outlet obstruction secondary to peptic ulcer disease.

IMPACT/DISCUSSION: Peptic ulcer disease (PUD) has many complications, including obstruction. Prior to the discovery of *H. Pylori* and proton pump inhibitors, PUD caused 90 percent of gastric outlet obstruction cases. Currently, PUD accounts for only five percent of cases of outlet obstruction. In fact, today obstruction is more likely to be caused by malignancy than PUD. Gastric outlet obstruction in PUD may arise from inflammation and edema from the ulcer in the acute setting as well as fibrosis and scarring in the chronic setting. Prolonged obstruction can also cause gastric atony, leading to gastric retention and symptoms of nausea and vomiting.

Management for gastric outlet obstruction involves intravenous hydration, nasogastric decompression, nutritional optimization, and proton pump inhibitor therapy. Intervention with endoscopic dilation or surgery is usually reserved for those who fail conservative management. Half of obstruction cases due to peptic ulcer disease respond to medical management, although some may eventually need intervention. Furthermore, evidence suggests that in cases of *H. Pylori*, eradication of the infection resolves the obstruction and prevents recurrence.

CONCLUSION: This case highlights the importance of maintaining a wide differential when approaching common presenting symptoms. What was initially thought to be a case of cannabis hyperemesis syndrome was actually a rare complication of peptic ulcer disease.

CONCOMITANT CRYPTOCOCCAL MENINGITIS AND AFRICAN TICK BITE FEVER IN A RETURNING TRAVELER

Tapuwa D. Mupfumira[1]; Jeremiah D. Johnson[5]; Ruwarashe R. Mupfumira[4]; Brannon L. Raney[2]; Diedre Hofinger[2]; Blavir Rukov[3]. [1]Infectious Diseases, Augusta University Medical Center, Augusta, GA; [2]Infectious Diseases, Raymond G. Murphy VA Medical Center, Albuquerque, NM; [3]Internal Medicine, Raymond G. Murphy VA Medical Center, Albuquerque, NM; [4]Psychology, University of New Mexico, Albuquerque, NM; [5]Internal Medicine, University of New Mexico, Albuquerque, NM. (Control ID #3369770)

LEARNING OBJECTIVE #1: High index of suspicion

LEARNING OBJECTIVE #2: Pre-travel counselling

CASE: We present a case of a man returning from safari in South Africa with African tick bite fever (ATBF) and cryptococcal meningitis.

A 35-year-old man presented to the hospital complaining of fever of 39.30 C at home, chills, severe headache for 1 day, dizziness, fatigue, and body aches for one week. He returned from safari in South Africa near Zimbabwe 7 days earlier and reported removing 5 ticks from his body while there. He had no medical conditions prior to travel. On admission, heart rate was 112 bpm and temperature was 37.60 C on Tylenol. Physical examination revealed periumbilical and left anterior thigh eschars with inguinal lymphadenopathy. Initial laboratory results were WBC 5.18 K/mm3, lactic acid 2.5 mmol/L, C-reactive protein 20.8 mg/L, blood glucose 141 mg/dL, normal coagulation profile, normal liver functions, and serum creatinine 1.39 mg/dL. Chest radiograph and computed tomography of the brain were normal.

Blood cultures, Influenza A and B, and malaria smear were all negative. His cerebrospinal fluid tested positive for cryptococcus antigen. He was admitted for presumed cryptococcus meningitis and ATBF. Treatment for ATBF with doxycycline 100 mg oral twice daily and cryptococcal meningitis with Amphotericin B Liposomal (AmBisome) 275 mg IV daily with Flucytosine 2 g orally every 6 hours was started. He developed acute kidney injury secondary to AmBisome with serum creatinine peaking at 2.03 mg/dL and returned to 1.43 mg/dl when treated with normal saline.

Eventually Rickettsia typhi IgG and IgM results came back negative. There are no specific tests for Rickettsia africae readily available, but other rickettsia panels may cross react allowing for confirmation of rickettsia infection. HIV 4th generation and serum cryptococcus antigen tested negative. Eschar biopsies showed non- specific inflammation.

The patient completed 7 days of Doxycycline and 14 days of induction antifungal therapy then transitioned to 8 weeks of outpatient consolidative therapy with Fluconazole 800 mg once daily. He was doing well at follow-up.

IMPACT/DISCUSSION: ATBF is a bacterial disease caused by Rickettsia africae spread by Amblyomma-type ticks in sub-Saharan Africa, West India and Oceania. Confirmatory testing with culture, PCR, or Immunofluorescence are often unavailable and do not return in a timely fashion. Clinicians need to have a high index of suspicion in returning travelers from endemic areas with tick bites and presumptive treatment should be started.

Patient also tested positive for another potentially fatal infection, cryptococcal meningitis. A fungal infection caused by *Cryptococcus neoformans* or *Cryptococcus gatti.* This emphasizes the importance of screening for other associated infections in returning travelers.

CONCLUSION: Ecotourism and adventure travel are increasingly popular worldwide, the incidence of travel-associated tick-borne rickettsioses is likely to increase. Pre-travel counselling regarding prevention measures is important.

CONFUSING CASE OF DELIRIUM

Matthew Cormier[1]; Ariana Mooradian[1]; Jennifer Schmidt[2]. [1]Internal Medicine, Saint Louis University, St Louis, MO; [2]General Internal Medicine, Saint Louis University, Saint Louis, MO. (Control ID #3383333)

LEARNING OBJECTIVE #1: Recognize multi-factorial delirium

LEARNING OBJECTIVE #2: Prioritize medication reconciliation

CASE: A 68-year-old male with history of paraplegia on the Medicine service with sepsis secondary to pyelonephritis and aspiration pneumonia has worsening confusion for 1 day. Due to a switch day, the entire Medicine team was new and had not previously examined the patient; mental status was not documented. Patient was increasingly somnolent on exam, requiring sternal rub for arousal. On chart review, patient's last bowel movement was 2 days ago. Straight catheterization revealed >700cc retained urine. Medication review showed patient received diazepam 10mg the day prior due to concern for withdrawal (listed as home medication but had not received for 3 days in hospital) as well as 15mg oxybutynin (home dose 5mg TID) due to dosing confusion. Team contacted patient's daughter who managed home medications and confirmed all medications patient was actively receiving at home. Patient was receiving baclofen 40mg QID in hospital but taking 20mg TID at home and patient not currently taking diazepam at home. Bowel regimen and routine bladder scans/straight caths were initiated in addition to medication adjustments to correct dosing. Overnight patient had a bowel movement, 1.2L urine output via catheterization.

Baclofen and oxybutynin doses were adjusted and diazepam was discontinued. Patient's mental status returned to baseline (oriented x4) approximately 48 hours later. Patient and family received medication education at discharge including updated EMR medication list.

IMPACT/DISCUSSION: Delirium is common in hospitalized patients, but can be difficult to identify and treat. It is a significant burden on society associated with increased risk for cognitive and function decline as well as increased cost of health care. While delirium is common in elderly hospitalized patients with a prevalence of 25%, it still poses a challenge for clinicians to recognize. Up to 70% of new cases of delirium are missed by clinicians and, even in recognized cases of delirium, the exact etiology often goes uncovered. This is in part because most cases of delirium have multifactorial causes and a wide range of presentations. Among all causes of delirium, polypharmacy and medication effects continue to be the number one reason for reversible delirium. Complicating the matter, infection or dehydration can trigger drug-induced delirium even without changes to patient's medication. There has been increased effort to implement medication reconciliation to minimize any associated adverse events such as delirium. Delirium continues to be difficult to diagnose and treat, but documenting mental status and reconciling medications early are easy steps to help reduce the prevalence of delirium and chances of poor outcomes from it.

CONCLUSION: Establish patient's baseline mental status during handoff

Reconcile medication list early in the patient's admission

Record person in charge of patient's medication regimen at home

CONNED BY CONN'S: A CASE REPORT ON THE MANIFESTATION OF CONN'S SYNDROME POST-RENAL TRANSPLANT IN A PATIENT WITH PCKD

Chaitanya Rojulpote[1]; Ashwin Mathew[2]; Patrick Huynh[3]; Madhurima Adulla[3]; Shu Xian Lee[3]. [1]Radiology, University of Pennsylvania, King of Prussia, PA; [2]Internal Medicine, University of Edinburgh, Edinburgh, United Kingdom; [3]Internal Medicine, Northside-Gwinnett Medical Center, Lawrenceville, GA. (Control ID #3367478)

LEARNING OBJECTIVE #1: Recognize the clinical manifestations of Conns syndrome in a patient with PCKD who underwent a successful renal transplantation.

LEARNING OBJECTIVE #2: Understand the mechanism by which Conns syndrome remains masked in such a patient.

CASE: We present a case of a 66-year-old male with End Stage Renal Disease (ESRD) secondary to a history of Polycystic Kidney Disease (PCKD). He successfully underwent a cadaveric renal transplant, prior to which he received peritoneal dialysis for 2 years. The newly transplanted kidney showed no signs of graft rejection and he sustained no post-operative complications. A regularly scheduled follow-up 2 months later revealed the patient to have worsening control of hypertension. Despite an increase in blood pressure lowering medications, it remained uncontrolled. Various causes of new onset hypertension such as anti-graft rejection medication (anti-calcineurin therapy), renal artery stenosis, and allograft injury were investigated and excluded. The patient's biochemistry panel revealed the presence of hypokalemia, a finding that was not present in previous reports. In view of these findings, plasma Aldosterone and Renin levels were ordered and the level was found to be elevated. The Aldosterone, Renin, and Aldosterone-Renin Ratio (ARR) were found to be 50.4 ng/dL, 0.4 ng/dL, and 126, respectively. A detailed review of the patient's past medical records revealed a routine CT scan performed in 2017, which showed an adrenal adenoma of 17 x 13 mm and was diagnosed as an incidental finding at that time. In view of the new symptoms, the patient was started on spironolactone with little to no improvement in blood pressure and potassium levels.

IMPACT/DISCUSSION: Conns syndrome presenting after renal transplant is exceedingly rare and as of date, there are only two such cases occurring in the context of PCKD which are published in literature. Early diagnosis of Conns represents a reversible cause of hypertension and moreover, high aldosterone levels is associated with detrimental cardiovascular outcomes. The mechanism behind unmasking Conns syndrome is related to the newly transplanted kidney being able to actively secrete potassium into the tubules which was previously impaired in the old kidneys. Presence of PCKD adds diagnostic difficulty as the cysts obscure an adrenal adenoma. Release of renin by renal cysts makes the diagnosis of Conns syndrome tougher. It is important not to rely solely on the presence of hypokalemia in such cases. When medical treatment fails, as in our case, surgical resection of adenoma is mainstay of treatment. We suggest having a high index of suspicion and not solely relying on the presence of hypokalemia in these cases.

CONCLUSION: For patients with pre-existing Conns in the setting of a renal transplantation, the condition may be clinically silent until successful transplantation. It may be useful to consider further testing with ARR in suspected cases.

CORONARY CONUNDRUM: ACUTE MYOCARDIAL INFARCTION AS INITIAL PRESENTATION OF CATASTROPHIC ANTIPHOSPHOLIPID SYNDROME

Nova T. John. Hospital Medicine, Emory healthcare, Atlanta, GA. (Control ID #3392132)

LEARNING OBJECTIVE #1: Recognize the uncommon cardiac manifestation of catastrophic antiphospholipid syndrome in a young adult

LEARNING OBJECTIVE #2: Manage catastrophic antiphospholipid syndrome in a multidisciplinary theraputic approach

CASE: A 35-year old African American woman with history of Systemic Lupus Erythematosus(SLE) complicated by Lupus nephritis and recurrent thromboembolism on Apixaban presented with acute pleuritic chest pain for one day. She was diagnosed with acute pulmonary embolism(PE). Electrocardiogram showed normal sinus rhythm without ST changes. Initial troponin of 1.03 rose to a peak of 48.3. Echocardiogram showed ejection fraction of 45% with apical akinesis. Right ventricular size and function were normal. Emergent cardiac catheterization showed multiple grade IV-V LAD thrombi, treated by thrombectomy and suctioning. During her prolonged hospital course, she developed left upper extremity acute deep vein thrombosis(DVT) and subacute infarct in right thalami despite therapeutic anticoagulation. Repeat laboratory tests revealed new positive lupus anticoagulant, although negative for cardiolipin and beta-2 microglobulin antibodies. The diagnosis was consistent with catastrophic antiphospholipid antibody syndrome (CAPS). She had progressive renal failure from contrast induced nephropathy, septic shock and lupus nephritis requiring hemodialysis and MRSA bacteremia

related to dialysis catheter. She also had massive hemoptysis presumably due to enlarging cavitory lung lesions eroding into vasculature. Ultimately resulting in hypoxic respiratory failure requiring intubation and pulseless electrical activity arrest. A multidisciplinary approach to care was followed in collaboration with rheumatology, nephrology, hematology and cardiology subspecialties. Multimodality therapy included steroids, cyclophosphamide, plasmapheresis and rituximab. Despite her tenuous clinical course over two months, she made remarkable clinical recovery. Therapeutic heparin was bridged to warfarin, with the addition of aspirin, hydroxychloroquine and steroid taper. She was discharged home in stable condition with close outpatient follow-up

IMPACT/DISCUSSION: Acute MI is uncommon in young adults and prothrombotic states like CAPS should be considered as potential etiology especially with evidence of widespread thrombosis. High index of clinical suspicion is necessary for prompt diagnosis of CAPS. An aggressive multidisciplinary therapeutic approach is of paramount importance. Cornerstone of APS therapy is long term anticoagulation with warfarin. In CAPS, therapy is directed towards immunosuppression with steroids, cyclophosphamide, rituximab and plasmapheresis.

CONCLUSION: This case highlights the need for a collaborative team approach to a patient with CAPS.

Overall mortality rate has declined from 53 to 33% in the last decade with effective first line multimodality theraputic strategy.

COULD BACTEREMIA BE A SIGN OF MALIGNANCY? A CASE OF CLOSTRIDIUM SEPTICUM BACTEREMIA DUE TO B-CELL LYMPHOMA

Kevin Stephenoff, Amar Kohli. Internal Medicine, UPMC, Pittsburgh, PA. (Control ID #3391945)

LEARNING OBJECTIVE #1: Determine when further abdominal imaging/workup is indicated in patients presenting with sepsis

LEARNING OBJECTIVE #2: Examine relationship of Clostridium species bacteremia with intraabdominal malignancy

CASE: 78 year old man with history of Parkinson's Disease and chronic constipation presented with 2 weeks of low grade fever and an acute onset of 2 days of severe weakness and malaise. On review of systems, he also reported a 3 month history of mild, crampy, right-sided abdominal pain and occasional night sweats. He reported no nausea, vomiting, or diarrhea. Vital signs showed Temp 38.2, BP 107/54, HR 83, RR 18. Physical exam revealed no lymphadenopathy, mild right sided abdominal tenderness to palpation, no rebound, guarding, or signs of peritonitis. Laboratory studies showed a lactate 2.3, WBC 17.6, Hgb 8.5. Initial infectious workup with CXR and UA were unrevealing. Blood cultures were obtained. The patient was treated for presumed sepsis with fluid resuscitation and empiric vancomycin and piperacillin/tazobactam. A CT abd/pelvis was obtained revealing a large (18.7x13.1x16.0 cm), necrotic, right-sided abdominal mass congruent with the hepatic flexure of the colon with pockets of gas. No abscess was identified. Anaerobic blood cultures resulted as *Clostridium septicum*.

Surgical biopsy and debridement of the mass was performed and pathology showed diffuse large B-Cell lymphoma. The patient was continued on piperacillin/tazobactam, blood cultures cleared after 2 days, and the patient was later started on chemotherapy.

IMPACT/DISCUSSION: *Clostridium septicum* is a gram-positive, spore-forming, anaerobic bacteria found in the gut. Tumors invading the bowel mucosa can lead to pathological spread into the bloodstream. This case illustrated sepsis as the original presentation of intraabdominal large B-Cell lymphoma causing *C. septicum* bacteremia. The patient exhibited some nondescript signs of lymphoma and abdominal pathology prior to presentation with sepsis. Prompt abdominal imaging aided in recognizing the source of bacteremia and initiating treatment. In patients presenting with sepsis with no source, an internist should look for subtle signs and symptoms that may indicate further abdominal workup should be pursued.

Internists must have high suspicion for intraabdominal malignancy (primarily GI and hematological) with *C. septicum* bacteremia. In 1979, Koransky et al. showed malignancy was associated with bacteremia from this organism in 71% of cases reviewed. Positive blood cultures for *C. septicum* should trigger further workup for occult malignancy. If imaging reveals gas pockets within a mass, consider anaerobic bacterial species such as Clostridium causing gas gangrene. These cases require prompt antibiotic therapy and referral for surgical resection.

CONCLUSION: -Early recognition of malignant abdominal processes causing bacteremia/sepsis is imperative

-Intraabdominal malignancies must be suspected in cases of *Clostridium septicium* bacteremia

COULD IT BE THE FILTER? – A RARE PRESENTATION OF HEMODIALYSIS-INDUCED THROMBOCYTOPENIA IN A CIRRHOTIC PATIENT

Joseph Granade, William Brown. Internal Medicine, University of Alabama at Birmingham School of Medicine, Birmingham, AL. (Control ID #3390756)

LEARNING OBJECTIVE #1: Recognize the importance of monitoring for adverse effects to all forms of medical intervention.

LEARNING OBJECTIVE #2: Apply a systematic approach to establishing association for suspected adverse effects.

CASE: A 26-year-old female with a history of alcoholic cirrhosis and chronic pancreatitis presented with progressive epigastric abdominal pain consistent with prior episodes of pancreatitis. Her course was complicated by oliguric acute kidney injury (AKI) attributed to receiving contrast while in a volume depleted state. Intermittent hemodialysis (iHD) was initiated using the standard polysulfone membrane. On admission, the patient's platelet count was 256 x 10^9/L. After two iHD sessions, the patient's platelets fell to a nadir of 57 x 10^9/L. iHD was held for six days while assessing for spontaneous renal recovery and the platelets rose to 138 x 10^9/L during that period. When iHD was resumed for an additional three sessions the platelet count fell to a nadir of 42 x 10^9/L. The patient began to have low-volume bleeding from her access site. A coagulation profile and a factor 8 level were obtained and were consistent with liver failure coagulopathy. Over the course of another six-day line-holiday, the platelets again gradually rose to 160 x 10^9/L. Within 24 hours of resumption of iHD, the platelets fell to 65 x 10^9/L. Hemodialysis sessions were transitioned from heparin to sodium citrate, but platelet factor 4/heparin antibodies were negative, and thrombocytopenia recurred despite substitution. The polysulfone membrane was then replaced with a cellulose filter. The patient underwent two iHD sessions while the platelet count rose from 42 x 10^9/L to 115 x 10^9/L. A subsequent iHD session was erroneously conducted with a polysulfone filter and within 24 hours platelets fell to 42 x 10^9/L and the patient developed bright red blood per rectum. The cellulose filter was reintroduced, and no additional episodes of thrombocytopenia post-dialysis were recorded.

IMPACT/DISCUSSION: Hemodialysis-associated thrombocytopenia has been demonstrated in the literature, though it is often a benign phenomenon. The patient's comorbid impairment in platelet production due to cirrhosis likely impeded her compensatory response to a common physiological reaction to filter exposure. This case is unique in that an unfortunate medical error clearly demonstrated the effect of different filter types. To prove the relationship between an intervention and an adverse effect, it is imperative to use a systemic approach, such as the Naranjo probability scale, which takes into account prior reports of the reaction, occurrence after exposure, improvement with withdrawal of intervention, recurrence with re- exposure, and absence of effect with placebo. With score of nine, a definitive association between filter exposure and thrombocytopenia was established.

CONCLUSION: Filter reactions may result in clinically significant consequences. Identification and reporting of suspected adverse reactions are crucial to ensuring patient safety.

COXIELLA BURNETII (Q-FEVER) A RARE CAUSE OF GRANULOMATOUS INFLAMMATION OF THE LIVER WITH NORMAL LIVER FUNCTION TEST.

Rohit Jain[2]; Zainab Shahid[1]; Ricci Kalayanamitra[2]; Rama R. Vunnam[2]; Dhirisha Bhatt[2]; Ravi Patel[2]; Rezhan Hussein[2]; Reshma R. Golamari[3]; Nitasa Sahu[2]. [1]Internal Medicine, LECOM, Erie, PA; [2]Internal medicine, Penn State Milton S. Hershey Medical Center, Hershey, PA; [3]Internal Medicine, Penn State Health Milton S Hershey Medical Center, Hershey, PA. (Control ID #3389211)

LEARNING OBJECTIVE #1: Recognize the rare infection with Coxiella burnetii (Q-fever) in patients with fever and unexplained abdominal pain, normal transaminases and/or liver mass with biopsy showing granulomatous inflammation.

CASE: A 37-year-old woman with a history of pancreatitis and gastroesophageal reflux disease who presented with mid back pain for few days followed by worsening epigastric and right upper quadrant (RUQ) abdominal pain. She reported she had a cat at home; she had a fever of 38.5°C, chills, and fatigue but she did not have jaundice, change in bowel habits, hematochezia or melena. On physical examination, she had epigastric and RUQ tenderness. She had normal transaminases. Her Computerized Tomography of the abdomen and pelvis showed a three, centimeter(cm) liver lesion with suspected malignancy, Magnetic resonance imaging (MRI) of the liver confirmed the Three, cm lesion in the medial left hepatic lobe. Further imaging including magnetic resonance cholangiopancreatography and RUQ ultrasound, Hepatobiliary scintigraphy, were normal. Liver lesion biopsy was negative for malignancy but showed necrotizing granulomatous inflammation.

Broad Range PCR and cultures for bacteria, mycobacterium, and fungi showed no growth. Her workup including Histoplasma, Blastomyces urine and serum Ag, Beta D glucan, toxoplasma IgM, Interferon- Gamma Release Assays (IGRA), serum cryptococcal antigen, Antinuclear antibody and antineutrophil cytoplasmic antibodies (ANCA) were negative. HIV test was non-reactive. Her Bartonella serology, Coxiella burnetii serology, was sent out. Bartonella serology returned normal but Coxiella serology showed a positive IgM phase 1 (titer 1:16), IgM phase 2 negative, IgG phase 1 & 2 negative. Coxiella Convalescent titers showed a positive Coxiella IgM phase 1 (titer 1:32) and a positive Coxiella IgM phase 2 (titer 1:16), IgG titers negative. She was treated with Doxycycline for two weeks, at the follow-up visit, her symptoms resolved. Repeat MRI of the liver, after two months from her illness, showed resolution of the liver lesion.

IMPACT/DISCUSSION: Per the literature review there are only 0.28 cases of Q-fever per 1 million people in the United States. More than 50% of Q fever are asymptomatic; around 2% gets hospitalized. If patients develop hepatitis with a fever of unknown origin, it shows characteristic granulomas on liver biopsy. Transaminases are typically elevated (85% cases); our patient had normal transaminases level, which made this case unique.

CONCLUSION: Consider infection with Coxiella burnetii (Q-fever) in the differential diagnosis of patients with fever, unexplained abdominal pain/liver lesion with granulomatous inflammation on liver biopsy. Although transaminases are typically elevated in granulomatous inflammation of the liver, the normal liver function test does not rule out Coxiella burnetii infection.

CRACKING THE CASE OF AN UNUSUAL CAUSE OF ABDOMINAL PAIN

Sara Abrahams[1]; Eun Ji Kim[2]. [1]Medical School, Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY; [2]General Internal Medicine, Northwell Hofstra School of Medicine, Lake Success, NY. (Control ID #3347077)

LEARNING OBJECTIVE #1: To recognize an abnormal cause of abdominal pain in the primary care clinic

LEARNING OBJECTIVE #2: Understand the radiologic work-up for left renal vein entrapment syndrome

CASE: A 44-year-old man with gastroesophageal reflux disease, nephrolithiasis, and history of appendectomy presented to primary care clinic with 6-8 weeks of worsening, intermittent abdominal pain localized to the left lower abdomen. The patient rated the pain as a 4-5/10, achy in nature, and it was not associated with eating or bowel movements. The abdominal pain differed from his pain with nephrolithiasis in location and severity. Review of systems was negative for hematuria, blood in the stool, and abdominal or scrotal masses. The patient had one rectal polyp removed on prior colonoscopy, completed due to family history of colon cancer. Vital signs were within normal limits. Abdominal exam did not reveal any visible or palpable masses, and the abdomen was non-distended, non-tender to palpation with normal bowel sounds. Laboratory findings from a complete blood count with differential, complete metabolic panel, and urinalysis were within normal limits. Abdominal ultrasound was completed with no significant findings. Next, computed tomography (CT) of the abdomen/pelvis with contrast was completed to investigate a possible underlying structural etiology and to rule out malignancy given the family history of colon cancer. This demonstrated left renal vein stenosis secondary to compression by the superior mesenteric artery, consistent with left renal vein entrapment syndrome (LVES) also known as Nutcracker Syndrome (NCS). The patient was referred to vascular surgery who recommended observation given the lack of serious clinical signs, such as hematuria or orthostatic proteinuria, and the high risk of morbidity and mortality associated with surgical intervention.

IMPACT/DISCUSSION: LVES occurs when the renal vein is compressed, commonly between the superior mesenteric artery and abdominal aorta. While this typically resolves, clinical

sequelae include renal vein hypertension, thrombosis, chronic kidney disease, and infertility. NCS can present as abdominal or flank pain, hematuria, orthostatic proteinuria, fatigue, and scrotal swelling. The current diagnostic gold standard of NCS is retrograde renal venography coupled with measuring renocaval pressure. However, this diagnostic test is controversial given its invasive nature. Increasingly, abdominal ultrasound and abdominal CT with contrast have been used as less-invasive and more cost-effective alternatives. Our patient's abdominal ultrasound was normal, and only upon further investigation with abdominal CT was the radiologic finding of the "beak sign", demonstrating narrowing of the left renal vein secondary to compression, revealed.

CONCLUSION: NCS represents a "must-not-miss" diagnosis for the common complaint of abdominal pain due to potential morbidity and mortality. A thorough differential diagnosis coupled with a stepwise radiologic work-up of abdominal pain were key to diagnosis.

CRACKING THE DIAGNOSTIC BIAS: A CASE OF PROGRESSIVE INTERSTITIAL LUNG DISEASE IN A TRANSFER PATIENT

Preetha Hebbar[2]; Andrew Schreiner[1]. [1]General Internal Medicine, Medical University of South Carolina, Charleston, SC; [2]College of Medicine, Medical University of South Carolina, Charleston, SC. (Control ID #3391825)

LEARNING OBJECTIVE #1: Recognize the role of cognitive bias in the diagnosis of patients undergoing transfers of care.

LEARNING OBJECTIVE #2: Identify the similarities between granulomatosis with polyangiitis (GPA) and cocaine-induced lung injury, and recognize the importance of obtaining an accurate exposure history.

CASE: A 60 year old female with progressive hypoxic respiratory failure presented from an outside hospital (OSH) for further evaluation. Evaluation of new-onset dyspnea began 18 months prior and revealed evidence of hypoxia, interstitial lung disease (ILD) on chest CT, and a positive anti-neutrophil cytoplasmic autoantibody (ANCA), resulting in a diagnosis of GPA. Glucocorticoids and rituximab therapies yielded little improvement. One week prior to presentation, she was admitted to an OSH with worsening hypoxia and transferred for evaluation of pulmonary HTN. On arrival, the patient had a negative review of systems with the exception of dyspnea. She denied occupational exposures or illicit drug use. Her RR was 24 breaths/min, and her O_2 saturation was 89% on 10 L of O_2, increased from a 7L/min home requirement. Heart exam revealed tachycardia and regular rhythm with a II/VI systolic murmur at the left lower sternal border. Pulmonary exam revealed fine crackles to the mid-lung bilaterally. Distention of neck veins and nail clubbing were present.

Labs revealed a hemoglobin of 11.7 g/dL, creatinine of 0.7 mg/dL, and urinalysis with no evidence of hematuria. A lung CT demonstrated diffuse ILD with extensive fibrosis, traction bronchiectasis, and honeycombing. Serologic studies revealed an ANCA of 1:80 with a negative anti-proteinase 3, with otherwise normal inflammatory markers and complements, A right heart catheterization showed elevated right and left heart filling pressures. High dose steroids led to minimal improvement. The progression and severity of the lung disease in absence of renal, sinus, ophthalmic and neurologic complications of GPA remained a concern. On day 6 of hospitalization, the patient disclosed for the first time previous crack cocaine use of 20 years. Given this relevant history, she was diagnosed with chronic cocaine-induced lung injury.

IMPACT/DISCUSSION: Internists routinely confront bias in the diagnostic process, particularly in transfers of care. This case highlights potential contributions of anchoring and framing bias. Without an accurate exposure history, the age of onset, ILD findings, and a positive ANCA confirmed suspicion for a vasculitis. As lung function worsened, the absence of common features of GPA raised doubt for this diagnosis. Further discussions with this patient built rapport and resulted in a disclosure of an accurate substance use history.

CONCLUSION: 1. Cocaine-induced lung injury can mimic GPA with radiographic evidence of interstitial lung disease and often positive ANCAs.

2. Obtaining an accurate exposure history plays a critical role in diagnosing ILD, and trust-building is required for patients to divulge the use of illicit and stigmatized substances.

CRASHING INTO A DIAGNOSIS: NEUROCYSTICERCOSIS, A CAUSE OF NEW-ONSET SEIZURE.

Fazad N. Mohamed. Internal Medicine, ChristianaCare, Newark, DE. (Control ID #3391948)

LEARNING OBJECTIVE #1: Diagnose neurocysticercosis in the setting of new-onset seizure.

LEARNING OBJECTIVE #2: Manage calcified lesions based upon Infectious Diseases Society of America (IDSA) guidelines.

CASE: A 53-year-old Spanish-speaking male with no past history presented to the Emergency Department (ED) following new-onset seizure and consequent motor vehicle collision. He reported a sudden syncopal episode followed by a return of consciousness in which he found himself within a crumpled car. During the moments leading up to loss of consciousness, he denied any headache, chest pain, dyspnea, or diaphoresis. The patient immigrated to the United States from Mexico fourteen years ago. He denied any sick contacts, recent travel or tuberculosis exposure. The patient had always eaten a lot of pork, but he had no recent dietary or lifestyle changes. He denied steroids, illicit drug, alcohol, or tobacco use. He reported no weight loss, fevers, chills, or night sweats. In the ED, the patient was hemodynamically stable but post-ictal. Laboratory results were significant for lactate of 8.7, anion gap of 19, troponin less than 0.01, and mild leukocytosis at approximately 12. Electrocardiogram (EKG) depicted normal sinus rhythm. Computerized Tomography (CT) of abdomen and cervical spine depicted no traumatic injuries. CT of the head revealed a six-millimeter calcified lesion within the left frontal lobe surrounded by vasogenic edema. The patient was given 1000 milligrams (mg) of levetiracetam in order to prevent further seizure activity.

During hospitalization, Human Immunodeficiency Virus (HIV) and Rapid Plasma Reagin (RPR) returned negative. Magnetic Resonance Imaging (MRI) of the brain confirmed a focal calcification in the left frontal lobe with peripheral rim enhancement. Findings were consistent with neurocysticercosis rather than primary malignancy, metastasis or vascular malformation. Per Infectious Diseases Society of America (IDSA) guidelines, no

antiparasitic treatment was indicated in the setting of significant lesion calcification. The patient was treated with 500mg of levetiracetam twice a day to prevent recurrent seizures.

IMPACT/DISCUSSION: Though clinicians in the United States may not be familiar with the sequelae of cysticercosis, infection with *Taenia solium* is a common cause of new-onset seizure throughout the world, especially in endemic areas such as Mexico. As immigration continues to contribute to the American patient population, medical professionals should consider neurocysticercosis in their differential diagnoses. This vignette also highlights IDSA guidelines which recommend seizure prophylaxis rather than antiparasitic therapy in the setting of lesion calcification.

CONCLUSION: Neurocysticercosis is the leading cause of adult-onset epilepsy worldwide.

When patients from endemic countries present with new/adult-onset seizure, consider neurocysticercosis in the differential diagnosis.

In the setting of calcified lesions, treatment is directed toward seizure prophylaxis rather than antiparasitic therapy.

CSF IS ALL YOU NEED: PRIMARY CNS LYMPHOMA IN AN IMMUNOCOMPETENT PATIENT

Akanksha Bhardwaj[1]; Robert J. DeGrazia[2]; Jennifer N. Goldstein[1]. [1]Internal Medicine, Christiana Care, Wilmington, DE; [2]Internal Medicine, Christiana Care Health System, Aberdeen, MD. (Control ID #3366834)

LEARNING OBJECTIVE #1: Recognize how to diagnose primary CNS lymphoma

LEARNING OBJECTIVE #2: Distinguish primary CNS lymphoma from other causes of leptomeningeal enhancement

CASE: 46 year old male with no past medical history presented for evaluation of progressive weakness. His symptoms began 4 months prior with a sore throat and cough followed by right-sided facial weakness. He was treated with steroids for presumed Bell's palsy without improvement in his symptoms. Over the next two months, he developed bilateral wrist pain along with paresthesia of the left arm and leg. In addition to neurological symptoms, he endorsed intentional weight loss of 60 pounds over 5 months. His physical exam revealed moderate bilateral facial weakness. Upper and lower extremities elicited 4/5 bilateral weakness with intact sensation. Deep tendon reflexes were 0/4 and Babinski sign was negative. The MRI of the brain and spine showed non mass-like enhancement of left 7th/8th cranial nerves along with leptomeningeal enhancement of thoracic spine and diffuse thickening and abnormal enhancement of the cauda equina. Lumbar puncture revealed CSF total protein of 618, RBC <1, glucose 21, and WBC of 410. Flow cytometry confirmed the presence of monoclonal B-cell lymphoma. He was started on MATRix regimen including methotrexate, cytarabine, thiotepa, and rituximab for primary CNS lymphoma and is currently on his fourth cycle of chemotherapy.

IMPACT/DISCUSSION: Primary central nervous system lymphoma (PCNSL) represents 4% of newly diagnosed primary CNS tumors. Historically, patients with immunodeficiency related to HIV have carried the greatest risk of developing PCNSL. However, with the advent of HAART, incidence has decreased among these patients and increased in immunocompetent patients to 51 cases in 10 million per year. MRI with gadolinium is the preferred imaging modality as CT scan can miss 10% of PCNSL. The most common radiographic features include solitary, non-hemorrhagic lesions in the periventricular region. Up to 40% of patients have meningeal involvement. Leptomeningeal enhancement can be seen in other conditions including autoimmune and infectious diseases, and other brain tumors. Diagnosis requires CSF evaluation including flow cytometry, and immunoglobulin heavy-chain gene rearrangement. Presence of neoplastic cells in CSF confirms the diagnosis of PCNSL. Full ophthalmologic evaluation using slit lamp should be performed even in the absence of visual symptoms. Up to 38% of patients with ocular involvement have no visual symptoms. Suspected involvement should be evaluated with intraocular biopsy. If CSF and ophthalmologic evaluation is inconclusive, then biopsy of cerebral tissue is performed to establish the diagnosis of PCNSL.

CONCLUSION: Incidence of PCNSL has decreased in immunodeficient and increased in immunocompetent patients

Presence of neoplastic cells in CSF avoids the need for cerebral biopsy

Ophthalmologic evaluation should be performed even in the absence of visual symptoms

CUSHING'S DISEASE WITH AN UNEXPECTED OVERLAP WITH ITP

Harriet King. Internal Medicine, University of Virginia, Charlottesville, VA. (Control ID #3390777)

LEARNING OBJECTIVE #1: Recognize the clinical features of Cushing's disease.

LEARNING OBJECTIVE #2: Differentiate between obesity-related metabolic syndrome and Cushing syndrome.

CASE: A 25 year-old male presented to a local Emergency Department after a fall at home. He was in his usual state of health prior to five months ago when he was diagnosed with diabetes. Since that time, he developed progressive weakness to the point that he had difficulty getting up from a chair without assistance. His diabetes became symptomatic with polydipsia and polyuria. He also reported worsening depression and insomnia.

His physical exam was remarkable for obesity, flat affect, round facial features without plethora, dorsal fat pad, supraclavicular fat pads, violaceous striae across his abdomen and arms, multiple ecchymoses, and proximal weakness in his upper and lower extremities. Initial laboratory evaluation was notable for potassium 2.2, glucose 451, and platelet count 70,000. Further evaluation demonstrated urine free cortisol 2,759 (normal < 45), morning serum cortisol 75.2 (normal < 18), ACTH 150 (normal < 63), free testosterone 22.4 (normal > 47), undetectable LH, undetectable FSH, and Prolactin 4.8. MRI Brain revealed a 7x10 mm hypo-enhancing anterior pituitary gland microadenoma.

Over the next week, his platelets decreased to 41,000. He did not respond appropriately to platelet transfusions, raising concern for ITP. Evaluation for other causes of thrombocytopenia, including bone marrow biopsy, was unrevealing. He began treatment with Romiplastin, a thrombopoietin receptor agonist. He also developed severe back pain and was found to have an acute T7 compression fracture. Given the continued delay in surgery, he began medical management of Cushing's with Ketoconazole. His platelet counts slowly normalized.

More than one month later, he underwent transsphenoidal resection of the microadenoma. His serum cortisol and ACTH declined appropriately post-operatively. His diabetes and accompanying polydipsia and polyuria resolved after surgery. He lost 109 pounds over the course of 3 months. He still requires use of a walker for long distances. His depression is improving with a noticeable change in his affect.

IMPACT/DISCUSSION: Endogenous Cushing syndrome is relatively rare but likely underrecognized given its subtle presenting symptoms and overlap with obesity-related metabolic syndrome. This case demonstrates the potential for severe complications of Cushing syndrome including myopathy, electrolyte disarray, osteoporosis, diabetes, hypertension, and depression with significant morbidity for this particular patient.

This case also demonstrates an unusual complication with thrombocytopenia, for which there is no known prior association between Cushing's disease and idiopathic thrombocytopenic purpura.

CONCLUSION: Consider alternative causes of diabetes, hypertension, unexplained weight gain, and depression, particularly in patients with increasingly difficult to manage diabetes and other symptoms concerning for Cushing syndrome.

CUTIBACTERIUM CAUSING AN UGLY COMPLICATION: A RARE CASE OF C. ACNES SEPTIC ARTHRITIS

Aleksandra Safonova, Yi Li, Amar Kohli. Internal Medicine, UPMC, Mars, PA. (Control ID #3391571)

LEARNING OBJECTIVE #1: Identify predisposing factors to Cutibacterium acnes infection in native joints.

LEARNING OBJECTIVE #2: Distinguish between infection and contamination of Cutibacterium acnes in culture.

CASE: A 37-year-old man with IgA nephropathy induced ESRD on HD through a right femoral TDC presented with one-week of left shoulder pain. Pain was described as sharp and progressively worsening over the last week. No recent trauma or previous shoulder surgeries. Exam revealed stable vitals. The left shoulder was erythematous and tender with limited range of motion. Labs revealed normal CBC, ESR of 75, and CRP of 12. CT of the left shoulder showed joint erosion and remodeling. Aspiration of the joint revealed 79000

WBC's and negative gram stain. The TDC could not be removed due to an exhaustion of alternate access sites. Blood and synovial fluid cultures showed no growth. Anaerobic deep wound culture grew C. acnes on day five. He was discharged on 2 weeks of IV cefazolin. He returned three weeks later with continued left shoulder pain. ESR was now 115 and CRP was 22.9. All culture data was negative and he was discharged on 4 weeks of cefazolin to treat suspected recurrent C. acnes. At follow up appointment two weeks later, patient was asymptomatic and clinically improved.

IMPACT/DISCUSSION: Septic arthritis in a native joint is most commonly attributed to S. aureus. Dubost et. al revealed the most common causes of septic arthritis in native joints were due to staphylococci, streptococci, and gram-negative rods with infections from anaerobes infecting 2 patients (0.5%). With an increase in shoulder surgeries, there has been an increase in septic joints infected with C. acnes. However, septic arthritis infections with C. acnes remains exceedingly rare.

C. acnes is considered normal skin flora. It is recognized as causing endocarditis, meningitis, and osteomyelitis and joint infections with the greatest predisposing factor being prior surgery or penetrating trauma. Since 1982, only 18 case reports of native joint infections with C. acnes have been published. Diagnosis can be delayed as cultures take up to 21 days to result. Culture of C. acnes from joints is commonly attributed to contamination as it is also prevalent in skin flora. In this case, the patient's x-ray showed joint destruction consistent with osteoarthritis, which was likely the predisposing factor for initial infection.

Anaerobic deep wound cultures took five days to grow, yet blood cultures and synovial fluid cultures finalized as negative. While the culture growing C. acnes could've been a contaminant, this seems unlikely in the setting of pure growth of C. acnes (whereas contaminants would show a variety of organisms), native joint infection with no possible contamination from surgical source, and clinical improvement on cefazolin.

CONCLUSION: Overall, there needs to be a strong suspicion for anaerobic bacterial infection, including C. acnes, in the setting of a native joint septic arthritis with negative cultures and an indolent time course.

CYCLOPHOSPHAMIDE-INDUCED PNEUMONITIS: A RARE COMPLICATION

MARIA T. GAMERO HUAMAN[1]; Sheema Zafar[1]; Yelena Averbukh[2]. [1]INTERNAL MEDICINE, MONTEFIORE MEDICAL CENTER, Bronx, NY; [2]Medicine, Montefiore Medical Center, Bronx, NY. (Control ID #3392346)

LEARNING OBJECTIVE #1: Distinguish the different etiologies of pneumonitis.

LEARNING OBJECTIVE #2: Recognize cyclophosphamide related pulmonary toxicity.

CASE: A 43-year-old female with SLE complicated by pericarditis and lupus nephritis Class 5, presented with chest pain and dyspnea five days following administration of a maintenance dose of CPA for management of SLE. Chest pain was described as constant, retrosternal, pleuritic-like, exacerbated with lying down, associated with shortness of breath and palpitations. Similar episodes had occurred after CPA administration before, but ultimately resolved without additional investigation or treatment. Physical exam was significant for presence of bibasilar crackles and absence of pericardial rub. ECG was negative for ST elevations and PR depressions. Serum dsDNA antibodies and C3/C4 complement level were normal.

C-reactive protein level was elevated to 9.8 mg/dl. Transthoracic echocardiogram was negative for pericardial effusion and showed normal cardiac function. Chest imaging showed diffuse interstitial ground glass pattern consistent with pneumonitis. Initial therapy with NSAIDS for presumed atypical pericarditis given patient's history was not effective to relieve patient's symptoms. As respiratory symptoms of dyspnea and cough continued to worsen requiring administration of oxygen therapy, high dose corticosteroid therapy was started for presumed CPA-induced pneumonitis with significant clinical improvement noted. Patient was discharged home on steroid taper regimen.

IMPACT/DISCUSSION: Pulmonary complications due to CPA are infrequent and described in less than 1% of patients treated with CPA. There are two types of CPA related pulmonary complications described: the early and the late-onset types. Depending of the type, time frame for complications after exposure to CPA, treatment and prognosis varies. In the early-onset type, symptoms of pneumonitis may develop within days to up to 6 months after CPA exposure, and typically improve with corticosteroid therapy. However, the late- onset type of pulmonary complications usually emerges years after CPA treatment, responds poorly to corticosteroid therapy, and is associated with high mortality rate of more than 60%.

In our patient, pneumonitis was found shortly following administration of CPA. Given the temporal relationship between onset of symptoms and the administration of CPA, medication related pneumonitis became the top differential. Patient responded very well to high dose steroid therapy confirming our diagnosis of CPA induced pneumonitis. Other etiology of pneumonitis such as SLE flare was rule out with non-elevated levels of dsDNA and normal complement C3/C4 levels.

CONCLUSION: The infrequency of pulmonary CPA-related toxicity requires high degree of clinical suspicion on a part of the diagnostician. Physicians need to be aware of CPA related pneumonitis as CPA is widely used for various medical conditions and may potentially lead to life threatening complications unless recognized in the timely manner.

CYTOMEGALOVIRUS COLITIS IN AN IMMUNOCOMPETENT PATIENT

Bing Chen, Pavan Paka, Geeta Varghese. Medicine, Mount Sinai St Luke's and West, New York, NY. (Control ID #3367443)

LEARNING OBJECTIVE #1: Learning Objective: Recognize cytomegalovirus colitis in immunocompetent hosts.

CASE: A 71-year-old male with history of hypertension, hyperlipidemia, and pre-diabetes presented to clinic with one episode of watery stool, which was associated with anorexia for 1 week. Over the last 4 months, he experienced a 17-pound weight loss. He denied fever, chills, abdominal pain, nausea, vomiting, or melena. Denied recent travel, or taking any glucocorticoids or other immunosuppressive medications. Vital signs were normal. His physical exam was normal including a soft, nontender abdomen. Labs revealed acute kidney injury (Cr: 1.34 mg/dL), hyponatremia (Na: 132 mmol/L), mildly elevated monocyte (979 cells/uL), and no other abnormalities. HIV test was negative. Given the unintentional weight loss and diarrhea, he was sent for a colonoscopy. The colonoscopy showed 4 polyps (3mm, 3mm, 8mm, 5mm) which were biopsied. In addition to tubular adenomas, the pathology showed areas of stromal inflammation with neutrophilic and histiocytic infiltrates that contain few large mesenchymal cells with granular nuclei and cytoplasm that were consistent with cytomegalovirus infection. Patient was admitted to a hospital for intravenous antiviral agent in setting of AKI for the treatment of CMV colitis and then discharged home on oral valganciclovir to complete a three-week course of treatment. In the follow-up visit, patient was doing well and had improved appetite with weight gain.

IMPACT/DISCUSSION: CMV colitis almost always occurs in immunosuppressed patients such as AIDS, transplant, and chemotherapy patients. It is rarely reported in immunocompetent hosts as in this patient. In a case series published in 2014, a total of 33 immunocompetent patients with CMV colitis were identified, of which the median age was about 70 years and that 75% of the patients were 60 years old or older. Diarrhea (76%), followed by abdominal pain (52%), hematochezia/melena/bloody stool (27%), and fever (18%) were the most common symptoms. Endoscopic findings included ulcerations, mucous edema, inflamed mucosa, and minimal findings. In 8 cases (24.2%), the disease was self-limited and improved without any treatments, which was similar to another study published in 2003, in which the spontaneous remission rate was 32%. Patients who received treatment usually had favorable outcomes. There is no clear criteria to distinguish patients who do not need to be treated. However, advanced age and male gender has been associated with higher morality. These risk factors, in addition to his symptoms and AKI contributed to his treatment decision.

CONCLUSION: This case reminds us that the CMV colitis can occur not only in immunocompromised patients but also in the immunocompetent host, especially in the elderly. Further research with more cases included is needed to study the risk factors, diagnose, and optimal treatment of those patients.

CYTOMEGALOVIRUS REACTIVATION IN A PATIENT WITH SYSTEMIC LUPUS ERYTHEMATOSUS ON LONG-TERM BELIMUMAB THERAPY

Joshpaul Dhillon. Internal Medicine, Medstar Washington Hospital Center, Washington, DC. (Control ID #3392377)

LEARNING OBJECTIVE #1: Understand the unique infections that can occur when using biologics for the treatment of SLE

CASE: 55 year old African-American female with a 12 year history of SLE with secondary Sjogren's. Her lupus was manifested by polyarthritis, proteinuria, and serologies positive for ANA, SSA, and RNP antibodies. She was managed with methotrexate (MTX) monotherapy for a number of years, however, because of poorly controlled arthritis, monthly belimumab infusions were added. At the time of presentation, the patient was on MTX 15 mg weekly and had been on belimumab IV infusions for approximately 2 ½ years. She had not been on prednisone for over a year. The patient presented to the ED with a one week history of fever, chills, myalgias, nausea, vomiting, and profuse watery diarrhea. On admission, she was noted to be febrile with tachycardia with labs significant for hyperkalemia (5.7 MMOL/L) and transaminitis (AST=166 U/L, ALT=119 U/L). Her workup was negative for Monospot, HIV, and Hepatitis B and C. CT scan of abdomen and pelvis revealed enlarged portal and left-sided inguinal lymph nodes but no other findings to account for her clinical presentation.

Further infectious testing revealed positive CMV IgM levels and an increased CMV viral load of 1493 copies/mL. She was started on Valganciclovir with a final diagnosis of CMV ileitis and hepatitis. MTX was held throughout her hospitalization and belimumab was subsequently discontinued.

IMPACT/DISCUSSION: A number of case reports and large scale studies have described CMV infection associated with SLE treatment, but almost exclusively in the setting of acute flares or high dose corticosteroid use. Our patient had a unique presentation of CMV infection after being on belimumab for a period of 2 ½ years in the setting of clinically quiescent SLE. It is unclear whether it was the combination of methotrexate and belimumab that predisposed her to CMV reactivation or beliumumab alone. However, since our patient did not have issues with infections while on MTX for over 10 years, one can postulate that belimumab perhaps contributed to her CMV infection, whether through additive immunosuppresion with methotrexate or via a different pathway.

CONCLUSION: This patient demonstrates the importance of ongoing monitoring for opportunistic infections especially when combining multiple immunosuppressive medications.

CYTOPENIA SECONDARY TO HAIRY CELL LEUKEMIA: A RARE INCIDENTAL DIAGNOSIS

Anisha Daxini[1]; Muqsita Nashat[2]

[1]Internal Medicine, Nazareth Hospital, Philadelphia, PA; [2]Internal Medicine, Nazareth Hospital, Philadelphia, PA. (Control ID #3388530)

LEARNING OBJECTIVE #1: Recognize Hairy Cell Leukemia as a rare cause of cytopenia in patients with splenomegaly without liver disease.

CASE: A 68-year-old Caucasian male who was a former smoker with a past history of coronary artery bypass surgery five years ago and a left hip replacement presented to the hospital with complaints of one-day history of acute on chronic right hip pain that started suddenly while he was walking to the bathroom. He drank 1 to 2 glasses of alcohol per week. His home medications included 81 mg Aspirin daily and had no family history of blood disorders. Physical exam showed normal vital signs, significant point tenderness of the right trochanteric area and splenomegaly. Blood work showed a WBC of 2700/μL, hemoglobin 14.5 gm/dL, MCV 102.8 fl, platelets 64,000/μL and absolute neutrophil count (ANC) 1400/μL. His complete metabolic panel, serum vitamin B12 and folic acid were normal. CT scan of the right hip showed acute fracture of the right femoral head and neck in underlying hip osteoarthritis. Ultrasound of the abdomen with doppler showed splenomegaly (17 cm), hepatic steatosis and patent portal vein. Serologies for Hepatitis B, C and HIV were negative. Further work up to evaluate his cytopenia and splenomegaly included peripheral blood flow cytometry which showed small population of CD103 positive clonal B cells representing Hairy Cell Leukemia (HCL) that tested positive for BRAFV 600 E mutation consistent with diagnosis of HCL. Patient had an open reduction and internal fixation of right hip and was discharged home with outpatient follow up with the Hematologist.

IMPACT/DISCUSSION: HCL is a rare hematological malignancy representing less than 1% of lymphoid neoplasms. It is an uncommon chronic B cell lymphoproliferative disorder and is characterized by collection of small mature B cells with abundant cytoplasm and hairy projections within the peripheral blood, bone marrow and splenic red pulp leading to peripheral cytopenia and splenomegaly. Exposure to radiation, pesticides and farming may be possible risk factors. Twenty five percent of patients are asymptomatic. Symptomatic patients present with generalized fatigue, weight loss, frequent infections, gingival bleeding, ecchymoses, epistaxis, or menorrhagia. Palpable splenomegaly is a classic feature on physical exam.

Laboratory findings may show pancytopenia in 60-80% of patients. Peripheral smear demonstrates cytopenia and HCL tumor cells. Flow cytometry and BRAF V600E mutation are important to confirm the diagnosis. Bone marrow biopsy is often not attainable because of fibrosis. Indications for treatment include constitutional symptoms that interfere with quality of life, symptomatic splenomegaly and significant cytopenia (Hb <11 g/dL, platelets <100,000/μL, and ANC <1,000/μL). Purine analogs are the preferred initial treatment with a durable response seen in greater than 90% of patients.

CONCLUSION: Hairy Cell Leukemia though rare should be considered in patients presenting with asymptomatic cytopenia and splenomegaly.

DANGERS OF SKIN POPPING: WOUND BOTULISM MIMICKING A MYASTHENIC CRISIS

Anthony Siudela[1]; David Janz[2]

[1]Medicine, Tulane University School of Medicine, New Orleans, LA; [2]Medicine, LSU School of Medicine in New Orleans, New Orleans, LA. (Control ID #3373130)

LEARNING OBJECTIVE #1: Describe skin popping as a route of administration for illicit drug use

LEARNING OBJECTIVE #2: Recognize the clinical presentation of botulism infection

CASE: A 33-year-old man presented with a 1-day history of progressively worsening diplopia. He later developed dysarthria, generalized muscle weakness, and shortness of breath. He used heroin by skin popping with his last use 1-2 days prior to presentation. He was diaphoretic and appeared uncomfortable while taking shallow breaths. Speech was slurred. He had bilateral ptosis with intermittent dysconjugate gaze as well as bilateral vertical nystagmus. Several erythematous, indurated lesions were present on his anterior forearms. Ice pack test revealed decreased ptosis with subjective improvement of diplopia. No acute infarct, mass lesion, or hemorrhage was appreciated on CT or MRI of the brain His respiratory status subsequently deteriorated and he required intubation. Antibody testing for myasthenia gravis returned negative and there was no evidence of thymoma on CT imaging. Anterior forearm abscesses were drained. C. botulinum and Botulinum toxin Type A were isolated from both the tissue culture as well as a wound swab culture from right arm. Treatment with antitoxin, ampicillin, and metronidazole was initiated. His strength and clinical picture improved.

IMPACT/DISCUSSION: Botulism is a rapidly progressive, but reversible, paralytic disease that is precipitated by infection with the neurotoxin produced by Clostridium botulinum. While traditional teaching is that the disease is a foodborne illness, there have been an increased number of reported wound botulism cases in recent years. This spike can be attributed to the growing number of intravenous drug users and opioid misuse in the United States. It is important that clinicians recognize the importance of including wound botulism in their differential diagnosis for a patient presenting with symptoms of progressive weakness, diplopia, and other bulbar symptoms, specifically in those with intravenous drug use. Botulism can cause severe respiratory distress which can be fatal making prompt identification of the disease a priority. Rapid administration of the botulinum toxin after symptom onset decreases mortality and morbidity associated with the disease.

The patient in this case practiced skin popping, a method of injecting illicit drugs directly into the skin in order to decrease the risk of overdose and to achieve slower absorption of the drug. Skin popping is a major risk factor to the development of wound botulism; it creates the perfect anaerobic environment that allows C. botulinum to germinate and produce its toxin. Most reported cases of wound botulism are associated with the use of black tar heroin produced in Mexico that is illegally transported to the United States.

CONCLUSION: While botulism has traditionally been associated with food-borne illnesses, new risk factors can lead internists to this diagnosis

as wound infections from skin popping can result in a similar clinical presentation.

DEADLY STRING: CONNECTING AN EYE TO THE LIVER

Tomoyuki Funato[1]; Akihito Yoshida[1]; Makito Yaegashi[2]; Sandra Y. Moody[3]

[1]General internal medicine, Kameda medical Center, Kamogawa, Chiba, Japan; [2]Department of General Internal Medicine, Kameda Medical Center, Kamogawa, Chiba, Japan; [3]Post-Graduate Education/Medicine, Kameda Medica Center & UCSF/SFVAMC, Kamogawa City, Chiba Prefecture, Japan. (Control ID #3387644)

LEARNING OBJECTIVE #1: Search for a source of infection in patients with endogenous endophthalmitis

LEARNING OBJECTIVE #2: Initiate antibiotics as soon as possible when endogenous bacterial endophthalmitis is suspected

CASE: A 78-year-old woman with hypertension, dyslipidemia, angina pectoris, and atrial fibrillation presented with one-day of left eye pain, decreased vision, and fever. On admission, she had a temperature of 38.3°C, hypopyon in her left eye and liver percussion tenderness. Her WBC was 13400/μL, AST 50 U/L, ALT 59 U/L, LD 291 U/L, ALP 635 U/L, and γ-GTP 164 U/L. Abdominal computed tomography showed two right lobe liver masses (55 and 50 mm). Two sets of blood cultures drawn on admission yielded Klebsiella pneumoniae with viscous colonies showing a positive string test. Presumed Klebsiella pneumoniae liver abscess and endogenous bacterial endophthalmitis of the left eye was diagnosed, and intravenous (IV) cefazolin and intravitreal ceftazidime and vancomycin followed by oral antibiotics were initiated for 6 weeks. On hospital day 3, drainage of the liver abscess was performed and the culture confirmed Klebsiella pneumoniae. Because her visual acuity deteriorated, evisceration of the left eye was performed on hospital day 9. IV antibiotic therapy continued, and the patient was discharged on hospital day 45 in stable condition.

IMPACT/DISCUSSION: An acute course of unilateral eye pain with hypopyon and visual impairment requires early intervention. Differential diagnosis for hypopyon includes bacterial endophthalmitis, cytomegalovirus retinitis, and uveitis caused by multiple diseases such as sarcoidosis, Behçet disease, Harada disease, fungal endophthalmitis, and acute retinal necrosis. Intravenous and intravitreous antibiotic treatment should be initiated as soon as possible to avoid the need for eye evisceration when endogenous bacterial endophthalmitis (EBE) is suspected. The incidence of EBE among patients with bacterial liver abscess ranges from approximately 1% to 8%. Over 60% of patients with EBE had an extraocular focus of infection and suppurative liver abscess was the most common source. A study reported that 77% of cases of endogenous endophthalmitis found in East Asia was caused by Klebsiella. Invasive liver abscess caused by Klebsiella pneumonia often yielded a positive string test, a formation of a viscous string larger than 0.5 cm in length. Nearly 80% of patients with endogenous Klebsiella pneumoniae endophthalmitis had poor outcomes (visual acuity worse than 4/200) and research reveals 27% required evisceration, which was also performed in our patient. Early diagnosis and intervention including systemic and intravitreal antibiotic treatment are essential for preventing poor visual outcomes.

CONCLUSION: Liver abscess is the most common source of infection in patients with endogenous bacterial endophthalmitis. Early investigation for a possible source of infection, including the liver, is crucial for the well-being of these patients.

DELAYED DIAGNOSIS OF MALIGNANCY IN A PATIENT WITH ALCOHOL USE DISORDER

Vanessa Kung

Internal Medicine, Emory University, Atlanta, GA. (Control ID #3391083)

LEARNING OBJECTIVE #1: Recognize clinical manifestations of exocrine pancreatic cancer.

LEARNING OBJECTIVE #2: Appreciate that cognitive biases among providers can contribute to health care disparities.

CASE: A 34-year-old female presents with epigastric pain. Social history was notable for polysubstance use disorder, with alcohol, marijuana, and tobacco use. The patient had been admitted three times within the past year for epigastric pain that was attributed to alcoholic pancreatitis.

On presentation, lipase was elevated (226) and transaminases were normal. CT abdomen showed an edematous pancreatic gland with focal areas of parenchymal hypodensities centered in the pancreatic body, and a normal appearing gallbladder and biliary tree. The patient was counseled on alcohol cessation and discharged.

The patient returned to the hospital two additional times with dyspnea and cough, was treated empirically for pneumonia, and counseled on tobacco and marijuana cessation. The patient presented again with unresolved cough and dyspnea. She reported quitting all substances after her second hospitalization for acute pancreatitis. CT chest showed diffuse groundglass and consolidative opacities as well as peribronchial wall thickening. Lung biopsy was performed, which revealed pancreatic adenocarcinoma. A subsequent repeat CT abdomen showed a hypodensity in the pancreatic body, compressing the superior mesenteric vein and causing ductal dilation. On retrospective chart review, the patient had experienced 20 kg weight loss over three years, and a hypodense pancreatic lesion creating a mass effect had been present on prior abdominal imaging.

IMPACT/DISCUSSION: Exocrine pancreatic neoplasms are relatively uncommon, particularly before the age of 45 years, but are highly lethal malignancies. Common presenting symptoms of these malignancies are weight loss (85%), abdominal pain (79%), and jaundice (56%). Abdominal pain can occur even with small (<2cm) pancreatic cancers, prior to the development of major laboratory or imaging abnormalities. The typical appearance of an exocrine pancreatic cancer on imaging is an ill-defined hypoattenuating mass.

Disparities in health care can occur across many dimensions, including populations struggling with substance use disorders. Substance use disorders are widespread, and nearly a third of Americans meet criteria for alcohol use disorder in their lifetimes. Despite this, they remain stigmatized. Physicians may have cognitive biases that negatively impact the provided care and health outcomes for patients with substance use disorders.

CONCLUSION: This case illustrates how a patient with a substance use disorder experienced delayed diagnosis of a deadly medical condition. Anchor bias related to the substance use disorder led to mistaken and delayed diagnoses, despite the patient's repeated efforts to seek care.

DERMATOPATHOLOGY CINCHES THE DIAGNOSIS FOR SPOR(E)ADIC FEVERS

Jennifer Shiroky. Internal Medicine, Johns Hopkins Bayview Medical Center, Baltimore, MD. (Control ID #3389197)

LEARNING OBJECTIVE #1: Recognize the clinical features of disseminated histoplasmosis

LEARNING OBJECTIVE #2: Appreciate the importance of investigating abnormal skin findings

CASE: Ms G is a 63 yo woman from Belize with a history of recurrent pleuropericarditis on long-term prednisone and mycophenolate, and a positive PPD who presented with 5 months of recurrent fevers.

Five months prior to admission she was visiting Belize and developed fevers, generalized weakness, and a productive cough. She was diagnosed and treated for Dengue fever based on serologies and pneumonia. However, her symptoms never fully resolved.

One month prior to admission her fevers recurred, she was hospitalized, treated with broad spectrum antibiotics and high-dose steroids without improvement. During that hospitalization she developed injected conjunctiva, oral ulcers, violaceous papules, and severe thrombocytopenia. Providers recommended she return to the US for further diagnostic work-up and management of fever of unknown origin.

Upon presentation her temperature was 39.7^0C and her physical exam was notable for cushingoid features, injected conjunctiva with chemosis, painful oral ulcers, diffuse umbilicated purple papules, and anasarca. Her labs were notable for acute macrocytic anemia and thrombocytopenia, and an elevated CRP. CT revealed subsegmental PE, nonspecific bilateral pulmonary nodules, and hypodensities within the spleen.

Dermatology found the lesions concerning for deep fungal infections or CMV, less likely an autoimmune process. Skin biopsy visualized dermal parasitized histiocytes and numerous small spores consistent with histoplasmosis. Serum, urine, and CSF infectious work up later confirmed disseminated histoplasmosis with histoplasmal meningitis. The remainder of the extensive infectious work up was negative and rheumatologic studies were unchanged from previous.

Her fevers resolved with a 4 week course of Ambisome with initial plans for a 1 year course of itraconazole for disseminated histoplasmosis. However, she was switched to posaconazole for recurrent fevers and persistently positive Histoplasma antigen in her serum and urine.

IMPACT/DISCUSSION: Ms G's risk factors for disseminated histoplasmosis included long term immunosuppression and frequent travel to an endemic area. The natural history of disseminated histoplasmosis can range from a rapidly fatal infection to a chronic, intermittent course lasting years. Histoplasmal meningitis cure rates are around 50% with high rates of relapse. What was particularly memorable about this case was that the skin biopsy results came back a few days before serum and urine testing. This emphasizes the importance of interdisciplinary collaboration in approaching complex, undifferentiated patients.

CONCLUSION: - Histoplasmosis has a wide range of presentations from asymptomatic to pulmonary complications to disseminated multiorgan involvement

- CNS involvement should be assessed in cases of disseminated histoplasmosis

- Dermatology consult for atypical skin findings should not be delayed

DIAGNOSING CASTLEMAN DISEASE IN AN AIDS PATIENT PRESENTING WITH LYMPHADENOPATHY

Alberto Batarseh[1]; Caroline Thomas[1]; Areta Bojko[2]; Adrienne N. Poon[3]

[1]Internal Medicine, George Washington University, Washington, DC; [2]Internal Medicine, George Washington, Washington, DC; [3]Department of Internal Medicine, George Washington School of Medicine and Health Sciences, Clifton, NJ. (Control ID #3391877)

LEARNING OBJECTIVE #1: Evaluate lymphadenopathy in a patient with AIDS given a broad differential diagnosis

LEARNING OBJECTIVE #2: Recognize the role of disseminated Karposi Sarcoma in AIDS and Castleman's Disease

CASE: A 36 year old Sierra Leonean woman with AIDS presented with abdominal pain, diarrhea, and fever. On admission she was febrile up to 38.8 C, hypotensive with blood pressures of 80s/50s mmHg and tachycardic up to 120 beats per minute. Labs were notable for pancytopenia with a white blood cell count of 1.8x103 cells/µl, a hemoglobin of 5.4 g/dL and platelets of 41x103 cells/µl. Her physical exam was notable for several soft, dark brown indurated plaques along the right upper thigh, left inner arm, and left lower back. She also had several violaceous exophytic nodules along the mons pubis, and palpable bilateral axillary, submandibular, and cervical lymphadenopathy. Given initial concern for sepsis, neutropenic fever, and anemia, she was started on broad spectrum antibiotics, transfused blood, and fluid resuscitated. Further work up revealed a CD4 count of 98 cells/µl and 2% on flow cytometry, HIV viral load of 104K units/d, and interleukin-6 level of 46.1 pg/mL (range 0.0-15.5 pg/mL). HHV-8 is pending. Biopsies of lesions on her back, right thigh and mons pubis were all consistent with Kaposi's sarcoma. A cervical excisional lymph node biopsy showed partial involvement of HIV-associated Kaposi sarcoma in the background of multicentric Castleman disease (MCD). A bone marrow biopsy showed 10-15% atypical B-cells, also concerning for MCD. She was started on antiretroviral therapy with Biktarvy (bictegravir, emtricitabine, and tenofovir alafenamide) with improvement in her pancytopenia, and was referred for a clinical trial with targeted therapy of Pomalidomide and liposomal doxorubicin.

IMPACT/DISCUSSION: In this report, we present a case of biopsy-proven multicentric Castelman's disease as well as Kaposi's sarcoma in a female patient with AIDS. The differential for lymphadenopathy in a patient with AIDS includes persistent generalized lymphadenopathy secondary to HIV, lymphoma, disseminated mycobacterium avium, tuberculosis, Ebstein-Barr virus or cytomegalovirus. MCD typically presents with nonspecific 'B-symptoms' including fevers, lymphadenopathy, and splenomegaly. Excisional node biopsy is the preferred method for diagnosis of MCD. Given MCD's association with HHV8, biopsied tissue should be stained for HHV8 specific markers. MCD can be with or without KS; however, in AIDS patients it is almost always associated with HHV-8. MCD is typically treated with rituximab, but because rituximab can cause KS flares, doxorubicin is added for patients with KS.

CONCLUSION: MCD with concomitant visceral KS is a rare disease usually seen in patients from areas with high incidences of HIV infection

The extensive workup involved in diagnosing MCD involves close collaboration between oncology, pathology and infectious disease

Few case reports discuss the findings and workup of a patient with lymphadenopathy and AIDS consistent with MCD

DIAGNOSING HEARTLESS ENDOCARDITIS

Jaya Bommireddipally[1]; Jennifer Schmidt[2]

[1]Internal Medicine, Saint Louis University School of Medicine, Saint Louis, MO; [2]General Internal Medicine, Saint Louis University, Saint Louis, MO. (Control ID #3387885)

LEARNING OBJECTIVE #1: Diagnose infective endocarditis (IE) with modified Duke criteria.

LEARNING OBJECTIVE #2: Recognize that echocardiogram evidence is not required for diagnosis of IE.

CASE: A 57-year-old male with distant history of IV drug use (IVDU) presents in clinic with worsening productive cough, chest and abdominal pain, fever and 30-lb weight loss. Labs are remarkable for WBC of 17.9. He is started on levofloxacin for 10 days. 4 months later, patient presents

to ED with worsening symptoms. Imaging shows multiple pulmonary and hepatic abscesses. Blood cultures are positive for *Streptococcus intermedius*. Hepatic drain is placed; patient is started on ceftriaxone and metronidazole. TEE is negative for vegetations. Patient receives MRI brain due to confusion and hallucinations. It shows multiple abscesses. Patient is treated with 6 weeks of IV antibiotics for presumed IE based on Duke criteria.

IMPACT/DISCUSSION: IE is diagnosed by the modified Duke criteria. It includes major and minor criteria diagnosing definite, possible, or rejected IE.[3] Major criteria are 1) two positive blood cultures for typical IE organisms, 2) *Coxiella burnetii* positive blood culture, or 3) echocardiogram evidence. Minor criteria are 1) IVDU or predisposing heart condition, 2) fever (>38°C), 3) vascular/immunologic phenomenon, 4) other microbiologic evidence. Definite IE diagnosis meets 2 major criteria OR 1 major and 3 minor criteria. Possible diagnosis meets 1 major and 1 minor criterion OR 3 minor criteria. Rejected diagnosis is when 1) a clear alternate diagnosis is made, 2) symptoms resolve with <5 days of antibiotic therapy, 3) surgery or autopsy shows no IE evidence after <5 days of antibiotic therapy, or 4) criteria for definite or possible IE are not met.[3] Therefore, IE diagnosis does not require evidence of endocardial involvement. Moreover, TTE sensitivity/specificity in detecting vegetations is 44-63%/91-98%.[2] TEE sensitivity/specificity is 87-100%/91-100%.[2] In patients with positive blood cultures, TEE found vegetations in 82% and TTE in 69% of patients.[1] Therefore, patients that meet the criteria should be treated for IE despite lack of echocardiogram evidence. Our patient meets 3 minor criteria for possible IE: history of IVDU, fever and *S. intermedius* positive blood cultures. He was treated with 6 weeks of IV antibiotics as no other clear source was identified.

1. Erbel, R., Rohmann, S., Drexler, M., … Meyer, J. (1988, January). Improved diagnostic value of echocardiography in patients with infective endocarditis by transoesophageal approach. A prospective study.
2. Evangelista, A., & Gonzalez-Alujas, M. T. (2004, June). Echocardiography in infective endocarditis.
3. Li, J. S., Sexton, D. J., Mick, N., … Corey, G. R. (2000, April). Proposed modifications to the Duke criteria for the diagnosis of infective endocarditis.

CONCLUSION: Based on the modified Duke criteria, it is important to reiterate that diagnosis of IE does not require evidence of endocardial involvement.

DIAGNOSING MYCOBACTERIUM TUBERCULOSIS BACTEREMIA IN AN IMMUNOCOMPROMISED FEMALE

Vickie Kassapidis[2]; Morris Jrada[1]; Myint Aye[1]

[1]Internal Medicine, NYU Langone - Brooklyn, Brooklyn, NY; [2]Internal Medicine, NYU Langone - Brooklyn, Brooklyn, NY. (Control ID #3392029)

LEARNING OBJECTIVE #1: Assess the various diagnostic modalities used to diagnose Mycobacterium Tuberculosis

LEARNING OBJECTIVE #2: Recognize the importance of a timely diagnosis and the utility of mycobacterial blood cultures

CASE: A 67-year-old female with a past medical history of psoriasis on adalimumab therapy presented with worsening chills, fever, and a non-productive cough for the past month. She denies any hemoptysis or night sweats but states she has had a 30-pound weight loss over the past two months.

In the ED, she was afebrile, normotensive, and was saturating 95% on room air. A Chest X-ray was notable for bilateral miliary nodules. A CT scan of her chest and abdomen was then done and showed extensive miliary lesions in her lungs and spleen. She was placed on airborne isolation and admitted to the medicine service for further workup.

Over the course of her hospital stay, the patient's lab work was significant for a negative fungal workup as well as a negative QuantiFERON Gold assay. Inflammatory markers and hepatic markers, specifically alkaline phosphatase and GGTP, were elevated. MRCP was then done and was notable for hepatic lesions.

Sputum AFB stain and culture were collected and acid fast bacilli were noted on day 1 with PCR positive for MTB. RIPE therapy was initiated immediately. Due to the extent of extrapulmonary manifestations, blood cultures were sent for AFB staining. A month later, they returned positive for Mycobacterium Tuberculosis.

IMPACT/DISCUSSION: Mycobacterium Tuberculosis is a communicable disease that is one of the top 10 causes of death worldwide. The timely diagnosis of TB is important due to treatment options and new drug resistance. A QuantiFERON Gold blood assay is used to detect TB, but does not differentiate latent from active disease. In order to diagnose a patient with active TB, confirmation via diagnostic microbiology, specifically the presence of acid-fast bacilli on sputum smear and a positive culture, is needed. Twenty percent of patients with active TB can have negative blood assay results. Therefore, with concern for extrapulmonary TB, a negative blood assay should not dissuade practitioners from obtaining blood and sputum cultures.

Hematogenous dissemination of TB should be suspected in patients with presumed miliary TB and warrants the collection of mycobacterial blood cultures. MTB bacteremia is especially common in immunocompromised adults with extrapulmonary tuberculosis. While blood cultures can assist in the diagnosis of tuberculosis, growth can take up to 6 weeks and treatment should not be withheld until blood cultures result.

CONCLUSION: Here we present a case of an immunocompromised female with miliary TB with a negative QuantiFERON Gold assay but with positive mycobacterium tuberculosis blood cultures. QuantiFERON Gold assay can be used to help rule in or rule out TB, but not to establish a diagnosis. When patients present with extrapulmonary manifestations, blood cultures can confirm a diagnosis, especially when patients lack pulmonary manifestations on radiographic imaging.

DIAGNOSTIC DELAY AND OPPORTUNITY COSTS OF A NOSEBLEED

Samuel Hand, Eliana Bonifacino

Internal Medicine, UPMC, Pittsburgh, PA. (Control ID #3392015)

LEARNING OBJECTIVE #1: Describe how social determinants of health alter disease presentation, management, and clinical trajectory

LEARNING OBJECTIVE #2: Recognize healthcare and medication access options for patients without insurance

CASE: A 37-year-old man with Type 2 Diabetes at a free medical clinic for patients without health insurance has isolated thrombocytopenia to 14,000 incidentally found (confirmed with repeat CBC and manual differential). He is diagnosed with Immune Thrombocytopenia (ITP) after ruling out other causes of thrombocytopenia. The patient declines emergency department (ED) presentation due to time constraints and insurance status, and he reports friends without insurance laden with crushing medical debt following ED visits. He ultimately presents to the ED 2 days later with spontaneous epistaxis. Platelet count at time of ED presentation is 12,000. After 2 steroid courses, his platelet count only reaches 25,000, and he loses 1 of his 2 jobs due to symptomatic glucocorticoid-induced hyperglycemia. His Emergency Medicaid application is pending to allow for appropriate management of steroid-resistant ITP. Due to social

determinants of health, the patient experiences delays in diagnosis and inadequate treatment of ITP.

IMPACT/DISCUSSION: ITP is immune-mediated platelet destruction in the absence of other causes of thrombocytopenia, typically treated when platelet count is below 30,000. Half of patients develop chronic ITP; fatal hemorrhage occurs in 3% per patient year. First-line therapy is glucocorticoids plus IVIG. Second- line therapies include further glucocorticoids, rituximab, thrombopoietin agonists, other immunosuppressants, and splenectomy.

The CDC defines social determinants of health (SDOH) as "conditions in which people are born, live, learn, work, play, worship, and age that affect a wide range of health, functioning, and quality-of-life outcomes and risks." Patient-specific examples of SDOH that affected presentation, management, and clinical trajectory are undocumented immigration status, living in concentrated poverty, transportation resources, access to health services, and employment situation.

Inquiring about SDOH as a routine part of encounters reveals barriers to good health outcomes. Simple phrases like "Have you had problems affording medicines or healthcare? How do you travel to office visits or work? What are you worried about when it comes to your health?" identify and address SDOH without adding time or hassle to encounters. Two easy-to-use and free resources exist for patients without insurance: (1) the GoodRx discount program (www.goodrx.com) provides major discounts on medications for patients without insurance; (2) The National Association of Free & Charitable Clinics (www.nafcclinics.org) lists 1,400 free and charitable clinics across the USA.

CONCLUSION: Address social determinants of health routinely in encounters given their influence on patient outcomes

Reference www.goodrx.com and www.nafcclinics.org to provide better care to patients without insurance

DIAGNOSTIC DILEMMA, SYMPTOMATIC OSTEOMALACIA: A REACTIVE ARTHRITIS MIMIC

Nitesh Gandhi[1]; Hanan Ibrahim[2]; Ayad Alkhatib[3]

[1]Internal Medicine, Henry Ford Hospital, Detroit, MI; [2]Internal Medicine, Henry Ford Hospital, Detroit, MI; [3]Rheumatology, Henry Ford Hospital, Detroit, MI. (Control ID #3386833)

LEARNING OBJECTIVE #1: Diagnose reactive arthritis and differentiate it from other causes of pains

LEARNING OBJECTIVE #2: Recognize vitamin D deficiency on laboratory work and being able to order the right workup

CASE: A 38-year-old 19 weeks pregnant female who presented with multiple joint pains that started with right ankle pain and then progressed to the left ankle and both knees over several weeks. She described her pain as sharp and aching dull pain, it was worse upon standing and resting, was associated with prolonged morning stiffness. She denied fevers, chills, rashes, ocular inflammation, dry eyes or mouth, ulcers in mouth or nose, Raynaud's, numbness or tingling and photosensitivity. Her physical exam showed tenderness to palpation over the ankles with evidence of swelling and erythema. Due to concerns for inflammatory arthritis, patient underwent further workup which was significant for CRP 1.2, ESR 59, +ANA(1:320, homogenous pattern), C3/4 were normal. RF, CCP, dsDNA, Smith antibody, RNP antibody, SSA and SSB were negative. Stool bacterial PCR, urine chlamydia and gonorrhea were negative.

Due to her history, clinical findings and the positive markers of inflammation but negative infectious studies patient was diagnosed with reactive arthritis of unknown etiology. She was started on prednisone taper with no improvement of her symptoms, intraarticular steroid in both ankles were given with minimal improvement in symptoms as well.

Given that she didn't improve to treatment MRI of right and left knee were done and showed diffuse osteopenia. Further workup revealed high ALP to 249, low Vitamin D levels to 8, BETA crosslaps were increased to 1042, elevated PTH to 101, calcium level of 9.7 and phosphorus level of 3.3. She was diagnosed with symptomatic osteomalacia and was treated with vitamin D and calcium supplementation with resolution of her symptoms thereafter.

IMPACT/DISCUSSION: Osteomalacia is a disorder of decreased mineralization of the bone markedly at the sites of bone turnover. It can be asymptomatic in most of the cases where osteopenia is the disease sign seen on imaging. Osteomalacia can be symptomatic as well, resulting in generalized bone pains, joint pains, and muscle spasms, the pain is usually dull aching pain in weight-bearing areas and in severe cases fractures can occur as a result. The most common lab finding is an elevation in ALP and PTH, the patient might also have low serum Ca and P, low vitamin D levels as well as low urinary Ca excretion.

Malabsorption disorders, gastric bypass surgeries, celiac disease, liver disease, and chronic kidney diseases are all risk factors.

CONCLUSION: According to the literature review, symptomatic osteomalacia has been reported in dark- skinned pregnant women, the presentation is similar to nonpregnant women. It is important to diagnose osteomalacia is such a population to prevent fractures and other related complications.

DIAGNOSTIC DILEMMA IN A CASE OF LIMITED SCLERODERMA MIMICKING CELIAC DISEASE

Ammar Qureshi[1]; Joline De Castro[1]; Youssef Ghobrial[1]; Adewale Ajumobi[2]

[1]Internal Medicine, Eisenhower Medical Center, Palm Desert, CA; [2]Gastroenterology, Eisenhower Health, Rancho Mirage, CA. (Control ID #3390117)

LEARNING OBJECTIVE #1: Recognize that scleroderma involving the gastrointestinal tract may mimic celiac disease even in the absence of small intestinal bacterial overgrowth (SIBO). Antibiotics are not required to manage these cases if the tests do no indicate features of a SIBO.

LEARNING OBJECTIVE #2: Although celiac disease may present with villous atrophy on duodenal biopsies, recognize the other causes of villous atrophy and chronic diarrhea; the so called mimickers of celiac disease.

CASE: We present an 82 year old female with a known history of limited scleroderma on symptomatic treatment who came to our clinic with a 6 month history of diarrhea. Physical exam was significant for digital Raynaud's and facial telangiectasia. Stool studies which included fecal leukocytes, ova, parasites, cultures, clostridium difficile and fecal elastase were negative. Duodenal biopsies taken on EGD showed villous blunting and increased intraepithelial lymphocytes (Marsh 3B-C lesion). Serology was positive for antigliadin antibodies but negative for tissue transglutaminase. She was then placed on a gluten free diet (GFD) without any resolution. Genetic testing for celiac disease (HLA -DQ2 and HLA-DQ8 alleles) were negative. Negative antienterocyte and anti-goblet cell antibodies ruled out autoimmune enteropathy. Irbesartan was stopped. Given the patients known history of limited scleroderma, SIBO was considered as a cause of the patient's symptoms. However, breath testing for SIBO was negative. She continued to have symptoms in spite of being on a GFD. Capsule endoscopy showed delayed passage of the capsule, duodenal villi atrophy with associated angioectasia. CT enterography

showed prominent distended small bowel loops and blunted folds of the proximal duodenum. With clinical features and imaging studies consistent with scleroderma, she was referred to rheumatology and was started on methotrexate.

IMPACT/DISCUSSION: While celiac disease is the most common cause of villous atrophy on duodenal biopsies, other causes have to be sought when celiac HLA typing is negative and the patient is non responsive to a GFD. Histological mimickers of celiac disease can be divided into 2 types, early which are characterized by increased intraepithelial lymphocytes without villous atrophy and late which have increased intraepithelial lymphocytes with villous atrophy. Differential diagnosis of late mimickers include common variable immune deficiency, giardiasis, SIBO, Crohn's disease, autoimmune enteropathy, Whipple's disease, tropical sprue and medications such as olmesartan. SIBO was a major differential in our study however the breath test was negative.

CONCLUSION: Patients with scleroderma involving the gastrointestinal tract can present with villous atrophy without SIBO.

DIARRHEA DILEMMA

Manisha Bhide. Internal Medicine, University of Colorado Denver, Aurora, CO. (Control ID #3348439)

LEARNING OBJECTIVE #1:

1. To present a dilemma of Clostridium difficile diarrhea not responding to fecal transplant
2. Cyclospora cayetanensis diarrhea related to travel in US.

CASE: 72 yr male, had an episode of C. diff in 12/2018. He was initially treated with treated with oral vancomycin for 10 days. His symptoms persisted and he remained positive, so he was treated with oral metronidazole for 10 days. He was persistently symptomatic and positive for C. Diff. Hence was treated with fidaxomicin 200 mg BID for 15 days. He remained symptomatic and positive. Hence received second round of Fidaxomycin with taper. He had a fecal microbial transplant(FMT) on 2/20/19 and reported that he does not feel he retained this well, inspite of imodium.

About one month ago, he started having what he describes to be the same symptoms as previous episodes of C diff with 3-6 loose stools daily with malaise and abdominal pain. This represents dilemma for treatment of diarrhea, since there are no guidelines/recomendations for this situation. He was treated with repeat FMT and is doing well for last 6 months.

70 year immunocompetant woman returned from 4 day travel to New Orleans. She had eaten a lot of seafood. She reported 8-10 loose watery stools with nausea, malaise, anorexia since 4 days after return from her trip. Stool testing showed Cyclospora cayetanensis.

She was treated with trimethoprim sulfamethoxazole 800/160 2 times/day for 7 days and improved.

IMPACT/DISCUSSION: Diarrhea is a very common illness seen in medical practice. Clostridium Difficile diarrhea is becoming common. Oral vancomycin, metronidazole, Fidaxomycin are recommended to treat it. Fecal transplant is considered the treatment of choice in antibiotic resistance. The case above illustrates a frustrating situation when neither antibiotics nor fecal tranplant was working. With our increasing load of frail geriatric patients with multiple co-morbidities we will be seeing this dilemma more frequently in the future. Hence it is important to be aware regarding the management of such patients.

Cyclospora cayetanensis is transmitted via food and water. This actually represents a reportable public health problem. The treating team may not be aware about the public health repercussions and thus it is important to highlight here.

CONCLUSION: Professional standard of care for recurrent C. Diff infection after fecal transplant is not establsihed at present.

Cyclospora cayetanensis is seen in travellers in US and is a reportable public health hazard.

DIARRHEA SO BAD IT WILL MAKE YOUR TONGUE SWELL

John S. Herndon[1]; Kirk Russ[2]

[1]Internal Medicine, University of Alabama at Birmingham, Birmingham, AL; [2]Division of Gastroenterology and Hepatology, University of Alabama at Birmingham, Birmingham, AL. (Control ID #3386602)

LEARNING OBJECTIVE #1: Recognize the importance of considering alternative diagnoses when diagnostic workup remains negative

LEARNING OBJECTIVE #2: Identify the clinical manifestations and diagnosis of gastrointestinal amyloid

CASE: A 70 year old male with prostate cancer treated with radiation was admitted with postprandial abdominal pain, distention, and intermittent nonbloody diarrhea. Vital signs were normal. Abdomen was soft, nontender, mildly distended. CBC with differential, CMP, and lipase were normal. Stool culture and testing for Giardia, Cryptosporidia, and C. difficile was negative. Contrasted CT abdomen & pelvis showed small bowel obstruction with multifocal areas of small bowel stricturing and thickening of the transverse colon and splenic flexure. With nasogastric tube decompression, partial small bowel obstruction resolved. Inpatient colonoscopy showed poor bowel prep and radiation proctitis. He was given trial of cholestyramine and discharged with GI follow up. One month later, his symptoms were unchanged. MR Enterography again showed multifocal inflammation and narrowing of small bowel, rectosigmoid colon and splenic flexure. EGD with gastric and duodenal biopsies was unremarkable. Repeat colonoscopy again showed radiation proctitis, with an area of narrowing and erythematous mucosa in sigmoid colon. Biopsies were unremarkable. Empiric trials of steroids (for possible inflammatory bowel disease) and two courses of antibiotics (for small intestinal bacterial overgrowth) failed to improve symptoms. He became frustrated with the lack of an underlying diagnosis and improvement in symptoms and was lost to follow up. Fortunately, he continued to follow with his primary care physician and began to complain of tongue swelling. Due to concern for amyloidosis, tongue biopsy and later bone marrow biopsy were performed. Both were negative for amyloidosis or malignancy.

Due to persistent suspicion for amyloidosis, Congo red staining was performed on previous stomach and colon biopsies with positive result. Mass spectrometry confirmed AL amyloidosis. The patient underwent autologous stem cell transplant and remains disease free with > 2 years follow up.

IMPACT/DISCUSSION: GI amyloidosis is uncommon but can present with GI bleeding, malabsorption, protein losing enteropathy, or GI dysmotility. If suspicion is high, Congo red staining should be requested on tissue. Treatment is autologous hematopoietic cell transplant for patients who are candidates, and chemotherapy for those who are not. Prognosis is poor with one perspective study showed median survival of AL amyloidosis with GI involvement to be 7.95 months and 15.84 without involvement. This case illustrates the importance of longitudinal care and a persistent search for the underlying etiology when the diagnosis remains unclear, when new clinical information arises, and/or there is a lack of clinical improvement with empiric therapy.

CONCLUSION: Negative biopsy does not always = normal

Reconsider the underlying diagnosis and results of past studies

DID OCTREOTIDE RESTORE THIS PATIENT'S LIFE?

Anchit Bharat[1]; Nikita Jain[2]; Azka Tasleem[1]; Sudarsana Srivangipuram[1]; Brandon Dickey[1]

[1]Internal Medicine, IU Health Ball Memorial Hospital, Muncie, IN; [2]Internal Medicine, Chicago Medical School, RFUMS, Northwestern Medicine, McHenry, McHenry, IL. (Control ID #3367267)

LEARNING OBJECTIVE #1: Octreotide can help patients prevent long term microvascular complications of DM – thus, providing high value care.

LEARNING OBJECTIVE #2: If employed early for refractory DGE, octreotide might reduce re- admissions for DKA. Thereby, markedly reducing the financial burden on the US health care industry.

CASE: A 50 year old female with poorly controlled DM was admitted for altered mentation, DKA and profuse, watery diarrhea. She had 11 admissions in the last 20 months for similar complaints, including 1 to the ICU. At presentation, she had 12-13 episodes of explosive diarrhea per day, without any blood and had lost 12-kgs in the last year. Over the last 4 years, patient failed OTC and outpatient management. Normal labs - stool electrolytes including Na, K and Cl, amylase, lipase, fecal occult blood, lactoferrin, fecal fat, HIV test, Wright stain for neutrophils and eosinophils. VIP < 50 pg/ml. Calprotectin < 16 mcg/gm. Serum IgA - 153 mg/dL; TTG IgA - 0.4 U/mL; TTG IgG < 1.0 U/mL. Gastrointestinal pathogen panel including C. diff was negative. Patient failed inpatient loperamide, metoclopramide and pancreatic enzyme replacement. An endoscopy and 8 colonoscopies were negative. A diagnosis of Diabetic gastroenteropathy (DGE) was made and she was put on a trial of octreotide 50 mCg subcutaneous injection Q8H. After 2 days, patient's diarrhea improved, her stool count went down to 4 and subsequently stayed in the range of 2-3 episodes/ day. She regained her appetite and gained 9-kgs within 2 weeks.

IMPACT/DISCUSSION: Although manageable, DM remains a global hazard, with an estimated increase in prevalence from 424.9 million patients in 2017 to 628.9 million by 2045. Dehydration secondary to diarrhea caused by chronic diabetic gastroenteropathy is one of the most common precipitating factors of DKA. DKA is a fatal but easily preventable complication of DM and is characterized by hyperglycemia, anion gap metabolic acidosis and ketonemia. In the US, based on CDC and NIS databases, DKA hospitalization rates increased by 54.9%, from 19.5 to 30.2 per 1,000 persons during 2009-2014, at an average annual rate of 6.3%. Since 2003, mean hospital charges for DKA went up from $18,987 per admission to $26,566 in 2014, costing $5.1 billion to the US health care industry.

The exact pathogenesis of DGE remains unknown. Involvement of enteric nervous system, causing an imbalance between excitatory and inhibitory neurons has been postulated. Involvement of motilin, a diarrhea causing hormone has also been implicated. Octreotide acts by affecting both pathways, thereby, reducing the overall gastrointestinal motility, with a relatively safe adverse effect profile.

CONCLUSION: Patient's remarkable improvement in stool frequency allowed us to discontinue her rectal tube. She was able to ambulate around the medical floor. This helps us to hypothesize that octreotide therapy improved her quality of life. Throughout her inpatient stay, her insulin requirement decreased by 40% with better glycemic control.

DIFFERENTIATING THE UNDIFFERENTIATED: A DIAGNOSIS TO CONSIDER IN INFLAMMATORY ARTHRITIS

Rebecca Shafer[1]; Nancy A. LaVine[2]. [1]Internal Medicine, Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY; [2]General Internal Medicine, Northwell Health, New Hyde Park, NY. (Control ID #3390740)

LEARNING OBJECTIVE #1: Define and diagnose Undifferentiated Arthritis [UA].

LEARNING OBJECTIVE #2: Treat Undifferentiated Arthritis to prevent progression to Rheumatoid Arthritis [RA].

CASE: 54 y/o male with no significant past medical history was hospitalized with worsening diffuse joint pain for two weeks. The pain started in bilateral shoulder joints, progressed to bilateral wrists, ankles and knees, and was associated with mild swelling and stiffness. He reported subjective fever and chills. He denied any recent travel, sick contacts, and was sexually active with his wife only. Exam was significant for tenderness, decreased strength and range of motion in bilateral shoulders, wrists, knees and ankles. Mild bilateral knee swelling was also noted. A full infectious, autoimmune and malignant workup was ordered, including CT scan of the abdomen/pelvis/chest and transthoracic echocardiogram, with no significant findings aside from elevated ESR [Erythrocyte Sedimentation Rate] and CRP [C-Reactive Protein]. Fevers (101-102) continued for a week while he was hospitalized. Patient chose to leave hospital despite recurrent fevers and no diagnosis. A diagnosis of Undifferentiated Arthritis (UA) was made in follow up with primary care and rheumatology. Patient was started on Methylprednisolone 8 mg daily and Methotrexate 10 mg weekly with folic acid. Within 4 weeks of starting therapy, he had resolution of his symptoms.

IMPACT/DISCUSSION: Undifferentiated Arthritis is an early inflammatory disorder that cannot be classified as a specific rheumatologic disorder. When treating a patient with arthritis, or painful inflammation and stiffness of joints, without other diagnostic findings to meet criteria for an alternate disorder, such as rheumatoid arthritis, crystal arthropathy, or infectious arthritis, it is important to consider the diagnosis of UA.

To diagnose UA, patients with symptoms of inflammatory arthritis must have at least 1 of the following on physical exam: at least 1 swollen joint or pain on range of motion of at least 1 joint. Workup includes laboratory testing [including auto-antibody and infectious testing], arthrocentesis [to rule out infectious arthritis or crystal disease], and plain radiography of affected joints [in which erosions convey a high risk of progression to RA]. UA can spontaneously resolve on its own (10-40%), or it can progress to RA (13-54%). UA should be identified as early as possible, as early treatment with Disease-Modifying Anti-Rheumatic Drugs, or DMARDS, with a short course (<6 months) of low-dose glucocorticoids can alleviate symptoms, as well as prevent functional impairment and progression to RA.

CONCLUSION: Consider UA in a patient with symptoms of inflammatory arthritis who does not meet diagnostic criteria for a defined rheumatologic disorder.

Patients with UA benefit from early treatment with a DMARD. In addition, combining multiple DMARDs or DMARDs with corticosteroids may be even more beneficial in alleviating symptoms and preventing progression to RA.

DIGITAL ISCHEMIA WITH MANY ANALOGS

Eric Woods, Scott Goldberg

General Internal Medicine, Montefiore Medical Center, Bronx, NY. (Control ID #3391189)

LEARNING OBJECTIVE #1: Recognize digital ulcers and Raynaud's phenomenon as common early manifestations of systemic sclerosis

LEARNING OBJECTIVE #2: Discuss interventions for these common systemic sclerosis skin manifestations and when to refer to a rheumatologist

CASE: A 46 year-old man with schizoaffective disorder presented to his primary care provider with months of persistent pain from necrotic lesions on the tips of his left 3rd and 4th fingers. Both digits had malodorous

eschars extending to the distal interphalangeal joints. The surrounding skin was swollen, erythematous and painful to palpation. There was sclerodactyly on his remaining fingers and thickening of the skin on his palms bilaterally but he had no skin changes elsewhere. He had a history of Raynaud's phenomenon and multiple digital ulcers. Seven months prior, his right 3rd finger was amputated after one of the ulcers became infected. He smoked cigars. He endorsed fatigue and mild gastroesophageal reflux disease but no diarrhea or dyspnea.

Antinuclear antibodies (>320, speckled pattern) and anti-centromere antibodies were positive. Anti-topoisomerase I (Scl-70) antibodies were negative. A CT angiogram of his chest did not show any thrombi or interstitial abnormalities. He underwent partial digit amputations which revealed gangrenous necrosis and acute osteomyelitis. Pathology specimens revealed vasculitis. He was diagnosed with systemic sclerosis, discharged on a calcium channel blocker, and given outpatient rheumatology follow-up.

IMPACT/DISCUSSION: One of the most common etiologies of digital ischemia is systemic sclerosis (SSc), a connective tissue disorder that is marked by fibrosis, vascular damage, and immunologic abnormalities with varying degrees of internal organ involvement. Prevalence estimates of SSc are 242 cases per million U.S. adults. Greater than 95% of these patients develop Raynaud's phenomenon and more than 40% develop digital ulcers. Digital ulcers, which have been associated with a worse disease course, can progress to ischemia via an interaction between vasospasm and vasculopathy. Since these digital manifestations often predate other disease symptoms by years, the diagnosis of SSc is often delayed, allowing progression to end organ damage. General internists play a pivotal role in recognizing initial symptoms associated with SSc, securing early diagnosis, and referring to a rheumatologist.

Non-pharmacologic modalities employed to prevent and reduce the burden of digital ulcers and ischemia include avoidance of precipitants like cold and stress, nicotine, hand injuries, and drugs that promote vasoconstriction. The first-line pharmacological treatment of SSc-related skin manifestations is calcium channel blocking medications.

CONCLUSION: Early detection of SSc via the identification of Raynaud's phenomenon and digital ulcers allows counseling on behavior modifications and early referrals to rheumatologists, which may preserve function and prolong patient survival.

DISCONTINUING DIAZEPAM: A CASE HIGHLIGHTING GAPS IN GENERALIST TRAINING THAT PERPETUATE HEALTH DISPARITIES FOR PATIENTS WITH DISABILITIES

Brittany Badesch[1]; Martha Brucato[1]; Sara Mixter[2]

[1]Department of Internal Medicine and Pediatrics, Johns Hopkins Hospital, Baltimore, MD; [2]Department of Medicine, Johns Hopkins University School of Medicine, Baltimore, MD. (Control ID #3388645)

LEARNING OBJECTIVE #1: Identify current gaps in training and support for general internal medicine providers in the care of adults with intellectual and developmental disabilities (ID/DD).

LEARNING OBJECTIVE #2: Describe the need to develop resources to enable current generalist providers to care for adults with ID/DD.

CASE: AB, a 37-year old non-verbal female with quadriplegic spastic cerebral palsy, intellectual disability, and seizure disorder, was admitted to the medicine service at our tertiary referral center with increased seizure frequency, increased tone, fever, and agitation. Her mother reported that 1.5 months prior, AB developed persistent fevers and agitation, and had her first generalized tonic-clonic seizure since childhood, requiring two admissions to a local hospital. Despite adjustment of her antiepileptic medications, her symptoms persisted, and her mother sought care at our institution. On exam, AB was febrile, tachycardic, and mildly diaphoretic with diffusely increased tone. Lab testing and imaging showed no evidence of an infectious cause of AB's symptoms. On further history, her mother revealed that two months prior, AB's primary care provider retired and she switched to a new physician in their rural community. Upon meeting AB, this new provider expressed concerns that she was overly sedated (despite being at her neurocognitive baseline per her mother) and reservations about long-term benzodiazepine use. She initiated a rapid wean of AB's diazepam, decreasing it from a total daily dose of 25mg to 10mg daily. With this additional history and evaluation negative for other causes, AB's symptoms were attributed to this rapid decrease of her antispasmodic medication. Her diazepam was gradually increased with resolution of her symptoms, and she was connected with a primary care physician who has a specific interest in caring for adults with ID/DD.

IMPACT/DISCUSSION: This case highlights gaps in medical training and access to appropriate care that perpetuate health disparities for adults with ID/DD. The provider in this case was certainly not intending to cause harm, but appears to have been unaware of the role of benzodiazepines in managing spasticity for patients with cerebral palsy. This patient's course is emblematic of deficiencies in medical training that leave providers inadequately prepared to care for adults with ID/DD. Research has shown the vast majority of primary care providers received no formal training in caring for adults with ID/DD. It is therefore not surprising that adult medicine providers might lack familiarity with common medication regimens for cerebral palsy or awareness of differences in neurocognitive baseline for people with ID/DD.

CONCLUSION: Deficiencies in medical education and training in the care of adults with ID/DD have real- life and potentially serious impacts on patients. Addressing these deficiencies by providing resources to current providers and adapting training for future generalists has potential to reduce disparities and improve health outcomes for adults with ID/DD.

DISSEMINATED BLASTOMYCES

Mitchell Padkins[1]; Mark Enzler[2]

[1]Internal Medicine, Mayo Clinic, Rochester, MN; [2]Infectious Diseases, Mayo Clinic College of Medicine, Rochester MN, Rochester, MN. (Control ID #3344759)

LEARNING OBJECTIVE #1: Recognize a common presentation of disseminated blastomyces.

LEARNING OBJECTIVE #2: Determine the appropriate treatment of disseminated blastomyces.

CASE: A 58 year old male presented to the ED due to syncope. A chest CT demonstrated an acute pulmonary embolus and new mediastinal lymphadenopathy and bronchiectasis. He was started on anticoagulation for his pulmonary embolus and followed-up with his primary care provider 2 weeks later.

The patient's past medical history was unremarkable. His social history was notable for big-game hunting in the north central United States. He was not on any medications prior to anticoagulation. He had a 20-pack-year smoking history.

At his follow-up appointment, he had developed a new exophytic lesion on his left nare. Bacterial cultures grew coagulase-negative staphylococcus. The lesion was treated with topical antibiotics without resolution. Additional findings included progressive weight loss, night sweats, and mild confusion.

Additional testing revealed positive Blastomyces serology by immunodiffusion. Fungal blood cultures grew Blastomyces dermatitidis one week later. A brain MRI revealed small enhancing lesions. A diagnosis of

disseminated blastomyces with skin and brain involvement was made and the patient was started on liposomal amphotericin B and voriconazole.

IMPACT/DISCUSSION: Blastomycosis is typically found in states bordering the Mississippi and Ohio River valleys and the Midwestern U.S. Risk factors include exposure to contaminated soil and water sources. Most infections are asymptomatic although mild pneumonia may progress to severe pneumonia with necrotizing features or mass formation. The infection may disseminate to lymph nodes, brain, skin, prostate, and bone. Central nervous system involvement affects less than 1% of patients. Diagnosis is difficult because of the wide spectrum of presentations. Pulmonary involvement can closely mimic bacterial pneumonia; thus a high index of suspicion is necessary when pneumonia symptoms do not respond to antimicrobials or patients are from an endemic area. Diagnosis is suggestive with serology and confirmed by culture or typical appearance of yeast forms on biopsy or biologic fluids. Urine or serum antigen testing may assist in confirming a blastomyces diagnosis. Unfortunately, there is considerable antigen cross-reactivity with different fungal infections. Treatment consists of liposomal amphotericin B for four weeks and itraconazole for 6-12 weeks. Studies have shown that when the CNS is involved, voriconazole may be favored due to higher CNS concentration. This patient was treated with liposomal amphotericin B for four weeks and voriconazole for 12 months.

CONCLUSION: Clinicians should have a high-index of suspicion for Blastomyces in patients with recurrent pneumonias or from an endemic area.

Pulmonary symptoms are the most common manifestation of Blastomyces infection.

CNS involvement is rare and treatment includes liposomal amphotericin B followed by prolonged voriconazole due to higher CNS penetration.

DISSEMINATED HISTOPLASMOSIS AFTER VEDOLIZUMAB USE FOR ULCERATIVE COLITIS

Ivanna O. Murskyj[1]; Joydip Joy[4]; David R. Henkin[2]; Nina Garza[3]; Vinay Shah[3]

[1]Internal Medicine, Henry Ford Hospital, Troy, MI; [2]Internal Medicine, Henry Ford Hospital, Detroit, MI; [3]Department of Internal Medicine, Henry Ford Hospital, Detroit, MI; [4]Wayne State University, Detroit, MI. (Control ID #3385617)

LEARNING OBJECTIVE #1: Recognize the importance of maintaining a broad differential, especially in patients taking immunomodulatory agents

LEARNING OBJECTIVE #2: Diagnose and manage disseminated histoplasmosis

CASE: A 41-year-old male with a past medical history significant for ulcerative colitis presented to the ED with fevers and chills in November 2019. He had been recently diagnosed with UC in July 2019, and was started on vedolizumab in the fall, although was only able to tolerate two infusions. He had no other past medical history. He lived his entire life in Michigan and had no recent travel outside the state. The patient was a construction worker and endorsed frequently chopping wood in the forest. A few weeks after the patient's last vedolizumab infusion, he presented to his PCP with fevers. Lab work revealed elevated AST/ALT and he was sent to the ED. He was started empirically on antibiotics given his recent vedolizumab use and suspicion for infectious process. Throughout his admission, the patient had cyclic fevers with temperatures reaching 102-103°F. Infectious workup ruled out atypical opportunistic infections. MRCP was performed given his transaminitis and was suggestive of possible small duct primary sclerosing cholangitis (PSC). Subsequent liver biopsy showed granulomas, encapsulated yeasts, and no evidence of PSC. Further testing revealed positive urine histoplasma antigen and positive blood beta-d-glucan. Disseminated histoplasmosis was suspected, and the patient was started on IV liposomal amphotericin B for one week. His fevers and transaminitis resolved. He was then transitioned to oral itraconazole for 3-6 months.

IMPACT/DISCUSSION: Histoplasmosis is a systemic mycosis endemic in the Ohio and Mississippi River valleys. Sources of exposure include farming, cutting down trees, and remodeling of old buildings. If immunocompromised, *H. capsulatum* can disseminate and cause a variety of symptoms including fever, fatigue, weight loss, and lymphadenopathy. Diagnosis requires a culture of *H. capsulatum*, detection of histoplasmosis antibody in serum, and the presence of histoplasmosis nucleic acid. In our case, however, diagnosis was made by the identification of granulomas and encapsulated yeasts on liver biopsy with positive antigen testing. According to the literature, only two cases of histoplasmosis after vedolizumab treatment have been reported. This is a rare case of disseminated histoplasmosis in a region not known to be endemic. In our patient, the history of immunomodulation therapy combined with a fondness of vigorous outdoor activities produced an optimal setting for the development of histoplasmosis. It is evident that a detailed social history becomes essential in the diagnosis of uncommon infections in immunocompromised individuals.

CONCLUSION: Maintaining a broad differential in immunocompromised patients is critical. Histoplasmosis can present in a variety of ways and should be considered in patients presenting with non-specific systemic symptoms.

DISSEMINATED LEPROSY PRESENTING AS MULTISYSTEM ORGAN-FAILURE IN AN IMMUNOCOMPROMISED ADULT

Anderson S. Marshall

Internal medicine-pediatrics, uab, Birmingham, AL. (Control ID #3392507)

LEARNING OBJECTIVE #1: Recognize factors and patient populations at risk for opportunistic infections such as leprosy

LEARNING OBJECTIVE #2: Identify a clinical history concerning for leprosy and potential treatment options

CASE: A 36-year-old female immigrant from Trinidad & Tobago with a history of diabetes mellitus and polyarteritis nodosa (PAN) presented to an outside hospital with chest pain, shortness of breath, and generalized fatigue. Patient was found to have pancytopenia marked by an absolute neutrophil count of zero. The patient was tachycardic to 138 in the setting of fever to 103 degrees Fahrenheit. Broad-spectrum antibiotics were initiated, and a bone marrow biopsy was performed with concern for mycobacteria. Patient was started on R.I.P.E. therapy and transferred to tertiary care center for escalation of care and further management.

Additional history revealed intolerance of Azathioprine for 2-3 months prior to presentation. Patient was maintained on oral prednisone for the past two years, with multiple unsuccessful attempts to taper because of worsening skin rash and pain. Her diagnosis of PAN was based on a biopsy of painful bullous lesions on her foot that regressed after starting steroid therapy.

Patient decompensated and developed renal and hypoxic respiratory failure. Skin exam showed erythematous-violaceous macules and patches distributed on her feet, legs, trunk. Biopsy of her skin lesions and repeat bone marrow biopsy was pursued. Patient had worsening respiratory failure that required intubation. Family meeting at that time resulted in comfort care approach with further invasive testing and procedures no longer pursued. The patient ultimately died of her illness.

Post-mortem analysis of her biopsied skin lesions and bone marrow revealed acid fast and Fite-positive organisms concerning for

disseminated mycobacterium. External testing confirmed the diagnosis of Leprosy with mycobacterim leprae DNA detected in biopsied samples and Mycobacterial peri-neural invasion was also noted on skin biopsy.

IMPACT/DISCUSSION: Leprosy is an infectious disease caused by Mycobacterium leprae and Mycobacterium lepromatosis involving the skin and peripheral nerves. It is largely a disease of the immunocompromised and the misfortunate. In the U.S., 205 cases of Leprosy were documented as recently as 2010. 75% of these individuals were known to be recent immigrants. Transmission of the disease is not fully known but is believed to be respiratory in nature by experts. Transmission is believed to be dependent on exposure, immune status, age, and contact with potential zoonotic reservoirs such as armadillos in the U.S.

CONCLUSION: Clinical presentation is classically persistent skin lesions refectory to standard treatments with sensory loss observed with in these lesions. Our patient exemplified this presentation with hypopigmented to reddish patches on her extremities with expected neuropathy. Severe disease, as in our patient's case, can present with prolonged exposure and can result in multi-system organ failure and death.

DISSEMINATED STRONGYLOIDIASIS IN A HLTV-1 POSITIVE PATIENT, A DANGEROUS COMBINATION

Julieta Madrid Morales[1]; Kanapa Kornsawad[1]; Vajeeha Sadi-Ali[1]; Juan Diego Velez Londoño[2]

[1]Internal Medicine, University of Texas Health Science Center, San Antonio, TX; [2]Fundacion Valle del Lili, Cali, Valle, Colombia. (Control ID #3390112)

LEARNING OBJECTIVE #1: Identify the early signs of disseminated strongyloidiasis

LEARNING OBJECTIVE #2: Recognize the impact of race when making clinical diagnosis

CASE: A63 year-old African American man with no past medical history, originally from the rural Pacific Coast in Colombia, presented with two months of diffuse abdominal pain, intermittent diarrhea and dry cough. Other symptoms included low-grade fever and a 40-pound weight loss. Denied rashes. Physical exam revealed a cachectic patient with pale conjunctivae, benign abdominal exam, no rash noted. Laboratory studies WBC 18,200 cells/uL with neutrophils predominant, normal eosinophil Hemoglobin 8.5 g/dL. Chemistry with albumin of 1.6 g/dL, negative HIV. CT abdomen and chest with diffuse inflammatory changes of the bowel wall, a right lower lobe consolidation and multiple pulmonary nodules. Upper GI endoscopy and colonoscopy were normal. Due to undiagnosis and concern for malignancy, an exploratory laparoscopy was done, showing distention of the proximal jejunum. Finally, patient underwent video-capsule endoscopy, which showed rhabditiform larvae, confirming the diagnosis of disseminated strongyloidiasis. Stool study showed rhabditiform larvae. Patient also developed ESBL Klebsiella pneumoniae bacteremia with secondary to pneumonia from hyperinfection. Further testing was positive for HLTV-1 (Human T lymphotropic virus 1). He was started on Meropenem and Ivermectin with full recovery.

IMPACT/DISCUSSION: Strongyloides stercolaris is estimated to infect about 100 million people worldwide, especially those coming from tropical and subtropical areas. It usually presents as a chronic asymptomatic disease. In immunosuppressed patient, hyperinfection or disseminated disease may occur. Definitive diagnosis of strongyloidiasis is made on the basis of detection of larvae in the stool, sputum or duodenal fluid. However, strongyloidiasis is difficult to diagnose since the parasite load is low and the larval output is irregular in majority of the patients. The disease can be overlooked in non-endemic areas.

Our patient presented with non-specific symptoms but with significant weight loss concern for possible gastrointestinal malignancy. However initial work up were completed with unclear diagnosis. Given his race, it should help raise concern for possible Strongyloides Stercoralis Hyperinfection Syndrome (SHS) and disseminated disease. Even though our patient has no eosinophilia and no rash noted. Patient was eventually found to have co-infection with HLTV-1 which is one of the most common risk factors for SHS. Patient in this group will have higher mortality associated with disseminated infection, and higher risk of developing HLTV-1 associated diseases, such as adult T-cell leukemia/lymphoma.

CONCLUSION: With increasing diversity in patient population, it is vital for internists to have a broader understanding of the epidemiology and background of patients, in order to have a high clinical suspicion in uncommon diseases.

DON'T CALL THE PSYCHIATRIST JUST YET; A CASE REPORT OF STIFF-PERSON SYNDROME

Ahmad Hallak[1]; Randa Hazam[2]; Muhammad Kashif Amin[1]; Khaled Alhbshi[1]; Sheikh Islam[1]; Mazin Saadaldin[3]

[1]Internal Medicine, Texas Tech University Health Sciences, Amarillo, TX; [2]Internal medicine, Ttuhsc, Amarillo, TX; [3]internal medicine, NWTHS, TTUHSC, Amarillo, TX. (Control ID #3391420)

LEARNING OBJECTIVE #1: Knowledge and awareness as well as high clinical suspicion are required for the diagnosis of Stiff-person Syndrome

LEARNING OBJECTIVE #2: Electromyography and serological testing for autoimmune antibodies are insightful for neurological workup when imaging is not

CASE: A 36-year-old female with a history of PTSD and chronic dystonia of unclear etiology presented with intermittent left-sided weakness, bilateral lower extremity numbness, truncal weakness, episodic tremors with the spasms of all limbs, dysphonia, and dysphagia. These symptoms were gradually worsening, jeopardizing her activities of daily living. Vital signs were normal. Physical exam revealed decreased power in limbs with normal bulk, tone, and reflexes when examined between episodes. MRI brain and spine were unremarkable. Workup including CSF analysis was negative for infection, multiple sclerosis, syphilis, Lyme disease, Huntington's disease, Wilson's Disease. EEG did not reveal epileptogenic activity. The patient was managed symptomatically and started on physical therapy and occupational therapy. She showed minimal improvement in her symptoms. Serology came back positive for anti-Glutamic acid decarboxylase (GAD) antibody confirming the diagnosis of Stiff Person Syndrome. Plasmapheresis was initiated resulting in gradual clinical improvement.

IMPACT/DISCUSSION: In recent years, neurological evaluation has been increasingly relying on imaging to aid diagnosis. While imaging provides insight for several pathologies, negative imaging results tend to mislead and provide false reassurance. This can lead to an increase in false psychiatric diagnoses and the underdiagnosis of rare neurological conditions.

Stiff-person syndrome, formerly called Stiff-man syndrome, is an exceedingly rare neurological disorder that has an estimated prevalence of about one case per million. It is first described in 1956. Most patients present between the ages of 20 and 50, and women are affected two to three times more than men.

The disease is characterized by progressively worsening muscle rigidity and stiffness with associated spasms. While the etiology remains unclear, about 80% of affected individuals have anti-GAD antibodies, as compared to about 1% of the general population. Other antibodies have also been recognized such as anti- amphiphysin antibody and anti-GABAa receptor-associated protein antibody. Electromyography with specific

features including spasmodic reflex myoclonus and co-contraction of antagonistic muscles helps confirm the diagnosis.

CONCLUSION: Stiff-person syndrome remains an underdiagnosed debilitating poorly understood neurological disease. Diagnosis is made based on history, physical examination, electromyography, and serological testing. Imaging generally does not aid in diagnosis.

DON'T FORGET HISTO: A CASE OF HISTOPLASMOSIS PRESENTING AS SMALL BOWEL OBSTRUCTION

Allyson Hughes, Michael Matheney, Imran Huda

Internal Medicine, UTHSC Nashville, Nashville, TN. (Control ID #3391534)

LEARNING OBJECTIVE #1: Recognize the presentation of gastrointestinal histoplasmosis

LEARNING OBJECTIVE #2: Understand susceptibility of patients on TNF-a blocking medications to histoplasma

CASE: A 56 year old male presented with persistent abdominal pain, nausea, and 50 pound weight loss. His medical history is significant for Crohn's disease, nephrolithiasis, peripheral vascular disease, and recent small bowel obstruction; surgical history is significant for bilateral lower extremity bypass grafts and abdominal surgery for bowel strictures at age 30. His Crohn's is managed by long term use of prednisone and infliximab. At presentation he was tachycardic, hypotensive, and had a lactate of 8.6. CT abdomen revealed a small bowel obstruction.

He was treated with aggressive IV fluid hydration, broad spectrum antibiotics, and high dose steroids. He initially improved but then acutely decompensated, and repeat CT abdomen showed bowel perforation. He underwent emergent exploratory laparotomy that noted extensive adhesions, obstruction, and perforation. The perforated tissue was removed. His bowel tissue was noted to be thickened and friable.

Pathology from the resected bowel showed mucosal ulceration, necrosis, transmural inflammation, and fungal histoplasmosis infection. Both urine and serum histoplasma antigen tests were negative. He was treated with Amphotericin B.

IMPACT/DISCUSSION: Histoplasmosis is a fungal infection endemic to the Ohio and Mississippi River Valley regions caused by inhalation of Histoplasma capsulatum. Though often asymptomatic or minimally symptomatic in immunocompetent adults, histoplasmosis can be severe in immunocompromised patients. Severe forms of disease usually present with disseminated or pulmonary histoplasmosis.

Gastrointestinal (GI) histoplasmosis is relatively common and affects around 70% of patients with disseminated disease. However, GI manifestations are clinically recognized less than 10% of the time. GI lesions include ulcerations or masses with predilection for the ileocecal valve and can lead to misdiagnosis of colitis.

TNF-alpha plays a critical role in host defense of histoplasma infection by activating macrophages and enabling their fungicidal capability. TNF-alpha blocking agents thus make a host more susceptible to disseminated histoplasmosis. Current literature recommends testing for histoplasmosis in patients with febrile illness and intestinal lesions prior to initiating TNF-alpha blocking medications. Testing for histoplasmosis with urine or serum antigen levels is recommended in endemic areas when diagnosis of Crohn's is not certain.

CONCLUSION: In endemic areas, histoplasmosis should remain on the differential in patients with GI symptoms, especially in those with immunocompromised states. GI histoplasmosis may present similarly to Crohn's disease. Special care should be taken to distinguish the two prior to initiation of TNF-alpha blocking medications.

DON'T WALK, RUN; PANTON-VALENTINE LEUKOCIDIN POSITIVE MRSA MAY REQUIRE AN ANTIBIOTIC BIG GUN

Anna A. Artymowicz, Gulnara Martorella, Yuhang Zhou, Hemali Patel, Stewart Schaefer

Internal Medicine, Dell Seton Medical Center at The University of Texas, Austin, TX. (Control ID #3392216)

LEARNING OBJECTIVE #1: Recognize the clinical features Panton-Valentine Leukocidin positive Staph Aureus (PVL+SA).

CASE: A 31-year-old man with type two diabetes mellitus that was untreated due to funding limitations presented to the emergency department with malaise, fever, nausea and a four-day history of an enlarging buttock abscess. The abscess was incised and drained. Intraoperative and blood cultures both grew vancomycin-sensitive MRSA. For several days, repeat blood cultures remained positive for MRSA despite therapy and source control. During this time he developed endophthalmitis and chorioretinitis in his left eye, requiring emergent vitrectomy with intraocular injection of ceftaroline. He also developed widespread intramuscular abscesses which were incised and drained when possible. Given treatment failure on vancomycin, treatment was escalated to daptomycin, linezolid, and eventually ceftaroline. The patient's clinical course raised suspicion for Panton-Valentine Leukocidin-positive MRSA. The laboratory test to confirm PVL positivity took 10 days to result.

IMPACT/DISCUSSION: The increase in morbidity and mortality associated with Panton-Valentine Leukocidin positive Staph Aureus (PVL+SA) has caused public health concerns worldwide. PVL is a prophage-encoded pore-forming leukocidin that is present in about 5% of S. aureus isolates and most community acquired MRSA strains. When present, the secreted toxin destroys white blood cells and contributes to recurrent skin and soft tissue infections. PVL+SA can cause severe invasive infections such as septicemia, osteomyelitis, endophthalmitis, and PNA even in previously healthy individuals. Necrotizing hemorrhagic pneumonia is the most serious clinical feature with a high mortality rate (> 60%). PVL+SA endophthalmitis is rapidly vision threatening and requires urgent vitrectomy with intraocular antibiotic treatment. To date, it is not clear why clinical outcomes of patients with PVL+SA vary; studies suggest a combination of bacterial gene expression and host factors. To minimize the infection risks to other patients in the hospital setting, clinicians can consider topical decolonization after the acute infection has resolved. **CONCLUSION:** The classic presentation of PVL+SA infections includes multiple soft tissue abscesses, necrotizing hemorrhagic pneumonia, and severe bacteremia. Suspect PVL+SA when standard therapy and source control fails to result in clinical improvement.

PVL testing in the US is often a send-out lab that can take weeks to return. In suspected PVL+SA, clinicians need to promptly escalate treatment to "big gun" antibiotics, namely linezolid, daptomycin, and ceftaroline if CNS Involvement is present.

DOUBLE TROUBLE: A CASE OF METFORMIN ASSOCIATED LACTIC ACIDOSIS AND EUGLYCEMIC DIABETIC KETOACIDOSIS

Usman Hasnie[1]; Jeffrey Z. Shen[1]; Ammar Hasnie[2]; Ashita J. Tolwani[1]

[1]Department of Medicine, University of Alabama- Birmingham, Birmingham, AL; [2]University of Missouri- Kansas City School of Medicine, Kansas City, MO. (Control ID #3361576)

LEARNING OBJECTIVE #1: Highlight a case of metformin associated lactic acidosis and euglycemic diabetic ketoacidosis

LEARNING OBJECTIVE #2: Review the diagnostic criteria for euglycemic diabetic ketoacidosis

CASE: An 84-year-old female with medical history significant for type II diabetes mellitus on metformin presented with episodes of diffuse muscle contractions and twitching arm movements. On admission she was found to have hypocalcemia, hypomagnesemia, acute kidney injury, and a mixed acid-base disturbance of high anion gap metabolic acidosis (due to lactic acidosis), metabolic alkalosis, and respiratory alkalosis.

Initial labs were notable for sodium 144 mmol/L, potassium 4.5 mmol/L, chloride 98 mmol/L, bicarbonate 15 mmol/L, BUN 48 mg/dL, creatinine 2.7 mg/dL (baseline 0.8), and glucose 125 mg/dL. On ABG, pH was 7.45, CO2 of 22 mmHg, O2 of 156 mmHg, bicarbonate of 15 mmol/L. Corrected anion gap was 33.7. On exam she had frequent muscle contractions of face and extremities. Calcium and magnesium were repleted with resolution of contractions. She was placed on a sodium bicarbonate drip, but anion gap remained high (28) and bicarbonate remained 15 in spite of lactic acid down trending. Urinalysis revealed trace ketones and concern arose for diabetic ketoacidosis causing a persistent anion gap. She was started on an insulin drip and D5W. In less than 24 hours, the patient's anion gap resolved.

IMPACT/DISCUSSION: Combined metformin-associated lactic acidosis and euglycemic ketoacidosis (MALKA) is a unique diagnosis. A diagnosis of euglycemic diabetic ketoacidosis (EDKA) can be made when there is a high anion gap metabolic acidosis, positive urine ketones, and serum ketones with a serum glucose < 250 mg/dL.[1] In our literature review there is one other case-series of MALKA. The pathophysiology of EDKA from metformin has not been fully explained. It is theorized that metformin causes inhibition of gluconeogenesis and stimulation of fatty acid oxidation which results in the underlying ketoacidosis.[2] In the setting of acute kidney injury it is likely this was a case of metformin associated lactic acidosis with concurrent euglycemic diabetic ketoacidosis. Metformin exerts it antidiabetic properties by decreasing hepatic gluconeogenesis and increasing peripheral glucose uptake.[3] It decreases the activity of pyruvate dehydrogenase and shunts towards anaerobic metabolism by increased inhibition of Complex 1 in the electron transport chain of the mitochondria.[4] This shift leads to increased lactate and with decreased clearance from the kidney causes the lactic acidosis.

CONCLUSION: This case was diagnostically challenging due to multiple metabolic derangements and mixed acid-base disorder. DKA masked by euglycemia must be considered when a patient is on oral antidiabetic medications. Untreated DKA is fatal, so a timely diagnosis and starting treatment early is crucial.

Treatment includes insulin and dextrose to reduce ketoacidosis and prevent hypoglycemia. Providers must consider MALKA in patients on metformin with an acid base disorder.

DOUBLE TROUBLE: CHOLANGITIS COMPLICATED BY SEPTIC ARTHRITIS IN A PATIENT WITH GOUT

William R. Doerfler, Emily Chan, Fred Rubin

Medicine, University of Pittsburgh, Pittsburgh, PA. (Control ID #3384213)

LEARNING OBJECTIVE #1: Recognize cholangitis as a cause of septic arthritis

LEARNING OBJECTIVE #2: Diagnose concomitant gout and septic arthritis, with recognition of gout as a risk factor for septic arthritis

CASE: A 69-year-old male attorney presented with four days of nausea, emesis, and bilateral ankle pain, left worse than right. Other associated symptoms included subjective fever and chills. He denied abdominal pain or diarrhea. Past medical history included tophaceous gout, bicuspid aortic valve with surgical replacement, chronic kidney disease, and type 2 diabetes mellitus. He had no prior orthopedic procedures. He consumed three shots of gin daily, but no tobacco or any illicit drugs. Medications included allopurinol, colchicine, aspirin, furosemide, insulin glargine, losartan, pravastatin, omeprazole and tramadol. His temperature was 36.9, blood pressure 132/62, pulse 79, respiration rate 16, and oxygen saturation 94% on ambient air. His ankles were warm, erythematous, and tender to palpation, with reduced active and passive range of motion, especially the left. His abdomen was soft and not tender to palpation. Laboratory evaluation revealed a white blood cell count of 8.7, normal serum aminotransferases, total bilirubin of 1.5, and alkaline phosphatase of 148. He was treated for suspected viral gastroenteritis and received oral prednisone for suspected polyarticular gout of the ankles. On the second hospital day, he developed a fever to 39.2. Peripheral blood cultures grew Escherichia coli. CT of the abdomen revealed choledocholithiasis and thickening of the common bile duct wall. Biliary stone removal was accomplished by endoscopic retrograde cholangiopancreatography (ERCP). His left ankle remained painful and erythematous. CT of the left ankle on the third hospital day revealed an acute pathologic fracture of the calcaneus and foci of gas near the hindfoot. Arthrocentesis revealed 146,000 white blood cells with 95% neutrophils, monosodium urate crystals, and cultures grew Escherichia coli. The left ankle was debrided. He completed a six-week course of ceftriaxone.

IMPACT/DISCUSSION: Septic arthritis requires prompt recognition given its potential to cause significant joint destruction. Bacteremia with hematogenous seeding of the synovial membrane is the most common mechanism, with gram negative bacilli identified as a causative organism in roughly 10-20% of cases of septic arthritis. Although cholangitis causing septic arthritis is uncommon, the risk is increased if a joint has pre-existing synovitis, such as by rheumatoid arthritis or crystalline arthropathy.

CONCLUSION: Cholangitis is a common cause of bacteremia, even in the absence of local pain. Gout increases the risk for septic arthritis, highlighting the need for prompt arthrocentesis to provide diagnostic and therapeutic clarity.

DO YOU HAVE A PROSTATE? EVALUATION OF HEMATURIA IN A TRANSGENDER WOMAN

Kyle Flattery, Carol Karmen, Basha Behrman

School of Medicine, New York Medical College, New York City, NY. (Control ID #3390716)

LEARNING OBJECTIVE #1: Recognize the clinical implications of prostate-sparing male to female gender affirmation surgery

LEARNING OBJECTIVE #2: Learn to evaluate hematuria in a transgender woman

CASE: A 71-year-old woman presented to her internist with a 1 day history of urinary symptoms including hematuria, urinary frequency, urgency and nocturia. No fever or back pain. Surgical hx was significant for male to female (MTF) gender affirmation surgery 15 years prior. Patient confirmed that the surgery spared prostate and that she had prostatitis in the past. Medications include estradiol transdermal patch.

BP 138/62 mmHg, HR 67. Afebrile. No CVA tenderness or suprapubic pain. Refused genito-rectal exam. Started on nitrofurantoin 100mg BID x 10 days and pyridium 100 mg/day. UA: SG 1.019. Dipstick: 2+ protein, 3+ blood, 2+ leukocyte esterase. Microscopy: 11 WBC/hpf, 8616 RBC, rare bacteria, and no epithelial cells. Urine culture: Serratia Marcescens >100,00 CFU/mL with resistance to nitrofurantoin and sensitivity to ciprofloxacin. Antibiotics changed accordingly.

Patient was referred for urological consultation. By this time, hematuria had resolved. DRE revealed a 20 g smooth symmetric prostate. Urine cytology: negative, with PSA <0.1 ng/mL. All symptoms resolved.

IMPACT/DISCUSSION: When approaching hematuria, common questions include an assessment of associated symptoms, age and gender. For example, the PPV of macroscopic hematuria for urological cancer in men is 22.1% and in women in the same age group it is 8.3%. One important detail to consider in the evaluation of hematuria is the presence of a prostate. Hematuria has a 1% PPV for prostate cancer. Thus, when a man presents with hematuria, prostate cancer must be considered. What about a MTF transgender woman with a prostate?

Radical prostatectomy is not routinely performed in MTF gender affirmation surgery. Therefore, hematuria in this population may be prostate cancer. However, the anti-androgenic effects of hormone therapy in transgender women may suppress the development of prostate cancer. A Dutch study of 2306 MTF transgender patients post orchiectomy treated with estrogen and anti-androgenic therapy found only one case of prostate cancer for a prevalence of 0.13%, compared to a control of 3.18% across 10 years in men without gender affirmation surgery. This demonstrates a marked difference in risk. The investigators suggest that since anti-androgens are used as therapy for active prostate cancer, feminizing hormones may guard against the development of prostate cancer.

CONCLUSION: While the risk of prostate cancer in MTF women may be reduced, it is not absent. The long-term administration of feminizing hormones and orchiectomy do not completely protect these patients from developing prostate cancer, as case studies show. In fact, if prostate cancer occurs, it may be more aggressive. Thus, the evaluation of macroscopic hematuria in anyone with a prostate, regardless of their gender, must include prostate cancer in the differential diagnosis.

DRESSED TO KILL; WHEN A RED RASH IS A HARBINGER FOR SEVERE DRUG REACTION

Jonathan C. Li[1]; Andrew Pajak[2]; Benjamin Berg[2]; Patrick Ho[2]; Chad Duffalo[3]

[1]Internal Medicine- Pediatrics, ChristianaCare, Wilmington, DE; [2]Internal Medicine, ChristianaCare, Newark, DE; [3]Infectious Disease, ChristianaCare, Newark, DE. (Control ID #3342242)

LEARNING OBJECTIVE #1: Drug reaction with eosinophilia and systemic symptoms (DRESS syndrome) is a rare and debilitating hypersensitivity reaction. Pathogenesis is believed to involve a drug-specific immune response but is also linked to viral reactivation from the Herpesviridae family. We present a patient with DRESS syndrome with profound HHV-6 viremia who developed fulminant liver failure.

CASE: A previously healthy 21-year-old female recently started therapy with lamotrigine. Three weeks into treatment, she developed a sore throat and fever. Despite negative testing for Streptococcus, she was placed on penicillin. One week later, she presented with persistent fevers, new-onset rash, facial edema, and vomiting. She was febrile, severely tachycardic to 156bpm, tachypneic, and hypotensive. Initial lab work was significant for a moderate transaminitis (AST 382u/L, ALT 536u/L), a WBC of 21,600/mm^3 with an absolute eosinophil count of 600mm^3 and atypical lymphocytes at 950/mm^3. Physical exam showed a critically ill- appearing patient with lip desquamation without mucosal involvement and an erythematous, coalescing morbilliform rash over her trunk, back, and extremities. Lamotrigine and penicillin were discontinued. She received high dose steroids, showed rapid improvement over the next 48 hours and was discharged on prednisone. Four days later, she was readmitted and found to have severe transaminitis, peaking at AST 1609u/L and ALT 2020u/L. A CT scan showed hepatosplenomegaly and axillary lymphadenopathy. Serum HHV-6 quantitative PCR returned with >2,000,000 copies/ml. Liver biopsy immunohistochemistry stained positive for HHV-6. The patient improved with supportive care and a prolonged taper of prednisone.

IMPACT/DISCUSSION: In DRESS syndrome, symptoms typically start 2 to 6 weeks after the initiation of a new medication and usually include fevers, facial edema, and rash. Patients have a high likelihood of developing end-organ damage, most commonly manifesting as liver failure, though severe pulmonary and renal damage have been reported, with mortality reaching 20%. A drug-induced hypersensitivity reaction, commonly to anticonvulsant medications (e.g. lamotrigine), plays an integral role in the pathogenesis of DRESS syndrome. Viral reactivation, often from the Herpesviridae family, is an emerging component of disease pathogenesis and likely influences the overall illness severity. It is suspected that the viremia has direct cytotoxic effects and/or causes an immune response that results in tissue damage. Management of DRESS syndrome includes discontinuation of the offending drug and the addition of steroids in severe disease. Specific antiviral therapy is rarely used, in part due to the toxicity of the agents. Recovery involves a relapsing and remitting course which can often take weeks to months.

CONCLUSION: As illustrated in this case, DRESS syndrome was associated with HHV-6 viremia. Further research is needed to determine if this association harbors prognostic or therapeutic implications.

DRUG INDUCED LIVER INJURY AND PROFOUND HYPERBILIRUBINEMIA IN THE SETTING OF LGD-4033 USE

Matthew J. Bittner[1]; Kathryn Leyens[2]; Michael G. Simonson[1]; Megan B. Raymond[3]

[1]Internal Medicine, University of Pittsburgh Medical Center, Pittsburgh, PA; [2]Internal Medicine, UPMC, Pittsburgh, PA; [3]Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA. (Control ID #3392411)

LEARNING OBJECTIVE #1: Understand the potential mechanisms of hyperbilirubinemia in hepatocellular injury

LEARNING OBJECTIVE #2: Enhance understanding surrounding the dangers of over-the-counter supplements and improve health literacy in at risk populations

CASE: A 34-year-old male with history of opiate use disorder in remission who presented with painless jaundice that progressed over one month. Patient is a member of the military and was attempting to 'bulk up' prior to his deployment. He took 5 to 10mg daily of a supplement called LGD 4033 (LIGANDROL capsule), a selective androgen receptor modulator, for one month with subsequent discontinuation. He took no other medications. One week after stopping, he developed painless jaundice that progressed over the next month, prompting his admission to the hospital. He additionally reported decreased appetite, worsening pruritus, dark amber urine, and cognitive 'clouding'. At the time of presentation, he was hemodynamically stable. His exam showed no stigmata of chronic liver disease outside of jaundice and scleral icterus. His ALT was 110 IU/L, AST 54 IU/L, Alkaline phosphatase 104 IU/L, gGTP 50 IU/L, NH3 51 uMol/L, and total bilirubin was 28.3 mg/dL with direct bilirubin of 21.6 mg/dL. He had a CT abdomen and pelvis with contrast which showed mild splenomegaly but did not demonstrate any additional pathology. He underwent a right upper quadrant ultrasound which showed no evidence of cirrhosis or underlying liver disease. A liver biopsy was performed which showed inflammation and diffuse cholestasis consistent with drug induced liver injury, but no evidence for additional underlying disease. Additional work-up included an autoimmune panel, chronic liver disease panel, hepatitis serologies, and HIV screen which were negative. His

altered cognition improved with lactulose administration. He left the hospital in stable condition, but his bilirubin remained elevated (29.3 mg/dL) on the date of discharge.

IMPACT/DISCUSSION: DILI is frequently encountered in the clinical setting and is a primary cause of medication discontinuation. The mechanism of injury is not defined in all cases but in adults the end result is often inflammation and resultant cholestasis. Individual genetics and concurrent medications are likely to play important roles. Reports of LGD-4033 causing DILI are rare. Flores et al have shown as similar picture in two other patients taking LGD-4033. One randomized study examined the safety of LGD-4033 in 76 patients and did not report any adverse health outcomes. However this study was underpowered to detect rare adverse events such as DILI and the doses used in the study (0.1mg, 0.3mg, and 1mg daily for 21 days) are significantly lower than what is available in over the OTC preparations.

CONCLUSION: LGD-4033, as well as many other medication supplements, is a potential concerning cause of drug-induced liver injury. More studies are needed to be done to evaluate the safety of LGD-4033 in the general population.

DUAL ANTIPLATELET AND ANTICOAGULATION CAUSING HEAVY MENSTRUAL BLEEDING IN A PREMENOPAUSAL FEMALE; A CASE REPORT WITH LITERATURE REVIEW

Ankita Aggarwal[1]; Anubhav Jain[2]; Devashree Nadgauda[1]; Sourabh Sourabh[3]

[1]Internal Medicine, Wayne State University-School of Medicine, Auburn Hills, MI; [2]Internal Medicine, Wayne State University, Auburn Hills, MI; [3]Internal Medicine, Wayne state university school of medicine, Rochester, MI. (Control ID #3391878)

LEARNING OBJECTIVE #1: Assess the safety of dual antiplatelet therapy (DAPT) in combination with direct oral anticoagulants (DOACs) in premenopausal women.

LEARNING OBJECTIVE #2: Manage heavy menstrual bleeding (HMB) in patients who require DAPT for other medical indications.

CASE: 45-year-old female with history of multivessel CAD status post-CABG initially presented with unstable angina for which she underwent angiography with stent placement to the saphenous vein graft. 1-week later she returned with new-onset atrial fibrillation for was started on apixaban. Following week, she presented again with lightheadedness and heavy vaginal bleeding. She was found to have hemoglobin of 5.1g/dl. Her initial physical exam, labs and gynecological workup were negative. In view of active bleeding, apixaban was held. Aspirin and Plavix were however continued due to recent drug-eluting stent placement. She was managed acutely with uterine packing and 3 units of transfusion. Following the acute management, her uterine bleeding stopped, and hemoglobin stabilized. A multidisciplinary team including the patient was involved in decision making regarding long term management. A decision was thus made to stop apixaban, continue DAPT and add medroxyprogesterone. Her uterine bleeding was stopped, and hemoglobin was stabilized by next day. She was planned for elective hysterectomy after 6 months when it will be safe to stop DAPT.

IMPACT/DISCUSSION: Over the last decade, there has been an increase in the incidence of coronary artery disease (CAD) and atrial fibrillation in premenopausal women. Due to this, we are increasingly seeing them on DAPT in conjunction with DOACs. Landmark trials involving DOACs such as ROCKET trial, ARISTOTLE trial, and RELY trial have not included or studied premenopausal women. Recently published PIONEER-AF trial and AUGUSTUS trial that evaluates the safety and efficacy of DAPT and DOACs combination have also excluded this population group. Neither of these trials specified the number of premenopausal women in their study group and the mean age of the study group was >60yrs. Premenopausal women being at higher risk of blood loss as compared to males and post-menopausal women, further studies are needed to assess the safety of these drugs and their combinations in this population. If premenopausal women must be on DAPT and DOACs combination, detailed gynecological evaluation should be performed to identify treatable causes of HMB. Ethyl-estradiol and Medroxyprogesterone acetate both can be used to manage HMB. Our literature review showed that medroxyprogesterone acetate is less thrombogenic as compared to estrogen derivatives. Thus, it should be preferred in managing HMB in females with CAD, especially those who underwent coronary stenting.

CONCLUSION: Caution showed be exercised when prescribing DAPT and DOACs in combination, to pre- menopausal women. If DAPT and DOACs are needed for any indication, detailed gynecological evaluation should be performed and medroxyprogesterone can be used in conjunction to reduce the risk of HMB.

DYSPHAGIA LUSORIA: A DEVIOUS DYSPHAGIA

Amy Goodrich-Harris[1]; wesley yang[1]; Matthew Chakan[2]

[1]Internal Medicine Residency, Eastern Virginia Medical School, Norfolk, VA; [2]Internal Medicine, Eastern Virginia Medical School, Norfolk, VA. (Control ID #3358228)

LEARNING OBJECTIVE #1: Recognize a rare cause of dysphagia.

CASE: A 57-year-old woman with history of gastroesophageal reflux disease presented to the outpatient clinic with chronic intermittent epigastric pain, progressive dysphagia to solids over several years, and aching substernal chest discomfort with perceived fullness in her throat. Physical examination was unremarkable.

Prior investigations for abdominal pain included a negative cardiac workup. Esophagogastroduodenoscopy (EGD) six years ago revealed mild gastritis. Recent computed tomography (CT) of the abdomen/pelvis was negative for intra-abdominal pathology. A trial of dexlansoprazole and linaclotide provided minimal relief of symptoms. She was referred for repeat EGD given progressive dysphagia and epigastric pain. EGD was negative for gross lesions in the stomach and duodenum, but identified a moderate sized area of extrinsic compression involving the upper one third of the esophagus. Subsequent CT angiography (CTA) of the chest demonstrated an aberrant right subclavian artery arising off the aortic arch distal to the left subclavian artery and coursing posterior to the esophagus. Focal smooth compression of the left lateral thoracic esophagus was reported on barium swallow. Barium swallow failed to identify gastroesophageal reflux despite multiple provocative measures. Clinical presentation and diagnostic findings were consistent with dysphagia lusoria. She was referred to cardiovascular surgery to determine optimal method of treatment.

IMPACT/DISCUSSION: Dysphagia lusoria is a rare congenital vascular anomaly that involves compression of the esophagus by an aberrant right subclavian artery (ARSA) causing dysphagia. ARSA arises distal to the left subclavian artery on the aortic arch traversing posterior to the esophagus. The prevalence of dysphagia lusoria is estimated to be 0.4-0.7%. Sixty to 80% of patients are asymptomatic while the remaining cases result in tracheoesophageal symptoms. The most common presentation is solid-bolus dysphagia consistent with a mechanical obstructive pattern. Other reported symptoms are dyspnea, retrosternal pain, cough, weight loss and abdominal pain. Dysphagia, epigastric pain and retrosternal pain were symptoms seen in our patient. The mean age of symptom onset is 50 years with a slight female predominance. Motility

abnormalities, esophageal stiffening and atherosclerosis with subsequent hardening of ARSA can account for the possibility of a later onset. Dynamic barium swallow studies can be a useful diagnostic screening tool. Endoscopic diagnosis is rare, but if present can manifest as a pulsatile posterior indentation in the upper esophagus similar to our case. CTA chest and magnetic resonance imaging are used to assess disease severity. Surgical correction is reserved in patients with severe symptoms.

CONCLUSION: Our case represents an exceedingly rare diagnosis of a common complaint in an outpatient setting and stresses the importance of a robust differential diagnosis.

DYSPNEA AND HYPOPITUITARISM: A UNIFYING DIAGNOSIS

Justin Holmes

Internal Medicine, UT Southwestern Medical Center, Dallas, TX. (Control ID #3387302)

LEARNING OBJECTIVE #1: Recognize the heterogeneity in presentation of sarcoidosis.

LEARNING OBJECTIVE #2: Identify the potential consequences of lesions affecting the hypothalamic- pituitary axis.

CASE: A 44-year-old African American man presented with subacute altered mental status, chest pain, and dyspnea. Mental status alteration was clarified as blunted emotion and forgetfulness; review of systems notable for 14-pound weight loss over two weeks, fatigue, headache, and vague report of blurred vision in right eye. Medical history was non-contributory. Vital signs were temperature 36.2 C, pulse 92, blood pressure 132/92, respiratory rate 30, and oxygen saturation 96% on ambient air. Exam demonstrated nasal flaring with clear lungs. He performed 2/3 delayed recall and could not identify the president but was otherwise oriented with no gross neurologic deficits. Labs revealed normal blood counts, ionized calcium mildly elevated to 1.31 mg/dL, ESR 46 mm/hr, CRP 17 mg/L, BNP 22 pg/mL, and negative troponin. Further studies found TSH level <0.01 mIU/L, morning cortisol 2.7 mcg/dL with normal ACTH stimulation test, prolactin level 31 ng/mL, urine osmolality 295 mg/dL, luteinizing hormone 0.5 mg/dL and free testosterone <0.1 pg/mL. Chest x-ray showed possible mediastinal lymphadenopathy, subsequently confirmed on chest CT. Brain MRI revealed homogeneous enhancement of pituitary gland and thickened stalk concerning for neurosarcoidosis involving the pituitary stalk, optic chiasm, hypothalamus, and basal ganglia. Mediastinal lymph node biopsy demonstrated non-caseating granulomatous inflammation with unremarkable flow cytometry, consistent with sarcoidosis. He was treated with corticosteroids and hormone replacement for thyroid, adrenal, and gonadal axes.

IMPACT/DISCUSSION: New diagnoses of sarcoidosis frequently stem from an initial presentation to a general internist and can be marked by heterogeneous and non-specific symptoms. This case presents a rare example of hypothalamic-pituitary involvement, reported in <1% of cases of sarcoidosis. Prior case reports exemplify variability in endocrine disorders that may result, and this case contributes to that literature. The thyroid, adrenal, and gonadal axes were predominantly affected, while this patient developed only mild hyperprolactinemia. He never developed diabetes insipidus, previously described as developing in the majority of pituitary sarcoid cases. Our patient ultimately required follow-up care with neurology, pulmonology, endocrinology, ophthalmology, and rheumatology, highlighting the interdisciplinary nature of sarcoidosis care and importance of the general internist in identifying sarcoidosis organ involvement to recruit appropriate specialty expertise.

CONCLUSION: - Sarcoidosis often manifests with heterogeneous presentation, often initially presenting to the general internist

- Hypothalamic-pituitary involvement is a rare presentation of sarcoidosis

- Type and severity of endocrine disorders are variable in neurosarcoidosis

DYSPNEA FROM STIFF LEFT ATRIAL SYNDROME

Milad C. El Hajj[1]; Benjamin Kalivas[2]; Ryan J. Tedford[3]

[1]Medicine, Medical University of South Carolina, Charleston, SC; [2]Medicine, Medical University of South Carolina, Charleston, SC; [3]Medicine, Cardiology, Medical University of South Carolina, Charleston, SC. (Control ID #3392209)

LEARNING OBJECTIVE #1: Provide update on the potential complications of modern atrial fibrillation treatment

LEARNING OBJECTIVE #2: Introduce the role of invasive cardiopulmonary stress testing in the evaluation of dyspnea

CASE: 84-year-old male with atrial fibrillation s/p repeat ablations presented with 2 years of isolated worsening dyspnea on exertion.

On physical examination, his cardiopulmonary exam was unremarkable. Echocardiography revealed preserved ejection fraction with normal left sided chambers, but enlarged right sided chambers. CT chest showed intralobular septal thickening, cardiomegaly and scattered left atrial (LA) calcification consistent with post ablation changes. Spirometry and 6-minute walk test were unremarkable.

He was referred for invasive cardiopulmonary exercise stress testing (iCPET), which is a right heart catheterization during supine bicycle exercise at increasing workloads. At rest, he had pulmonary hypertension (PH) with a mean pulmonary artery pressure (mPAP) of 30mmHg and a normal pulmonary artery wedge pressure (PAWP) of 15mmHg with abnormally high V waves to 45 mmHg. His mPAP increased to 40mmHg at peak exercise and his PAWP increased to 25mmHg with V waves to 80mmHg. In the absence of significant mitral regurgitation, his large V waves were indicative of stiff LA syndrome. An increase in mPAP with increasing exercise load suggested exercise-induced PH. Given the high LA pressures during exercise, he was referred for a left atrial septostomy in order to decompress the pulmonary vasculature.

IMPACT/DISCUSSION: Atrial fibrillation (AF) is the most common arrhythmia and is estimated to occur in 2.7-6.1 million Americans and 9% of people aged 65 years or older. With the aging US population and the recent incorporation of digital technology in the early diagnosis of AF (Apple Heart Study 2019), the general internist will likely encounter and manage more AF than in previous years. The recent Castle-AF trial demonstrated that catheter ablation improves the composite outcome of all-cause-mortality and unplanned heart failure hospitalizations, compared to medical therapy, in patients with AF and symptomatic systolic heart failure. Referrals for catheter ablation are therefore now increasingly common. Refractory AF may require repeat ablations which can cause atrial scarring, decrease compliance and lead to isolated atrial hypertension, a phenomenon known as stiff LA syndrome. In this patient with dyspnea on exertion of unclear cause, iCPET can help make the diagnosis of a stiff LA.

There are no proven therapies for stiff left atrial syndrome. Diuretics can be considered in volume overloaded patients. Pulmonary vasodilators may precipitate pulmonary edema in patients with elevated filling pressures. Atrial septostomy could potentially be considered in select patients with the understanding that it may worsen right heart failure.

CONCLUSION: This case illustrates a very real complication of repeat AF ablations and highlights the role of invasive hemodynamic CPET in the diagnosis of stiff LA syndrome.

DYSPNEA IN MALNOURISHED PATIENT: AN UNUSUAL CAUSE

Malik Shehadeh[1]; JALAL EL-AKAWI[2]; Emil Oweis[3]

[1]Internal Medicine, Medstar Washington Hospital Center, Washington, DC; [2]Internal Medicine, Medstar Washington Hospital Center, Washington, DC; [3]Pulmonary and Intensive Care Medicine, Medstar Washington Hospital Center, Washington, DC. (Control ID #3392485)

LEARNING OBJECTIVE #1: To recognize poor nutritional status as one of the stressors that can cause Takotsubo cardiomyopathy

CASE: A 64-year-old African American female patient with medical history of COPD on home oxygen and an obstructing esophageal mass (negative for malignancy on tissue biopsy) requiring placement of a percutaneous gastrostomy tube for nutrition. She presented to our hospital with a 2-week history of progressively worsening post-feeding abdominal fullness and pain, resulting in refusal of any further enteral feeds.

Upon arrival to the hospital, her vital signs were normal and laboratory investigations were only significant for hypoalbuminemia 1.5 g/dl (normal 3.5-5 g/dl). Chest computerized tomography revealed apical emphysema and hyperinflation with a dependent right upper lobe opacity that was suspicious of aspiration pneumonitis. Empiric broad-spectrum antibiotics were discontinued shortly after presentation given negative culture data.

While in the hospital, she became acutely tachypneic and diaphoretic with impending respiratory failure requiring intubation. Her chest X-ray didn't show any new abnormalities. Electrocardiogram showed >2 mm ST-segment elevation in the precordial leads. Initial troponin I levels were 0.180 ng/mL and serial measurements showed rising values. Antiplatelet therapy was immediately administered in anticipation for an emergent left heart catheterization.

Coronary angiography was unremarkable. Left ventriculography showed an ejection fraction of 30% with hyperkinetic basal segments and akinesia of the apical segments, consistent with Takotsubo cardiomyopathy.

IMPACT/DISCUSSION: Takotsubo cardiomyopathy (TCM) is a transient wall motion abnormality of the left ventricular (LV) apex accompanied with emotional or physical stress that usually resolves completely within weeks. However, there are some reports of serious TCM complications, including hypotension, heart failure, ventricular rupture and torsade de pointes.

The patient described above was diagnosed with TCM after fulfilling all four of the Mayo Clinic's diagnostic criteria. As a newly recognized disorder, much remains unknown about TCM, especially etiology. Other aspects are also puzzling, such as why postmenopausal women are mostly affected and why the apex of the left ventricle is so impaired while the remainder is relatively spared. TCM is a rare but potentially fatal condition, initially indistinguishable from acute coronary syndrome.

Our patient did not have a clear trigger for her overt Takotsubo cardiomyopathy other than poor nutritional status and failure to thrive.

CONCLUSION: Poor nutritional status is one of the stressors that can induce catecholamine release, which is postulated to be behind the pathophysiology of TCM. Optimizing nutritional status should be targeted in such patients.

EARLY-ONSET COLORECTAL CANCER: A "CAN'T MISS" DIAGNOSIS

Rachel Levy

Internal Medicine, Montefiore Medical Center, Bronx, NY. (Control ID #3369339)

LEARNING OBJECTIVE #1: Recognize the epidemiology of early-onset colorectal cancer

LEARNING OBJECTIVE #2: Identify the clinicopathological features of early-onset colorectal cancer

CASE: A 24 year-old woman presented with severe, stabbing, intermittent epigastric pain and 25lb unintentional weight loss over one year. She reported recurrent episodes of diarrhea alternating with constipation, narrow stools, and hematochezia for two months, with weakness and fatigue for several weeks. She had a history of menorrhagia. She was found to have fever, multiple aphthous ulcers in the oral mucosa, tenderness to palpation in the epigastrium and left-sided abdomen. A tender, firm mass was palpated to the left of the umbilicus. She had microcytic anemia (Hb 6.7g/dL) and leukocytosis. CT abdomen and pelvis revealed short segment wall thickening of the distal transverse colon with a 5cm peripherally enhancing lesion in the left mid-abdomen. She underwent exploratory laparotomy with transverse colectomy and pathology confirmed a high-microsatellite instability (MSI-H), BRAF negative, T3N2a, moderately differentiated colonic adenocarcinoma with mucinous features. She had no family history of colorectal cancer (CRC). She is currently undergoing chemotherapy.

IMPACT/DISCUSSION: CRC is the third most common cancer diagnosed annually and is the second leading cause of cancer-related death in the United States. According to data from the National Cancer Institute, while the overall incidence of CRC in the U.S. is decreasing (by 2.5% yearly for patients ≥50), there is a rise in early-onset CRC (EOCRC) in patients under 50 (by 2% annually). When young patients without a family history of CRC present with non-specific symptoms, they are often diagnosed with more common, benign conditions, which may not entirely explain their presentations.

Causes of increasing incidence of EOCRC are poorly understood, but may be related to early life exposures, obesity, physical inactivity, and a diet high in processed foods. 20% of patients with EOCRC have a family history, and 30% are found to have at least one pathogenic cancer susceptibility gene mutation. The remaining 50% of patients with EOCRC have neither family history nor mutations suggestive of hereditary syndromes. Most younger patients do not have tumors with MSI, and those that do tend to be associated with Lynch syndrome.

Patients with EOCRC are more likely to be diagnosed at more advanced stages and have poor prognostic histological features, such as mucinous and signet ring characteristics and poor differentiation. EOCRC is more often found in the distal colon or rectum. Current guidelines recommend earlier screening for higher risk population. However, 70% of cases of EOCRC are sporadic.

CONCLUSION: The incidence of EOCRC is rising and is often not associated with a family history. Therefore, clinicians should consider CRC in patients with suspicious features, despite their young age or lack of family history. Moreover, genetic counseling and testing should be recommended for all patients with EOCRC.

EASTERN EQUINE ENCEPHALITIS PRESENTING WITH ACUTE STROKE

Sara Brenner, Anisha Contractor, Christopher Lumpkin

Internal Medicine and Pediatrics, Baystate Medical Center, Springfield, MA. (Control ID #3391895)

LEARNING OBJECTIVE #1: Recognize that EEE may present with stroke or focal neurological deficits

CASE: A 74-year-old male with history of past stroke presented with acute onset syncope and altered mental status. Patient returned to mental baseline for several hours before developing fevers and left-sided

weakness. Broad-spectrum antibiotics and acyclovir initiated due to concern for meningitis. CT head and CT angiography revealed new right vertebral artery occlusion and narrowing of the right MCA. Thrombolysis was given and he was transferred to a tertiary medical center for further management. The patient's hospital course was complicated by altered mental status and hypotension requiring pressor support, intubation, hyperventilation, and 3% saline due to concern for herniation. Repeat CT head showed extensive effacement of sulci on right side and flattening of right lateral ventricle.

Further workup included EEG, CSF studies, HIV and Lyme serologies, and New England Tick Panel. While EEG demonstrated evidence of right sided slowing and fast activity attenuation, remainder of studies returned negative except for Eastern Equine Encephalitis (EEE) IgM. Given confirmation of viral infection, antibiotics were discontinued. Vasopressors and sedation were weaned. Patient was started on IVIG and steroids without clinically significant response. MRI on HD8 showed worsening right hemisphere edema extending to deep brain structures and brainstem. Patient's care changed to comfort measures only with subsequent death on HD26.

IMPACT/DISCUSSION: Eastern equine encephalitis is a mosquito-borne *Alphavirus* found primarily in the Atlantic and Gulf Coast states and the Great Lakes region. Rates of EEE have increased this past year. As of December 17, 2019, the CDC reported 38 confirmed cases of EEE. Presenting symptoms are highly variable. The most common presenting symptoms of EEE infection include fever, headaches, nausea/vomiting, general malaise, and confusion.

There have been several reported cases with focal neurological deficits on exam, which may be mistaken for a stroke. Focal lesions on imaging in EEE are commonly documented. However, we note only one other case in which a possible stroke was seen on imaging. While our patient had risk factors for stroke, it raises the question of whether this viral encephalitis could have increased his risk for a cerebrovascular event. Past studies suggest increased risk of stroke following CNS infection, which has been attributed to resulting vasculitis. Such association has been observed in young adults with Herpes zoster. Additionally, there have been case studies of stroke in patients with West Nile Virus and HSV encephalitis. Thus, further assessment of stroke risk in association with EEE infection, should be considered.

CONCLUSION: Presenting features of EEE are variable and can include stroke. Thus EEE should be considered in patients with stroke and associated infectious symptoms.

EFFECTIVE MANAGEMENT OF SEVERE ILLNESS ANXIETY DISORDER UTILIZING COMPREHENSIVE PRIMARY CARE PLUS (CPC+) CARE COORDINATION

Andrew Nashed, Lisa Kearns

Internal Medicine, Ohio State University, Columbus, OH. (Control ID #3392161)

LEARNING OBJECTIVE #1: Recognize the economic burden and underdiagnosis of Illness Anxiety Disorder.

LEARNING OBJECTIVE #2: Utilize integrated primary care models such as CPC+ Care Coordination in the management of Illness Anxiety Disorder.

CASE: A 29-year-old female with a history of tobacco use, depression, IVDU was evaluated in clinic with concerns for palpitations and chest pain. Social history was notable for unemployment, relationship strain, and low socioeconomic status. Over the course of nine months, she had 68 ED visits across four unique healthcare networks. Symptoms varied often and included several organ-systems. She sent frequent EMR messages to her many providers, was well-versed in medical terminology and sought innumerable costly work-ups due to concerns for grave deadly diseases all of which were negative. Patient was established in our primary care clinic and initiated with CPC+ care coordination which included weekly scheduled phone calls with nursing, consistent EMR chat messaging with ancillary staff and regular in-office visits. Impressively, ED visits were entirely eliminated in the two consecutive months post-program enrollment.

IMPACT/DISCUSSION: Illness Anxiety Disorder leads to significant health care use, costing the US health system an estimated $100 billion annually. The condition leads to disproportionately high rates of visits to physicians, specialty consultations, laboratory tests, and surgical procedures. Management strategies focus on brief but frequent regular visits, however, this treatment strategy can be overwhelming and impractical in a traditional primary care clinic.

CPC+ is a unique public-private multiplayer practice transformation model led by the Centers for Medicare and Medicaid Services (CMS). The model de-emphasizes fee-for-service and increases payment to support practice improvement and capacity building. One of the most promising care models is the patient-centered medical home (PCMH) which prioritizes behavioral health needs in the primary care setting. Care coordinators who oftentimes as in our case are nurses are increasingly featured in patient-centered medical home models. In our case, the utilization of CPC+ Care Coordination led to a dramatic reduction in costly health care utilization. Unfortunately, a search of our institution's healthcare network of over three million patients revealed that only 90 patients had been formally diagnosed in the EMR with Illness Anxiety Disorder in the past six months demonstrating that this condition although largely recognized is highly underdiagnosed.

CONCLUSION: Illness Anxiety Disorder is estimated to be present in up to 7% of primary care patients and is underdiagnosed and difficult to manage. Utilization of an integrated primary care system such as CPC+ Care Coordination can result in positive outcomes and enormous health care savings.

ELECTRONIC VAPING-ASSOCIATED LUNG INJURY (EVALI) AMONG THREE YOUNG ADULTS: A CASE SERIES FROM DELAWARE

Andrew Pajak[1]; Jonathan C. Li[2]; Soraya Bascoy[2]; Michaela Seigo[3]

[1]Internal Medicine, ChristianaCare, Bear, DE; [2]Internal Medicine-Pediatrics, ChristianaCare, Wilmington, DE; [3]Internal Medicine, Christiana Care Health System, Delaware, DE. (Control ID #3385906)

LEARNING OBJECTIVE #1: Recognize EVALI frequently presents with nonspecific gastrointestinal and respiratory symptoms and remains a diagnosis of exclusion

LEARNING OBJECTIVE #2: Utility in obtaining and trending biomarkers such as CRP, ESR, bilirubin, and procalcitonin

CASE: Three previously healthy individuals aged 18-20 years, each presented individually after a few days of non-specific gastrointestinal and pulmonary symptoms (nausea, vomiting, cough, dyspnea). Each endorsed electronic vape use of THC-containing products with frequency ranging from daily to thrice weekly. On admission, each patient was tachycardic, dehydrated, and required supplemental oxygen. UDS was positive for cannabinoids in each case. Initial chest x-rays were concerning for multifocal pneumonia and lab work was significant for leukocytosis with neutrophil predominance. All patients were initially started on empiric antibiotics for community-acquired pneumonia. Severely elevated C-reactive protein (>230mg/L) and elevated total bilirubin were observed in each case. Two patients who were tested for

procalcitonin had elevated levels. CT chest with contrast confirmed the presence of bilateral ground-glass opacification and consolidations. Exhaustive infectious, autoimmune, and vascular workups were negative. One patient required direct admission to the ICU where steroid therapy was initiated immediately. The other patients initiated steroid therapy on Days 4 and 5 of hospitalization. After clinical improvement and biomarker downtrending, each patient was discharged on Day 6 of hospitalization with a prolonged steroid taper.

IMPACT/DISCUSSION: To date, over 2,500 hospitalizations and/or deaths have been reported to the CDC. Vitamin E acetate within THC-containing vape products is the leading suspected cause of EVALI. This case series illustrates the salient features of EVALI that are reported nationwide including recent history of vaping THC-containing products and the respiratory and gastrointestinal symptomatology. Bloodwork and imaging findings were consistent with those reported in literature. CRP, procalcitonin, bilirubin, and ESR were initially elevated and downtrend with steroids. We suggest trending inflammatory markers and procalcitonin as biomarkers in supporting a diagnosis of EVALI, which can distinguish the efficacy of antibiotics versus steroid therapy. Hyperbilirubinemia has not yet been published in literature. Each patient was initially started on empiric antibiotics but did not show improvement until steroids were initiated.

CONCLUSION: Despite many recent advances in our understanding of EVALI, there is still a paucity of information known. Classic symptoms include both respiratory and gastrointestinal. Workup typically reveals neutrophilic leukocytosis and a bilateral diffuse process on imaging. CRP, ESR, LFTs including bilirubin, and procalcitonin should be obtained upon admission and trended with different therapies. Diagnosis remains that of clinical indication and corticosteroids remain the mainstay of treatment.

ELEVATED ANA AND CHRONIC URTICARIA: CLINICAL SUSPICION FOR AUTOIMMUNE DISEASE

Phillip Groden[1]; Alexis Tchaconas[2]; Joseph Truglio[3]

[1]Medical Education, Icahn School of Medicine at Mount Sinai, New York, NY; [2]Internal Medicine and Pediatrics, Icahn School of Medicine at Mount Sinai, New York, NY; [3]Internal Medicine, Pediatrics and Medical Education, Icahn School of Medicine at Mount Sinai, Maplewood, NJ. (Control ID #3391389)

LEARNING OBJECTIVE #1: Recognize the presentation of chronic spontaneous urticaria and its association with autoimmune disease.

LEARNING OBJECTIVE #2: Describe the management approach to elevated ANA in patients with non- specific symptoms for potential autoimmune conditions.

CASE: MK is a 22 year old female with a history of contact dermatitis who presented to the clinic with an erythematous, pruritic rash affecting her chest, abdomen, thighs, and wrists of three weeks duration associated with one week of rhinorrhea, sore throat, productive cough, and swollen neck glands. She denied fever, shortness of breath, chest, abdominal, or joint pain, sick contacts, or changes to detergents or soaps. On exam, a scattered morbilliform rash was present on the chest and abdomen without lesions or ulcerations. Nasal exam revealed moderately erythematous and inflamed turbinates; bilateral cervical lymphadenopathy was present. A rapid strep test was positive, and the patient was administered intramuscular benzathine penicillin. Laboratory analysis revealed a highly elevated antinuclear antibody (ANA) titer (1:1,280) with a homogenous, speckled pattern; subsequent analysis showed an identical ANA pattern and negative: anti- double-stranded DNA, anti-Smith, anti-thyroglobulin, and anti-thyroid peroxidase. ESR, CBC, RPR, protein/creatinine ratio, and urinalysis were all within normal limits. On follow-up presentation, faint urticaria were noted on the patient's maxilla bilaterally; the patient was given the diagnosis of chronic spontaneous urticaria (CSU).

IMPACT/DISCUSSION: The diagnosis of an autoimmune disease requires a high degree of clinical suspicion— combining an array of laboratory tests in the context of relatively non-specific patient signs and symptoms. Elevated ANA titers are associated with numerous autoimmune conditions, including systemic lupus erythematosus (SLE), scleroderma, and Graves' disease. Though roughly one-third of all healthy individuals display elevated ANA at an accepted laboratory level (1:40), certain patients may test positive up to decades before the development of an autoimmune disease. CSU is characterized by recurrent urticaria or angioedema for at least six weeks; the condition affects roughly one percent of the general population and is seen in women twice as often as men. Similarly, autoimmune conditions are increasingly diagnosed in patients with CSU and often up to a decade after initial presentation. Elevated ANA is also more prevalent in CSU patients than in the general population. Accordingly, both patients with CSU and elevated ANA should be carefully monitored for the development of signs or symptoms associated with autoimmune disease; those with elevated ANA should have this value trended over time.

CONCLUSION: Appropriately diagnosing autoimmune disease is a challenge due to the combination of non-specific symptoms and laboratory markers. An elevated ANA in otherwise healthy patients with CSU warrants close clinical monitoring for a concurrent or impending autoimmune disease.

ELUSIVE CAUSE OF ACUTE MITRAL REGURGITATION AND DISSEMINATED INTRAVASCULAR COAGULATION: ENTEROCOCCUS FAECALIS INFECTIVE ENDOCARDITIS ONLY DIAGNOSED BY MITRAL VALVE SURGERY

Shun Yamashita[1]; Masaki Tago[1]; Naoko E. Katsuki[1]; Shu-ichi Yamashita[2]

[1]General Medicine, Saga University Hospital, Saga, Japan; [2]General Medicine, Saga medical university, Saga, Japan. (Control ID #3346013)

LEARNING OBJECTIVE #1: Recognize the presence of infective endocarditis (IE) which could be an extreme diagnostic challenge only diagnosed by cardiac surgery.

CASE: A 70-year-old woman complaining dyspnea for 5 days caused by acute mitral regurgitation (MR) was transferred to our hospital. On admission, she had acute heart and respiratory failures and disseminated intravascular coagulation (DIC). Although infective endocarditis was suspected, repeated blood cultures and transesophageal echocardiography (TEE) could not reveal any findings of infective endocarditis. Because the etiology of her condition was not determined by various detailed examinations, mitral annuloplasty, required to treat her mitral regurgitation, was performed for definitive diagnosis and treatment revealing the presence of vegetation on the mitral valve. *Enterococcus faecalis* was detected by cultures of mitral valve and blood after the surgery.

IMPACT/DISCUSSION: The unusual presentations of our case, complicated acute MR and DIC, made the diagnosis extremely elusive. The modified Duke criteria have been used universally to diagnose IE. Positive blood cultures and confirmation of the presence of vegetation by echocardiography are the decision-making points of these criteria. Although three consecutive sets of blood cultures are useful bacteriological tools, 10–30% of IE patients could have negative blood cultures. The two major causes are antibiotic treatments prior to examinations and the involvement of fastidious organisms, which are difficult to culture. TEE is the most useful imaging modality for detecting vegetation with sensitivity of 86%, specificity 97%, positive predictive value (PPV) of 89% and negative

predictive value of 96%. Despite the lack of prior antibiotic therapy, our case did not definitively fulfill the modified Duke clinical criteria on the basis of negative results of 8 sets of blood cultures (8 bottles) and twice repeated TEEs. In such cases, it is mandatory to take cardiac valve operation into consideration as a definitive diagnostic tool. It is reported that 0.9% of patients who were diagnosed as having non-infectious endocarditis and underwent cardiac valve operation were diagnosed with IE after operation. Actually on the present case, we could make the correct diagnosis of IE only by performing surgical operation on the mitral valve, which made it possible to detect vegetation and perform bacterial culture on the valve, growing *E. faecalis.*

CONCLUSION: IE on native mitral valve complicated with acute MR and DIC without underlying systemic disorders, which fails to fulfill definitively the modified Duke criteria, is rare and difficult to be diagnosed correctly. In such case, cardiac surgery could be the only instrument to make a definitive diagnosis.

ENCEPHALOPATHY IN A PATIENT WITH DIABETES

Rachel Naramore[1]; Ryan Kraemer[2]

[1]Internal Medicine, UAB Hospital, Birmingham, AL; [2]Medicine, University of Alabama at Birmingham, Birmingham, AL. (Control ID #3391812)

LEARNING OBJECTIVE #1: Recognize epilepsy as a mimicker of dementia

LEARNING OBJECTIVE #2: Be able to re-evaluate the initial diagnosis when symptoms do not respond to interventions as expected

CASE: A 63 year old woman with type 2 diabetes presented to the emergency department with gait instability, slurred speech, blurry vision, polyuria, and polydypsia after discontinuing her medications five days prior. Physical exam was notable for dysarthric speech with inappropriate response to questions (such as responding "Yes" to "what day is it?") and intermittent inability to follow commands. Her labs were notable for glucose of 698, anion gap 11, sodium 128, and a CT of her head showed no acute abnormalities. She reported resolution of her symptoms after 8 u regular insulin. She was placed on basal bolus and returned to baseline mental status with improved glycemic control.

However, as the patient was preparing for discharge, she again began intermittently answering questions inappropriately despite a blood sugar of 291. On further history, her daughter stated that her mother had seemed less able to care for herself recently. She expressed concern for dementia, and a SLUMS performed at bedside was 7. Further behavioral abnormalities were noted including answering "yes" to every question asked, intermittent schizophasia, and drawing motions in the air. Given the intermittent nature of her symptoms, a long term electroencephalogram was performed and revealed 2-3 temporal lobe seizures per hour. These completely resolved after initiation of levetiracetam. MRI showed only microangiopathic disease, and a repeat SLUMS was 23.

IMPACT/DISCUSSION: Encephalopathy is often a challenging diagnosis for clinicians with many potential causes including structural, metabolic, and psychiatric. We initially thought the cause of this patient's encephalopathy was straightforward hyperglycemia related to non-adherence to diabetes medications. However, prior to discharge her encephalopathy recurred despite improvement in her hyperglycemia. At this point, a repeat history and physical exam led to recognition that her decreased ability to care for herself had occurred over too long a time period to be due to HHS alone and broadening of the differential diagnosis. This case demonstrates the importance of repeated history and physical examination for avoidance of anchoring.

Temporal lobe epilepsy presents most commonly as complex partial seizures. These may manifest externally as staring spells and may be associated with amnesia both before and after the seizure episode, which may explain this patient's apparent recent cognitive decline. Mesial temporal lobe seizures may also manifest with automatisms which in rare cases include vocalization, as with this patient.

CONCLUSION: Because temporal lobe seizures have varied manifestations and are associated with amnestic episodes, they may be mistaken for dementia

Frequent reassessment of the initial diagnosis should be undertaken if the aspects of the clinical picture do not fit with what is expected

EN LAS MANOS DE DIOS: CREATING SPIRITUAL ALIGNMENT WITH LATINO PATIENTS

Carine Davila[2]; Sarah Byrne-Martelli[2]; Justin Sanders[1]

[1]Palliative Care, Psychosocial Oncology and Palliative Care, Dana Farber Cancer Institute, Boston, MA; [2]Division of Palliative Care and Geriatric Medicine, Massachusetts General Hospital, Boston, MA. (Control ID #3390827)

LEARNING OBJECTIVE #1: Integrate techniques to apply cultural curiosIty in exploring patient's unique palliative care needs

LEARNING OBJECTIVE #2: Describe techniques for effectively engaging spiritual care providers to enhance patient care at the end of life

CASE: A 66-year-old Spanish-speaking woman with end-stage renal disease on hemodialysis and intra- abdominal tuberculosis was admitted for medical management of a small bowel obstruction. She developed septic shock and required intubation in the intensive care unit. After several days with ongoing decline, the medical team recommended compassionate extubation. The patient's family was strongly opposed to this, citing "hope for a miracle from God". The medical team worried this represented family denial of the severity of her illness and terminal prognosis, and palliative care was consulted.

The patient's family avoided engaging in discussions around goals of care and continued praying for a miracle. A Spanish-speaking palliative care clinician worked closely with a chaplain to share the family's hope for a miracle, creating spiritual alignment with the family. The family was then able to accept that compassionate extubation would not prevent God from granting a miracle. Two days later, the family agreed to compassionate extubation and the patient died shortly thereafter.

IMPACT/DISCUSSION: By 2050, Hispanics/Latinos (Latinos) are expected to comprise over 25% of the U.S. population (US Census Bureau, Projections for the United States: 2017 to 2060). Compared with non-Latino white patients, Latino patients have less access to palliative care and use hospice services less commonly (NHPCO Facts and Figures 2018). Patients from Latino communities frequently cite religion and spirituality as an important strategy for coping with serious illness and as a key factor in healthcare decision- making. Yet, healthcare professionals may not recognize this role of spiritual care near the end of life. In our patient's case, the integration of palliative care and a hospital chaplain into the team to provide spiritual support for the family was critical in creating spiritual alignment. Research has shown that for patients with community spiritual support, receiving spiritual support from a hospital chaplain or medical team was associated with higher rates of hospice, fewer aggressive interventions, and fewer patient deaths in the

intensive care unit (Balboni JAMA 2013). We will outline ways to ask about spirituality and include strategies and language to create partnerships with chaplaincy, patients, and families.

CONCLUSION: The need for culturally sensitive palliative care for Latinos is growing. Palliative care clinicians should become facile with engaging Latino patients and families around spiritual care concerns to provide effective and compassionate care at the end of life.

EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS: ATYPICAL FEATURES IN THE PRESENTATION OF A RARE DISEASE

Cindrel Tharumia Jagadeesan[1]; Surabhi Uppal[1]; Jeremy P. Feldman[2]

[1]Internal Medicine, St.Joseph's Hospital and Medical Center, Phoenix, AZ; [2]Pulmonology/Critical care, St.Joseph's Hospital and Medical Center, Phoenix, AZ. (Control ID #3388265)

LEARNING OBJECTIVE #1: Atypical presentation of Eosinophilic granulomatosis with polyangitis

CASE: A 58-year-old man, with a history of skull base chondrosarcoma treated with multiple transsphenoidal resections, presented with worsening dyspnea and subjective fever for 1 week. He endorsed nasal congestion and frequent sinus infections which started 6 months after his last surgery, all treated with steroids and antibiotics. He was a former smoker. On admission, he denied having chest pain, hemoptysis, rashes, hearing difficulties, joint pains or myalgia, but did note unquantifiable weight loss and anorexia. He endorsed peripheral neuropathy of a year's duration. Vitals revealed low-grade fever, tachycardia, tachypnea and hypoxia with an oxygen saturation of 82% on room air. On exam, he appeared in distress and had scattered rales and wheezing on lung auscultation. Significant labs included a WBC count of 11,500/microL, of which 18.7% were eosinophils with an absolute eosinophil count of 2100/microL. Further work-up revealed positive ANCA (Antineutrophil cytoplasmic antibodies) and PR3 and negative serologies for *Coccidioides sp.*, *Legionella sp.*, and *Aspergillus sp*. A nasopharyngeal swab for viral PCR, Quantiferon test, and blood and sputum cultures were negative. High resolution chest CT showed apical and lingular ground glass opacities with mild bronchiectasis. Histopathology of bronchoscopic sample showed 24% eosinophils and was negative for malignancy. He was started on oral prednisone at a dose of 40 mg daily, inhaled corticosteroids and supplemental oxygen. He showed improvement and was discharged with close pulmonology follow up. Two weeks after discharge, he was seen in the office and was feeling well and had normal spirometry results. We tapered his prednisone gradually. Two months later, he was taking 10 mg of prednisone daily and had increased symptoms of dyspnea. His prednisone was increased to 20 mg and he again had prompt improvement. Authorization for anti-IL5 (benralizumab) therapy was submitted. We expect to start treatment shortly.

IMPACT/DISCUSSION: EGPA is a potentially life-threatening disease with multi-organ involvement. Cardiac complications are responsible for 50% of deaths. It is interesting to note that our patient had never suffered from asthma in the past. His recent transsphenoidal surgery complicated his acute presentation with progressive respiratory symptoms. He had no cardiac, gastrointestinal or skin involvement but met 5 of the 6 ACR criteria as required for diagnosis. As seen in ours, ANCAs are positive in about 40% of cases. Early diagnosis and treatment can prevent organ damage and should be tailored based on the presence of poor prognostic factors. Gold standard remains high-dose corticosteroids +/- cyclophosphamide. Biologics like rituximab or benralizumab are promising alternatives. Late relapses are uncommon and treatment can be discontinued in most patients.

CONCLUSION: Early diagnosis and treatment of atypical presentation of EGPA can prevent organ damage.

EPIDIDYMO-ORCHITIS: HOW A COMMON PEDIATRIC CONDITION PRESENTS IN ADULTS

Vickie Kassapidis[1]; David Rhee[2]

[1]Internal Medicine, NYU Langone - Brooklyn, Brooklyn, NY; [2]Internal Medicine, New York University School of Medicine, New York, NY. (Control ID #3390301)

LEARNING OBJECTIVE #1: Recognize the presentation of epididymo-orchitis in adults

LEARNING OBJECTIVE #2: Assess a patient's risk factors when they present with unilateral testicular swelling

CASE: A 65-year-old man with a history of multiple systems atrophy, BPH, type 2 diabetes, and asthma presented with several days of lethargy. He had subjective fevers, decreased urine output, and worsening cough. A review of systems revealed a one-week history of unilateral testicular swelling and pain in the setting of a chronic Foley.

In the ED, the patient was febrile to 102.6F, tachycardic to 133bpm, tachypneic to 20 respirations/minute, hypertensive to 162/68, and saturating 96% on room air. He was toxic-appearing, diaphoretic, with increased work of breathing and waxing and waning mental status. Further examination revealed mild diffuse expiratory wheezing and an enlarged tender scrotum with left sided swelling. His cremasteric reflex was intact bilaterally.

Laboratory studies revealed a leukocytosis 44K, Cr 1.35, and lactate 3.64. UA revealed large amounts of leukocyte esterase and 67 WBCs with negative bacteria/nitrites. Scrotal ultrasound demonstrated increased left testicular vascularity consistent with left-sided orchitis. CT abdomen pelvis revealed bilateral hydroceles with increased vascularity of the left testicle supporting ultrasound imaging.

The patient decompensated, becoming hypotensive to 90/60s and requiring hemodynamic support in the MICU. He slowly began to improve with broad antibiotic coverage. His blood, urine, and sputum cultures grew no organisms after several days. His presentation was most consistent with septic epididymo-orchitis secondary to infect enteric gram-negative organism and he was discharged home on PO Levaquin.

IMPACT/DISCUSSION: Epididymo-orchitis is infrequently encountered. Male patients will typically endorse unilateral testicular pain/swelling and may complain of hematuria, dysuria, and increased urinary frequency. Orchitis in men >35 years old is most commonly due to urinary tract pathogen with STIs more commonly in men <35 years old.

The diagnosis of epididymo-orchitis is made clinically. Physical exam reveals tender, swollen, or indurated epididymis, erythematous scrotum or edematous testicle, with an intact cremasteric reflex. Diagnostic workup depends on the suspected cause. Testicular ultrasound is important to rule out testicular torsion. In the case of epididymitis, ultrasound reveals increased blood flow to the affected testis.

In rare cases, epididymo-orchitis can present with sepsis. The condition has been more prominently documented in the pediatric population with few cases in older adults.

CONCLUSION: Patients presenting with sepsis should be carefully evaluated. While exceptionally rare, sepsis can result from untreated epididymo-orchitis.

Risk factors for epididymo-orchitis include a history of recurrent UTIs, prolonged sitting, and BPH.

Treatment should be guided based on the suspected organism after obtaining a detailed sexual history.

EPIPLOIC APPENDAGITIS: A COMMON AND OFTEN OVERLOOKED CAUSE OF ABDOMINAL PAIN

Joy Underwood[1]; Chris G. Pasvantis[1]; Tracey Doering[2]

[1]Internal Medicine, University of Tennessee Nashville, Nashville, TN; [2]Internal Medicine, University of TN, St. Thomas Midtown Hospital, Nashville, TN. (Control ID #3387618)

LEARNING OBJECTIVE #1: Recognize the role of a broad differential diagnosis in seemingly common cases of abdominal pain.

LEARNING OBJECTIVE #2: Assess the need for conservative versus surgical management of epiploic appendagitis.

CASE: A 46-year-old man with a history of GERD and prior appendectomy presented to clinic with 3 days of constant, non-radiating abdominal pain, worsened with deep inspiration and standing upright. There were no associated factors including fever, nausea, anorexia, changes in bowel movements, or NSAID use. Physical exam was relevant for normal vital signs, tenderness to deep palpation of the bilateral lower abdominal quadrants, and absence of peritoneal signs. Initial differential diagnosis included diverticulitis, pancreatitis, cholecystitis, and infectious or ischemic etiologies. CBC, CMP, urinalysis, and lipase all returned within normal limits. CT of the abdomen/pelvis with contrast showed a 4.2 x 1.3 cm fatty lesion anterior to the descending colon in the left lower quadrant with surrounding inflammatory changes, consistent with epiploic appendagitis. The patient was treated with NSAIDS and was pain free after 3 days.

IMPACT/DISCUSSION: Epiploic appendagitis is an acute inflammation and infarction of an epiploic appendage, a 2-3 cm pericolic adipose-filled serosal sac on the outer colon. Infarction is most often due to thrombosis of the tortuous central draining vein that predisposes to torsion. Infarction leads to fat necrosis, associated with an acute dull, constant, non-radiating left lower quadrant pain without rebound tenderness or accompanying symptoms. Though the exact incidence is unknown, predisposing factors include obesity, strenuous exercise, and male gender. As the differential diagnosis usually includes acute appendicitis, diverticulitis, and nephrolithiasis, cases are typically incidentally diagnosed by a CT scan and less frequently by abdominal ultrasound. Characteristic findings include a 3 cm low attenuation paracolic ovoid mass with adjacent fat stranding and peritoneal wall thickening. Blood and urine lab values are unremarkable. Conservative management with NSAIDs or a short-course of opiates is anecdotally recommended. Surgery, either laparoscopic or exploratory laparotomy, is reserved for those with worsening symptoms such as fevers, increasing pain, or recurrent vomiting. This occurs almost exclusively in the presence of one of the rare complications including abscess, gangrenous necrosis, obstruction, or intussusception. Nearly all cases resolve completely within 3-14 days without elevated risk of recurrence.

CONCLUSION: Epiploic Appendagitis is a self-limited process caused by inflammation and infarction of a normal outpouching of pericolic fat, reported in 5% of patients with suspected diverticulitis and 1% of patients with suspected appendicitis. Patients can be managed conservatively in the outpatient setting, but due to its broad differential diagnosis, many undergo unnecessary hospitalization, antibiotic administration, and surgical intervention.

EXTRA-NODAL NATURAL KILLER/T CELL LYMPHOMA (ENKTCL) MIMICKING FACIAL MYOSITIS AND ORAL HERPES

Yiyun shi[1]; Amy Mathew[2]; Katrina Byrd[3]; Cheston Cunha[3]

[1]Internal medicine, rhode island hospital, Providence, RI; [2]Internal Medicine, Brown University, Providence, RI; [3]Infectious Diseases, Brown University, Providence, RI. (Control ID #3388556)

LEARNING OBJECTIVE #1: Discuss a rare complication of Epstein-Barr virus (EBV) Infection

LEARNING OBJECTIVE #2: Discuss non-infectious etiologies of oral lesions

CASE: A 43-year-old Guatemalan female presented with months of sore throat. Flexible laryngoscopy showed bilateral arytenoid and false vocal fold erythema and edema. She was treated with a proton pump inhibitor and intermittent steroids for months. Six months prior to presentation, she developed right sided facial swelling and ophthalmoplegia. MRI scan showed edema of multiple facial and extraocular muscles. Right temporalis muscle biopsy showed inflammatory myositis. Extensive autoimmune and neoplastic work up was unrevealing. Given imaging findings, she was diagnosed with inflammatory myositis and was started on high dose prednisone. She then developed fever, leukopenia and multiple painful oral ulcers. Her oral swab was positive for Herpes simplex virus (HSV) I PCR, so she was started on acyclovir and fluconazole given appearance of thrush on exam. Despite appropriate therapy, the patient's soft palate ulcerations did not resolve, prompting biopsy of the lesions, as HSV resistant acyclovir is extremely rare. Biopsy showed extra nodal natural killer/T cell lymphoma – nasal type. Further work up included high Epstein-Barr virus (EBV) DNA viral load at 2.4 million and PET – CT scan showing very high fluorodeoxyglucose uptake in sites of presumed myositis such as the face, suggesting lymphomatous involvement.

IMPACT/DISCUSSION: Extra nodal Natural killer/ T cell lymphoma (ENKTL) nasal type (NT) is a rare disease with a predilection in East Asia and Latin America. It is associated with EBV infection in immunocompetent hosts. Presentation commonly includes nasal obstruction, midfacial edema. Palatal ulcers are the most specific sign for this disease. Due to the infiltrative progression presenting as right facial swelling, it remained a diagnostic challenge.

Lastly, her oral ulcers were initially treated as HSV infection given positive HSV PCR, without clinical response. Acyclovir resistant HSV is reported in only 0.3% of immunocompetent hosts, and 4-7% of immunocompromised hosts, making treatment failure in this patient less likely. The atypical location, large size of the lesion and lack of clinical response to acyclovir prompted ulcer biopsy and serum EBV viral load, which led to the final diagnosis of ENKTL.

CONCLUSION: - ENKTL is a rare disease that is closely related to EBV infection. Although EBV infection typically causes either asymptomatic or moderate clinical disease, this case is a reminder that it can present as a life-threatening lymphoproliferative process.

- ENKTL may present as an infiltrative process that mimics rheumatological and infectious processes.
- This case prompts clinicians to ask critical questions and look for alternative diagnosis in the face of treatment failure of common diseases or lack of clinical improvement on current therapies.

FACTOR VIII INHIBITOR: FACTORS TO CONSIDER

Aula Ramo[1]; Hiba Jabbour[2]; Vrushali Dabak[2]

[1]Internal Medicine, Henry Ford Hospital, Detroit, MI; [2]Henry Ford Hospital, Detroit, MI. (Control ID #3387559)

LEARNING OBJECTIVE #1: Diagnose bleeding diathesis with isolated prolonged partial thromboplastin time (PTT) with mixing studies

LEARNING OBJECTIVE #2: Etiology of acquired factor inhibitor should be examined to guide treatment

CASE: A 76 year old female with history of rheumatoid arthritis (RA) presents with spontaneous bruising of the left arm and left leg that progressively enlarged over a few days and were accompanied by moderate pain. Initial workup revealed hemoglobin of 5.8 g/dL with PTT of 94 seconds and normal PT and INR. Mixing studies did not correct. Factor VIII activity was <1% and factor inhibitor level at 9 BU. At outside hospital, she was started on methylprednisolone, cyclophosphamide and given prothrombin complex concentrate and was transferred to our institution. At our institution, she was given Obizur (recombinant antihemophilic factor) with correction of PTT and normalization of factor VIII activity in a day. She received prednisone and cyclophosphamide and was discharged with stability of the intramuscular hematomas. She was seen in hematology clinic a month later and was found to be stable with no new evidence of bleeding. Factor VIII activity sustained within normal limits and PTT closer to the normal range. She was started on a taper of prednisone and cyclophosphamide. Notably, she has a longstanding history of RA with discontinuation of therapy in over a year for unclear reasons but has been previously treated with methotrexate and tocilizumab.

IMPACT/DISCUSSION: Acquired factor VIII inhibitor and subsequent factor VIII activity deficiency is a rare cause for a bleeding diathesis. Autoimmune diseases (RA being the most common) has been described as a risk factor. However, there is still paucity of literature to describe the mechanisms guiding the development of disease in some patients with RA and not others. A study has shown that a current use of tocilizumab for treatment of RA is associated with factor VIII deficiency when compared with treatment with other biologics. However, there is no literature examining the effect on factor VIII levels long-term after medication discontinuation such as in our patient. Secondly, it is unclear whether lack of RA control, such as in our patient, contributes to inhibitor development. There has been a case of disease development with Systemic Lupus Erythematosus flare which improved with control of the autoimmune disease, suggesting that it is a possible mechanism to ponder.

This case challenges our understanding of the factors contributing to development of factor VIII inhibitor and bleeding sequalae. It is possible to speculate that uncontrolled RA and the prior of use of a biologic agent are associated with factor deficiency and have put the patient at a greater risk of disease development

CONCLUSION: Acquired Factor VIII inhibitor can take place in context of rheumatoid arthritis. However, the details of the autoimmune disease activity and its treatment may provide further insights into the etiology of the disease and potentially its treatment

FACTOR XA INDUCED HEPATOBILIARY DYSFUNCTION IN AN EASTERN ASIAN MALE

Daniel Benhuri, Yesha Patel Rana, Thida Aye

Internal Medicine, Mount Sinai Beth Israel, New York, NY. (Control ID #3391682)

LEARNING OBJECTIVE #1: Recognize Factor Xa Inhibitors as potential risk factors for liver injury

LEARNING OBJECTIVE #2: Distinguish whether Factor Xa Inhibitors confer increased risk of acute liver injury in Eastern Asian people

CASE: 72-year-old Chinese Male presents with jaundice, pruritis and elevated liver enzymes six weeks after starting Apixaban following a stroke. Due to hyperbilirubinemia, the patient was switched to Rivaroxaban, an alternate Factor Xa Inhibitor, yet his liver enzymes continued to increased. The patient was admitted to our hospital for further testing. Rivaroxaban was held during his course, along with Atorvastatin and Metformin which the patient took for Hyperlipidemia and Diabetes Mellitus respectively. The patient denied any history of alcohol or drug abuse and all hepatitis testing was negative. Labs showed an elevated Alk phos of 759, AST 204, ALT 475 and a T. Bilirubin of 16.7 (D. Bilirubin of 13.4). CT of his abdomen and MRCP was negative for acute hepatobiliary pathology. One week following discontinuation of Rivaroxaban, the patient's liver enzymes substantially decreased and continued to decrease until back to near baseline four weeks later.

IMPACT/DISCUSSION: We believe that the most likely cause for our patient's acute liver injury was Factor Xa Inhibitors. There was a direct correlation between the initiation of Apixaban and this patient's elevated liver enzymes. Furthermore, the patient's liver enzymes subsequently decreased to near normal levels after permanently discontinuing any Factor Xa Inhibitors. Factor Xa induced liver injury has been recognized as a possible but rare complication of this medication class, due to a mechanism that is not fully understood. The literature has shown that some patients with liver injury due to one Factor Xa inhibitor have tolerated an alternate Factor Xa Inhibitor without recurrence of liver injury. However, our patient continued to have elevated liver enzymes despite being switched to an alternative Factor Xa Inhibitor. This finding raises the concern for a possible increased susceptibility of acute liver injury in Eastern Asian Males on Factor Xa Inhibitors.

CONCLUSION: Factor Xa inhibitors are approved for the prevention of clot formation in non-valvular atrial fibrillation and for treating deep venous thromboembolism and pulmonary embolism. This class of medications are known CYP3A4 and CYP2J2 inhibitors vulnerable to drug-drug interactions and are known to be risk factors for GI bleeding. Although not a common finding, these medications are possible risk factors for acute liver injury, as seen in our patient. Our case serves to raise awareness of the potential risk of acute liver injury in Factor Xa Inhibitors and to open the door for further studies on whether there is an increased risk of liver injury in Eastern Asian people.

FASCINATING FISTULA: A RARE CASE OF CHOLEDOCHODUODENAL FISTULA FROM PEPTIC ULCER DISEASE

Aula Ramo[1]; Sophia Binz[1]; Odaliz Abreu-Lanfranco[1]; Raef A. Fadel[2]

[1]Internal Medicine, Henry Ford Hospital, Detroit, MI; [2]Internal Medicine, Henry Ford Health System, Detroit, MI. (Control ID #3379661)

LEARNING OBJECTIVE #1: Identify a rare complication of peptic ulcer disease

LEARNING OBJECTIVE #2: Recognize clues for diagnosis of choledochoduodenal fistula

CASE: A 90 year old man with ischemic cardiomyopathy presented with subacute diffuse abdominal pain, melena, and poor appetite. He was afebrile, not tachycardic nor hypotensive. Abdominal exam revealed mild diffuse tenderness with a positive Murphy's sign. Initial workup revealed a hemoglobin of 9 from a baseline of 12 g/dL, leukocytosis of 12.5, alanine aminotransferase 153 IU/L, aspartate transferase 307 IU/L, and normal bilirubin levels. Fecal occult test was positive. Computed Tomography (CT) abdomen/pelvis was performed, which noted gallbladder distention concerning for possible cholecystitis as well as small amount of pneumobilia. Ultrasound revealed a distended gallbladder filled with sludge without stones, trace pericholecystic fluid, and wall thickening at 5.3 mm, equivocal for cholecystitis. Blood cultures were positive for *E.coli*. Patient underwent esophagogastroduodenoscopy that revealed a

duodenal ulcer with evidence of a recent bleed. Pantoprazole infusion and antibiotics were initiated. Hemoglobin remained stable. He was taken for a laparoscopic cholecystectomy on hospital day 3. It was converted to an open cholecystectomy due to discovery of perforated ulcer with food particles and purulence in the gallbladder neck. Choledochoduodedal fistula secondary to perforated D1 ulcer was discovered. He underwent repair and closure of the duodenal stump. Repeat cultures were negative, his pain resolved, and he was ultimately discharged to subacute rehab.

IMPACT/DISCUSSION: We present a rare case of concomitant acalculous cholecystitis and choledochoduodenal fistula from perforated duodenal ulcer discovered intraoperatively with the only imaging clue being pneumobilia.

In the United States, peptic ulcer disease (PUD) affects about 4.5 million each year. Its main complications include bleeding and perforation. A rare complication is fistulation with choledochoduodenal fistula being exceedingly rare. It is, however, difficult to diagnose due to its overlapping symptoms and imaging limitations.

Although not specific to fistulation, pneumobilia on ultrasound and computed tomography as well as contrast extravasation into the biliary tree in a barium swallow study can elucidate the diagnosis. Often, fistula is only discovered intraoperatively or during endoscopic retrograde cholangiopancreatography. This often leads to delayed diagnosis.

CONCLUSION: Fistula formation is a rare complication of PUD

Concurrent gallbladder disease with known PUD should raise suspicion of possible fistulation, which may impact imaging selection and may necessitate operative management

FATAL CASE OF TYPE B LACTIC ACIDOSIS IN METASTATIC COLORECTAL CANCER

Christina Thoonkuzhy

General Internal Medicine, University Hospital Cleveland Medical Center, Cleveland, OH. (Control ID #3391713)

LEARNING OBJECTIVE #1: Recognize the clinical presentation of Type B Lactic Acidosis.

LEARNING OBJECTIVE #2: Distinguish Type B Lactic Acidosis from other causes of elevated lactate.

CASE: A 60-year-old female with a past medical history of relapsing and remitting colorectal cancer with a history of metastasis to the liver s/p hepatic resections and ablations presented to the hospital for abdominal pain and hypotension after a recent paracentesis. The patient received treatment with cetuximab and pembrolizumab two weeks prior to presentation. Patient's BP was noted to be 77/48, which responded to 2L IVF normal saline. Labs on admission were significant for leukocytosis (29.4) AKI (Cr 1.23, baseline 0.78) hyponatremia (122) and hyperkalemia (6.0). LFTs were normal and the lactate level was 14.5. Peritoneal fluid analysis was initially concerning for spontaneous bacterial peritonitis (SBP) with 474 PMNs, but with RBC correction did not meet criteria for SBP. She remained hemodynamically stable. Despite finding no source of infection, this patient was started on cefepime, flagyl and vancomycin. A CT A/P with contrast was obtained which showed significant increase in tumor burden with extensive mesenteric and peritoneal deposits with omental caking throughout abdomen and pelvis. No new liver lesions noted. Her serum lactate continued to rise despite treatment of possible infection and hemodynamic stability. Antibiotic coverage patient was broadened from cefepime to meropenem. All cultures remained negative. Patient was started on a bicarbonate drip with no improvement. She continued to clinically deteriorate despite hemodynamic stability, with lactate reaching 23.6 and pH reaching 7.11. Calculations showed a pure anion gap (31) metabolic acidosis with appropriate respiratory compensation. In the setting of Type B lactic acidosis, her bicarbonate drip was stopped. Due to poor prognosis, the patient was made DNR-CC and passed 5 days after admission.

IMPACT/DISCUSSION: Lactic acidosis has been divided into two distinct categories: Type A & B. Type A, the most common, is associated with clinical evidence of tissue hypoxia with acidosis resulting from overproduction or underutilization of lactate. Type B has no evidence of inadequate tissue oxygen delivery. It represents a rare and deadly complication of a malignancy, usually hematologic. This is due to the Warburg effect, or the observation that most tumor cells favor anaerobic glycolysis instead of oxidative metabolism, even in the setting of normal oxygen concentrations. Although Type B lactic acidosis is not common outside of hematologic malignancies, this case illustrates that it can be seen in solid tumor cancers. Type B lactic acidosis remains an appropriate consideration when analyzing lactic acidosis in all cancer patients.

CONCLUSION: Type B lactic acidosis should be considered in cancer patients presenting with hemodynamic stability and elevated lactate levels. As it a poor prognostic indicator, goals of care discussions should be initiated early.

FATAL FUNGUS. A STORY OF SOCIAL ISOLATION

Katherine Fong[1]; Hyun Jung[2]; Ammar Ahmed[1]; Sherine Salib[1]

[1]Internal Medicine, Dell Medical School, University of Texas, Austin, TX; [2]Dell Medical School, The University of Texas, Austin, TX. (Control ID #3379592)

LEARNING OBJECTIVE #1: Recognize the presentation and diagnostic challenges of subacute cutaneous mucormycosis

LEARNING OBJECTIVE #2: Identify social isolation's impact on mortality in the geriatric population

CASE: The patient was an 81 year-old socially-isolated man with a history of well-controlled diabetes and complex cardiac history who presented to the hospital with a large necrotic wound on his forehead. The wound started as a minor abrasion from a fall, which developed into a 3x5 cm erosion with overlying eschar.

Dermatologic evaluation with outpatient biopsy showed fat necrosis with adjacent mixed acute and chronic inflammation and dermal fibrosis. He was presumptively diagnosed with pyoderma gangrenosum. For the following 6 months, his wound fluctuated in size, but progressed despite trials of mycophenolate, prednisone, and mupirocin ointment. He was admitted to the hospital with new facial redness. At the time, he denied pain, headache, or vision changes. He was afebrile and his exam showed a 9x11 cm erosion with eschar on his forehead with accompanying right facial edema. Initial labs revealed a leukocytosis of 26,000 mm3. CT head indicated mild right frontal and periorbital soft tissue swelling without abscess or postseptal orbital extension.

A repeat punch biopsy showed numerous fungi within the dermis and subcutis, consistent with mucormycosis. Infectious disease was consulted and IV amphotericin was started. Debridement in the operating room revealed mucormycotic invasion down to the bone. A xeroform wet dressing was applied to cover the skull, but skin grafting was deferred given his perioperative cardiac risk. After 3 weeks of IV amphotericin, he was switched to oral posaconazole due to worsening creatinine. During his 4th week of hospitalization, his clinical status rapidly deteriorated, requiring intubation and hemodialysis. His medical power of attorney transitioned him to comfort care. He was palliatively extubated and shortly passed after a prolonged 2-month total hospitalization.

IMPACT/DISCUSSION: Although mucormycosis is typically rapidly progessive and found in immunocompromised states, there are rare circumstances of subacute presentation over several months' duration and it may occur in well-controlled diabetic and immunocompetent patients. Additionally, social isolation, particularly in the geriatric population, is positively correlated with increased mortality. In this case, it may have delayed correct diagnosis and was an independent risk factor for mortality.

CONCLUSION: Although typically associated with acute deterioration, cutaneous mucormycosis may present with an indolent course.

Mucormycosis should be considered in necrotic wounds that fail to heal with prescribed treatments.

Early recognition of atypical presentations is important.

Social isolation may impact timely diagnosis and management, particularly in geriatric patients

FEELING LOUSY A CASE OF CHRONIC LICE INFECTION LEADING TO END-ORGAN DAMANGE

Alex L. Woods

Internal Medicine, NYU Langone, Brooklyn, NY. (Control ID #3390718)

LEARNING OBJECTIVE #1: Diagnosis of lice induced anemia

LEARNING OBJECTIVE #2: Assess populations at risk for lice induced anemia.

CASE: A 53-year-old male presented with subacute progressive generalized fatigue. His past medical history included a hospitalization 7 years prior for syncope, where his workup was notable for heavy lice infestation, severe iron deficiency anemia (hemoglobin [hgb] 6.8 g/dL), and an esophagogastroduodenoscopy which revealed a small healed ulcer in the duodenum. His hgb at outpatient follow-up was 13 g/dL.

On this admission, he was covered with lice on triage and washed with pyrethrin shampoo. Initial workup demonstrated stable vitals, hgb was 3.2 g/dL (MCV 59.8 fl), lactate was 14.4 mmol/L, venous pH was 7.33, bicarbonate was 13 mEq/L, anion gap was 19, creatinine was 1.6 mg/dL and troponin I within normal limits. Serum ferritin was 2.6 ng/mL, total iron was 15 mcg/dL, total iron binding capacity was 331 mcg/dL, transferrin saturation was 4%, and B12 was 505 pg/mL. He received 4 units of packed red blood cells during his hospitalization with resolution of his presenting symptom, and his labs on discharge were hgb 8.8 g/dL, lactate 1.7 mmol/L, and creatinine 1.0 mg/dL. There were no signs of gastrointestinal bleeding during the hospitalization.

The patient was independent with activities of daily living, held odd jobs, and demonstrated decision-making capacity, though he remained apathetic regarding his life-threatening lice infection. He denied toxic habits or psychiatric history, supported by chart review of his previous hospitalizations and rare clinic visits. New York City Adult Protective Services were contacted to assist in de-lousing the patient's apartment, and the patient was discharged home.

IMPACT/DISCUSSION: This is the first case report of a patient with a prior history of lice-induced anemia, presenting again (7 years apart) with end organ damage, as demonstrated by lactic acidosis and acute kidney injury from severe anemia secondary to repeated heavy lice infestation. Given his stable hemodynamics, laboratory findings, and the presumed etiology of his anemia, we suspected he had chronic systemic hypoperfusion and presented after he was no longer able to compensate for his fatigue. It has been estimated that about 3,000 head lice would result in a loss of 0.7mL of blood a day [6] or 1.8L over 7 years. However, there are no published estimates of the number of lice that could infest someone, and no estimates of the potential blood loss from body louse (which are larger and presumably feed more). Although the patient did clinically well with transfusions, his isolated apathy towards his home hygiene was troubling in the absence of intoxication or active psychosis. Unfortunately, all that could be provided was counseling and supportive referrals.

CONCLUSION: Severe and chronic lice infestation can, in rare cases, result in iron deficiency anemia.

In psychiatric, undomiciled, and patients with poor hygiene, lice infestation should be considered a potential etiology of iron deficiency anemia.

FEVER, ARTHRALGIA, RASH, OH MY! AN UNUSUAL PRESENTATION OF ADULT-ONSET STILL'S DISEASE

Kevin B. Harris[1]; Avery Kundrick[1]; Sushmita Prahbu[1]; Isadora Sande Mathias[1]; Abhishek Bhardwaj[2]; Prabalini Rajendram[2]

[1]Internal Medicine, Cleveland Clinic, Cleveland, OH; [2]Respiratory Institute, Cleveland Clinic, Cleveland, OH. (Control ID #3364393)

LEARNING OBJECTIVE #1: Recognize the clinical features of persistent papular pruritic adult-onset Still's disease (AOSD).

LEARNING OBJECTIVE #2: Develop a treatment plan for patients with AOSD.

CASE: A 31-year-old female with no significant past medical history presented to the ED with three weeks of high fever, sore throat and shortness of breath. She tested negative for influenza but positive for EBV and was discharged with a diagnosis of mononucleosis. She then developed worsening fatigue, dyspnea, lower extremity edema, decreased urine output, knee pain and a persistent pruritic rash of her arms, chest and face. She again presented to the ED complaining of pleuritic chest pain. She denied recent travel, sick contacts or substance abuse. She was febrile to 102.4, tachycardic to 133, and saturating in the low 90s. CT PE showed no signs of pulmonary embolism but was remarkable for bilateral pleural effusions and a circumferential pericardial effusion. Bedside TTE revealed no signs of tamponade. Initial labs were remarkable for a moderate microcytic anemia, leukocytosis of 29K and negative mononuclear spot. Further investigation revealed an elevated ferritin (36915), elevated haptoglobin (519), low reticulocyte count (0.4), normal iron studies, elevated inflammatory markers (ESR 118 and CRP 45) and normal triglycerides. Blood cultures, UA, HIV and remote hepatitis panel were negative. Parainfluenza was positive, but did not explain her overall clinical picture. ANA, dsDNA, C3, C4, C-ANCA and P-ANCA were negative. UPEP was normal but SPEP revealed an M spike. Skin biopsy revealed dyskeratosis with intraepidermal and subcorneal abscesses consistent with AOSD. She was started on 60 mg of IV solumedrol daily and improved clinically within 24 hours of starting steroids. Bone marrow biopsy showed no evidence of dysplasia or malignancy. She was transitioned to anakinra 100 mg daily and oral prednisone 60 mg daily with plans for an outpatient taper.

IMPACT/DISCUSSION: AOSD is an inflammatory disease that typically presents with a triad of fever, arthralgia and a characteristic rash. This is a clinical diagnosis made using the Yamaguchi criteria, which should only be applied once infection, malignancy and other autoimmune disorders have been ruled out. The typical rash in AOSD is a transient, salmon-pink, maculopapular rash predominantly found on the proximal limbs and trunk. However, unusual cutaneous manifestations have been reported including a persistent papular and pruritic form. Patients are treated with immunosuppression including corticosteroids and biologics. It is vital that general internists are aware of AOSD and its various presentations to prevent delays in treatment.

CONCLUSION:

- AOSD is a diagnosis of exclusion. The Yamaguchi criteria should only be applied once infection, malignancy, and other autoimmune disorders have been ruled out.
- Though the typical cutaneous finding in AOSD is a transient salmon-pink skin rash, atypical cutaneous manifestations may present including a rare persistent papular pruritic rash.

FEVER, TACHYCARDIA AND HYPOXIA: SEPSIS OR HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS (HLH)?

CATHERINE L. TENG

Yale New Haven Health, Greenwich Hospital, Greenwich, CT. (Control ID #3373513)

LEARNING OBJECTIVE #1: Include HLH in differential diagnosis among patients with suspected sepsis but unresponsive to antibiotics treatment

LEARNING OBJECTIVE #2: Familiarize with diagnostic criteria for HLH

CASE: A 35 year-old 26-week pregnant female presented with fever and body aches that were not resolved by tamiflu. Her fever was 103.6 F, heart rate 120 bpm, and SaO2 98% on room air. Infectious disease workup was negative and chest X-Ray was normal. She was given fluid resuscitation, ceftriaxone then zosyn for presumed sepsis. Her labs were significant for transaminitis, leukopenia, and thrombocytopenia with bandemia. Extensive infectious workup including anaplasma and rickettsa were normal. Her fetus was safe but the patient's symptoms continue to worsen. Two days after admission, the patient quickly developed severe hypoxemic respiratory failure and required intubation. In addition to another infectious disease workup, the patient underwent extensive rheumatology and hematology workup, which was notable for positive sIL2 and 1601 ng/dL ferritin. Peripheral blood smear was nonspecific. Her repeat abdominal ultrasound showed splenomegaly up to 15.5 cm. A bronchoscopy was unrevealing. The diagnostic criteria of HLH was met. The patient received Intravenous immunoglobulin (IVIG) and dexamethasone, resulting in significant improvement. Three days after initiation of IVIG, her fever subsided and she was extubated.

IMPACT/DISCUSSION: So far, the understanding of adult hemophagocytic lymphohistiocytosis is still lacking. The common etiology of HLH is infection, autoimmune disease, spontaneous or iatrogenic immunosuppression, and post organ transplant. In this case, the etiology of HLH remains unconfirmed. The patient delivered a healthy baby and continues to be followed by hematology and rheumatology. She remains healthy to date. The extensive infectious disease workup was unrevealing, and the fact that her fever subsided shortly after IVIG speaks against infection induced HLH. Whether pregnancy played a role of triggering HLH is unclear as well.

The teaching points of this case are:

1. Recognition of HLH in adults is necessary given its rapid evolution and dismal outcomes if left unrecognized
2. Differentiating between sepsis and HLH is critically important as they are both life threatening but with completely different treatment approaches.
3. The diagnostic criteria of adult HLH requires five of the following: fever > 38.5 C, splenomegaly, two out of three peripheral cytopenia (hemoglobin < 9 g/dL, platelet < 100, 000/microL, absolute neutro count <1000/microL), hypertriglyceridemia and/or hypofibrinogenemia, hemophagocytosis, low NK cell activity, ferritin > 500 ng/mL, and elevated soluble IL-2 receptor alpha.

CONCLUSION: Adult onset hemophagocytic lymphohistiocytosis (HLH) is an aggressive and life-threatening syndrome with a dismal outcome of up to 80% of mortality. Understanding of the disease is limited, however, and the list of triggers associated with secondary HLH is extensive but not well studied.

FEVER IN THE TRAVELING PATIENT

Rayan N. Kaakati, Laura Leuenberger, Daniel Cronin

Internal Medicine, University of Michigan, Ann Arbor, MI. (Control ID #3375464)

LEARNING OBJECTIVE #1: How to work up fever in traveling patients

LEARNING OBJECTIVE #2: Recognize the importance of sending diagnostic tests for dengue and complications

CASE: identify mimics of dengue

IMPACT/DISCUSSION: 41 year old F admitted with fever after traveling to Yemen and Dubai. While in Yemen, developed fevers, malaise, severe back pain. Exposure: ate "street food", no known mosquito bites, needle exposures, sexual encounters. Hospital in Yemen r/o malaria (high prevalence in area). Discharged w/ supportive measures. Subsequently traveled to Dubai w/ continued fevers, severe joint pain, mental fogginess, &difficulty breathing. Noted 2 relatives who traveled w/ her who went to the ICU for similar symptoms and received platelet transfusions. Presented to our ED with continued malaise, joint paint and mental fogginess. Physical Exam: unremarkable. labs: WBC 17.8(55% lymph), Plt 135, transaminitis. 1 week later +IgG, IgM Dengue antibodies. negative: blood cultures, Chikungua, HIV, Lepto, EBV

Diagnosis: Based on clinical suspicion in a febrile traveler in a dengue—endemic area (use CDC healthmap which includes recent outbreaks) and a combination of ≥2 clinical findings. Clinical findings include: Nausea/vomiting, rash, joint pains, a +tourniquet test, leukopenia. Our patient was in a dengue endemic area (CDC map also showed Dengue outbreaks during the time she visited) w/ hx of fever, severe joint paint, and nausea. mimics: Chikungua, Zika, need to r/o w/ antibody testing for these infections as well (all spread through infected Aedes species Mosquito).

Some patients will go on to develop "severe dengue" with warning findings after 24-48 hours after fever clears such as: severe bleeding, transaminitis, impaired consciousness, fluid accumulation, ARDS. These patients need acute recognition and transfer to ICU care. Our patient continued to improve w/ supportive Tylenol. She received empiric Ceftriaxone to cover for potential Typhoid (dengue antibodies take around a week to come back)

Treatment: No anti-viral treatment exists. Supportive measures which includes hydration and Tylenol. Prevention: Educating patients prior to traveling to Dengue endemic areas. Importance of mosquito repellant. Patient who develops Dengue, may be eligible for vaccine. Despite prior infections, pts can still get re- infected with other strains, which puts them at an increased risk of developing severe Dengue.

CONCLUSION: Dengue can be quickly recognized based on clinical suspicion and utilizing CDC healthmap with antibody testing distinguishing from mimics (Zika, Chikungua)

Dengue is treated with supportive measures, but the clinincian must be warry of "warning symptoms" that can predict which patients will develop severe dengue and need ICU level care

We can reduce transmission through education and recommending vaccination to those with a history of prior infection to reduce the chance of severe dengue occuring with re-infection with different strains.

FINDING FINGERS POINTING TO LIVER DISEASE

Abigail Phelps, Christine Talley, Marlowe Maylin

Tulane University, New Orleans, LA. (Control ID #3391270)

LEARNING OBJECTIVE #1: Recognize malignancy as a cause of arterial thromboembolism

LEARNING OBJECTIVE #2: Identify the differential diagnosis of arterial thromboembolism

CASE: A 66-year-old man presented with acute gangrene of the digits. There was no history of trauma. Past medical history included recently treated hepatitis C, hypertension, and tobacco abuse with a 120-pack year smoking history. He was a cachectic male with dusky skin. Digits two through on the right hand four were cold bilaterally, with black discoloration noted distally on the second digit. Radial pulse was 2+ bilaterally. TSH, A1C, ABI and WBI were within normal limits. Autoimmune workup, including ANA, anticardiolipin, and beta2-glycoprotein I antibodies, returned negative. EKG and telemetry monitoring did not reveal any arrhythmias.

Transesophageal echocardiogram had no evidence of valvular disease or vegetations. Pathology report from a skin biopsy of the right index finger noted thromboembolism with medium-sized vessel vasculitis. Malignancy workup began with a CT chest, which incidentally revealed three large hypoechoic liver masses, the largest measuring 9.6 x 7.5 cm, in addition to mediastinal and hilar lymphadenopathy. A diagnosis of hepatocellular carcinoma was made by IR guided liver biopsy.

IMPACT/DISCUSSION: Any patient presenting with an arterial thromboembolism (ATE) without history of recent trauma or intervention to the presenting limb should have a thorough cardiac workup as the majority of arterial embolisms that travel to the extremities originate in the heart. Initial evaluation should include the following: EKG and telemetry monitoring to assess for atrial fibrillation, echocardiogram to assess for valvular disease, endocarditis, myxoma, and left ventricular dysfunction, and risk stratification with hemoglobin A1C, lipid panel, and TSH. If no source of ATE is identified, further workup should focus on causes of hypercoagulable states. Antiphospholipid syndrome should be excluded with testing for anticardiolipin and beta2-glycoprotein I antibodies. Malignancy should be considered as a possible etiology with age appropriate cancer screening as early stage cancer carries a significantly increased risk of ATE. In our patient with 120-pack year smoking history, malignancy workup began with lung cancer screening. As with our patient, thromboembolism could be the initial presentation of a malignancy.

CONCLUSION: While cancer is frequently associated with venous thromboembolism, this case highlights the association of arterial thromboembolism and new-onset malignancy.

FIRST, DO NO HARM; THE TREATMENT OF HYPERTENSIVE URGENCY IN THE AMBULATROY SETTING

Jesse Cann[3]; David M. Cline[2]; Claudia L. Campos[1]

[1]Internal Medicine, Wake Forest University, WInston- Salem, NC; [2]Emergency Medicine, Wake Forest School of Medicine, Winston- Salem, NC; [3]Wake Forest School of Medicine, Winston Salem, NC. (Control ID #3390318)

LEARNING OBJECTIVE #1: Recognize adverse effects of acutely lowering blood pressure (BP) with oral clonidine in the setting of Hypertensive Urgency (HU)

CASE: 61 year old female with HTN, prior CVA without residual deficits, stage 3 CKD presents to nephrology clinic for follow-up. Her BP was 190/129. She denied headaches, facial droop, nausea/vomiting, changes in speech or vision, chest pain, dyspnea, abdominal pain, or lower extremity edema. She endorsed running out of her usual antihypertensive regimen (lisinopril 20 mg daily) one week prior to her appointment. The rest of her pysical exam was unremarkable with normal cranial nerve examination, no murmurs, or gallops, no bruits; lungs were clear to auscultation bilaterally, and no lower extremity edema. No outpatient labs/imaging were obtained. Patient received 0.2mg clonidine PO in the clinic and refills of her lisinopril prescription. During the drive home, the patient started developing slurred speech and right-sided facial drooping at which point the husband brought her to the emergency department (ER). Upon arrival in the ER, she was found to have a BP of 98/70. Head CT showed no acute intracranial abnormalities. The patient was then given IV fluids, aspirin and admitted to the hospitali. She was diagnosed with diffuse cerebral ischemia from a 100 mmHg drop in systolic BP. MRI demonstrated microhemorrhages in the cerebral hemisphere, cerebellum and brainstem likely secondary to hypertensive vascular disease. She was discharged 3 days later on her home dose of lisinopril with improvement of her symptoms and continued secondary stroke prophylaxis.

IMPACT/DISCUSSION: Hypertensive urgency (HU), defined as acute severe uncontrolled hypertension without end-organ damage, is a commonly seen in the outpatient setting. Despite its association with long-term morbidity and mortality, guidance regarding immediate management is sparse. This case highlights that pharmacologic rapid lowering of blood pressure with clonidine can precipitate ischemic stroke symptoms. Through arteriolar constriction and reflex vasodilation, cerebral autoregulation maintains a constant cerebral blood flow within a wide range of perfusion pressures, ensuring that the brain is protected from higher mean arterial pressures. While this process is protective, over time the autoregulatory system becomes impaired, especially in patients with prior stroke or with end-stage kidney disease. This places patients at risk for cerebral and/or cardiac ischemia with even slight drops in blood pressure. To our knowledge this is the first reported case of stroke symptoms after administration of oral clonidine. Similar side effects were reported with sublingual nifedipine in the 1980s that lead to an FDA ban of the medication in HU.

CONCLUSION: This case questions the safety of acute oral antihypertensive loading to treat HU; this common practice should be reconsidered. Longer-term management of individuals who have experienced HU continues to be an area requiring further study.

FLUOROQUINOLONE INDUCED AORTITIS

Matthew Mulligan[2]; Paloma Cariello[1]

[1]Infectious Diseases, University of Utah, Salt Lake City, UT; [2]General Internal Medicine, University of Utah, Salt Lake City, UT. (Control ID #3392200)

LEARNING OBJECTIVE #1: Understand the differential for causes of aortitis

LEARNING OBJECTIVE #2: Recognize complications of fluoroquinolones

CASE: A 65 year old male with a history of psoriasis previously on Humira and right-sided facial, neck, and pre-septal cellulitis one month earlier that was complicated by group A streptococcal bacteremia who presented with several days of progressive neck pain. The patient had significant clinical improvement on two

weeks of IV penicillin for cellulitis and bacteremia, and his antibiotics were switched to Augmentin and levofloxacin approximately two weeks prior to his presentation. On presentation he was noted to be febrile, had no purpura, and had similar blood pressures in all extremities. His labs showed a WBC of 16, ESR 77, CRP 15.3, and normal renal function. He had a CT-Neck, which showed wall thickening of the ascending thoracic aortic and aortic arch with surrounding mediastinal inflammation. Further imaging did identify abdominal aortic inflammation. Blood cultures were negative, TTE was without vegetations, and RPR, HIV, and IGRA were negative. He was switched back to IV penicillin from levofloxacin and Augmentin, and had quick clinical improvement with resolution of neck pain and fevers. Approximately two weeks later, a repeat CT-Chest showed significantly decreased wall thickening and surrounding inflammation of the thoracic aorta, and the CRP and ESR had normalized.

IMPACT/DISCUSSION: Aortitis is a potentially life threatening finding. The differential for causes of aortitis is broad and includes infectious causes such as staphylococcus, syphilis, mycoplasma, and salmonella; systemic vasculitides such as Takayasu, GCA, Behcet's, IgG4 disease, and small vessel vasculitides; and idiopathic causes. In some cases, a clinically isolated aortitis can be the first manifestation of a systemic vasculitis and thus requires long term monitoring. In this case the negative workup for infectious causes, lack of other features suggestive of a systemic vasculitis, and clinical improvement with drug withdrawal suggests a fluroquinolone induced aortitis.

To date this is the first reported case of suspected fluoroquinolone induced aortitis. Fluoroquinolones have known adverse risks to collagenous structures and can lead to tendinopathy and retinal detachment through unknown mechanisms. The aorta is also a collagen rich structure, and systemic reviews have shown an association with fluoroquinolones and an increased an risk of aortic aneurysms and aortic dissections prompting the FDA to release a safety warning in 2018. The radiologic and clinical findings present in this case may suggest a pathway to explain the association between fluoroquinolones and the increased risk of aortic aneurysms and dissections.

CONCLUSION: This case of suspected fluoroquinolone induced aortitis is the first known to date, and suggests a pathway between fluoroquinolones and the increased risk of aortic aneurysms and aortic dissections.

FLU TO DOCTORS: DON'T YOU EVER TAKE ME FOR GRANTED!

Juan A. Trias

Internal Medicine, Montefiore Medical Center, Bronx, NY. (Control ID #3391501)

LEARNING OBJECTIVE #1: To acknowledge how severely Influenza can impact health

LEARNING OBJECTIVE #2: To recognize importance of vaccination and related prevention of illness progression

CASE: A 61-year-old man with asthma and drug abuse was brought by ambulance to emergency department after being found with altered mental status by his wife. Patient had upper respiratory infection symptoms and poor oral intake for five days. He did not receive Influenza vaccine this season. On arrival, patient was confused, hypothermic and in respiratory distress thus was intubated for acute respiratory failure. Physical exam was significant for confusion and ecchymotic skin on abdomen. He later became hypotensive requiring vasopressors. Initial labs revealed Platelets 138, Potassium 6.4, Creatinine 5, pH of 7.01, PCO2 77, Lactic acid 11. AST 1,700, ALT 2,800 and Influenza A positive. CT Abdomen revealed pneumoperitoneum, bowel ischemia as well as bilateral pleural effusions.

Patient was admitted to ICU with multiorgan failure secondary to Influenza and bowel perforation. He was treated with vasopressors, fluid resuscitation, broad spectrum antibiotics and Oseltamivir. Goals of care discussion was held because of very poor prognosis.

IMPACT/DISCUSSION: 36,000 deaths per year are attributed to Influenza; majority are due to underlying conditions or superimposed bacterial infections. It is not completely understood how Influenza predisposes an individual to develop bacterial infections. One proposed mechanism is exposure of respiratory epithelium during viral replication, making it easier for bacteria to adhere. Influenza impairs antibacterial body mechanisms by increasing neutrophil apoptosis, monocyte and neutrophil dysfunction that suppresses chemotaxis and phagocytosis.

Extrapulmonary complications such as multiorgan failure have been described in influenza infections, and have been attributed to high-level viral replication and cytokine dysregulation. Studies had revealed that pro-inflammatory cytokine levels correlate with patient's outcome.

According to CDC, during 2017-2018, vaccination prevented 3.2 million influenza-associated medical visits, 91,000 influenza-associated hospitalizations, and 5,700 influenza-associated deaths. A 2018 study showed that among adults hospitalized with flu, vaccinated patients were 59% less likely to be admitted to ICU if they received the vaccine. In ICU patients with flu, vaccinated patients spent fewer days in the hospital.

In our case, we must keep in mind that patient's severity of presentation can be attributed to Influenza. The fact that he did not get vaccinated might have put him at higher risk of developing further multiorgan failure.

CONCLUSION: During Influenza season, all patients with upper airway respiratory symptoms, fever, sepsis or septic shock should get tested for the flu, most importantly, since prevention is key, patients should be vaccinated to prevent devastating consequences before is too late.

FLYING HIGH: HOW AN AMBULATORY ICU TOOK A NOVEL APPROACH FOR A HOMELESS PATIENT IN NEED OF DAILY INSULIN

David Elwell[1]; Jennifer Flores[1]; Jeremy Long[2]

[1]General Internal Medicine, Denver Health, Denver, CO; [2]GIM, Denver Health, Denver, CO. (Control ID #3392232)

LEARNING OBJECTIVE #1: To consider innovative collaborations between primary care, emergency medicine, and endocrine teams to provide high intensity outpatient care for Type 1 diabetics at risk for complications from independent insulin dosing.

CASE: A 60 year old homeless male with a history of diabetes mellitus type 1, depression and substance use disorder who was hospitalized frequently for hypoglycemia due to intentional insulin overdose. He had a history of abusing acid, opioids, and marijuana. He was admitted frequently for hypoglycemia related to insulin abuse. Several of these episodes were due to reported suicide attempts. On other occasions he overdosed because he reported enjoying the sensation of hypoglycemia similar to abusing other illicit substances. His case was complicated further as he became homeless and was placed into a transitional housing program. He was transferred to the high utilizer clinic at Denver Health Medical Center in September 2018 due to his frequent admissions. His primary care provider (PCP) attempted to manage his diabetes with self-dosing of insulin for approximately a month with persistent episodes of hypoglycemia.

Given his high risk for complications the decision was made to have him come into the clinic each day of the week for insulin dosing administered by clinic staff. He presented to the emergency room on the weekends for daily dosing. His PCP worked with endocrinology to adjust his dosing, and communicated with the emergency department regularly regarding any changes. He agreed to the plan and has been compliant with daily dosing. His admissions have declined from greater than ten in 2018 to two in 2019.

IMPACT/DISCUSSION: Management of type 1 diabetic patients can be complicated even under the best circumstances. This case presents a highly complex scenario of a homeless patient with a history of insulin abuse who was considered too high risk to continue self-dosing. Despite these issues he continued to display capacity and did not wish to live in an assisted living facility. In order to help him maintain his independence and prevent further complications his PCP created an innovative outpatient management plan through collaboration with endocrinology and emergency medicine. It has proved successful by significantly reducing hospitalizations over the past 12 months, and can provide a model for managing insulin-dependent diabetics at risk of insulin overdose in the outpatient setting.

CONCLUSION: 1. Diabetic mellitus type 1 patients with a history of insulin abuse can be very difficult to manage in the outpatient setting

2. Collaboration between internal medicine and other specialties can lead to improved outpatient care for this vulnerable population

FOCAL, YET ATROPHIC, MYOSITIS!

Ayman Aouthmany, Sarah Makadsi, Ziyad Iskenderian

Internal Medicine, Ascension Providence Hospital/Michigan State University, Southfield, MI. (Control ID #3390812)

LEARNING OBJECTIVE #1: Recognize and diagnose Focal myositis (FM), a rare disease process.

LEARNING OBJECTIVE #2: Manage acute and longterm Focal Myositis

CASE: A pleasant 59-year-old female with PMHx of hypertension, hyperlipidemia, and diabetes mellitus type 2, presented to the hospital due to right leg pain. Her pain started 3 weeks after a cerebrovascular accident and had been worsening for 3 months. On physical exam, there was tenderness on the right anterior thigh, and right knee was warm and had reduced flexion. There was no right knee effusion. Lab studies revealed elevated CPK at 372, sedimentation rate of 95, and aldolase of 10.7, while autoimmune panel was negative. MRI of the right femur without contrast revealed diffuse edema involving the subcutaneous and deep compartments more prominently involving the anterior compartment, indicating myositis. There was no focal area of fluid collection. A muscle biopsy was taken and patient was started on empiric steroids and discharged after improvement in pain severity. Final biopsy pathology returned a few weeks later revealing skeletal muscle with features of neurogenic atrophy and Type 2 myofiber atrophy, along with abnormal immunohistochemical staining for MIIC Class I antigens and membrane attack complex C5b-9.

IMPACT/DISCUSSION: This case demonstrates the workup and management of a very rare case of focal myositis with neurogenic atrophy, and serves as a reminder to clinicians to keep a broad differential. An isolated rapidly growing mass within a muscle can cause major pain and be a source of significant stress to our patients. Signs and symptoms of a systemic inflammatory process should be clinically assessed. Laboratory and imaging studies that are routinely and commonly done for an inflammatory musculoskeletal process should be considered. Although focal myositis is likely to show marked hypertrophy of muscle fibers, more rare pathology shows features of neurogenic atrophy, as seen with our patient. Biopsy with positive immunohistochemical staining supports the diagnosis.

CONCLUSION: Most patients have a slow, spontaneous and favorable recovery. Treatment with corticosteroids should be reserved to those with severe pain. Follow up is recommended and necessary to monitor improvement and rule out another non-focal inflammatory myositis.

FOOD FOR THOUGHT

Laura M. Greenwood[1,2]; Sabyasachi Roy[1]

[1]Internal Medicine, Creighton Alliance at St. Joseph Hospital, Phoenix, AZ; [2]Barrow Neurological Institute, Phoenix, AZ. (Control ID #3391603)

LEARNING OBJECTIVE #1: Diagnose copper and micronutrient deficiencies in vulnerable populations in settings that are not typical presentations of such disorders.

CASE: 59 year old white woman with a history of Roux-en-Y gastric bypass, depression and vitamin B12 deficiency presented with multiple falls, hallucinations, insomnia and confusion from a skilled nursing facility. Routine labs in the ED revealed a UTI with normocytic anemia and leukopenia. Delirium was attributed to the UTI and patient was started on a course of antibiotics. CT scan of the head was normal. Multiple anti-psychotics were suspended. Serum Iron panel, Vitamin B12, and folate levels were normal. Delirium, however, continued to worsen. Patient underwent a MR brain and LP for CSF analysis; both were normal. Clinical and biochemical indicators of severe protein calorie malnutrition and failure to thrive, along with dysphagia prompted a duo tube placement for tube feeding; later on a GJ tube was placed. Further work-up for anemia, leukopenia and neurological symptoms revealed undetectable serum levels of copper and Vitamin C. Zinc level was normal. A further thorough clinical exam revealed clinical signs of scurvy. Patient was started on IV Copper replacement therapy and oral Vitamin C supplementation. After almost 2 weeks, patient's symptoms started improving. On day of discharge the patient was completely normal, AOx3, without any hallucinations, confusion or insomnia.

IMPACT/DISCUSSION: Patients with history of Roux-en-Y gastric bypass are more likely to have multiple macro and micronutrient deficiencies. This risk is further increased by lack of financial resources to eat a healthy nutritious diet or afford necessary dietary supplements. Copper deficiency is not generally associated with mental status changes, but in combination with the patient's UTI and other nutritional deficiencies, it played a significant role in the delirium. Our patient was only 59 years old, yet she experienced delirium with her UTI, which is more typical in older population. The patient's severe malnutrition had resulted in her being debilitated to the point of being at a skilled nursing facility for a while prior to admission. However, with the correct diagnosis and treatment, her debility resolved quickly.

CONCLUSION: * In patients with gastric surgeries and protein calorie malnutrition, especially if they have limited income, it is very important to diagnose and assess for micronutrient and vitamin deficiency.

* In settings of acute delirium assess for multiple contributing factors to the delirium, including both instigating factors (like a UTI) and chronic underlying factors (like malnutrition) that contribute to causing delirium.

* Hallmarks of copper deficiency are hematological and neurological: anemia, leukopenia, normal platelets and myeloneuropathy.

FORMS OF ELDER ABUSE AND A PROVIDER'S ROLE

Naomi Karlen

Southeast Louisiana Veterans Health Care System, New Orleans, LA. (Control ID #3354106)

LEARNING OBJECTIVE #1: Recognize categories of elder abuse.

LEARNING OBJECTIVE #2: Understand the importance of reporting elder abuse and adequately addressing challenging ethical cases.

CASE: A 93 year-old man lives with his adult daughter and son-in-law. This living arrangement works for several years, until his health slowly deteriorates and he begins to lose capacity due to progressive cognitive impairment, at which point he appoints his daughter as his proxy.

He is seen by his health care team in his bedroom on the second floor of the family home. The internist has several significant concerns, most notably that his daughter refuses to install durable medical equipment in the family home, including a chair lift, and that he lacks access to food, water, or the restroom while his family is out during the day. The man essentially becomes trapped upstairs as he progressively becomes unable to ascend or descend stairs without assistance. The internist files an elderly protective service (EPS) case. EPS investigates the reports and improvements are made which, per his desire, allow the patient to remain safely in the home—after which the case is closed.

IMPACT/DISCUSSION: Physicians are often faced with challenging situations when caring for the elderly. Attempting to navigate these situations to help patients often requires assisting in socially complex situations that affect patients' health.

While physical abuse is often easily seen, it is equally important to recognize and assist elderly patients when we suspect other forms of abuse. First, we must recognize that isolation, sexual abuse, neglect, misuse and stealing of property, and emotional harm and bullying are all potential forms of elder abuse. Then, we must know what to do with that information. In order for internists to promote the health and wellbeing of this vulnerable population, they must understand how adult and elderly protective services function in their state. For example, in Louisiana, willful lack of reporting by a mandatory reporter can be punishable by law.

Data have shown that at least 10% of adults in the United States aged 65 and older will experience some form of elder abuse in any given year. Consequences of unaddressed abuse can be disastrous. In this particular case, this patient was exposed to abuse in the form of isolation and caregiver neglect. His healthcare team appropriately recognized the abuse and assisted in intervening while maintaining a therapeutic alliance.

CONCLUSION: Unfortunately, the EPS case did not solve all the patient's issues. However, just because complex situations are not "cured" with a single intervention does not absolve the physician's duty to intervene. Without the crucial initial steps of recognizing and reporting elder abuse, vulnerable elderly patients are at an even higher risk for poor outcomes. Thus, recognizing elder abuse and understanding one's role are important in furthering our ability to meet patient challenges, especially in the setting where they may not be able to advocate for themselves.

FRANCIS BACON SYNDROME

Amy Dreessen, Michael P. Smith

Internal Medicine, University of Nebraska Medical Center, Omaha, NE. (Control ID #3392396)

LEARNING OBJECTIVE #1: Recognize the clinical manifestations of disseminated Aspergillus

LEARNING OBJECTIVE #2: Develop an approach for ring-enhancing CNS lesions in immunocompromised individuals

CASE: A 56-year-old man presented after a lung mass was found on CT scan. He noted five days of worsening right-sided weakness and limited vision in his right eye. Past medical history included neurosarcoidosis diagnosed two months prior when he presented with neurologic findings, for which he was being treated with infliximab, methotrexate, and dexamethasone. He was a non-smoker, and he sprayed chemicals on crops for a living, resided in a rural area but no contact with animals. He did not have any significant travel history. Family history was remarkable for malignancy in three relatives, including gynecologic cancer, leukemia, and renal cell carcinoma. He had 4/5 weakness and decreased vibratory sensation of the right lower extremity. He had conjunctival injection and a fixed, mid-dilated pupil of the right eye. There were innumerable rim-enhancing lesions up to 4 cm in size on brain MRI. CSF analysis revealed very high protein without many cells and was negative for Cryptococcus. Blood serologies were unrevealing. Fungitell was strongly positive, and galactomannan was negative. His lung mass was biopsied, which showed fungal hyphae. During admission, the patient developed chemosis of his right eye. His right eye continued to worsen, and he progressed to a point where he was unable to see out of his right eye. Cultures from his eye and lung mass both grew Aspergillus

IMPACT/DISCUSSION: Increasingly, patients are being treated for conditions with immunosuppressant medications, and the risks associated with these medications are something the general internist needs to understand. Aspergillus is a fungus with a broad spectrum of disease, ranging from noninvasive to rapidly fatal in disseminated infections. Disseminated aspergillosis remains a major cause of morbidity and mortality. While disseminated aspergillosis most commonly affects the lungs, the eye is the second most common infection site. Aspergillus endophthalmitis results in a rapid onset of pain and visual loss, and cultures of vitrectomy specimens are frequently required for diagnosis.

In immunocompromised patients, the differential diagnosis of CNS ring-enhancing lesions is broad and includes cerebral toxoplasmosis, primary CNS lymphoma, and CNS fungal infections. For our patient, this differential diagnosis also included worsening of his neurosarcoidosis and malignancy, given his family history. Because our patient had rapid development of both lung and CNS involvement, we were able to focus on infectious etiologies of his presentation, which ultimately led us to a diagnosis of disseminated Aspergillus.

CONCLUSION: Medications that suppress the immune system are being used to treat an increasing number of conditions and the general internist must employ a systematic approach to determine if new symptoms are a progression of the original disease or an effect of its treatment.

FROM FUNDOSCOPY TO BRAIN TUMOR: UNUSUAL CASE OF ATYPICAL MENINGIOMA WITH VISUAL HALLUCINATIONS

Rasha Saleem, Cary Dash

Internal Medicine, Baystate Medical Center, Springfield, MA. (Control ID #3343098)

LEARNING OBJECTIVE #1: Effective utilization of fundoscopy can aid in early diagnosis of slow growing meningiomas in minimally symptomatic patients.

LEARNING OBJECTIVE #2: Physicians need to be mindful that classical presentation of elevated intracranial pressure may not be present until very late into disease process.

CASE: 56 year old sales person with past medical history of stable age related bilateral macular drusens presented with three year history of sudden attacks of short lived painless visual disturbance involving left eye. He described flickering lights and wiggly lines lasting for a few seconds before normal vision returned. His visual symptoms resolved spontaneously and he was otherwise healthy with no other complaints. Physical exam was initially unremarkable but fundoscopy revealed new mild bilateral optic disk swelling. Patient underwent MRI orbits which showed no acute pathology, however MRI brain with IV contrast interestingly uncovered a 6.1-cm enhancing mass overlying the right parieto-occipital region with vasogenic edema, regional mass effect and subfalcine herniation. The patient was urgently evaluated by neurosurgery and proceeded with gross total resection. Pathology report confirmed stage II atypical meningioma with parenchymal invasion. At this time patient is nine months status post resection, asymptomatic, with serial MRI Brain scans demonstrated interval recurrence of residual meningioma, likely warranting the need for adjuvant radiation therapy in the future.

IMPACT/DISCUSSION: Clinical presentation of meningiomas can vary widely, depending on size of tumor, location, and temporality. Patients with late presentation may complain of nausea, vomiting, focal neurological deficits, seizures, or in advanced cases can exhibit features of obstructive hydrocephalus including papilledema and classic early morning headache. However, the majority of meningiomas are asymptomatic due to slow growth, often discovered incidentally on neuroimaging studies or at autopsy. In our case the presence of optic disc swelling and visual hallucinations were due to posterior intracranial space occupying lesion affecting the optic tract/radiation, resulting in gradually elevated intracranial pressure. Fundoscopy is a quick and very effective exam in detecting meningioma. Unfortunately this is frequently overlooked by many physicians, leading to delayed diagnosis and treatment.

CONCLUSION: This case explores delayed presentation of atypical meningioma with transient visual hallucinations in an otherwise healthy patient. Effective utilization of fundoscopy can aid in early diagnosis of slow growing meningiomas in minimally symptomatic patients. Internists need to be mindful that classical presentation of elevated intracranial pressure may not be present until very late into disease process.

FROSTBITE ARTHRITIS IN A 33 YEAR OLD MALE

Joshpaul Dhillon, Kosuke Yasukawa

Internal Medicine, Medstar Washington Hospital Center, Washington, DC. (Control ID #3392360)

LEARNING OBJECTIVE #1: Long-term complications of frostbite include tissue atrophy, scarring, peripheral neuropathy, and rarely, arthritis. Here we present a case that illustrates the importance of recognizing unique causes of arthritis.

CASE: 33 y/o undomiciled M originally from Kenya with a history of recurrent pancreatitis and alcohol abuse who presented with acute pancreatitis. During this admission, the patient was noted to have morning stiffness (lasting about 1 hour) and pain in bilateral hand PIP and DIP joints. Of note, two years before his presentation, he had sustained frostbite injury to the bilateral hands, after which he started having swelling and pain in his fingers. A physical examination was notable for enlargement of the proximal interphalangeal (PIP) joints and distal interphalangeal (DIP) joints of the second to fifth digits bilaterally with sparing of the thumbs. X-ray of hands revealed marginal erosive changes in bilateral (L > R) DIP and PIP joints, with sparing of the MCP joints and the joints of the thumbs. Extensive labwork including ANA, dsDNA, RF, C3 and C4, and antiphospholipid serologies was unremarkable. Patient subsequently received Magnetic resonance imaging (MRI) of the hands with and without contrast which showed multifocal bilateral DIP and PIP arthropathy, synovitis, as well as areas of osteonecrosis including medullary bone infarction and avascular necrosis at the articular surfaces. He was started on a trial of Prednisone with symptomatic improvement.

IMPACT/DISCUSSION: Only a few previous case reports spanning over multiple decades have described the development of arthritis following frostbite. Our patient had features of erosive arthritis that were not immediately explained by more common diagnoses such as osteoarthritis or spondyloarthritis. However, the sparing of the MCP joints and the joints of the thumb in the patient is a unique clinical and radiological finding in the diagnosis of frostbite arthritis. Although there were no apparent changes in these joints on X ray in our patient, the MRI showed small areas of osteonecrosis in the left third and fifth metacarpals and right first proximal phalanx, suggesting these joints are also affected but to a lesser extent. Previous reports have indicated that the time interval between frost injury and radiographic changes suggestive of erosive arthritis can be apparent within six months. However, in one case report, the patient's hands were essentially free of symptoms for seven years before he developed stiffness in PIP joints. Our patient was unique in that he had developed some initial pain and swelling but presented with persistent symptoms about two years after the initial exposure. With regards to management, the use of NSAIDs or steroids at low dose, which provided relief to our patient, has been suggested, but the standard management has not been established.

CONCLUSION: The above case demonstrates the importance of obtaining an adequate history when finding new, unexplained erosive arthritis in a patient.

FUNGAL ENDOCARDITIS: ENVIRONMENTAL RISK FACTORS AND CHALLENGING DIAGNOSIS OF A FATAL DISEASE

Kelsey R. Grossman[1]; Ioannis Zacharioudakis[2,1]; Andrew Fleming[2,1]; Tania Kupferman[2,1]

[1]Medicine, NYU, New York, NY; [2]Infectious Disease, NYU, New York, NY. (Control ID #3392054)

LEARNING OBJECTIVE #1: Recognize risk factors associated with development of fungal endocarditis

LEARNING OBJECTIVE #2: Diagnose the etiology of culture negative endocarditis by thorough clinical history and review of histopathology

CASE: A 41-year-old man was admitted to the hospital with acute onset dyspnea and chest pain. He had been discharged from a drug rehabilitation program two days prior and reported relapse with intravenous (IV) heroin.

On arrival, he was afebrile, tachypneic and profoundly hypoxemic. Exam revealed decreased breath sounds at the right base, a systolic murmur at the right upper sternal border, a diastolic murmur at the apex, and pitting edema. There was no evidence of peripheral embolic phenomena. Labs showed a WBC count of 17 $x10^3$/mcL and a lactate of 8 mmol/L. Multifocal consolidations and pleural effusions were apparent on chest radiograph.

He was empirically treated with cefepime and doxycycline for presumed pneumonia, intubated, and initiated on vasopressors. Bacterial blood cultures had no growth. Transthoracic echocardiogram revealed moderate- to-severe aortic insufficiency (AI) with several highly mobile vegetations on the aortic valve (AV).

On hospital day 6, he underwent AV replacement for severe AI. Cultures of the explanted valve had no growth, but tissue pathology uncovered coccobacilli and acute angle branching hyphae consistent with *Aspergillus*

spp. Upon further questioning, he reported using discarded cigarette filters as syringe filters to inject heroin.

Dual coverage with amphotericin B and voriconazole was initiated. After recovery, he started suboxone and long-term voriconazole. Unfortunately, he relapsed and was re-admitted with S.aureus bacteremia.

IMPACT/DISCUSSION: The diagnosis of Aspergillus endocarditis is challenging due to the high frequency of negative blood cultures and lack of infectious signs such as fever in debilitated hosts. Thus, there is high associated mortality due to delays in diagnosis, high incidence of large embolic events, and ineffectiveness of fungal therapy alone. Providers must maintain a high index of suspicion for the disease in order to promptly diagnose and improve the chances of survival.

All diagnostic avenues including detailed history and direct evaluation of tissue should be pursued to clench the diagnosis. In this patient, the use of cigarette filters for IV injection is the suspected source of fungemia, as tobacco and marijuana are known to harbor Aspergillus spores.

Effective treatment of Aspergillus endocarditis involves initial surgical intervention and prolonged antifungal therapy. Given the high risk for fungal relapse, lifelong antifungal therapy is often recommended, and opioid use disorder should be treated to minimize reinfection risk.

CONCLUSION: IV drug use is one of the greatest non-surgical risk factors for fungal endocarditis

Detailed history can provide clues to the microbiologic etiology of the infection

While fungal endocarditis connotes a grave prognosis, early initiation of appropriate medical and surgical management can improve survival

GALLBLADDER AGENESIS AND CYSTIC DUCT ABSENCE IN AN ADULT PATIENT DIAGNOSED INTRAOPERATIVELY: CASE REPORT AND REVIEW OF THE LITERATURE

Nahla Elzubeir[1]; Kevin Nguyen[1]; Muhammad Nazim[2]

[1]Pharmacy, Texas Tech University Health Sciences Center at Amarillo, Amarillo, TX; [2]Surgery, TTUHSC at Amarillo, Amarillo, TX. (Control ID #3374098)

LEARNING OBJECTIVE #1: Gallbladder agenesis (GA) is a rare congenital malformation. Majority are asymptomatic. However, symptomatic patients present with clinical picture similar to biliary colic. Work up usually shows contracted gallbladder (GB) on ultrasound (US), and HIDA scan shows non-visualization. Magnetic Resonance Cholangiopancreatography (MRCP) can be helpful in the diagnosis, however, the diagnosis without the latter can only be established intraoperatively. Management should be conservative treatment with antispasmodic drugs.

CASE: 35-year-old female presented to the emergency department (ED) with nausea, vomiting, & worsening right upper quadrant (RUQ) abdominal pain after meals. Stable vitals, tender RUQ. WBC of 12,000, normal liver function test (LFT), and US reported "contracted GB, cholelithiasis, 4.2 mm wall thickeness & no ductal dilation." Surgical consultation was promted by the diagnosis of acute cholecystitis. She was taken for laparoscopic cholecystectomy; however, no GB was found (figure 1). Confirmed by intraoperative Indocyanine Green Cholangiography (Figure 2). The procedure was aborted. Postoperatively, CT scan showed absent GB. HIDA scan showed non-visualization of the GB after 4 hours. Gastroenterologist performed upper enoscopy, that showed gastritis. Upper GI with small bowel follow-through study showed mild delayed gastric emptying & contrast in the colon in 45 minutes

IMPACT/DISCUSSION: GA is a rare congenital malformation 1st described in 1701 by Lemery. Incidence of 10–65 per 100,000. Commoner in females, 3:1 ratio. 70% sporadic. 1st literature review in 1988 by Bennion et al, who categorized GA into 3 types: a) Patients with multiple fetal anomalies, usually die of other congenital defects. b) Asymptomatic, discovered at autopsy. c)Symptomatic, usually with biliary disease picture. GA is attributed to failure of the CBD bud to proliferate/canalize to develop into cystic duct and GB in the 5th gestational week.

The challenge still presents as to diagnose GA before undergoing unnecessary operation. Symptomatic patients with "constricted GB" and hyperechogenic shadows seen on US, are misinterpreted as gallstones. These US findings was previously described as possible duodenal wall and gas shadows by Hammond. HIDA scan confirms the false positive diagnosis of acute cholecystitis, by "non-visualization" of the GB, which is in fact, absent. Malde in 2010 presented an algorithm when it is impossible to visualize GB under US or described as contracted chronic cholelithiasis, to perform additional investigations: MRCP, CT, ERCP, and endoscopic US. MRCP is preferred for diagnosis of GA and it is non-invasive test. We think that other three methods should be chosen if MRCP could not be performed.

CONCLUSION: When US shows contracted GB, additional imaging is required considering the diagnosis of GA. MRCP is the test of choice. Management is usually conservative with smooth muscle relaxants without the need for surgical operation.

GASRTROINTESTINAL BLEEDING DUE TO DIEULAFOY'S LESION

Nicole Basler[1]; ramin motarjemi[1,2]

[1]Hospital medicine, UCSD, San Diego, CA; [2]VA San Diego, San Diego, CA. (Control ID #3392138)

LEARNING OBJECTIVE #1: To diagnose a rare but potentially life-threatening etiology for upper GI bleeding

CASE: 70 years old male with history of CAD, HF with preserved EF and bladder cancer in remission who presented to the Emergency Department with active hematemesis. He reported four prior episodes of hematemesis earlier that day with severe epigastric and right upper quadrant abdominal pain. His recent history included two previous admissions for active hematemesis during that year.

His vital signs were significant for tachycardia and hypotension. On exam, patient was in moderate distress, actively producing hematemesis. Abdominal exam was significant for a soft, ventral hernia without evidence of incarceration, epigastric and right upper quadrant tenderness without rebound tenderness or guarding, and hypoactive bowel sounds. The remainder of the exam was unremarkable. Labs were significant for hemoglobin of 8.5 g/dL, from baseline of 12 g/dL. He was given 1 unit of blood due to the blood loss and started on pantoprazole as well as ondansetron and morphine for the nausea and pain. He also underwent an urgent esophagogastroduodenoscopy (EGD) and CT abdomen/pelvis. EGD showed a fundal stomach with an actively bleeding and a Dieulafoy's lesion which was controlled with the application of hemostatic clipping. The remainder of the esophagus, stomach, and duodenum were normal. The procedure effectively resolved the patient's hematemesis. CT abdomen/pelvis showed focal robust inflammatory changes at the right hemicolectomy anastomosis, likely responsible for the patient's continued abdominal pain, which improved over his hospital course.

IMPACT/DISCUSSION: This case demonstrates a rare cause of upper gastrointestinal bleeding that is nevertheless associated with high morbidity and mortality if left untreated or missed. Therefore, prompt identification and treatment are warranted. Dieulafoy's lesion (DL) is a relatively uncommon, but potentially life-threatening condition that accounts for approximately 1-2% of acute gastrointestinal (GI) bleeding. Dieulafoy's

lesions are abnormally large submucosal arteries that are at risk of protrusion through the mucosa and spontaneous bleeding. 75% of these lesions appear at the lesser curvature of the stomach within 6 cm of the gastroesophageal junction. These lesions were described by Sir Paul Georges Dieulafoy who studied three young men who died of gastric hemorrhage in 1898 The etiology of these lesions remains unclear. However, they are mainly seen in elderly men with cardiovascular disease, alcohol abuse, diabetes mellitus and kidney disease and those taking NSAID's and warfarin. Endoscopic therapy has shown high rates of success in achieving hemostasis, and in this case, hemostatic clipping effectively controlled the patient's bleeding.

CONCLUSION: Dieulafoy's lesion (DL) is a relatively uncommon, but life-threatening etiology of upper GI bleeding. Esophagogastroduodenoscopy can successfully stop the bleeding.

GASTRIC VOLVULUS: A RARE DIFFERENTIAL IN A YOUNG PATIENT WITH EPIGASTRIC PAIN

Rabin Neupane[1]; Ahmad A. Nakshabandi[2]; Maoyin Pang[2]

[1]Internal medicine, Medstar Washington Hospital Center, Silver Spring, MD; [2]Gastroenterology, Medstar Georgetown University Hospital, Washington, DC. (Control ID #3379414)

LEARNING OBJECTIVE #1: Identify gastric vovulus as one of the differential in patient with worsening abdominal pain.

LEARNING OBJECTIVE #2: Early imaging and surgical consult if gastric volvulus is suspected

CASE: Patient is a 31 year old obese male with past medical history of hypertension and gastric esophageal reflux disorder(GERD) who came in the clinic for complaints of episodic abdominal pain and recurrent vomiting since the last 2 weeks. Vomiting was intermittent, occurring usually after few hours of eating, non- bloody and non-bile stained. He denied any dysphagia and odynophagia. Pain was intermittent, moderate to severe in intensity on bilateral upper abdominal pain unrelated to food. He denied any hematemesis. He never had EGD or colonoscopy. Remote history of reported hiatal hernia. His vitals were stable, and his work up revealed normal basic metabolic panel and normal CBC. Chest X- ray was done showing supradiaphragmatic air-filled stomach/hiatal hernia. Ct scan was done showing the rotated supradiaphragmatic gastric fundus.

The body, antrum and pylorus along with duodenal bulb was seen herniating into the chest, consistent with mesentero-axial volvulus without obstruction. Surgery was consulted and he underwent laparoscopic repair of the paraesophageal hernia with Nissen fundoplication and laparoscopic gastropexy. Intraoperatively, 2/3rd of the stomach was found herniated which was healthy with no signs of ischemia.

IMPACT/DISCUSSION: Gastric volvulus is a lesser known condition characterized by the abnormal rotation greater than 180^0 of the stomach either in organoaxial axis or in mesenteroaxial axis or both. It is one of the rare entities causing gastric outlet obstruction and is fatal if missed from incarceration and strangulation. It is usually seen at the age 50 and in children less than 1 year old. It can be primary, without any underlying condition or secondary, in association with disorder of diaphragm, stomach or liver. Volvulus can occur in two different axis namely organoaxial, where the stomach rotate around the axis joining the gastroesophageal junction and the pylorus and mesenteroaxial where the stomach rotates around the axis perpendicular to the longitudinal axis running perpendicularly from lesser curvature to the greater curvature. First described in 1866 as a postmortem finding, only about 100 such cases reported in literatures. The mesenteroaxial type, which is seen in our patient, only encompasses 29% of the total incidence and the majorities reported are chronic volvulus and seen more in young adults and children unlike in our patient where it was acute in onset.

The presentation usually depends on the speed and the degree of obstruction. Diagnosis is made through imaging. Barium swallow and abdominal CT have been found equally effective. Surgical repair remains the major modality for treatment.

CONCLUSION: Gastric volvulus is a rare diagnosis, often missed unless suspected. Given the subtle presentation and acuity of the complications, the degree of suspicion for gastric volvulus should be high.

GASTRODUODENAL CROHN'S DISEASE : AN UNCOMMON PRESENTATION

Zaid Ansari[1]; Ishani Shah[2]; Savio Reddymasu[3]

[1]Internal Medicine, Creighton University/ St. Joseph's Hospital and Medical Center, Phoenix, AZ; [2]Internal Medicine, Creighton University St. Joseph's Hospital and Medical Center, Phoenix, AZ; [3]Internal Medicine, Creighton University, Omaha, NE. (Control ID #3390872)

LEARNING OBJECTIVE #1: Recognize that upper gastrointestinal involvement occurs in less than 15% of all cases of Crohn's disease (CD), with duodenal involvement occurring in only 0.5-4% of these patients.

LEARNING OBJECTIVE #2: Recognize gastroduodenal obstruction as a presenting feature of CD.

CASE: A 73-year-old man presented with nausea, vomiting and epigastric pain for 4 days. His history was significant for stricturing CD of the ileum, for which he had been on maintenance therapy with budesonide and methotrexate. Prior history was negative for any bowel excision surgeries. On arrival, he was afebrile with stable hemodynamics. Abdominal exam revealed hyperactive bowel sounds and mild tenderness to palpation in the epigastric region. Laboratory workup was within normal limits. An upper GI series revealed focal strictures of the third and fourth portions of the duodenum, each measuring 1.5 and 1 cm in length respectively. He was started on treatment with IV fluids, steroids and PPI. He underwent an EGD with push enteroscopy, which revealed erosive esophagitis, gastric antral erythema, a clean-based circumferential pyloric ulcer and six duodenal strictures associated with intermittent areas of ulceration. Balloon dilation of the strictures was performed. Histopathologic evaluation of gastric and duodenal biopsies revealed chronic active inflammation and villous blunting, which was consistent with CD. His condition improved over the next two days and he was able to tolerate a diet. He was then discharged in a stable condition. Six weeks later, he followed up in our GI clinic, when he complained of recurring symptoms of nausea and heartburn. A repeat EGD showed significant pyloric and duodenal ulceration associated with multiple strictures, which had to be dilated again, leading to symptom resolution. Methotrexate was discontinued, and he was started on infliximab. He has been tolerating it well for a few weeks now, and is scheduled to undergo another EGD in four weeks.

IMPACT/DISCUSSION: Gastroduodenal involvement in CD can present with clinical features mimicking peptic ulcer disease and gastric outlet obstruction. Recent studies have shown that use of TNF inhibitors such as infliximab led to good results in complicated disease involving the duodenum. PPIs have been known to provide symptomatic relief. Endoscopy and surgery continue to be the mainstay of treatment. Most patients either require frequent endoscopic stricture dilation or end up getting a bypass surgery with gastrojejunostomy. In such a situation, endoscopic dilation

serves as a safer and less invasive alternative to surgery, without causing complications such as short gut syndrome, anastomotic leak, stomal ulceration and nutritional derangements.

CONCLUSION: CD should be considered as a differential diagnosis in patients with gastroduodenal strictures/obstruction. These patients often require TNF inhibitors and are resistant to steroids. Endoscopic dilations will be frequently required.

GASTROINTESTINAL BLEED DUE TO CANNABIS PROPAGATING EFFECTS ON WARFARIN

Sona Franklin[1]; Muhammad Z. Khan[1]; Bina E. Franklin[2]; Gabriel Lerman[1]

[1]Medicine, St Mary Medical Center, Langhorne, PA; [2]Lenox Hill Hospital, New York, NY. (Control ID #3391973)

LEARNING OBJECTIVE #1: Cannabis can affect warfarin metabolism and INR levels.

LEARNING OBJECTIVE #2: Cannabis use with warfarin can lead to gastrointestinal bleeding.

CASE: A 76-year-old female with a past medical history of saddle embolus requiring thrombectomy, DVT and atrial fibrillation on warfarin. She had difficulty maintaining a therapeutic Initial International

Normalized Ratio (INR), with values ranging from 1.5 to 5.0 for a few weeks, with several adjustments of her warfarin dose. She had used marijuana for sleep. She was admitted for voluminous bloody stool with clots. She denied chest pain, coffee ground emesis, hematemesis or dyspnea. Vitals on admission: temperature 36.8 Celcius, blood pressure 80/50mmHg, heart rate 65bpm, respiratory rate 18, oxygen saturation 100% on room air. She denied taking her antihypertensive medications that day. Labs on admission: hemoglobin 10g/dl, hematocrit 30.9%, white blood cell count 6.7K/UL, platelets 269K/UL, BUN 24mg/dL, creatinine 1.01mg/dL, prothrombin time 30.5 seconds, activated partial thromboplastin time 37 seconds. Hemoglobin decreased to 6.8 on hospital day 1, initial lactic acid was 3.8 and increased to 4.6mmol/L. Her INR was 2.5, and she was transfused 2 units fresh frozen plasma to normalize her INR with a goal of less than 1.6. Her INR then reduced to 2.0 and received another 2 units of FFP, and she was started on pantoprazole. Computed tomography angiogram showed active right colonic gastrointestinal hemorrhage. She became hypotensive due to gastrointestinal hemorrhage and was started on norepinephrine which was subsequently titrated down with blood pressure stable off pressors. She underwent embolization of a small branch of the mesentery with resolution of hematochezia. Her warfarin was discontinued and she was started on apixaban prior to discharge. In total she received 7 units PRBCs, 4 units plasma and 1 unit platelets.

IMPACT/DISCUSSION: The interaction between various herbs and warfarin,[1] including cannabis has been reported in previous case reports. Studies have shown that delta-9-tetrahydrocannabinol (THC), which is the main psychoactive cannabinoid in cannabis, may inhibit the cytochrome P450 enzyme CYP2C9. Thus, cannabis use may lead to an increased risk of drug to drug interaction with the substrates of this enzyme.[2] There is a paucity of published cases citing elevated INR levels with recreational use of cannabis.[3] With the rising use marijuana and other cannabis based products for medicinal use, the resultant increase of INR in patients on warfarin may lead to unexpected bleeding. Here we present a case of a patient that was admitted for lower gastrointestinal bleed who was using marijuana for sleep.

CONCLUSION: Our patient presented with gross hematochezia on warfarin with limited use of cannabis for sleep. With the use of cannabis in a myriad of formulation, we aim to bring light to the notion that cannabis may possibly be responsible for difficulty in maintaining a therapeutic INR in patients on warfarin, as well as lead to gastrointestinal bleeding.

GAVE AS A RARE CAUSE OF AN ACUTE GI BLEED IN A 35 YEAR OLD MALE

Pooja Goel[1]; Aleksandra Pivovarova[2]; Jessica S. Lavender[2]

[1]School of Medicine, University of Mississippi Medical Center, Jackson, MS; [2]Department of Internal Medicine, University of Mississippi Medical Center, Jackson, MS. (Control ID #3371976)

LEARNING OBJECTIVE #1: Assess GAVE as a cause of an acute GI bleed in young males

LEARNING OBJECTIVE #2: Recognize that even though GAVE is associated with cirrhosis and connective tissue disease, it can also present in absence of the two

CASE: A 35 year-old South Asian-American male with a history of hiatal hernia, GERD, and esophageal spasms was admitted for symptomatic anemia. Patient was complaining of fatigability and dizziness for a few days. He denied bleeding gums, easy bruising, epistaxis, hematemesis, hematuria, melena or hematochezia. Past medical history included palpitations and right femoral neck fracture, and home medications included B12, Lovenox, Fluticasone, and Oxycodone. Past surgical history was significant for a recent right femoral neck fracture repair. Family history was unremarkable and patient is a nonsmoker and nonalcohol drinker. Upon examination, he was pale with stable vital signs, had an unremarkable abdominal exam, but positive fecal occult blood test. At the time of presentation, laboratory data was significant for low hemoglobin (6.6 g/dL) and hematocrit (38.2), normal platelets, and normal WBC count. Previous hemoglobin of 15 g/dL less than a month ago. Patient received blood transfusion. Recent esophagogastroduodenoscopy in July and colonoscopy in April were unremarkable. Patient had high haptoglobin, erythrocyte sedimentation rate, c-reactive protein, INR, prothrombin time, and D-dimer. Normal liver enzymes and normal appearance of liver on abdominal ultrasound. Upper endoscopy was performed, revealing moderate gastric antral vascular ectasia without bleeding in the gastric antrum consistent with GAVE. Negative ANA and centromere antibody. His hematocrit remained stable during his admission. Proton pump inhibitor was initiated and patient was discharged home in stable condition.

IMPACT/DISCUSSION: GAVE aka "watermelon stomach" is a rare cause of chronic gastric hemorrhage and iron deficiency anemia. The name "watermelon stomach" is originated from the endoscopic appearance of rows of red stripes of ectatic mucosal vessels radiating from the pylorus of the stomach in the antrum. GAVE usually causes low-grade GI bleed, and less commonly acute bleeding. GAVE can also be associated with cirrhosis and connective tissue disease (Payne). It has also been reported to be common in patients with scleroderma, calcinosis, esophageal dysmotility, and sclerodactyly (Ward). Median age 74, with 80 % of patients being women. The diagnosis of GAVE is based on endoscopic appearance, and can be confirmed by biopsy. Our case is unique due to patient's young age, male gender, and absence of any underlying liver or connective tissue disease.

CONCLUSION: GAVE is a rare but an important cause of upper GI bleeding. Diagnosis of GAVE can be overlooked in young males but should be considered in obscure GI bleeding. Endoscopic therapy using APC is the main treatment option.

GIVE ME SOME SUGAR: LATE-ONSET HYPOGLYCEMIC EPISODES AFTER BARIATRIC SURGERY

Kira Xie

Internal Medicine, Icahn School of Medicine at Mount Sinai, New York, NY. (Control ID #3392294)

LEARNING OBJECTIVE #1: Identify nesidioblastosis as a cause of hypoglycemia after bariatric surgery

LEARNING OBJECTIVE #2: Differentiate nesidioblastosis from other causes of post-gastric bypass hypoglycemia

CASE: A 47 year old male with a history of Roux-en-Y gastric bypass (RYGB) 2014 presented with nighttime hypoglycemia. He reported 2-3 months of awakening from sleep disoriented almost nightly with blood glucose in the 30s-40s. Symptoms resolved with juice or glucose tablets, which he started taking 2-3 times daily. He also endorsed mild abdominal pain and nausea without emesis or diarrhea, and unintentional 20-lb weight loss during this time. He denied any fevers, localizing illness, or recent stressors. His diet recently became vegetarian and consisted of many simple starches. He drank 16-18 alcoholic drinks a week.

A1c, serum glucose, insulin, and C-peptide were normal. TSH and random cortisol were normal. Endocrinology was consulted and diagnosed him with post-RYGB nesidioblastosis. He was told to decrease carbohydrate intake and have small frequent meals throughout the day. He was later started on acarbose for persistent symptoms.

IMPACT/DISCUSSION: Nesidioblastosis was seen primarily in infants, but adult-onset associated with bariatric surgery is increasingly reported in the literature. Nesidioblastosis, or non-insulinoma pancreatogenous hypoglycemia syndrome (NIPHS) is hyperplasia of pancreatic beta islet cells, thought to be due to increased growth factor production in response to high nutrient loads presented to the distal jejunum. Cohort studies suggest a conservative estimate of 0.2-1% prevalence in post-gastric bypass patients. NIPHS presents 0.5-8 years after bypass surgery. The differential for post-gastric bypass hypoglycemia also includes insulinoma, dumping syndrome, and medications. Initial labs include serum glucose, insulin, and C-peptide levels. Sulfonylurea, insulin antibody, and glucagon stimulation tests can also be ordered. Imaging and arterial calcium stimulation testing may identify larger insulinomas. Definitive diagnosis is histological, but the clinical presentation, history, and laboratory/imaging work-up can help exclude other likely causes. Mild to moderate NIPHS can be managed with dietary changes and acarbose. Severe or refractory NIPHS is treated with partial pancreatectomy (usually >70%), which can often result in permanent diabetes mellitus.

Bariatric surgeries have been rising in popularity given the rapid effectiveness and associated improvement in metabolic syndrome. However, this case underscores an important complication of bariatric surgery that both patients and physicians should be cognizant of.

CONCLUSION: 1. NIPHS should be considered on the differential for post-bariatric surgery hypoglycemia

2. Presentation, history, labs, and imaging can help to differentiate NIPHS from other common causes of hypoglycemia
3. Treatment is dietary +/- acarbose for mild to moderate cases, and partial pancreatectomy (usually >70%) for severe or refractory cases

GIVING BREATH TO OTHERS

Cynthia Masotti, LCSW[1]; Lauren Drake[2]; Christopher Schultz, MD[1]; Thida Thant, MD[1]; Hillary Chrastil[1]

[1]General Internal Medicine, University of Colorado, Aurora, CO; [2]Medicine, University of Colorado, Aurora, CO. (Control ID #3391256)

LEARNING OBJECTIVE #1: - Recognize the clinical advantages to the patient of integrated mental health (IMH) in an internal medicine clinic.

LEARNING OBJECTIVE #2: - Recognize the advantages of a collaborative approach to treatment that includes the clinical social worker, consulting psychiatrist, and primary care provider.

CASE: The patient is a 35-year-old African American male, who relocated for his wife's job. He left behind his support system and was unable to find work in his field. PCP referred patient for mental health treatment following ER visits for cardiac symptoms thought to be related to anxiety.

Patient described symptoms of major depressive disorder and anxiety with panic. His childhood was notable for poverty, neglect and trauma. Trauma history was significant for engagement in gang violence. Protective factors included parental love and support.

The patient's primary concern was panic symptoms followed by difficulty securing employment. This difficulty led to feelings of worthlessness as he had previously gained self-worth through his work. Treatment focused on psychoeducation regarding diagnosis and exercises for affective regulation and managing panic attacks. Immediately following the first session, the consulting psychiatrist recommended Lexapro which the PCP promptly prescribed.

With notable improvement, he found the motivation to return to school to pursue a career as a respiratory therapist. At our final session he remarked: "I recognize that my experience growing up often put me in a position of watching people 'lose their breath' (e.g. die) as a result of gun violence, my chosen profession as a respiratory therapist allows me to give breath to others."

IMPACT/DISCUSSION: Before IMH treatment the patient:

- Had two ED visits predicated by psychosomatic factors
- Was positive for depression and anxiety with panic attacks
- Was unemployed

After IMH treatment the patient:

- Has not had any ED visits
- Is no longer positive for depression and anxiety with panic attacks
- Is pursuing a professional degree

An integrated multi-disciplinary care team in primary care:

- Provides seamless care as all mental health and internal medicine providers are collaboratively managing the patient.
- Empowers the PCP to maximize the benefits of psychotropic medications by leveraging the consulting psychiatrist's expertise.
- Enables the therapist and psychiatrist to leverage the PCP's rapport with the patient.

How does this case add to the literature?

- IMH improves access and patient retention by providing psychiatric treatment through the PCP in the medical home.
- IMH improves care efficiency from the perspective of the patient, PCP, psychiatrist, and therapist.

CONCLUSION: - Due to established rapport with PCP and immediate availability of IMH, patient quickly overcame inertia and readily accepted IMH treatment.

- IMH breathes new life into collaborative care in the primary care setting by making it faster and easier for the treatment team to provide whole person care.

GRANULOMATOSIS WITH POLYANGIITIS PRESENTING AS ACUTE RENAL FAILURE

Abigail Entz[1]; Muhammad Usman[2]

[1]Internal Medicine, Henry Ford Hospital, Detroit, MI; [2]Pulmonary and Critical Care Medicine, Henry Ford Hospital, Detroit, MI. (Control ID #3392432)

LEARNING OBJECTIVE #1: Recognize the highly variable presentation of granulomatosis polyangiitis (GPA)

LEARNING OBJECTIVE #2: Understand the cornerstone of therapy for GPA

CASE: We present the case of a 69-year old female with a history of hypertension who presented for evaluation of persistent congestion, shortness of breath and cough of 1 month's duration after failing multiple courses of outpatient antibiotics. On presentation to another facility, she was afebrile with increased oxygen requirements. Labs revealed anemia and acute kidney injury. Multiple lobar infiltrates were noted on chest x-ray. She was started on treatment for pneumonia. Over the next 2 days she experienced respiratory decompensation with worsening anemia, requiring intubation for hypoxic respiratory failure. Bronchoscopy revealed diffuse pulmonary hemorrhage. C-antineutrophil cytoplasmic antibody (C-ANCA) was positive, anti-glomerular basement membrane antibody was negative and creatinine continued to worsen. Upon transfer to our facility, she underwent treatment with emergent plasma exchange with pulse-dose steroids. Renal biopsy revealed necrotizing, crescentic glomerulonephritis. The renal biopsy was pauci-immune on direct immunofluorescence, confirming the diagnosis of granulomatosis with polyangiitis (GPA). Although her renal disease quickly necessitated hemodialysis, she experienced improvement in her respiratory symptoms and was extubated. She was transitioned to oral prednisone and monthly intravenous cyclophosphamide and unfortunately continues to require intermittent hemodialysis.

IMPACT/DISCUSSION: Granulomatosis with polyangiitis is an ANCA-associated inflammatory disease of small blood vessels. The symptoms of GPA are extremely variable and can include multiple sites/organ systems. Respiratory and upper airway symptoms including rhinosinusitis, cough, shortness of breath, and hemoptysis are most common symptoms, though hemoptysis is only present in two-thirds of patients. Patients also present with systemic symptoms of fatigue, weight loss, fever, and arthralgias.

Prompt recognition of GPA is essential as studies estimate two-year mortality rates up to 90% in untreated patients. The cornerstone of therapy is glucocorticoids combined with immunosuppressive agents. Most regimens prefer the use of cyclophosphamide or rituximab, although methotrexate can be used in less severe cases. One trial (CYCLOPS) showed that monthly IV cyclophosphamide had higher relapse rates but lower rates of adverse events when compared to oral daily dosing of cyclophosphamide. In select populations, including patients with rapid worsening of kidney function and pulmonary hemorrhage, there is evidence that supports the use of plasma exchange in addition to steroids and immunosuppressive therapy.

CONCLUSION: Our patient highlights the variable presentation of GPA, often leading to a delay in diagnosis. As in this case, patients with severe disease may benefit from a combination of steroids, immunosuppressive therapy, and plasma exchange.

GRAVE EFFECTS FROM DELAYS IN CARE OF THYROID EYE DISEASE

Areej A. Ali[1]; Vasilii Bushunow[2]; Amar Kohli[3,1]

[1]Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA; [2]Medicine, University of Pittsburgh Medical Center, Pittsburgh, PA; [3]Internal Medicine, UPMC, Mars, PA. (Control ID #3392681)

LEARNING OBJECTIVE #1: Recognize clinical characteristics of thyroid eye disease (TED)

LEARNING OBJECTIVE #2: Diagnose TED in the absence of typical hyperthyroidism

CASE: A 54 year old man with 40 pack year smoking history presented with vision loss.

His sympoms began nine months prior with watery eyes, and were attributed to allergies. His vision deteriorated, and he was referred to Ophthalmology. Due to insurance issues, he did not re-present for another six months. He reported a shadow over the center of his left-eye visual field. Visual acuity was 20/30 on the left and 20/25 on the right. Exam was notable for bilateral lid retraction, conjunctival injection, and exophthalmos; 24 mm on the right and 29 mm on the left. Left eye had red desaturation and an afferent pupillary defect. There was no goiter.

He was hospitalized due to concern for TED with left optic nerve compression. Orbital CT showed asymmetric extraocular muscle enlargement and crowding of the left orbital apex. He had a TSH of 7.44 uIU/mL, T4 of 8.0 ug/dl, Free T4 of 1.12 ng/dl, and rT3 of 17 ng/dl. Antibody serology was positive for: thyroid peroxidase (anti-TPO) at 17 IU/ml, TSH receptor (TRAb) at 24.6%, and thyroid stimulating immunoglobuin (TSI) at 450% baseline. Thyroid ultrasound was unremarkable.

The patient was treated with 3 days of intravenous steroids with drastic improvement. He was discharged on levothyroxine, and underwent a total thyroidectomy one month later. Post-operative visual acuity was 20/25 on the left, and 20/20 on the right.

IMPACT/DISCUSSION: TED is an autoimmune disease of orbital and pre-orbital tissue that commonly occurs with hyperthyroidism, where TSI mimics TSH by binding to thyroid hormone receptors, leading to increased hormone production. Increased thyroid receptor activation and increased IGR-1R activity lead to exopathalmos due to stimulation of orbital fibroblasts.

This case illustrates the 10% of atypical presentations where TED occurs without hyperthyroidism. The elevated TSH was likely due to transient hypothyroidism in the setting of Graves' disease rather than Hashimoto's thyroiditis, in keeping with the patient's TSI and prior heat intolerance. Elevated TSIs occur in 80-90% of Graves' disease but in only 10-20% of Hashimoto's thyroiditis. Anti-TPO antibodies occur in 50-80% of Graves', and 90-100% of Hashimoto's.

CONCLUSION: The patient's lack of insurance, low health literacy, and difficulty navigating the system contributed to his delayed, sight-threatening presentation. Early interventions with social work support may have prevented his deterioration and 3 day hospitalization.

Despite atypical hormone levels, this clinical presentation was classic of TED, with eyelid retraction, seen in 91% of patient's, and proptosis, seen in 62% of patients. Lastly, this case highlights the importance of counseling of smoking cessation, as it is one of the strongest risk factors associated with TED. In patients with Graves' disease, the number of cigarettes smoked after diagnosis had a greater association with TED than lifetime use.

HAILEY HAILEY DISEASE

Surabhi Gupta[2]; Sujata Bhushan[1,2]

[1]Section of General Internal Medicine, Dallas VA Medical Center, Dallas, TX; [2]Internal Medicine, UT Southwestern Medical Center, Dallas, TX. (Control ID #3390786)

LEARNING OBJECTIVE #1: Recognize the rash and inheritance pattern of Hailey-Hailey disease (HHD)

LEARNING OBJECTIVE #2: Management of Hailey Hailey disease

CASE: A 54-year-old man presented with groin pain, fevers, and urinary urgency for 3-4 days. Medical history included HHD with 20 years of painful blisters in his axilla, groin, and antecubital and popliteal fossae

often complicated by abscesses. Medications were chronic suppressive doxycycline, tramadol and topical clobetasol. His maternal great-grandmother, grandfather, mother, and sister all had HHD. On exam, heart rate was 106, afebrile. He had a tender, fluctuant, erythematous left hemi-scrotal mass, hyperpigmented macules and erythematous papules with hemorrhagic and serous crusts forming plaques on the axilla, groin, buttocks, and antecubital and popliteal fossae. Labs showed a leukocytosis of 24.5 and creatinine of 3.42 (baseline 1.5). Imaging showed a 7 cm heterogeneous fluid collection in the left hemi-scrotum suggesting an abscess. After incision and drainage and broad-spectrum antibiotics, he rapidly improved. He was discharged on ciprofloxacin followed by resumption of doxycycline. At Dermatology clinic follow-up he was started on naltrexone for severe HHD.

IMPACT/DISCUSSION: Discussion: Hailey-Hailey disease, or familial benign chronic pemphigus, is a rare autosomal dominant disease. It is due to haploinsufficiency of the enzyme ATP2C1, (folded from the protein hSPCA1), which disrupts intercellular desmosomes causing acantholysis. Age of onset is 20-40 years. It symmetrically affects flexural areas, sparing mucosa. Flaccid vesicles on erythematous skin progress to macerated, exudative plaques of erosions with crusts. Postinflammatory hyperpigmentation is common. 70% have linear white bands on the nails. Colonization and infection with bacteria (*Staphylococcus*, *Streptococcus*) and fungi (dermatophytes, *Candida*) is common. Sweat, friction, UV radiation and infection are exacerbating factors. Diagnosis is via exam, history, and biopsy with a "dilapidated brick wall" appearance. A lack of oral lesions and intercellular antibodies distinguishes it from autoimmune pemphigus. Average time to diagnosis is 8 years, as it may be misdiagnosed as intertrigo, dermatitis, or inverse psoriasis. Therapy involves controlling exacerbating factors, infection and inflammation. Standard treatment is topical and systemic antibiotics and/or steroids, and Botulinum toxin or glycopyrrolate may reduce sweating. Severe cases can be treated with low-dose naltrexone, methotrexate, cyclosporine, tacrolimus or acitretin. Recalcitrant cases are treated with surgical or laser therapy. It has a chronic relapsing and remitting course. Patients have a normal life expectancy but with impaired quality of life.

CONCLUSION: The rarity and presentation of Hailey-Hailey disease can cause significant delay in diagnosis and treatment. Internists may benefit from familiarity with its manifestations and complications.

HASHIMOTO'S HYPOKALEMIA

Michelle Chen, Galina Glazman, Alexander M. Barbaro, Zaki Azam, Jennifer McKenna

Internal Medicine, Montefiore Medical Center, New York, NY. (Control ID #3392059)

LEARNING OBJECTIVE #1: To recognize hypothyroidism as a precipitant of rhabdomyolysis in the setting of hypokalemia

CASE: A 43-year-old man with history of hypothyroidism and hypertension presented with diffuse muscle cramps and weakness of his extremities. The symptoms initially started one week prior to admission while he was working his construction job and became progressively worse. On admission, he was hypertensive to 190/90 with physical exam notable for difficulty with extension and flexion of his extremities and digits. His initial creatine kinase (CK) was greater than 37,000, potassium was 2.7, urine pH was 6.5, and creatinine was 1.3. Aggressive fluid repletion was initiated. Thyroid stimulating hormone (TSH) was found to be 96, with a free thyroxine (FT4) of 0.3 and anti-thyroid peroxidase antibodies over 1000, so levothyroxine was initiated. CK improved by about 5,000 per day. He also required daily potassium repletion during this time. On follow- up one month later, CK levels were within normal range, TSH and FT4 improved to 0.5 and 1.7, respectively, and the patient no longer required potassium supplementation.

IMPACT/DISCUSSION: Hypothyroidism commonly presents with cold intolerance, weight gain, and myopathic symptoms such as fatigue, cramps, and myalgia. Mild elevations in creatine kinase are not uncommon, however rhabdomyolysis can be a rare but serious complication of severe hypothyroidism. It is diagnosed by a level of creatine kinase that is at least five times the upper limit of normal. Typically, the onset occurs with a precipitating factor such as use of statins, trauma, alcohol abuse, or an electrolyte abnormality. In this case, hypokalemia induces necrosis in muscle tissue by causing vasoconstriction leading to impaired blood flow to muscles. Distal renal tubular acidosis, a cause of hypokalemia, has been associated with autoimmune conditions such as Sjögren syndrome, systemic lupus erythematosus, and autoimmune hypothyroidism. While the pathophysiology has not been fully elucidated, it is thought to involve the production of auto-antibodies against intracellular carbonic anhydrase II or acid-base transporters of alpha- intercalated cells in the distal nephron. Aggressive fluid repletion may not suffice to prevent these patients with rhabdomyolysis from developing renal failure, and such patients require additional potassium supplementation and initiation of thyroid replacement therapy.

CONCLUSION: In patients with rhabdomyolysis caused by hypokalemia, hypothyroidism should be considered since treatment of the underlying cause is important in preventing the progression and serious complications of rhabdomyolysis.

HEART-TO-HEART: THE CURE TO CHEST PAIN

Kacey Chae

Internal Medicine, Johns Hopkins Bayview Medical Center, Baltimore, MD. (Control ID #3391841)

LEARNING OBJECTIVE #1: To recognize the social stigma associated with substance use and how it affects provider perception

CASE: A 57-year-old man presented to the ED for 2 weeks history of exertional chest pain, usually relieved upon rest. His symptoms progressed to persistent chest pain. He initially hesitated in seeing a medical provider and only decided to come to the ED at the repeated behest of his partner. Past medical history was notable for CAD with stents placed at age 33. Patient was not taking any medications. He reports 50 pack year smoking history and uses crack cocaine weekly. EKG showed inverted T waves in the inferior leads. Troponin was 3.63. Toxicology screen was notable for cocaine and cannabinoid. Patient was started on dual anti-platelet agents and heparin. Upon initial discussion, patient was not interested in further cardiac intervention. The provider also felt that medication adherence would be a challenge. The preliminary plan was to discharge him only on medical therapy. As I was preparing for his discharge in the afternoon, my attending physician requested that I continue his heparin: to my surprise, the patient had decided to pursue a cardiac catheterization. The decision was the result of the patient and the attending conversing about the patient's priorities. The attending connected the patient's symptoms to his heart disease and his high-risk habits. That sparked a realization in the patient to take his health more seriously. That same afternoon, his cardiac catheterization showed 99% stenosis of his left main coronary artery and complete occlusion of his right coronary artery. Patient pursued a bypass surgery thereafter.

IMPACT/DISCUSSION: Despite efforts in medical education to train learners in recognizing implicit biases, overcoming these biases in practice proves to be a challenge. In particular, substance use disorder (SUDs) elicits negative attitudes, to which physicians are not immune (Yang 2017, Fingerhood 2015). In a 1998 survey, over 70% of people perceived that individuals with cocaine use

disorder were "not very" or "not at all" able to make treatment decisions (Pescosolido 1999). The negative attitude leads to making certain assumptions and discrimination.

This is important to recognize because many assumptions about our patient in the case were made by providers—that he would not be interested in a cardiac catherization and that he would not adhere to therapy, both of which were untrue. These assumptions nearly prevented him from life-saving interventions.

How we could address these assumptions is through open and honest conversations with the patient, often enlisting help from stakeholders. Implicit biases are difficult to overcome but learning to recognize it in the arena of patient care and combatting it with more time at the bedside is crucial.

CONCLUSION: One way to combat stigma against patients with SUDs is compassionate care at the bedside.

HELPING THOSE WHO NEED IT MOST

Akash Patel

Medicine, NYP Weill Cornell, New York, NY. (Control ID #3390681)

LEARNING OBJECTIVE #1: Identify characteristics of help-rejecting patients

LEARNING OBJECTIVE #2: Identify strategies to care for help-rejecting patients

CASE: This is a 60 year old woman with past medical history of anxiety and depression with prior suicide attempt in 2017 who presented to clinic in August to establish care. Her primary complaint was "paralyzed panic" and anxiety, which started after her mother, for whom she cared, died in February. She resided in her mother's apartment for the past 1.5 years and left the apartment only 4 times during that time span. She reported a long history of antidepressant use, including fluoxetine, sertraline, bupropion, and most recently escitalopram, however has been off all medications since June because they "numbed" her. She endorsed passive SI but denied present plan or intent. She was referred to social work, who provided a psychiatry appointment the following week. She declined because she had "a bad felling" about the psychiatrist. She was referred to a local mental health center and walk-in clinic, but expressed concern about the quality of care at the local center. Finally, the hospital's mobile crisis team met the patient at her home, but she declined to engage with them. During an interval follow-up appointment one month later, patient expressed that she would be willing see the clinic's psychiatrist, however declined once again when staff called her to set up an appointment.

Psych history:

Depression – with prior suicide attempt by hanging in 2017

No psychotherapy in the past

Anxiety

No family history of depression or suicide

Meds: None

Social History:

Former smoker

No other substances

Married to husband and has 1 daughter

No domestic violence history

IMPACT/DISCUSSION: Help rejecting patients are difficult patients to treat. They can be identified as those who seek help and advice but reject any help that is offered. Tendencies include portraying their problems as unsolvable, feeling hopelessness toward their problems, and behaving passively when attempting to alleviate their troubles. Providers caring for help-rejecters are placed in difficult situations. After repeated attempts to help these patients, providers may become hopeless and frustrated themselves. For that reason, it is important to recognize help-rejecting traits. Rather than proposing solutions that are likely to be rejected, care for help-rejecting patients may be re-framed. Strategies may include acknowledging the problem, asking what the patient has done to address the problem, and asking what solution the patient proposes for the future. In this case, patient was provided with monthly appointments to discuss concerns. Initially, every effort was made to plug the patient in with social work and psychiatric services. After repeated rejections, patient was provided the telephone number of her insurance company help line and told to call when she was ready to ask for options outside the NYP health system. She made an appointment, has seen a psychiatrist twice, and has started on medication.

CONCLUSION: See impact/discussion

HEMATEMESIS IN A NEWLY DIAGNOSED HIV PATIENT

JALAL EL-AKAWI[1]; Malik Shehadeh[1]; Chaand Ohri[2]

[1]Internal Medicine, Medstar Washington Hospital Center, Washington, DC; [2]Internal Medicine, Medstar Washington Hospital Centerq, Washington, DC. (Control ID #3392097)

LEARNING OBJECTIVE #1: To recognize intestinal diffuse large B cell lymphoma as a serious potential complication in patients with advanced human immunodeficiency virus (HIV) infection who present with gastrointestinal symptoms.

CASE: A 25-year-old male patient without significant medical history presented to our hospital with epigastric pain and hematemesis of 1-week duration.

Upon arrival to the hospital, his vitals were unremarkable except for sinus tachycardia in 120s. His labs showed Hemoglobin of 5.5 g/dl (normal range 12.5-16.5 g/dl). His HIV test was positive with viral load of > 200,000 and CD4 count < 50. He also had an evidence of past infection with hepatitis B (HBsAg negative, HBcAb positive, HBsAb positive). The patient was given blood transfusions and volume resuscitation after which his hemoglobin and hemodynamics stabilized.

A computed tomography angiogram was done and showed thick walled 6.4 cm complex collection involving the second segment of the duodenum with no evidence of active extravasation. No embolization was performed. An esophagogastroduodenoscopy showed large, circumferential, partially obstructing, non- bleeding duodenal ulcerated mass in the second portion of the duodenum. The mass was biopsied and revealed diffuse large B cell lymphoma. Left iliac crest bone marrow biopsy was performed and showed normocellular marrow without any evidence of lymphoma.

He was started on chemotherapy for his localized tumor and continued to be on Biktarvy for his HIV and to protect him from hepatitis B reactivation commonly associated with rituximab treatment. Patient tolerated chemotherapy well without any evidence of tumor lysis syndrome or duodenal perforation.

IMPACT/DISCUSSION: Patients with human Immunodeficiency virus (HIV) infection are at higher risk for different types of malignancies when compared to general population. The incidence of Non-Hodgkin lymphoma is much higher in individuals with HIV infection compared to general population with diffuse large B cell lymphoma being the most common subtype.

The gastrointestinal tract is the most common site of extranodal involvement in non-Hodgkin's lymphomas, and the stomach is the most common involved organ. However, HIV-associated duodenal lymphomas are very rare.

Up to our knowledge, there are very few reported cases of duodenal diffuse large B cell lymphoma in HIV patients.

Early diagnosis and treatment with chemotherapy and antiretroviral medications are crucial to improve survival in such patients.

CONCLUSION: Duodenal non-Hodgkin's lymphomas are rare. However, such lymphomas have higher incidence in patients with HIV. Prognosis and survival of these patients largely depend on early recognition and treatment.

HEMOGLOBIN SE DISEASE PRESENTING AS HIGH-ALTITUDE MASSIVE SPLENIC INFARCTION

Alice Liu[1]; Andrew Pajak[2]; Shaina Nazare[2]; Jonathan C. Li[3]; Bruce J. Smith[2]

[1]Sidney Kimmel Medical College, Philadelphia, PA; [2]Internal Medicine, ChristianaCare, Newark, DE; [3]Internal Medicine-Pediatrics, ChristianaCare, Newark, DE. (Control ID #3388540)

LEARNING OBJECTIVE #1: Identify HbSE disease as a hybrid hemoglobin variant and its potential to cause detrimental outcomes including vaso-occlusive crisis (VOC).

LEARNING OBJECTIVE #2: Manage sickle VOC infarcts with supportive therapy and have a conservative approach to anticoagulation and surgical intervention.

CASE: A previously healthy 55-year-old woman of South Asian descent, presented after four days of worsening left upper quadrant pain (LUQ) that started acutely while she was atop a Swiss mountain. In the emergency department, her initial vital signs and labs were notable for tachycardia, leukocytosis (21,900/mm^3), anemia (11.7 g/dL), and thrombocytopenia (122,000/μl). Subsequent workup was concerning for hemolytic anemia with an undetectable haptoglobin, elevated lactate dehydrogenase, and elevated bilirubin. Greater than 50% splenic infarct was detected on CT abdomen. Family history was notable for sickle cell disease (SCD) among distant family members, but the patient had never been tested. Due to suspicion for a thrombotic event, she was started on enoxaparin.

Two days later, she experienced worsening LUQ pain and was found to have worsened leukocytes (31,600/mm^3), anemia (6.2 g/dL), new thrombocytosis (436,000/μL), and new lactic acidosis (4.0 mmol/L). An emergent CT-angiogram detected active hemorrhage of the initial splenic infarct. Immediate vascular intervention with coil embolization was performed. Overall, the patient was transfused 3 units of uncrossmatched packed red blood cells.

Hemoglobin electrophoresis revealed HbS 68.6%, HbE 26.3%, HbA 0.0%, HbA2 3.7%, and HbF 1.4%, suggestive of hemoglobin SE disease. She was immunized for functional asplenism and made a complete recovery.

IMPACT/DISCUSSION: HbS and HbE are the most common hemoglobinopathies worldwide, but double heterozygosity is exceedingly rare. HbE is common among patients with South Asian ancestry and leads to an under-expressed variant beta globin. While HbE trait is clinically silent, heterozygosity with HbS produces a phenotype similar to HbS/β+ thalassemia. Based on limited reports, many patients remain asymptomatic. HbSE VOCs predominantly present in adulthood, likely due to accumulation of vascular damage from subclinical microinfarcts. This case demonstrates that high altitude exposure may provoke VOC in previously benign sickle cell variants. The majority of sickle-related splenic infarcts resolve with conservative therapies directed at vaso-occlusion rather than anticoagulation. Anticoagulation should be approached with caution in patients with a family history of SCD and a clinical picture consistent with a VOC due to the risk of hemorrhagic conversion.

CONCLUSION: HbSE disease is a rare, heterozygous hemoglobinopathy and clinical manifestations, if present at all, occur in adulthood. Stressors such as high altitude may trigger a VOC resulting in infarction. If SCD is suspected, initiation of anticoagulation for an infarct is a serious clinical decision with risk for life- threatening hemorrhagic conversion.

HEMOLYTIC ANEMIA AND RENAL FAILURE AS EXTRAHEPATIC MANIFESTATIONS OF ACUTE HEPATITIS A

Mona A. Haj, Ira Willner

Internal Medicine, Medical University of South Carolina, Charleston, SC. (Control ID #3392358)

LEARNING OBJECTIVE #1: Recognize that hemolytic anemia can occur in patients with acute Hepatitis A and ultimately lead to renal failure

LEARNING OBJECTIVE #2: Manage potential extrahepatic complications of acute Hepatitis A

CASE: A 54-year-old African American man with hypertension presented with 3-days of nausea, abdominal pain, and jaundice. He frequently ate at diners and road-side restaurants due to his job as a truck driver, but denied any new medications or supplements for the previous year. He had been well previously, and he denied any history of previous liver disease. Laboratory data on admission were notable for an AST and ALT of 1840IU/L and 3860IU/L respectively, total bilirubin of 24.0, and a positive IgM hepatitis A virus (HAV). Further workup for acute liver injury (ALI) was negative, and patient was felt to have ALI secondary to acute hepatitis A. Given that he had no evidence of synthetic impairment (INR 1.2) or encephalopathy, discharge with supportive care was planned. However, 36 hours after admission he developed worsening renal function, with serum creatinine (Cr) 3.6mg/dL and urine output of 100mL over the previous 24-hours. He had no response to intravenous fluid resuscitation and his renal function continued to worsen, with Cr reaching 8.8mg/dL by hospital day 3, requiring initiation of hemodialysis. He also developed marked anemia, with a hemoglobin of 6.2g/dL without any obvious source of bleeding. He had an extensive workup that was notable for haptoglobin <8.0mg/dL, lactate dehydrogenase (LDH) >4000U/L, urinalysis with large blood (but no RBCs), elevated reticulocytes, and a plasma hemoglobin of 570mg/dL all concerning for hemolytic anemia. He was subsequently started on plasmapheresis with improvement in plasma free hemoglobin levels to <50mg/dL. A renal biopsy revealed acute tubular necrosis (ATN) with heme pigment casts and hemosiderin deposits, as well as bile nephrosis. He was subsequently discharged with continued hemodialysis needs and monitoring for resolution of renal function.

IMPACT/DISCUSSION: Extrahepatic manifestations such as hemolytic anemia and renal failure are known complications of hepatitis B and C virus infection. Although HAV infection is common, with nearly 2 million clinical cases encountered worldwide annually, it is typically mild and self-limited, with rare extrahepatic manifestations. Notwithstanding, extrahepatic manifestations of acute HAV may be encountered, particularly in patients with fulminant HAV disease, and include hemolytic anemia, acute renal failure, and acute reactive arthritis – presumably because an aggressive immune reaction not only leads to extensive hepatocyte injury, but also immune activation in the periphery. Our patient emphasizes that these immune mediated processes may also occur in non-fulminant states.

CONCLUSION: We emphasize that given the increase in acute HAV cases particularly in the Southern United States, it is important as internists to be cognizant of the potential complications of acute HAV.

HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS- DELAYED TREATMENT IS POOR PROGNOSIS!

Dimple Shah, Deyun Yang

Medicine, Zucker SOM, Manhasset, NY. (Control ID #3392104)

LEARNING OBJECTIVE #1: To recognize the early signs of HLH and initiate prompt medical intervention

CASE: 20 year old male with no medical history presents to the hospital with one week of fevers, dysphagia, neck swelling and joint pains. He presented to an urgent care and hospital a few days prior where he was given antibiotics and steroids, without improvement. On admission, patient was febrile to104, BP 110s/70s, HR 100s and O2 sat 99%. Physical exam was significant for bilaterally cervical lymphadenopathy, parotid swelling, erythematous pharynx, tenderness to palpation diffusely over the abdomen, bilateral hand joint and feet swelling, and waxing and waning rash over the legs and wrists. Initial laboratory values showed anemia to 9.8, WBC count of 11, platelet 130, Cr of 1.67, AST/ALT of 155/88 and ferritin of 5352. Patient was started on broad spectrum antibiotics. Blood cultures, viral serologies and rheumatologic serologies were all negative. During the first 48 hours of admission, patient remained persistently febrile, with worsening lymphadenopathy and arthralgias. Day 2, labs showed ferritin > 10,000, TAG 391 and platelets 71, meeting 4/8 1994 criteria for HLD. Hematology conducted a bone marrow (BM) biopsy. Given diffuse lymphadenopathy, there was suspicion for lymphoma which would require a core biopsy, however given rapid decline of patient, a consensus decision was made amongst the specialties to initiate the HLH 94 protocol with dexamethasone. Patient with worsening difficulty maintaining secretions and was transferred to the ICU for airway management and started on etoposide as biopsy showed hemophagocytes. He was intubated in the ICU for airway protection and required renal replacement therapy due to tumor lysis syndrome. Patient made a remarkable recovery with chemotherapy and supportive care, and was extubated and taken of hemodialysis. He was discharged with outpatient etoposide therapy.

IMPACT/DISCUSSION: HLH is a rapidly progressive syndrome caused by unregulated immune activation, and if untreated, is fatal. Our patient presented with diffuse cervical lymphadenopathy with hematologic manifestations of anemia and thrombocytopenia with intractable fevers. Infectious, autoimmune and neoplastic, including lymphoma, were all on the differential. However, given his rapidly decline, it was of the utmost importance to initiate treatment for HLH early as it is universally fatal if not treated, and to bypass the lymph node biopsy. We administed dexamethasone per HLH94 protocol, and initially held off on etoposide due to long term side effects, which was was ultimately started the next day with the positive biopsy results. At the time of discharge, the underlying cause of HLH was not elucidated, (ddx includes lymphoma and Still's disease (per Yamaguchi criteria)). Repeat biopsy 2 months after treatment showed resolution.

CONCLUSION: HLH, although an uncommon disease entity, is universally fatal if untreated. Early recognition and intervention is vital to decrease morbidity and mortality.

HEPATIC METASTASES FROM AMPULLARY NEUROENDOCRINE TUMOR MASQUERADING AS LIVER CIRRHOSIS

Youssef Ghobrial[1]; Ammar Qureshi[1]; Joline De Castro[2]; Adewale Ajumobi[2]

[1]Internal Medicine, Eisenhower Medical Center, Palm Desert, CA; [2]Internal Medicine, Eisenhower Health, Palm Desert, CA. (Control ID #3392306)

LEARNING OBJECTIVE #1: Ampullary neuroendocrine tumors are extremely rare. It is important to recognize their clinical features especially in the presence of hepatic metastasis.

LEARNING OBJECTIVE #2: Hepatic metastatic neuroendocrine tumors can mimic cirrhosis by presenting as nodular liver. It is important to distinguish both these entities based on clinical features, imaging, and biopsies.

CASE: An 86-year-old male with perforated sigmoid diverticulitis was found to have intraoperative ascites and a nodular liver. CT scan showed a cirrhotic liver, moderate amount of ascites and intrahepatic and extrahepatic dilatation. The serum-to-ascites albumin gradient was 1.5 g/dL and the ascitic total protein was 1g/dL. Viral and autoimmune serologies were negative. Liver enzymes throughout the patient's clinical course revealed hyperbilirubinemia with mildly elevated AST and ALT. Alkaline phosphatase levels ranged from 200-500. Ultrasound of the liver showed a mildly nodular hepatic contour. Esophagogastroduodenoscopy (EGD) done for variceal screening revealed a periampullary mass. Biopsies of the mass revealed high-grade adenocarcinoma. The liver nodules were later biopsied. Histology showed a poorly differentiated high-grade neuroendocrine tumor (NET). Histology from the ampulla of Vater was reanalyzed. It was determined to be a high-grade neuroendocrine tumor as well. He was started on chemotherapy with 4 cycles of carboplatin, etoposide, and atezolizumab. The ampullary mass and liver nodules have regressed in size.

IMPACT/DISCUSSION: Neuroendocrine tumors of the ampulla of Vater are exceedingly rare, with the annual incidence of all gastroenteropancreatic neuroendocrine tumors being 0.2 per 100000 according to data from the SEER program. Neuroendocrine tumors of the gastrointestinal tract usually occur in the esophagus, stomach, pancreas or large bowel. Studies have shown that at least 57% of the patients already have metastases at the time of diagnosis. The most common sites of metastasis are the lymph nodes and liver. Given the aggressive nature of metastatic NETs, palliative chemotherapy is the most common management modality.

CONCLUSION: Ampullary neuroendocrine tumor is a rare disease with very limited data on treatment modalities and prognosis. Patients with ampullary NET and nodular liver will benefit from liver biopsy to confirm the presence of liver metastases.

HE SAID, SHE CAN'T SAY: OBTAINING HISTORY WHEN THE PATIENT IS ALTERED

Charles J. Bettag[1]; Brooke Herndon[2]

[1]Internal Medicine, Dartmouth Hitchcock, Hanover, NH; [2]Department of Medicine, Dartmouth-HItchcock, Lebanon, NH. (Control ID #3371659)

LEARNING OBJECTIVE #1: Appreciate the benefits and pitfalls of obtaining history from family members of patients who are not able to provide history themselves

CASE: A 48 yo woman with history of multiple sclerosis presents to the ED for altered mental status. Husband is present and reports two days of weakness, as she is unable to communicate. Altered mentation started this morning, before that she was at her baseline and able to communicate. She has been wheelchair bound but with some retained strength for the last five years, with urinary incontinence due to MS. She has not sought medical care in five years.

Her husband has limited history to report. She has had difficulty swallowing bread and dry mouth for the last several days. She has had frequent urination for several weeks, unable to specify further. ROS otherwise negative. Medications are omeprazole and a multivitamin.

She is an occasional smoker. Social alcohol use with rare marijuana. No other drug use.

On exam, she is an obese woman, restless in bed and appearing uncomfortable. She is answering questions inappropriately and disoriented. Mucous membranes are dry. Diffuse, nonspecific abdominal tenderness is present, with bilateral costovertebral angle tenderness. Neurologic exam is nonfocal, and lungs are clear. Cardiac exam reveals tachycardia.

Labwork shows a creatinine of 1.53 from a baseline of ~1, glucose of 848, sodium of 164. White count 17.7. Osmolarity is elevated at 402, with beta-hydroxybutyrate elevated at 4.37. Urine notable for >500 glucose, 20 ketones, 100 protein, large blood with 2 RBC, 35 WBC. A1c is 12.0.

She is treated with half normal saline and an insulin drip to address her volume depletion, hypernatremia, and hyperglycemia, as well as a short course of antibiotics for UTI. Her sugars came down to the normal range, and her sodium and mental status gradually improve as well with the above treatment. Further history is obtained, and it is revealed she has been drinking more than 2L of Mountain Dew per day in addition to at least a half quart of Gatorade daily, with no water intake. She is diagnosed with type 2 diabetes and discharged on 50 units lantus, glimepiride, and metformin.

IMPACT/DISCUSSION: The initial history made it difficult to know what was going on with the patient. Given her corrected Na was in the 180s, it seemed likely that she might have a concurrent hyperosmolar hyperketotic state and diabetes insipidus. However, she improved with volume resuscitation and insulin, suggesting that she was severely volume depleted as well as an undiagnosed diabetic. In the days following her presentation, it became easier to see why she was so dehydrated, as she was able to provide further history about her oral intake.

CONCLUSION: The limited initial history made this case challenging. Once the patient's mental status improved and she provided more history, her initial presentation and labs made sense. Family members are an important source of history, but it must be understood that the history provided will often be incomplete.

HIDDEN DIAGNOSES: THE SEARCH FOR HIV

Fadumo Warsame, Jason Halperin

Medicine, Tulane University School of Medicine, New Orleans, LA. (Control ID #3391521)

LEARNING OBJECTIVE #1: Discuss the prevalence of HIV and HBV coinfection in the United States

LEARNING OBJECTIVE #2: Recognize the impact of not identifying HIV coinfection in an individual with hepatitis B

CASE: A 59-year-old presented to his primary care physician after labs returned positive for hepatitis B. He was referred to hepatology and tenofovir treatment was initiated. Six months later he was admitted to the hospital for dysphagia and a diagnosis of HIV was made at that time.

At a recent follow up visit he was started on entecavir for his HBV as well as emtricitabine, Prezcobix, and dolutegravir for HIV. The genotype returned with an M184V mutation and abacavir was added. He was referred to the HIV Outpatient Program (HOP) for further management of his HIV complicated by worsening cirrhosis. His initial viral load was 5,444 with a CD4 count of 313 cells/μL and a CD4% of 41.5. The patient's HIV regimen was optimized. His Prezcobix discontinued in favor of darunavir and ritonavir given patient's worsening renal function. Juluca was approved and patient's medications were then switched to juluca for HIV and entecavir and emtricitabine for HBV.

He continued to have complications from decompensated cirrhosis such as ascites and worsening renal function, and later required a liver-kidney transplant. HBV DNA was undetectable two months after the surgery. After further antiviral adjustments, HIV viral load returned undetectable and the CD4 count was 317 cells/μL and CD4% of 32.3. The patient remains asymptomatic.

IMPACT/DISCUSSION: In the United States, 1.1 million residents are living with human immunodeficiency virus (HIV) infection and about 6-10% of those residents are co-infected with hepatitis B virus. HIV and HBV can both be acquired through injection drug use and sexual transmission. Social factors that place people at risk of acquisition are similar; therefore, coinfection occurs frequently. HIV infection can increase susceptibility to subsequent infection with Hepatitis B. HIV infection can also further increase HBV viremia, thus accelerating liver damage. Early studies of the natural history of HIV-HBV coinfection demonstrated that liver-related mortality in this population was nineteen times that in HBV infection without HIV, and 8 times higher than in individuals with HIV mono-infection. Mortality rates increased in individuals with lower CD4+ T-cell counts. Coinfected patients are at a greater risk for both liver morbidity and mortality as well as all-cause morbidity and mortality, when compared with those who are monoinfected.

CONCLUSION: Identifying co-infected patients with HIV and Hepatitis B is of critical public health importance. Missing the diagnosis of co-infection with the viruses can be detrimental and worsen outcomes as seen in this patient.

HIDDEN HYPERTENSION: SYNCOPE AND SYMPTOMATIC ORTHOSTATIC HYPERTENSION

Justin Haloot[1]; Thuylinh Nguyen[1]; Jason Phillips[2]

[1]Internal Medicine, University of Texas Health San Antonio, San Antonio, TX; [2]Cardiology, University of Texas Health San Antonio, San Antonio, TX. (Control ID #3388417)

LEARNING OBJECTIVE #1: To demonstrate a presentation of symptomatic Orthostatic Hypertension

LEARNING OBJECTIVE #2: To review current medical regimen for Orthostatic Hypertension

CASE: A 70-year-old man with history of benign prostatic hyperplasia (BPH), hypertension, and aortic stenosis presented with increasing pre-syncopal episodes, one syncopal episode, dyspnea on exertion, and left-sided chest pain. He was transferred to Audie L. Murphy Veterans Affairs (ALMVA) Hospital for evaluation of severe symptomatic aortic stenosis with blood pressure (BP) in the 80s/40s.

On arrival to ALMVA, he was stable, in no acute distress, and had a BP of 149/77. A transthoracic echo demonstrated an ejection fraction of 60-65%, severe aortic stenosis with aortic valve area of 0.8 cm^2 by continuity equation, peak velocity of 4.2 m/s, and a mean gradient of 39 mm Hg. Left heart catheterization was performed and Judkins right catheter easily crossed the valve and obtained an aortic valve area of 1 cm^2 and mean gradient of 32 mm Hg. Final report concluded moderate-to-severe aortic stenosis. As part of the work up, orthostatic vitals had been ordered with supine BP 153/70 and sitting BP 196/71. Upon standing, he was flushed, diaphoretic, light headed, and tremulous with a BP 230/60. At this point, there was concern for Orthostatic Hypertension (OHTN) playing a role in his symptoms. His home BPH medication of terazosin, originally held due to hypotension, was restarted for alpha blockade and metoprolol tartrate added for adrenergic blockade. His symptoms improved dramatically and he was walking down the hallway without symptoms.

IMPACT/DISCUSSION: This case demonstrates an uncommon presentation of symptomatic OHTN masked by coinciding severe aortic

stenosis. Current evidence suggests OHTN patients may have increased adrenergic activity or hypersensitivity. The Japan Morning Surge-1 (JMS-1) Study demonstrated patients treated with alpha blockade had a reduction in OHTN. This case supports the proposed as seen by the response to sympathetic inhibition. This improvement with adrenergic blockade may have implications for further research into management of this disease.

CONCLUSION: OHTN is a rare disease still being studied. We report a unique case of symptomatic OHTN and a marked response to adrenergic blockade. This agrees with current studies that recommend alpha blockers for treatment of OHTN. We encourage further research into this rare disease to improve diagnosis and management.

HIDE AND SEEK: AN ELUSIVE CASE OF SECONDARY HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS (HLH)

Ronaldo Panganiban[1]; Prashanth R. Moku[2]; Ravi Patel[1]; Nabeel Akhtar[1]; Nitasa Sahu[1]

[1]Internal Medicine, Penn State College of Medicine, Hershey, PA; [2]College of Medicine, Penn State Hershey College of Medicine, Hershey, PA. (Control ID #3364400)

LEARNING OBJECTIVE #1: Diagnose HLH as a source of fever of unknown origin (FUO).

LEARNING OBJECTIVE #2: Recognize malignancies as a cause of secondary HLH.

CASE: An 80-year-old man presented with persistent fevers, chills, and fatigue. Over the last 6 months, he was seen in other hospitals for similar symptoms. Each time, he received antibiotics and clinically improved. Because of this history, a workup for FUO was started. He was found to have splenomegaly, elevated ferritin (4219 μg/L), elevated triglycerides (545 mg/dL), and pancytopenia (ANC: 1.2 K/uL, hemoglobin: 7.9 g/dL, platelets: 22K/uL). The soluble IL-2 receptor level was also markedly elevated (88,300 pg/mL). Activated macrophages with hemophagocytosis were seen in the marrow biopsy. Combined, these findings were consistent with HLH. Because the patient was elderly, primary HLH was deemed unlikely. Work up for an underlying malignancy was performed. This included the previously described bone marrow biopsy, peripheral blood smear, and imaging studies but no causative malignancy was identified. The patient was treated for primary HLH with etoposide infusions and dexamethasone. After 2.5 weeks of inpatient treatment, he was discharged with continued outpatient chemotherapy.

One month later, he was readmitted for worsening fatigue and rising ferritin despite treatment. Alemtuzumab was initiated as salvage therapy for refractory HLH. Despite this, WBC rose from 1.9 K/ul to 47.5 K/ul with 42% blasts over 48 hours. Repeat marrow biopsy was concerning for T-cell large granulocytic leukemia. Therapeutic splenectomy was performed. Spleen histopathology showed hepatosplenic T-cell lymphoma (HSTL), a rare disease with dismal prognosis. Thus, the patient elected for hospice care.

IMPACT/DISCUSSION: Because of its similarity to sepsis with multisystem organ dysfunction, HLH is an underrecognized but often treatable cause of FUO. Its diagnosis hinges on the presence of 5 of the 8 findings based on the HLH-2004 criteria: 1) fever≥ 38.5°C 2) splenomegaly 3) any bicytopenia (hemoglobin <9 g/dL, ANC <1 K/uL, platelets < 100 K/uL) 4) hypertriglyceridemia (>265 mg/dL) or hypofibrinogenemia (< 150 mg/dL) 5) hemophagocytosis in the bone marrow, spleen, or lymph nodes 6) low NK cell activity, 7) ferritin ≥ 500 μg/L and 8) soluble IL-2 receptor greater than 2 standard deviations above normal. In our patient, 7 of these 8 findings were established.

While primary HLH occurs in adults, secondary HLH is more common. An undetected malignancy is often a triggering etiology. Our patient was eventually diagnosed with HSTL, a lymphoma characterized by hepatosplenomegaly, thrombocytopenia, and B symptoms. Diagnosis is through marrow and liver biopsies. No standard therapy exists, and the median overall survival is less than 1 year.

CONCLUSION: The diagnosis of HLH is based on the HLH-2004 criteria. Timely recognition of this disease is important and should prompt the clinician to work up a potential underlying malignant etiology.

HIDING IN PLAIN SIGHT–A CASE OF ATYPICAL LYMPHOMA AND FEVER OF UNKNOWN ORIGIN

Mohammad Khan, Nathan Radakovich, Bryce Montane, Juan Barbastefano

Internal Medicine, Cleveland Clinic Foundation, Beachwood, OH. (Control ID #3392449)

LEARNING OBJECTIVE #1: Recognize the most common causes of causes of fever of unknown origin.

LEARNING OBJECTIVE #2: Diagnose lymphoma when imaging results are normal.

CASE: A 58-year-old African-American female presented for further evaluation of fever of unknown origin.

Over a period of several months, she developed symptoms of recurrent fever, productive cough, dyspnea, weight-loss, and generalized fatigue. Admission was recommended by her PCP after outpatient workup yielded no diagnosis. Her past medical history was significant for rheumatoid arthritis (RA), tobacco abuse, and a recent CT-chest with incidental findings of a sub-centimeter pulmonary nodule and ground-glass opacities. Of note, she had a negative TB test earlier this year, no history of HIV, and recently self- discontinued her RA medications—adalimumab and leflunomide. She denied illicit drug use and reported practicing safe sex habits. She experienced a prolonged hospital course complicated primarily by recurrent, high-grade, nocturnal fevers and lactic acidosis.

After a normal physical exam, investigation focused on ruling out infectious, autoimmune and neoplastic causes. Initially, her lactic acidosis, was treated aggressively with empiric antibiotic therapy and aggressive fluid hydration. Infectious workup remained negative for duration of her stay—including urine cultures, serial blood cultures, HIV testing and TB testing. She underwent a bronchoscopy given her recent CT- findings with cultures negative for atypical infections such as legionella, nocardia, aspergillus, CMV, and PJP. Autoimmune disorders were unlikely after negative screening serologic testing for rheumatologic disorders. Neoplastic workup began with peripheral smear with evidence of atypical lymphocytes and elevated LDH levels. A CT-abdomen/pelvis was ordered for suspicion of lymphoma but showed no evidence of mass or lymph node enlargement. Flow cytometry was ordered and confirmed presence of a few atypical B cells. As a result, a bone marrow biopsy was performed with results of an aggressive lymphoma with differential including mantle cell lymphoma and atypical CLL. She followed with hematology post-discharge with a favored diagnosis of atypical CLL in the setting of TNF inhibitor use.

IMPACT/DISCUSSION: Despite expansion of the definition of fever of unknown origin (FUO) and improved accuracy of diagnostic testing, FUO remains a challenging dilemma for clinicians. It is essential for clinicians to approach the workup of FUO in a systematic fashion and order testing directed at identifying the most common causes—infections, autoimmune diseases, and neoplasms. Lymphoma is a common neoplastic cause of FUO that can easily be missed when relying solely on imaging. Within this case, flow cytometry was valuable in establishing the eventual diagnosis of lymphoma.

CONCLUSION: Evaluation of FUO should ensure start with testing directed at the most common causes of FUO—infection, autoimmune, and neoplastic.

Imaging alone does not rule out lymphoma and flow cytometry is a valuable diagnostic tool.

HIT OR MISS? THE USE OF RIVAROXABAN…

Deep Patel, David Wynne

Internal Medicine, Brookwood Baptist Heatlth, Birmingham, AL. (Control ID #3346454)

LEARNING OBJECTIVE #1: 1. Recognize that Heparin induced thrombocytopenia (HIT) is a rare but important cause of thrombocytopenia and life-threatening thrombosis.

LEARNING OBJECTIVE #2: 2. Explore the use of rivaroxaban in treating HIT.

CASE: A 66-year-old African American male with a past medical history of a renal mass was admitted for abdominal pain and blood in his urine. He was told he had a renal mass in 1990 yet never pursued follow up. He reported a 15-pound weight loss and subjective fevers for two weeks prior to admission. On exam, he appeared cachectic with temporal wasting and had no palpable abdominal mass. He denied the use of tobacco, alcohol and drugs. Pertinent lab findings included WBC of 13 k/cmm, Hemoglobin 13 g/dl, platelet count 203 k/cmm, creatinine 2.24mg/d and gross blood on urinalysis. CT scan of abdomen revealed a left renal mass with intrarenal hemorrhage.

The patient underwent left sided nephrectomy. Prophylactic subcutaneous heparin was started on postoperative day one. His platelet count dropped from 204K/cmm on day ten to 64k/cmm on day eleven. The heparin was discontinued and lower extremity ultrasound revealed distal right femoral deep vein thrombosis. Rivaroxaban was started on day eleven and the heparin antibody test resulted positive with an optical density of 2.438. His thrombocytopenia resolved the following 48 hours and he was discharged on Rivaroxaban with close follow-up.

IMPACT/DISCUSSION: HIT is characterized by drop in platelet count after heparin exposure. Type 1 HIT usually occurs within a few days of heparin exposure, the platelet count usually remains above 100k/cmm and it is rarely associated with thrombosis. Type 2 HIT is rare (incidence of 1%) and typically occurs between 5-14 days of heparin exposure, the platelet count invariably drops below 100k/cmm and it is commonly associated with thrombosis. The treatment of HIT requires cessation of all heparin products and initiation of an alternate anticoagulant. Life threatening thrombosis due to HIT requires the use of a non- heparin anticoagulant. Argatroban is the one used most commonly. However, for non-life threatening thrombosis Rivaroxaban (a factor Xa inhibitor) has been shown to be effective. It is available orally and negates the need for Warfarin. These benefits make Rivaroxaban an attractive alternative for treating non-life threatening thrombosis associated with HIT.

CONCLUSION: This case highlights the importance of suspecting HIT in patients with reduced platelet count after exposure to heparin products. Any patient on heparin product with an acute 50% decline in platelets should be suspected of having HIT. The heparin antibody test is 95% sensitive and the positive predictive value is low. An Optical density of >1.0 makes this test more specific. HIT remains a challenging diagnosis and requires the immediate replacement of all heparin products. The American Society of Hematology 2018 guidelines recommends the use of Rivaroxaban in patients with HIT who do not have life- threatening thrombosis.

HOW DO YOU DIAGNOSE AND MANAGE THE PATIENT WHO HE CAN EAT, DRIVE, SPEAK BUT CANNOT BREATHE?

Mako Hishinuma[4]; Yasuhiro Ito[1]; Takamasa Tanaka[2]; Mitsunori Iwase[3]

[1]Neurology, TOYOTA Memorial Hospital, Toyota, Japan; [2]General Internal Medicine, TOYOTA Memorial Hospital, Toyota, Japan; [3]Cardiology, Toyota Memorial Hospital, Toyota, Aichi, Japan; [4]Integrated Medicine, TOYOTA Memorial Hospital, Toyota, Japan. (Control ID #3390866)

LEARNING OBJECTIVE #1: Amyotrophic Lateral Sclerosis (ALS) has some clinical phenotypes.

LEARNING OBJECTIVE #2: Leg Amyotrophic Diplegia (LAD) type, a specific subtype of ALS, exhibits respiratory failure prior to bulbar symptoms.

CASE: A 41-year-old man presented with progressive distal leg weakness X-5 years ago. Weakness started in the left leg and progressed to involve both legs. He was diagnosed as ALS X-3 years ago. Muscle weakness in both legs progressed to 0/5 (Medical Research Council) irrespective of treatment. However, muscle power on upper extremities, respiratory and bulbar function remained normal, so he could eat, speak, work and drive with his remodeled car. On day X, he presented to our hospital with dyspnea, which emerged 6-weeks ago. He had tachypnea and his respiratory rate was 22/min with O_2 saturation of 77% on room air, however the rest of his vital signs were normal. On Laboratory finding, the arterial blood gas data revealed pH 7.34, pO_2 56.3mmHg, pCO_2 83.2mmHg, HCO_3 44.3mmol/L, indicating the accumulation of carbon dioxide and respiratory dysfunction. Chest Computed Tomography was normal. Although oxygen limited to 1L/minute was administered using nasal cannula, his consciousness soon dropped and respiratory function worsened. He developed carbon dioxide narcosis and he was urgently intubated. His respiratory ability was so poor and the mechanical ventilation was induced after the consent. His breathing condition dramatically improved, and tracheostomy was undertaken on day 9. During the hospitalization, the muscle strength on upper extremities and bulbar function remained stable. Finally, he went home and lives a daily life with eating, drinking for himself and talking with his family under the respiratory control.

IMPACT/DISCUSSION: ALS is a neurodegenerative disease that selectively affects upper and lower motor neurons and is fatal within 3-5years after the onset if not for the mechanical ventilation. ALS has some clinical subtypes. This includes classical, progressive bulbar palsy, spinal progressive muscular atrophy type and so on. In these phenotypes, muscle weakness in the cranial and upper and lower extremities develops in the early stage and respiratory dysfunction emerges as a final symptom. However, it is known that there are some other specific clinical subtypes. LAD-type ALS is one of the characteristic phenotypes. According to literatures, this type was first reported in 1918, accounting for 2.5% to 6.5% of all ALS, developed with muscle weakness limited to the lumbosacral region, and reported to have a better prognosis than normal ALS. However, little is known about the general clinical course of LAD-type ALS. This case showed respiratory failure occurs without bulbar paralysis or weakness of upper extremities. Considering this uncommon clinical course, it is very important for LAD-type ALS patients to be aware and suspect respiratory failure even in the early stage.

CONCLUSION: We should take into consideration the respiratory failure may immerge in the early stage on LAD-type ALS patient.

HOW DO YOU SPELL DRESS SYNDROME?

Dylan B. Stephens

College of Medicine, Penn State College of Medicine, Hershey, PA. (Control ID #3393044)

LEARNING OBJECTIVE #1: Recognize the challenges in diagnosing DRESS

LEARNING OBJECTIVE #2: Differentiate DRESS from other possible diagnoses

CASE: An otherwise healthy 30-year-old male presented with flu-like symptoms and a pruritic rash. One week before, he had started trimethoprim-sulfamethoxazole for prostatitis. Five days later he began experiencing severe weakness, malaise, myalgias, arthralgias, anorexia, nausea, fevers, sore throat, and a migraine-like headache followed by the rash. The review of systems was otherwise negative. He denied recent travel, camping, tick bites or sick contacts. He was febrile to 38.7 C, tachycardic and normotensive. His exam was significant for periorbital edema, conjunctival injection, pharyngeal erythema without exudates, anterior and posterior cervical lymphadenopathy, petechiae on his forearms and thighs and a diffuse, warm maculopapular rash with coalescence from his shoulders to his knees. He was given IV fluids, acetaminophen, diphenhydramine and empiric vancomycin & ceftriaxone. Labs were notable for an AKI with a creatinine of 2.1 mg/dL (baseline 1.0 mg/dL), BUN of 26 mg/dL and a CBC with thrombocytopenia at 96 K/uL, 40% bands, atypical lymphocytes, 2.1% eosinophils, and a normal WBC count. A chest x-ray and EKG were normal, and blood cultures, urine cultures, and urinalysis were unremarkable. Measles, EBV, HIV, CMV, HHV6 & HHV7, Lyme, Babesia, Rocky Mountain spotted fever, and *Legionella* & *S. pneumoniae* urine Ag screens were all negative. Given the recent drug initiation and the negative infectious work-up, the patient was diagnosed with DRESS syndrome. He was given methylprednisolone and the antibiotics were discontinued. The patient felt better, was transitioned to topical steroids, and was discharged home two days later.

IMPACT/DISCUSSION: Classically, 2-6 weeks after drug exposure, Drug Reaction with Eosinophilia & Systemic Symptoms (DRESS) syndrome presents with fever, abnormal LFTs, renal impairment, & myocarditis, as well as a morbilliform rash and eosinophilia. This presentation is similar to various viral, bacterial & tick-borne illnesses, or autoimmune & hypersensitivity reactions such as Stevens-Johnson Syndrome or vasculitis. Confusingly, it is actually possible to have DRESS without a clear D (drug), without rash, without E (eosinophilia) or even without SS (systemic symptoms). Our patient did not have many of the classic systemic symptoms or eosinophilia, and presented well under the usual 2-6 weeks. In order to cut through the ambiguity, RegiSCAR, a scoring system developed for classifying potential cases of DRESS as excluded (<2), possible (2-3), probable (4-5) or definite (6+), was used. Our patient scored a 6 using this system, which is considered “definite” for DRESS.

CONCLUSION: Not all cases of DRESS present classically. The medication, exposure and past medical history, as well as immunological status must be explored for other diagnoses. The RegiSCAR score can be used to identify definite cases or where more exploration is needed.

HOW HIGH IS TOO HIGH

Arunava Sarma[1]; Deep Sangani[1]; Jerald L. Taggart[2]

[1]Internal Medicine, Tulane University, New Orleans, LA; [2]Medicine, SLVHCS/Tulane University, New Orleans, LA. (Control ID #3391526)

LEARNING OBJECTIVE #1: Recognize hypertriglyceridemia as a cause of pancreatitis

LEARNING OBJECTIVE #2: Discuss a unique treatment plan for acute pancreatitis

CASE: A 39-year-old alcoholic man presented with nausea, vomiting, abdominal pain, and decreased oral intake for one day. He reported having several drinks in the past 24 hours. His vitals included a temperature of 98.3 F, HR 111, and BP of 180/114. He appeared uncomfortable on exam. Abbdominal tenderness was present in the left upper quadrant without rebound or guarding. Blood alcohol level returned undetectable. Lactic acid was 2.8mmol/L, liver function studies were within normal limits, blood glucose was 341mg/dL, and lipase was elevated at 94 IU/L. Triglyceride (TG) level returned at 4830 mg/dL with a cholesterol of 1059 mg/dL and an LDL of 200 mg/dL. A CT of the abdomen revealed stranding around the pancreas consistent with pancreatitis and a mildly dilated pancreatic duct. He was fluid resuscitated and provided symptomatic relief for presumed acute on chronic pancreatitis. Repeat TG levels remained elevated (4328 mg/dL). The patient was transferred to the ICU for insulin infusion and hourly glucose checks.

IMPACT/DISCUSSION: Once an internists establishes a diagnosis of pancreatitis, focus turns toward determing an underlying etiology and disease management. While not as common as gallstones or alcohol-induced pancreatitis, hypertriglyceridemia is the third most common cause of pancreatitis. To cause acute pancreatitis, typically, TG levels will need to exceed 1000. If levels exceed 2000, 10-20% of patients can develop acute pancreatitis. Hypertriglyceridemia-induced pancreatitis can result is associated with increased severity and complications when compared with other causes of pancreatitis, necessitating prompt recognition of the etiology.

Treatment for pancreatitis regardless of etiology includes fluid resuscitation, medication to address pain and nausea symptoms, and nutritional support. If elevated triglyceride levels are the underlying etiology, it is additionally important to reduce the TG levels which requires insulin infusion and frequent glucose monitoring. Alternatively, intravenous heparin or plasmapheresis can be utilized. An evidence-based algorithimic approach does not exist to determine which therapy is most approrpriate for patients with such elevated triglyceride levels. In this case, the patient's level exceeded 4000 which prompted a transfer to the ICU to rapidly reduce triglyceride levels. Although early return to feeding has been shown to reduce duration of inpatient stays in cases of "simple" pancreatitis, in this case, the patient was kept NPO while on the insulin drip in order to prevent increases in the triglyceride levels.

CONCLUSION: Prompt clinical recognition of hypertriglyceridemia as an underlying etiology for acute pancreatitis is critical. Appropriate treatment can be initiated resulting in a decrease in the severity of illness and the prevention of complications or recurrences of pancreatitis.

HUMAN HERPESVIRUS 6 ENCEPHALITIS IN IMMUNOCOMPETENT PATIENT TREATED SUCCESSFULLY WITH GANCICLOVIR

Randa hazam[1]; Assad Mohammedzein[1]; john kimbugwe[1]; moutasim souliman[1]; hina yousuf[1]; Mazin Saadaldin[2]; Scott Milton[1]

[1]Internal Medicine, Texas Tech University Health Science Center, Amarillo, TX; [2]internal medicine, NWTHS, TTUHSC, Amarillo, TX. (Control ID #3387500)

LEARNING OBJECTIVE #1: HHV-6 can cause encephalitis in adult immunocompetent patients.

LEARNING OBJECTIVE #2: ganciclovir could be an effective treatment for immuncompetent patients with Human Herpesvirus 6 (HHV-6) encephalitis

CASE: A 62-years-old Caucasian female with a history of diabetes, hypertension, stroke, renal disease, and Hypothyroidism presented with altered mental status. She was found unresponsive with seizure-like activity. She was afebrile without neck stiffness. She had residual right-sided weakness with upgoing plantar reflexes. Initial lab work was unremarkable. MRI of the head showed no acute changes. Electroencephalography showed epileptic foci in the left parietal and temporal lobes. Her family witnessed the patient having visual hallucinations while in the ICU. PCR testing of CSF was positive only for HHV-6. HIV was negative. She was started on intravenous Ganciclovir. Repeated EEG on day 5 showed no ictal discharges. By day 8 she was alert and responding appropriately. She finished 10 days of Ganciclovir, and was discharged home without neurological sequelae.

IMPACT/DISCUSSION: HHV-6 primary infection occurs early in life. CNS involvement is felt to be rare and is thought to occur by reactivation in the CNS in immunocompromised patients as well as HIV 1 infected individuals. A recent case series identified 17 immunocompetent patients. In this series 4 died while 30% of those who survived had permanent neurological sequelae. Our patient is unique in that there was no CSF pleocystosis. Further, the EEG and visual hallucinations were reminiscent of HSV encephalitis. The presence of the free viral DNA in CSF argue against incorporation in chromosomal DNA. The availability of PCR analysis allows identification of the virus in patients presenting with encephalitis of unknown etiology.

CONCLUSION: We conclude that; HHV-6 may be associated with encephalitis in adult immunocompetent patients and Gancyclovir appears to be more effective than acyclovir.

HYDRALAZINE-INDUCED LUPUS OR VASCULITIS

Michelle Crough[1]; Carolyn Chan[2]; Maria Antonelli[3]

[1]Medicine, Case Western Reserve University School of Medicine, Cleveland, OH; [2]Internal Medicine, MetroHealth Hospital, Cleveland, OH; [3]Rheumatology, MetroHealth Hospital, Cleveland, OH. (Control ID #3391882)

LEARNING OBJECTIVE #1: Compare and contrast clinical and laboratory findings of two hydralazine- induced autoimmune diseases: drug induced lupus and ANCA-positive vasculitis.

CASE: A 70- year old male presented to the hospital with a three month history of hemoptysis and an associated 16-lb weight loss over 3 months, with associated acute kidney injury and pancytopenia. Past medical history includes atrial fibrillation on coumadin, diastolic heart failure, hypertension, and remote prostate cancer. Home dedications included warfarin, hydralazine, atorvastatin, and metoprolol.

His lungs were clear to auscultation. His chest x-ray demonstrated patchy right basilar ground glass opacities and CBC demonstrated pancytopenia: 2.6/8.9/128. He had acute kidney injury (AKI) with a Cr of 1.67 from baseline of 0.9. A V/Q scan demonstrated a low probability for a pulmonary embolus. A CT chest without contrast demonstrated patchy ground class opacities in all lobes of lungs. A bronchoscopy was performed demonstrating diffuse alveolar hemorrhage; cultures were negative. During his hospital course his AKI worsened, as did his pancytopenia. A work-up for AKI was negative: with a normal renal ultrasound, normal serum electrophoresis, free kappa lambda. His work-up for pancytopenia noted a slightly low B12 level and normal TSH. During his course he develop a malar rash.

Clinical concern for a pulmonary-renal rheumatologic syndrome developed. An autoimmune screen was positive while his anti-neutrophil cytoplasmic antibodies (ANCA) were positive at 1:650. His anti-histone antibody was positive, double-stranded DNA was negative, while both his C3 and C4 levels were low.

The patient's hydralazine was discontinued. He received methylprednisolone IV for empiric treatment of an autoimmune process pending final labs. As a result there was a subsequent increase in his hemoglobin and platelets and downtrend in creatinine.

IMPACT/DISCUSSION: Hydralazine is a medication commonly used for chronic conditions such as heart failure and hypertension and exposure can lead to multiple autoimmune conditions. Differentiating between hydralazine induced lupus (DIL) or vasculitis (DIV) can be challenging as they demonstrate many overlapping symptoms and laboratory values. There are no set diagnostic or clinical criteria for DIL, however it is classically less severe with cutaneous and arthritic findings, although renal and hematologic manifestations are possible as in this patient. ANA and anti-histone positivity are suggestive of DIL whereas presence of ANCA-positive antibodies with MPO confirmation suggests DIV. The patient deferred a biopsy so definitive diagnosis of lupus or vasculitis could not be made. DIL was determined as his final diagnosis due to symptom resolution with prednisone.

CONCLUSION: This patient was diagnosed with hydralazine-induced lupus although his laboratory values supported both DIL and DIV due to resolution of his ground glass opacities and hemoptysis with prednisone and hydralazine cessation.

HYPERCALCEMIA AND CANCER; NOT THE USUAL SUSPECTS

Pedro Giro[1]; Julie Knoeckel[2,1]

[1]Internal Medicine, University of Colorado, Denver, CO; [2]Medicine, Denver Health Medical Center, Denver, CO. (Control ID #3390853)

LEARNING OBJECTIVE #1: Recognize the prognostic importance of hypercalcemia in cancer patients

LEARNING OBJECTIVE #2: Distinguish hypercalcemia of malignancy from hyperparathyroidism in a cancer patient

CASE: A 67 year old undomiciled male with a history of alcohol abuse and schizophrenia was brought to the ED with altered mental status of unknown duration. He endorsed drinking 3 pints of alcohol weekly, but none recently. He was disoriented, but did not have any focal deficits or signs of alcohol withdrawal. His labs revealed a calcium level of 14.1 mg/dL with an albumin of 3.8 g/dL and an ionized calcium of 1.62 mmol/L. A CT brain without contrast was negative for acute changes. Given concern for malignancy, a CT chest was performed showing a hepatic mass. CT liver protocol demonstrated a large heterogenous arterially enhancing and centrally necrotic mass favored to be hepatocellular carcinoma (HCC). AFP was elevated and chronic HBV and HCV were also diagnosed. Further studies included a PTHrp of 30 pmol/L, PTH of 9 pg/ml, 25-(OH)D of 28, 1,25 (OH)D of 84, and negative imaging for osseous lesions. The patient initially responded to IV fluids and bisphosphonates, but then required denosumab, cinacalcet, and prednisone for control of calcium levels. His mental status improved with normalization of calcium, and he was able to engage in goals of care discussions regarding HCC treatment.

IMPACT/DISCUSSION: Although HCC causing hypercalcemia is rare, it is known that any tumor can cause hypercalcemia. Humoral hypercalcemia of malignancy, mediated by PTHrp, accounts for 80% of cases. However, many cancer patients have non-malignant causes for hypercalcemia with primary hyperparathyroidism being the leading cause. Hypercalcemia in a cancer patient with concomitant hyperparathyroidism and an elevated PTH has been associated with longer survival when compared to the poor outcomes of hypercalcemia of malignancy.

The workup of hypercalcemia in cancer patients should include PTH, PTHrp, Vitamin D levels and targeted radiology studies looking for osteolytic lesions. Suppressed PTH in the setting of hypercalcemia and cancer confirm the diagnosis of hypercalcemia of malignancy, however, elevated PTH with hypercalcemia is inappropriate and could suggest hyperparathyroidism with ectopically produced PTH being a much rarer alternative.

Our patient had hypercalcemia in the setting of elevated PTHrp and low PTH thus excluding primary hyperparathyroidism. He had clinically significant HCC, but no evidence of bone lesions and thus a humoral hypercalcemia of malignancy was diagnosed. Interestingly, his vitamin D level was elevated and thought to be a contributor to his hypercalcemia, which is a less common mechanism of hypercalcemia of malignancy.

CONCLUSION: Hypercalcemia in cancer patients merits a full evaluation as it has several pathophysiologic etiologies including significant non-malignant causes, most important primary hyperparathyroidism, which should be differentiated from malignant causes as it has implications for treatment and prognosis.

HYPERCALCEMIC CRISIS: A CASE REPORT

Farha N. Ebadi, Ali Alkhayat, Rachel Biancuzzo

Internal Medicine, Kent Hospital, West Warwick, RI. (Control ID #3387053)

LEARNING OBJECTIVE #1: Recognize the clinical features of hypercalcemic crisis

Identify/assess common etiologies of hypercalcemia

CASE: An 80-year-old elderly female, with past medical history of oxygen dependent COPD, CAD, hypertension, CKD stage III, hypothyroidism, chronic lower back pain, and provoked pulmonary embolism, presented to the hospital with a 1 week history of confusion, worsening generalized weakness, lower extremity pain, and polyuria. In the emergency department, the patient's vital signs were within normal limits. Physical exam was significant for dry mucous membranes, decreased skin turgor, mild tenderness to lower extremities bilaterally, and she was oriented to person and place only. Laboratory studies revealed a calcium of 18 mg/dl, ionized calcium of 2.28 mmol/l. Further testing was resulted: TSH of 0.96 mcl/ml, PTH of 9 pg/ml (12-88), PTH related peptide 0.3 pmol/l, Vitamin D 1, 25–dihydroxy 18 pg/ml, and vitamin D 25- hydroxy 48.8 ng/ml. Lastly, patient's kappa/lambda chain ratio was mildly elevated at 1.67 however M spike, SPEP, UPEP were negative. The patient denied taki ng any calcium supplements or antacids, but was on a low dose thiazide (HCTZ–losartan 25 mg /100 mg) which was discontinued on admission. Additionally she denied any excessive vitamin K intake, which increases the absorption of calcium. Chest x-ray and lumbosacral spine noted no lytic lesions. Treatment included aggressive IV hydration with normal saline, calcitonin, and IV zoledronic acid. In addition IV Lasix 40 mg was recommended by nephrologist after euvolemia was achieved to help further decrease calcium levels. Her calcium then returned to normal limits within 4 days. The etiology of patient's hypercalcemia remained unclear. The patient was referred to hematology and nephrology in the outpatient setting.

IMPACT/DISCUSSION: Hypercalcemic crisis or severe hypercalcemia is a life-threatening emergency. The main symptoms of hypercalcemic crisis include oliguria or anuria as well as somnolence or coma. Treatment of choice for acutely lowering calcium is extensive hydration, calcitonin, and bisphosphonates (which takes 2-3 days before taking into effect). Hypercalcemia of this caliber is commonly attributed to malignancy. Thus genetic mutations should be further evaluated to discover possible etiology of hypercalcemia in a patient with no known external or internal factors, such as malignancies, intoxication, or granulomatous disorders. The unusual etiology of hypercalcemic crisis in this case was likely multifactorial; hydrochlorothiazide use, CKD stage III, Vitamin D and calcium supplementation, and dehydration. Upon strict recommendations regarding supplemental intake and discontinuation of hydrochlorothiazide, patient's re-admission one year later (May 2019) demonstrated normal calcium levels.

CONCLUSION: Few etiologies of hypercalcemia cause levels >14

Hypercalcemia of this magnitude was determined to be multifactorial

Evaluation of genetic mutations predisposing individuals to high calcium levels is warranted

HYPERCAPNEIC RESPIRATORY FAILURE DUE TO SKELETAL ABNORMALITIES IN RENAL OSTEODYSTROPHY

PRIYANKA BHUGRA[1]; Abhishek Maiti[2]

[1]Houston Methodist Hospital, Houston, TX; [2]Internal Medicine, University of Texas Health Science Center at Houston, Houston, TX. (Control ID #3392071)

LEARNING OBJECTIVE #1: Chronic kidney disease- mineral and bone disorder (CKD-MBD) is an important complication in patients with chronic kidney disease (CKD) which leads to significant morbidity and mortality.

LEARNING OBJECTIVE #2: Early recognition and appropriate treatment can help prevent devastating complications of renal dystrophy.

CASE: A 40-year-old woman with end-stage renal disease (ESRD) due to lupus nephritis presented with arteriovenous graft infection. She was receiving hemodialysis 3-times a week for 13 years, but reported non-adherence to medications and dietary restrictions. Physical examination showed prominent jaw bones consistent with uremic leontiasis ossea. Skull radiograph also showed thickening of calvaria and classic "salt- and-pepper sign". Hand radiographs showed diffuse demineralization and extensive acro-osteolysis of the distal phalanges and cortical tunneling. She also had severe kypho-scoliosis which had progressed over years leading to restrictive lung disease and chronic hypercapneic respiratory failure. Her serum parathormone (PTH) level was higher than 1900 pg/mL (201 pmol/L) and serum phosphorous level was consistently above 5.5 mg/dL (1.78 mmol/L). These findings were consistent with advanced CKD-MBD. She was treated with antibiotics, arterio-venous graft resection, and was discharged on sevalamer.

Over the following two years, the patient required multiple hospitalizations for hypercapneic respiratory failure needing mechanical ventilation and eventually passed away in hospice.

IMPACT/DISCUSSION: CKD-MBD is a systemic disease characterized by abnormalities in mineral hemostasis leading to biochemical abnormalities (serum calcium and phosphorous), endocrine dysfunction (PTH and vitamin D metabolism), anomalous bone turnover and extra-skeletal calcification. It is associated with increased cardiovascular calcification, morbidity and mortality. Renal osteodystrophy is the skeletal component of CKD-MBD and refers to the alterations in bone morphology which often leads to elevated fracture risk in these patients. Since bone biopsy is invasive and expensive, circulating PTH levels are commonly used as surrogate indicator for bone turnover. Bone mineral density is sensitive in predicting vertebral fractures in hemodialysis patients. Proactive management, including optimal control of serum calcium, phosphate, PTH levels and, sometimes timely parathyroidectomy can prevent such severe manifestations.

CONCLUSION: CKD- MB is an inevitable complication of CKD, which is often difficult to treat. Timely identification and treatment can help improve quality of life of patients with CKD-MBD.

HYPERCOAGULABILITY AND INFLAMMATION: A CASE OF IBD AND EXTENSIVE VENOUS THROMBOEMBOLI

Brittany T. Abel[1]; Alice Tang[2]

[1]Medical College, Weill Cornell Medicine, New York, NY; [2]Medicine, Weill Cornell Medicine, New York, NY. (Control ID #3352495)

LEARNING OBJECTIVE #1: Recognize venous thromboembolism (VTE) as a major sequelae of inflammatory bowel disease (IBD)

LEARNING OBJECTIVE #2: Appreciate the safety of VTE prophylaxis in hospitalized IBD patients

CASE: A 55-year-old woman with recurrent *Clostridium difficile* colitis presented to the emergency department for five days of bloody vaginal discharge and rectal pain. Over the preceding two months, she had 25 bloody bowel movements daily and 25 pounds weight loss, but denied fevers, chills, abdominal pain, nausea, vomiting, or anorexia. Social history was notable for an 8 pack-year smoking history.

On physical exam, she had a jugular venous pressure of 12 mmHg; soft, nontender abdomen; erythematous tender nodules on bilateral shins; and symmetric pitting edema. Gynecologic exam showed a rectovaginal fistula. Her labs revealed anemia, hypoalbuminemia, elevated inflammatory markers, and fecal calprotectin >1250 μg/g. GI PCR and *C. diff* stool antigen excluded acute infection. CT abdomen and pelvis showed severe colitis and non-occlusive left renal vein thrombosis. Flexible sigmoidoscopy found cookie cutter rectal ulcers with chronic active colitis, consistent with IBD. She was started on a heparin drip and IV methylprednisolone for a severe IBD flare.

An echocardiogram revealed a mass in right ventricular (RV) inflow tract, with cardiac MRI identifying a 1.3 x 0.9 cm thrombus. CT chest showed segmental and subsegmental pulmonary emboli and lower extremity duplex showed a left femoral vein thrombosis.

Medical management was continued for RV thrombus given hemodynamic stability. She responded quickly to IV steroids and was transitioned to Lovenox injections and prednisone prior to discharge, with plans to initiate biologics outpatient.

IMPACT/DISCUSSION: Patients with IBD are at two to three times greater overall risk of DVT and PE compared to the general population, a risk which increases to eight times that of controls during an acute IBD flare. This excess VTE risk is attributed to incompletely understood abnormalities in the coagulation cascade triggered by inflammation. VTE can be a marker of activity and extent of disease and is associated with fistula, stenosis, abscess, use of steroids and hospitalization. Hospitalized IBD patients with VTE are at twice the risk of mortality compared to those without VTE. We present a case of a new diagnosis of inflammatory bowel disease presenting with rectovaginal fistula and extensive venous thromboemboli, including left renal vein thrombosis, left femoral DVT, right ventricular thrombus, and multiple pulmonary emboli.

Despite often presenting with rectal bleeding, hospitalized IBD patients should receive prophylactic anticoagulation to reduce elevated VTE risk. Studies demonstrate no increase in bleeding rates among IBD patients who receive prophylaxis.

CONCLUSION: In patients with acute inflammatory bowel disease flare, clinicians must have a high index of suspicion for venous thromboembolism and prescribe prophylactic anticoagulation during hospitalization.

HYPEREOSINOPHILIC SYNDROME LEADING TO EOSINOPHILIC MYOCARDITIS

Jeong Min Yu[1]; Mariko Ishimori[2]. [1]Internal Medicine, Cedars-Sinai Medical Center, West Hollywood, CA; [2]Cedars-Sinai Medical Center, Los Angeles, CA. (Control ID #3391242)

LEARNING OBJECTIVE #1: Recognize the difficulty in differentiating the etiology of hypereosinophilia between idiopathic HES and EGPA.

CASE: A 63-year-old man with asthma, chronic rhinosinusitis, and fifty-pound weight loss in the past seven months, was admitted to the hospital for left parietal and right occipital stroke. Asthma was diagnosed in childhood and was well-controlled without recent exacerbation. Patient had focal right hand weakness of 4/5 strength, petechiae on the left lateral thigh, and violaceous plaque on the right lateral thigh that was non-blanching. Work-up for stroke revealed hypereosinophilia and a new non-dilated cardiomyopathy with ejection fraction of 25% and left atrial appendage thrombus. His white blood cell count was 21,600/UL on admission, with an eosinophil count of 12,410/UL (57.5%). Duration of hypereosinophilia was unknown as patient had not seen a doctor for many years. Cardiac MRI was highly suggestive of eosinophilic myocarditis, later confirmed with endomyocardial biopsy. Skin biopsy revealed leukocytoclastic vasculitis with numerous eosinophils but no granulomas. Flow cytometry, genetic mutation analysis, and bone marrow biopsy were all negative for myeloid and lymphoid neoplasms. Immunologic studies were non-diagnostic. Nasal polyp pathology revealed chronic inflammation with numerous eosinophils. Fungal, viral, and parasitic infectious workup were negative. Patient was started on high dose pulse intravenous corticosteroids with subsequent decline of hypereosinophilia and near normalization of ejection fraction. However, patient had recurrence of hypereosinophilia with steroid taper. Prednisone was increased to a higher dose and given that patient developed perforated gastric ulcer requiring surgical management as a complication of steroid use, a decision was made to start cyclophosphamide. After the first infusion of cyclophosphamide, patient was discharged home with outpatient hematology, rheumatology, and cardiology follow-up.

IMPACT/DISCUSSION: Unlike in HES, the precise role of eosinophils in disease complications and clinical manifestations in EGPA remains unknown. Both disorders usually respond to glucocorticoids initially but subsequent treatment strategies can differ. Documented eosinophilic vasculitis on tissue biopsy is helpful in diagnosing EGPA, although early in disease, pathology usually reveals eosinophil tissue infiltration without the distinguishing granulomas and frank vasculitis of late-stage EGPA. For patients with HES and features of EGPA and severe organ involvement who are unresponsive to glucocorticoids, cyclophosphamide would be the preferred next agent.

CONCLUSION: Hypereosinophilic syndromes (HES) are a rare group of disorders caused by sustained overproduction of eosinophils, leading to eosinophil infiltration and mediator release causing multi-organ damage. Non-neoplastic HES can be difficult to differentiate from disease entities associated with hypereosinophilia (HE) such as eosinophilic granulomatosis and polyangiitis (EGPA).

HYPER-RESPONSIVENESS TO DOFETILIDE LEADING TO TORSADES DE POINTES

Yusuf Alalwan[1]; Waleed Al-Darzi[2,3]; Gurjit Singh[3]. [1]IM, Henry Ford, Detroit, MI; [2]Internal Medicine, Henry Ford Hospital, Detroit, MI; [3]Cardiology, Henry Ford, Detroit, MI. (Control ID #3392018)

LEARNING OBJECTIVE #1: Recognize side effect of Dofetilide and adequate monitoring

LEARNING OBJECTIVE #2: Manage Dofetilide induced ventricular arrhythmia

CASE: 67 year-old-male with a history of hypertension and atrial fibrillation (Afib), not on medications for 2 years, presented with dyspnea. Found to have Afib with rapid ventricular response (RVR). Echocardiogram (ECHO) showed ejection fraction (LVEF) of 17%. Left atrial appendage was free of thrombus by trans- esophageal ECHO with subsequent unsuccessful cardioversion. Electrophysiology recommended starting oral Dofetilide 500mg BID with telemetry monitoring and obtaining EKG 2 hours after each dose to monitor QTc. Baseline QTc was normal (423 ms). An hour after administration of first dose of Dofetilide, he developed pulseless ventricular tachycardia with rhythm strip showing torsades de pointes (Tdp). He received unsynchronized shock twice with performing advanced cardiac life support measures including amiodarone 150mg and 4g of magnesium. Return of spontaneous circulation (ROSC) was achieved. Post ROSC EKG showed sinus rhythm with prolonged QTc (619 ms). No electrolytes derangement on lab review. He underwent coronary angiography that demonstrated non-obstructive CAD. Subsequently, he had successful implantation of a bi-ventricular defibrillator in anticipation of future AV nodal ablation. Unfortunately, he had recurrent episodes of Afib/flutter with RVR. After risk versus benefit discussion with him, he elected to proceed with atrial flutter ablation with wide-area circumferential pulmonary vein ablation of all pulmonary veins. He converted to normal sinus rhythm. He then tolerated Metoprolol and amiodarone. He was discharged with 3 months follow up ECHO showing significant improvement in his LVEF to 52%.

IMPACT/DISCUSSION: Dofetilide is a class III antiarrhythmic drug. Dofetilide blocks rapid component of cardiac delayed rectifier K^+ current resulting in prolongation of action potential duration and effective refractory period. Therefore, it can prolong QT interval and increase risk of Tdp. In a Danish study, 1518 patients with left ventricular dysfunction were randomly assigned to receive dofetilide versus placebo. Dofetilide was effective in converting to and sustaining sinus rhythm. Risk factors of Tdp in their sample included severe HF, female gender, and baseline Qtc prolongation. However, some patients like the present case could exhibit hyper-responsiveness to Dofetilide regardless of baseline QTc. Majority of events occurred within the first three days after giving Dofetilide. Dofetilide requires inpatient oral loading with EKG and electrolytes monitoring. Dofetilide induced Tdp should be managed similarly to ventricular tachycardia from any other cause.

CONCLUSION: Dofetilide is an effective medication for treatment of Afib; however, it has known potential side effects. Optimizing patient before administration by correcting electrolyte derangement and monitoring with telemetry with frequent QTc checks are critical with drug load to avoid fatal arrhythmias.

HYPERSENSITIVITY PNEUMONITIS: A WORK PLACE HAZARD

Andres Lopez, Margaret C. Lo, Diana Hatamleh, Meghan Humbert. Medicine, Internal Medicine, University of Florida College of Medicine, Gainesville, FL. (Control ID #3391736)

LEARNING OBJECTIVE #1: Differentiate between the clinical and diagnostic features of pneumonia from hypersensitivity pneumonitis

LEARNING OBJECTIVE #2: Diagnose and manage hypersensitivity pneumonitis

CASE: A 48-year-old healthy male presented with acute dyspnea and dry cough. In the ED, he could not speak in full sentences and was severely hypoxic (oxygen saturation 70% room air), requiring BIPAP stabilization. Chest CTA revealed bilateral infiltrates concerning for multifocal pneumonia. He was started on Vancomycin and Cefepime and admitted for acute hypoxic respiratory failure. On admission, his vitals were otherwise normal. CBC and CMP were normal; blood and sputum cultures were negative. Further history revealed patient is a chemist and has been working with trifluoroacetic acid (TFA) in his lab. Given no signs of infection and recent TFA exposure, he was diagnosed with hypersensitivity pneumonitis. Empiric antibiotics were stopped. Bronchoscopy found no abnormal findings; cytology was negative for infection or malignancy. Patient was placed on high-flow nasal cannula oxygen, scheduled inhalers and aggressive pulmonary hygiene for supportive treatment. Pulmonary consult advised against systemic steroids. Patient's respiratory status eventually improved and he was slowly weaned off oxygen after a 13-week hospitalization. CT Chest 3 months later showed resolution of airspace opacities.

IMPACT/DISCUSSION: This case teaches the dangers of pattern recognition as a diagnostic heuristic and demonstrates that not all multifocal pulmonary infiltrates indicate infectious etiology. A detailed history including occupational exposures is imperative to elicit such risks for hypersensitivity pneumonitis (HSP). While no case reports exist of HSP secondary to TFA inhalation, CDC reports common post-exposure symptoms include cough, dyspnea and delayed pulmonary edema. In this case, CTA Chest found no pulmonary edema, al though patient did experience protracted symptoms. Distinguishing between pneumonia and HSP is important to dictate proper treatment. Bacterial pneumonia warrants a course of antibiotics, and in severe cases, even steroids whereas neither is indicated in acute HSP. The key treatment for HSP is the identification and avoidance of causative exposure with common triggers being workplace exposures and pets. While systemic glucocorticoids are unnecessary in acute HSP, chronic cases warrant a course of systemic steroids. Prognosis for recovery is overall good, particularly in acute cases with complete removal of triggering exposure. Our patient now wears a N95 mask and works under a fume hood when handling TFA at work.

CONCLUSION: Although the clinical presentation (e.g. acute respiratory failure) and radiographic findings (e.g. multifocal infiltrates) can be similar in pneumonia, the recent TFA exposure and lack of infectious signs solidifies the diagnosis of hypersensitivity pneumonitis.

Bacterial pneumonia warrants a course of antibiotics and steroids, whereas avoidance of causative agent is key in hypersensitivity pneumonitis.

HYPOGLYCEMIA IN THE NON-DIABETIC PATIENT

Rosette M. Charles, Margaret Lo, Ralph Atkinson. Internal Medicine, University of Florida, Gainesville, FL. (Control ID #3389205)

LEARNING OBJECTIVE #1: Recognize the risk factors and diagnostic clues for presyncope due to hypoglycemia in nondiabetic patients.

Diagnose and manage hypoglycemia due to bariatric surgery.

CASE: A 68-year-old male bus driver with history of Wolff Parkinson White syndrome (WPW), aortic Insufficiency and Roux-en-Y gastric bypass for peptic ulcer disease presents to clinic with frequent lapses of memory, confusion and lightheadedness. He has had sporadic episodes of forgetting his bus route with associated nausea, lightheadedness, flushing and weakness. He denies syncope, diarrhea, weight loss, insulin or sulfonylurea use. He reports no inciting factors. A third of these events occurred postprandially. At a clinic visit, he acutely developed flushing, diaphoresis, dizziness, palpitations, and nausea. POCT glucose was 50. Blood glucose level improved to >100 with snacks and his symptoms resolved completely. Cardiac and neurologic evaluation were negative including EKG, Holter monitor, EEG, CT and MRI brain. HbA1c, C-peptide and serum insulin levels were normal.

IMPACT/DISCUSSION: This case demonstrates the diagnostic dilemma associated with the evaluation of presyncope and the risk of a shotgun approach to its work-up. Vasomotor and cardiovascular causes lead the

differential diagnosis for presyncope. Yet hypoglycemia remains an important cause of presyncope in both diabetic and nondiabetic patients. Neuroglycopenic presyncope can occur with either fasting or reactive hypoglycemia which occurs a few hours postprandially. Obtaining a detailed clinical history and knowing risk factors for neuroglycopenic presyncope are vital. Risk factors in nondiabetic patients include anorexia, severe liver or kidney disease, drugs e.g. alcohol, salicylates and history of Roux-en-Y gastric bypass, as true in our case. Roux-en-Y surgery causes reactive hypoglycemia due to early and late dumping syndromes causing metabolic and nutritional derangements. While early dumping syndrome is self-limiting, late dumping syndrome can present months to years later causing recurrent endogenous hyperinsulinemic hypoglycemia.

In our patient with WPW, our initial diagnosis was arrhythmia. However, the negative Holter monitoring, history of bariatric surgery, documented hypoglycemia during an episode and resolution of symptoms upon euglycemia solidified the diagnosis of neuroglycopenic presyncope. As treatment of post-bypass hypoglycemia, patient was advised to eat small meals or snacks about every 3 hours, eat a variety of foods including protein and high fiber, and limit high sugar foods. A high-protein, low-carbohydrate diet has not proven effective for hypoglycemia prevention. In severe cases, acarbose and pancreatectomy nay be warranted.

CONCLUSION: Have a high index of suspicion for neuroglycopenic presyncope in those with history of bariatric surgery and other risk factors.

Diagnostic clues for neuroglycopenic presyncope include predominantly postprandial symptoms and resolution with return of euglycemia.

HYPONATREMIA AND HYPERTENSION AS PRESENTING SIGNS OF SHEEHAN SYNDROME

Rebecca K. Tsevat[1]; Brian Hagan[2]; Neal Shah[3]. [1]Internal Medicine and Pediatrics, UCLA, Los Angeles, CA; [2]Internal Medicine, UCLA, Los Angeles, CA; [3]Internal Medicine, Olive View - UCLA Medical Center, Los Angeles, CA. (Control ID #3389873)

LEARNING OBJECTIVE #1: Recognize that sodium disorders can be caused by late-onset disturbances of the HPA axis.

CASE: A 67-year-old woman with a history of hypertension, hyperlipidemia, and type 2 diabetes presented to the ED with a headache of 2 months' duration. On admission, her blood pressure was 233/106, and she was euvolemic with no signs of end-organ damage. Her initial serum sodium level was 126, but all other electrolytes were normal. Her hyponatremia was associated with a low serum osmolality (264 mOsm/kg), and her urine studies demonstrated a urine sodium level of 114 mmol/L with an elevated urine osmolality of 501 mOsm/kg. Diagnostic evaluation of her hyponatremia yielded a normal TSH (3.53 uIu/mL) with a low free T4 (<0.4 ng/dL), as well as a low morning cortisol level of 3.6 mcg/dL with an inadequate response (peak serum cortisol concentration of 14.8 mcg/dL) after an ACTH stimulation test. On further questioning, she disclosed a history of a severe postpartum hemorrhage 30 years prior to presentation requiring multiple blood transfusions with resultant secondary amenorrhea; however, her ability to breastfeed remained intact for 2 years following the hemorrhage. The diagnosis of Sheehan syndrome was made after an MRI of the brain revealed an empty sella turcica. She was initially treated with sodium chloride tablets and subsequently with hydrocortisone and levothyroxine, and her serum sodium level improved to 134 mmol/L by discharge. For her hypertensive urgency, she was initially treated with hydralazine and then started on amlodipine as well as an increased dose of her home benazepril with eventual normalization of her blood pressure.

IMPACT/DISCUSSION: Hyponatremia is the most common electrolyte abnormality in patients with Sheehan syndrome, and in one study, 59% of patients with Sheehan syndrome were noted to have hyponatremia (1). Two notable features of this patient's case were the delayed onset of presentation from the initial insult to her pituitary as well as her severe hypertension rather than the more expected hypotension. However, late-onset Sheehan syndrome presenting with hyponatremia 30 years after a postpartum hemorrhage has previously been documented in the literature, suggesting that pituitary gland necrosis can develop over a long period of time (2). Additionally, 10% of patients with Sheehan syndrome in one large cohort were noted to have hypertension, suggesting that hypertension cannot exclude a diagnosis of adrenal insufficiency (1).

CONCLUSION: Electrolyte disturbances are common in patients with Sheehan syndrome. It is important to maintain a high index of suspicion for this disease in patients presenting with hyponatremia and a remote history of postpartum hemorrhage.

HYPOTENSION ASSOCIATED WITH HYPOCALCEMIA IN A PATIENT WITH A REMOTE HISTORY OF COMPLETE THYROIDECTOMY

Danielle G. Engskow[1]; April Barbour[2]. [1]Internal Medicine, George Washington University School of Medicine, Arlington, VA; [2]Medicine, George Washington University, Washington, DC. (Control ID #3377896)

LEARNING OBJECTIVE #1: Identify hypocalcemia as a complication of complete thyroidectomy.

LEARNING OBJECTIVE #2: Recognize hypocalcemia as a contributor to refractory hypotension.

CASE: A 54 y/o woman with history of Grave's Disease, medullary thyroid carcinoma s/p complete thyroidectomy, Crohn's Disease, diabetes mellitus type II, and hypertension presented to the hospital with diarrhea after initiation of Vedolizumab for Crohn's Disease flare. She was admitted to the ICU for initiation of phenylephrine due to hypotension unresponsive to fluid resuscitation. Labs were notable for WBC 24K, creatinine of 2.6 mg/dL, and calcium 8.3 mg/dL. Admission CT abdomen/pelvis was consistent with an active flare of Crohn's Disease. Evaluation for infectious process was negative. She was started on methylprednisolone 30mg IV BID on hospital day 2 for Crohn's disease and persistent hypotension. This was transitioned to prednisone 40mg PO daily on hospital day 8. On hospital day 5, phenylephrine drip was transitioned to PO midodrine then stopped on hospital day 14. She was discharged on hospital day 15 on prednisone 40mg PO daily. On follow up with her primary care provider she was orthostatic off all antihypertensive medications (previously on amlodipine 5mg, lisinopril 40mg, and HCTZ 25mg). Outpatient labs were notable for critically low corrected calcium of 7.2 mg/dL. She was admitted to the hospital with Chvostek sign. Chart review noted ionized calcium 1.6 mg/dL, vitamin D 1,25 level <12.5 pg/mL, PTH intact 37.3 pg/mL. She was previously on calcium supplementation with calcitriol but it had been discontinued a year earlier without sequela. Her calcium was acutely corrected and calcitriol was restarted with plan to continue indefinitely. As her serum calcium levels improved, she had rapid improvement in her blood pressure thus necessitating she restart lisinopril 20mg-HCTZ 12.5mg. Oral prednisone was tapered without any episodes of hypotension.

IMPACT/DISCUSSION: Hypocalcemia is a rare complication of complete thyroidectomy. It occurs due to damage to the parathyroid resulting in hypoparathyroidism. Between 0.2% and 1.9% of people undergoing total thyroidectomy have permanent hypocalcemia. This is almost always

detected one to three days post- operatively. Patients with hypocalcemia secondary to hypoparathyroidism require supplementation with calcitriol. This patient had a history of post-operative hypocalcemia but had done well for nearly a year off of calcium supplementation. Her development of severe hypocalcemia was attributed to low PTH reserves secondary to complete thyroidectomy which was exacerbated by decreased gut absorption of vitamin D, magnesium, and calcium due to her persistent flare of Crohn's Disease.

CONCLUSION: Hypocalcemia, though rare, should be considered in cases of refractory hypotension as it is easily corrected. Discontinue calcium supplementation with caution in patients with a history of hypocalcemia after thyroidectomy as there is a risk of hypocalcemia during critical illness due to low PTH reserve.

I.F. THE CYANOCOBALAMIN LEVEL IS NORMAL...CAN IT STILL B A B12 DEFICIENCY?

Karla Z. Duhaime[1]; Tanya Nikiforova[2]. [1]Internal Medicine-Pediatrics, University of Pittsburgh Medical Center, Pittsburgh, PA; [2]Internal Medicine, University Of Pittsburgh Medical Center, Pittsburgh, PA. (Control ID #3385007)

LEARNING OBJECTIVE #1: Identify the clinical and diagnostic features of vitamin B12 deficiency.

LEARNING OBJECTIVE #2: Diagnose vitamin B12 deficiency when laboratory B12 measurements are normal.

CASE: A 56-year-old woman with a history of hypothyroidism presented with fatigue. Physical exam demonstrated glossitis but was otherwise normal. Initial labs demonstrated macrocytosis with normal hemoglobin, folate and B12 (1446) levels. TSH was mildly elevated and the patient was restarted on levothyroxine. Over the next several months she had persistent fatigue and developed shortness of breath, a metallic taste in her mouth, and paresthesias in her distal extremities. Repeat labs showed a macrocytic anemia with hemoglobin 11.0 (MCV 111) and normal B12 level of 815, now with normal TSH. Over the next month her hemoglobin decreased further to 8.6, and there was evidence of hemolysis with undetectable haptoglobin and elevated LDH >2000 (ULN 170). Methylmalonic acid (MMA) and homocysteine levels were significantly elevated with MMA >4000 and homocysteine level of 282 (ULN 10). Together these findings confirmed B12 deficiency despite normal serum B12 levels. Anti-intrinsic factor antibody returned positive providing a diagnosis of pernicious anemia. Cyanocobalamin injections were initiated, and her hemoglobin increased to 10.2 with improvement in her symptoms.

IMPACT/DISCUSSION: The classic presentation of B12 deficiency is a megaloblastic anemia with hemolysis and associated symptoms, as well as various neurologic manifestations, most commonly paresthesias or ataxia. Glossitis is also a common feature. The main causes of B12 deficiency are dietary (now uncommon aside from strict vegan diets) or poor absorption from various underlying disorders, in this case pernicious anemia due to anti-intrinsic factor antibodies. The symptoms of B12 deficiency are caused by the role of B12 as a cofactor in DNA synthesis for dividing cells. As this pathway is unable to proceed it causes a buildup of reactants, namely MMA and homocysteine. The literature reports several cases of B12 deficiency in the setting of normal B12 blood levels, most often in the setting of pernicious anemia as in this patient, given that the antibodies may interfere with the laboratory test. The MMA and homocysteine will remain elevated as in this case, allowing the diagnosis to be made when clinical suspicion is high. Treatment of B12 deficiency includes correction of the underlying disorder if possible and repletion of B12. This case demonstrates the classic presentation of B12 deficiency and illustrates the importance of proper lab interpretation.

CONCLUSION: B12 deficiency classically presents as a megaloblastic anemia with hemolysis, neurologic symptoms such as peripheral neuropathy, and glossitis.

Laboratory B12 levels can be falsely elevated, especially in the setting of pernicious anemia, and if clinical suspicion is high the diagnosis can be supported by elevated levels of the reactants MMA and homocysteine.

I CAN'T HEAR YOU, YOU SAID I HAVE WHAT?

Zackquill Morgan[1]; Leslie Cler[2]; Leigh K. Hunter[3]. [1]Internal Medicine Residency Program, Dallas Methodist Medical Center, Dallas, TX; [2]Hospitalists, Methodist Dallas Medical Center, Dallas, TX; [3]Infectious Diseases, Methodist Dallas Medical Center, Dallas, TX. (Control ID #3342744)

LEARNING OBJECTIVE #1: Recognize the common findings of Wernicke Encephalopathy

LEARNING OBJECTIVE #2: Identify auditory symptoms as a rare manifestation of Wernicke Encephalopathy

CASE: A 46 year old African American woman presented with 1 week of worsening hearing loss along with 3 days of vision changes, confusion, visual hallucinations, and difficulty ambulating. She had history of invasive ductal cell carcinoma status-post mastectomy and chemotherapy.

Vital signs were within normal limits other than tachycardia with heart rate to 110 beats per minute. The initial physical examination was notable for a reasonably well-nourished appearing woman although her BMI had dropped from 27 to 22 within the previous 18 months. She spoke very loudly and complained of difficulty hearing questions or reading written questions. Responses were inappropriate at times, which could have been attributable to misunderstanding questions asked. She was alert, intermittently oriented, and also complained of visual hallucinations. Neurologic examination was notable for end-gaze horizontal nystagmus, dysmetria as measured with finger-to-nose exam, decreased visual acuity and decreased hearing bilaterally. Laboratory evaluation was significant for WBC count 14.4 x 10^3uL, AST 106 U/L, and ALT 15 U/L. The patient was initiated on broad spectrum antibiotics for suspicion of meningitis. CT of brain and MRI of brain were normal. Lumbar puncture was performed and showed grossly normal CSF studies with negative cultures and PCR studies. Wernicke encephalopathy was suspected, and intravenous thiamine supplementation was initiated with subsequent improvement of auditory and visual disturbances, confusion and ataxia. Serum thiamine level returned undetectable and she later admitted to significantly more alcohol intake than the "occasional use" reported at admission.

IMPACT/DISCUSSION: Wernicke encephalopathy is a condition of thiamine deficiency commonly affecting those with alcohol use disorder or gastric bypass history. Though traditionally associated with encephalopathy, ophthalmoplegia, and ataxia, it can rarely be associated with auditory deficits as well. Wernicke encephalopathy should be suspected in any patient presenting with altered mentation and alcohol intake history, but also in those with auditory deficits. Recovery of deficits is possible with prompt diagnosis and treatment, and mortality from untreated disease is high.

CONCLUSION: Wernicke encephalopathy classically presents with the triad of encephalopathy, oculomotor dysfunction, and ataxia, but only one-third of patients have the full triad. Other less common findings include vestibular dysfunction, peripheral neuropathy, hypothermia, protein calorie malnutrition, and rarely hearing loss. It is imperative that internists consider this entity in the differential diagnosis even when classic findings are not present in order to provide prompt treatment, prevent morbidity, although residual deficits are common.

IDIOPATHIC GRANULOMATOUS MASTITIS: AN UNCOMMON DIAGNOSIS IN YOUNG WOMEN WITH SEVERE BREAST PAIN

Aparna Sarin. Medicine, Mount Sinai Hospital, New York, NY. (Control ID #3387389)

LEARNING OBJECTIVE #1: Recognize the presentation of idiopathic granulomatous mastitis (IGM), a less typical etiology for breast pain and swelling especially in women of childbearing age

LEARNING OBJECTIVE #2: Review the treatment guidelines of IGM, and its complex and lengthy nature, despite being a benign disease

CASE: 36 year old female with PMH of intermittent asthma and prediabetes, presented to an urgent care center with right breast pain for 12 days. She stated that her right breast was tender and swollen but denied skin changes, redness, nipple discharge, fevers and chills. She had no other significant PMH, PSH of family history. Her children were 3, 5, & 7 yrs old. Her exam was only significant for swelling and tenderness in the upper outer quadrant of the right breast, with no erythema, warmth, nipple discharge, fluctuance, skin changes, or LAD. Right breast ultrasound showed edema but no focal abnormality (brds 2). For the next 2 months, she was monitored with serial breast exams by her PCP, and her exam fluctuated – from improvement in symptoms/findings to tender, indurated areas to eventually diffuse edema of the breast. Repeat imaging suggested an infectious process but no drainable collection. Breast surgery was consulted, Keflex given for 10 days, but with no improvement. Finally, a biopsy revealed acute and chronic mastitis with non-necrotizing granulomas, suggesting IGM.

IMPACT/DISCUSSION: IGM is a rare, benign, but complicated breast disease. Etiology is unclear, but in two small retrospective studies, IGM tends to affect young women between 23-38 years of age, and 63-86% have been pregnant within the past 5 years. It presents as a unilateral, painful, discrete mass without systemic symptoms. It's differential includes malignancy, fungal/bacterial infections, and granulomatous (tuberculous/sarcoid) mastitis. Symptoms are relapsing and remitting, persisting for 3-16 months prior to diagnosis. Imaging is often non-conclusive and biopsy is required to make the diagnosis. With no clear consenus on mangement, antibiotics are often prescribed (57%) despite negative cultures. Long courses of steroids (8-12 weeks) are often tried, but a large majority of the patients (64%) require some surgical intervention (wide local excision or partial mastectomy). IGM can take 2-24 months to attain symptom resolution, and with a recurrence rate of 15-20%.

CONCLUSION: IGM is a rare, benign, breast disease with challenges in diagnosis and management. It should remain in the differential diagnosis of women of reproductive years, especially with recent pregnancy, who present with a painful breast mass. Work up and mangement can often require multiple rounds of imaging, biopsies, antibiotics, steroids, surgery, over several weeks and months, and despite that can recur. Providers need to approach this diagnosis with compassion, patience and reassurance, since the work up and treatment can be extremely frustrating and anxiety-provoking, especially in young women who are also often supporting a work-life balance at the same time.

IFOSFAMIDE-INDUCED DIABETES INSIPIDUS

Brock Kabat, Dawn Caster. Internal Medicine, University of Louisville, Louisville, KY. (Control ID #3387780)

LEARNING OBJECTIVE #1: Recognize risk factors for ifosfamide nephrotoxicity

LEARNING OBJECTIVE #2: Manage diabetes insipidus with desmopressin

CASE: A 64-year-old African American woman with chronic kidney disease and stage IV leiomyosarcoma previously treated with several chemotherapy regimens before recieving four cycles of ifosfamide presented with increasing urinary frequency and urge incontinence. Vital signs showed tachycardia but stable blood pressures and no fever. Exam showed dry mucous membranes, mucositis, and decreased skin turgor with polyuria.

Labs on admission showed Na 153, K 2.2, HCO3 12, Phos 1.4, Ur osm 184, creatinine 2.4, and proteinuria. She was treated with hypotonic fluid resuscitation, aggressive electrolyte replacement, and started on desmopressin 2mcg IV bid. Labs showed gradual improvement of electrolyte deficiencies and acidosis, but patient remained hypernatremic and polyuric. Desmopressin was transitioned to twice daily intranasal spray and required eighteen days of therapy until labs continued to improve, trending to Na 137, K 4.2, HCO3 24, Phos 2.8, Ur osm 413, creatinine 1.8 and resolution of polyruria at time of discharge. Patient was continued with outpatient desmopressin nasal spray and followed in clinic where therapy was eventually able to be discontinued.

IMPACT/DISCUSSION: Ifsofamide is a potent alkylating agent with known nephrotoxicity resulting in tubular injury, Fanconi syndrome, and rarely nephrogenic diabetes insipidus. Risk factors for ifosfamidenephrotoxicity include age under five years, concomitant use of cisplatin, cumulative dose >90g/m2, and underlying chronic kidney disease. Most cases occur in children receiving ifosfamide with cisplatin, however our adult patient had no other active concurrent chemotherapies. She did, however, previously undergo six cycles of gemticabine/docetaxel followed by letrozole before transitioning to an oloratumab/doxorubicin regimen one month before beginning ifosfamide.

Our patient contributes another report of ifosfamide-induced Fanconi syndrome with rare nephrogenic diabetes insipidus. Consistent with several cases in the paucity of literature, our patient slowly recovered proximal tubular function and was able to resolve the insult with desmopressin support. Although nephrogenic diabetes insipidus would theoretically be unresponsive to desmopressin, repeated administration of DDAVP may act on enough of the spared or recovering tubules to show clinical and laboratory improvement of diabetes insipidus. This may be due to a partial down-modulation of the basolateral arginine vasopressin receptor 2 (AVPR2), as seen in cases of partial nephrogenic diabetes insipidus due to congenital mutations in the AVPR2 gene.

CONCLUSION: Diabetes inspidus is a rare complication of ifosfamide therapy. Risk factors may include concurrent kidney disease as well as prior chemotherapy. This may be due to vasopressin receptor downregulation, which may still be responsive to desmopressin therapy.

IF YOU GET PREGNANT, I CAN HELP WITH THAT TOO: PREVENTING, ANTICIPATING AND ADDRESSING UNINTENDED PREGNANCY IN PRIMARY CARE

Alexandra Bachorik[1]; Meghan C. Geary[2]; Mindy Sobota[3]. [1]General Internal Medicine, Boston Medical Center, Boston, MA; [2]General Internal Medicine, Brown University, Providence, RI; [3]Division of General Internal Medicine, Brown, Providence, RI. (Control ID #3390733)

LEARNING OBJECTIVE #1: Describe how general internists can routinely assess contraceptive and preconception health needs

LEARNING OBJECTIVE #2: Describe how general internists can reduce barriers to abortion care by anticipating the potential for unintended pregnancy and providing office-based abortion care

CASE: A 24-year-old woman presents to establish primary care. She denies plans for pregnancy in the next year; when asked about her interest in contraception, she denies sexual activity or interest in contraception. One year later, she presents to the Emergency Room with nausea,

vomiting, and delayed menses, and is diagnosed with early pregnancy. She expresses interest in terminating the pregnancy and receives information about outpatient abortion care. She is seen in primary care clinic two days later, where her internist explores her attitudes toward the pregnancy and reviews options for abortion care; she is clear in her desire to terminate and expresses a preference for medication abortion. She is referred to Planned Parenthood and receives a medication abortion.

IMPACT/DISCUSSION: Unintended pregnancy is common, and associated with adverse medical and socioeconomic outcomes. To prevent these adverse outcomes, general internists should elicit patients' reproductive plans at routine visits and offer appropriate contraceptive or preconception care. Multiple frameworks exist to efficiently and sensitively engage in these conversations, including the evidence-based One Key Question ®: "Would you like to become pregnant in the next year?"

However, not all patients engage in reproductive planning. For those who do, plans may change or unfold differently than expected—as in this case. Thus, both patients who do and do not engage in planning may experience unintended pregnancy. Forty percent of these pregnancies will result in abortion. Although abortion is common and safe, many barriers face those who seek abortion care, including stigma and provider scarcity. Our patient required three visits to receive abortion care, including one Emergency Room visit.

We propose two clinical practices to address the barriers of stigma and provider scarcity. Internists should normalize pregnancy options by communicating to patients their willingness to support prenatal or abortion care in the event of an unintended pregnancy. Additionally, internists should consider pursuing training to provide office-based abortion care, as the literature indicates that medication abortion can be safely provided in the primary care setting.

For our patient, these interventions might have resulted in more efficient care in a familiar setting.

CONCLUSION: - Prevent unintended pregnancy by routinely assessing patient desire for pregnancy and providing appropriate preconception or contraceptive care

- Anticipate the potential for unintended pregnancy and communicate willingness to assist with abortion or prenatal care
- Consider addressing unintended pregnancy by incorporating office-based abortion care

IF YOU HAVE BEEN A HEAVY ALCOHOL DRINKER, YOU CAN GET INFECTED TO PASTEURELLA MULTOCIDA EVEN WITHOUT ANY BITE

Takahiro Furuta[1]; Takamasa Tanaka[1]; Motoki Oeda[3]; Mitsunori Iwase[2]. [1]Internal medicine, Toyota memorial hospital, Toyota, Aichi, Japan; [2]Cardiology, Toyota Memorial Hospital, Toyota, Aichi, Japan; [3]Neurosurgery, Toyota memorial hospital, Toyota, Aichi, Japan. (Control ID #3390868)

LEARNING OBJECTIVE #1: *Pasteurella multocida* resident in pets such as dog and cat may cause brain abscess as well as respiratory infections

LEARNING OBJECTIVE #2: Brain abscess by *Pasteurella multocida* may occur in immunocompromised patient such as cirrhosis.

CASE: A 67 years old woman who has been a heavy alcohol drinker visited our hospital due to fever and anorexia. Her medical strory was unknown. She was drinking one liter of beer every day. She has kept one cat, but had no bites or scratches. The inspection reavealed a traumatic right putamen hemorrhage confirmed by head CT in addition to fever associated with sepsis. Abdominal CT also comfirmed surface irregularities on the liver suggesting alcoholic cirrhosis. We began to be administration of Meropenem (1g / q8h) for 1week as a treatment of sepsis / DIC and admitted her to the ICU. After that, both blood and sputum cultures demonstrated *Pasteurella multocida (P. multocida*), and we switched to Ampicillin (2g / q6h) for 1 week. Then she recoverd well and was discharged, but after five days she was taken to the emergency again due to fever and headache. Head-contrast CT revealed multiple chamber ring-enhanced masses around the right cerebral hemisphere. Accordingly, a brain abscess caused by *P. multocida* was suspected. No signs of cerebral hernia or paralysis were observed, so we decided to treat with Ampicillin (3g / q6h) without surgical treatment. *P. multocida* was detected again from the blood culture and the sensitivity of Ampicillin was good. With 6 weeks of antibacterial treatment, her symptoms disappeared in a few days and was discharged without leaving sequelae. Follow-up at outpatient for half a year, but no relapse is confirmed.

IMPACT/DISCUSSION: *P. multocida* is a gram-negative coccus that is resident in the oral cavity and digestive tract of many mammals and is often transmitted by abrasion or bite. In cases of atraumatic infection, the major causes are due to respiratory infections. Central nervous system infection is rare. Although bites by domestic cats could not be confirmed, there are some case reports of infection by a contact such as licking. In this case, severe infection is likely to be established by immunodeficiency due to the cirrhosis. Then it is presumed that the patient had a brain abscess after cerebral hemorrhage. The antimicrobial susceptibility at first hospitalization was good, but both the administration period and quantity of antibiotics were judged to be inadequate, and a treatment period of 6 weeks or more was selected as the treatment period for brain abscess.

CONCLUSION: We experienced the rare patient who got infected with brain abscess due to *P. multocida*.

IMMOBILITY: A RARE CAUSE OF SYMPTOMATIC HYPERCALCEMIA

Faiza Javed, Lis Ronald. Internal medicine, Montefiore Medical center, Wakefield campus, Bronx, NY. (Control ID #3388386)

LEARNING OBJECTIVE #1: - Hypercalcemia due to immobilization is a diagnosis of exclusion.

LEARNING OBJECTIVE #2: - Re-mobilization or physical therapy is the best long-term treatment for hypercalcemia due to immobility.

CASE: A 76-year-old woman with prior stroke with right-sided hemiparesis, chronic kidney disease (CKD), total parathyroidectomy was brought in by the family for altered mental status for one month, worse over the last two days. Following her stroke eight months prior, the patient had mostly been in bed or in wheelchair.

On arrival, she was hemodynamically stable with GCS 7. Labs revealed a corrected calcium level of 17 mg/dl and creatinine at baseline. CT scan head did not reveal any new changes. Hypercalcemia workup showed normal parathyroid hormone (PTH), normal thyroid-stimulating hormone, low PTH-related peptide, low 25 Vitamin D and 1,25 Vitamin D levels, and borderline low alkaline phosphatase. Serum/urine protein electrophoresis, cortisol, angiotensin-converting enzyme, and vitamin A level were normal. The bone scan did not reveal any lesions. She was treated with intravenous fluids, one dose of pamidronate 90 mg IV and calcitonin 8 U/kg q12 hours (for 48 hours). Calcium level slowly trended down over one week, to 9 mg/dl. Physical therapy was started, and mental status recovered slowly in the next few days.

IMPACT/DISCUSSION: Severe hypercalcemia can manifest as muscle flaccidity, lethargy, acute kidney injury, and altered mental status. Primary hyperparathyroidism and underlying malignancy account for 90% of cases. Our patient already had total parathyroidectomy and a normal PTH level. Her malignancy workup was also negative. Hypercalcemia due to immobilization is a diagnosis of exclusion. It is mostly seen in patients with prior vascular events like stroke, spinal cord injuries, or

multiple fractures. Prolonged immobilization causes increased bone resorption rather than formation because of the lack of mechanical stress. This causes the movement of calcium out of the bones and induces hypercalciuria and suppression of the parathyroid-1,25-vitamin D axis. Our patient had CKD, which decreased the renal excretion of calcium, further intensified by dehydration. Most of the reported cases of hypercalcemia due to immobility occurred in men, age less than 21 with either complete neurologic injuries or high cervical levels of spinal cord injury. It is uncommon to see such a high level of calcium 17 mg/dl. In the past calcium levels as high as 15 mg/dl have been reported in adults/pediatric populations due to immobilization. Although our patient did not have complete paralysis, her decreased activity along with risk factors of CKD and dehydration lead to such high calcium levels.

CONCLUSION: - Symptomatic hypercalcemia due to immobilization requires extensive workup to rule out other malignant and nonmalignant causes.

- Dehydration and chronic renal failure can trigger hypercalcemia even in partially immobilized elderly patients.

IMPACT OF DRIVING RELATED FINES AND FEES ON A 29-YEAR-OLD SINGLE MOTHER WITH LADA

Mahala Schlagman, Desiree Barron. Internal Medicine, University of Rochester Medical Center, Rochester, NY. (Control ID #3390096)

LEARNING OBJECTIVE #1: Recognize how transportation-related fines and fees can impact access to health care.

LEARNING OBJECTIVE #2: Develop a model for joint patient-clinician advocacy to influence national policy for transportation-related patient care.

CASE: DB, a 29-year-old female with LADA (Hba1c 12%), was jailed for traffic related fines and fees.

Family notified her primary care doctor after arrest. DB had previously been unable to pay driving related fines and fees and, unbeknownst to her, as a result her driver's license was suspended. She has known poorly controlled diabetes and per her report had at least one hypoglycemic event in jail where she did not receive access to glucose supplies. She was ultimately gifted multiple cups of juice by other incarcerated women, allowing her to avoid hypoglycemic coma.

With DB's permission, her doctor notified her public defender of her risk of death, ultimately assisting in expediting her release from jail. Prior to this intervention, the legal system and public defender had questioned her diagnosis and refused to verify. Following initial release from jail, DB was jailed two additional times and, in each instance, had medical supplies taken away. She lost a position of employment and endocrinologist in part due to difficulty with transportation access. DB was referred for personal assistance with her driving related fines and fees. The patient and clinician jointly participated with an external advocacy organization, the Fines and Fees Justice Center's Free to Drive Campaign, to educate a national coalition of advocacy groups working to end incarceration for driving related fines and fees about DB's experience.

IMPACT/DISCUSSION: Currently in 44 states unpaid driving related fines and fees can result in loss of a driver's license (finesandfeesjusticcenter.org). Currently in zip code 14611, 1/3 of adults have driver's license suspensions due to unpaid fines and fees. Loss of a driver's license can limit access work, school and health care. Individuals who are unable to afford initial fines and ultimately incarcerated for driving-related fines and fees are disproportionately individuals of color living below the federal poverty line in NYS (drivenbyjustice.org). Physicians have power to advocate for release of their patients jailed in unsafe medical conditions. We have an opportunity to identify key social and legal barriers to patient safety, bear witness to those barriers, and partner with patients to advocate for a more just legal system.

CONCLUSION: Physician-patient partnerships that highlight how social determinants of health impact our communities are a key opportunity to advocate for those with unmet legal needs related to traffic related fines and fees. This model, joining a physician, patient and advocacy organization may be implemented on other social determinants related topics. Further research is needed on the impact of driver's license loss on access to health care across a larger population.

*Note the co-authors are the patient and physician involved in this case.

INCARCERATION AND HEALTH: A LACK OF TRANSITION OF CARE IN MANAGEMENT OF CHRONIC CONDITIONS IN PRISON

Ethan M. Cohen[1]; Siri S. Sarvepalli[1]; Tyler E. Russeth[1]; Diane L. Levine[2]. [1]Medical Student, Wayne State University School of Medicine, Detroit, MI; [2]Internal Medicine, Wayne State University, Detroit, MI. (Control ID #3357305)

LEARNING OBJECTIVE #1: Recognize the impact of improper continuity of care in a jail setting.

CASE: A 33-year-old male inmate presented with a history of well-controlled ulcerative colitis (UC). Upon entry to jail, he did not receive a health screen, and his adalimumab was not prescribed. Over the next four months, he experienced a severe flare up of UC and was admitted. The patient presented with eight to nine bloody bowel movements a day, severe left lower quadrant (LLQ) pain, and a 70-pound weight loss. During hospitalization, he had a nutrition and gastroenterology consultation, a colonoscopy, and was treated with steroids and adalimumab. Prior to discharge, the medical team spoke with the jail and determined that if the patient received one dose of adalimumab, it would be continued in jail. This medical regimen was documented on his transition of care document and discharge summary, both of which were sent to the jail. However, in jail the medical staff only provided the patient with Tylenol for pain. The patient's condition further deteriorated, and he was readmitted to the hospital four days later with worsening symptoms of bloody bowel movements, LLQ pain radiating to the perianal region, low hemoglobin count, and anemia. He was treated with blood transfusion and IV methylprednisolone and discharged with the same medical regimen as recommended on the first admission. On return to jail, he received the recommended treatment.

IMPACT/DISCUSSION: This case demonstrates the improper treatment of chronic medical conditions in jail and the negative health and financial outcomes that result. In the United States, non-violent, pre-arraigned individuals are held in jail prior to being sent to prison, a more long-term institution. Improper screening and continuity of care during short jail stays is associated with a significant increase in preventable costs for avoidable medical interventions and hospitalizations. Today, 50% of inmates report having at least one chronic medical condition while nearly 70% of new jail inmates report absence of an admission health screen, a necessity for institutions to understand the medical conditions of their population. Had the jail screened for pre-existing chronic health conditions on our patient's arrival or had provided the recommended treatment after his first admission, his UC likely would not have flared and negative health outcomes could have been avoided. In all, we estimate the cost of his emergency visits, hospital stays, and procedures at $25,000 - an avoidable expense. Scenarios like our patient's can be prevented with proper screening upon entry to jail and continuity of care across the health system and the jail system.

CONCLUSION: Many inmates with chronic conditions do not receive proper treatment in jail which cause chronic condition exacerbations. In order to save on healthcare spending and avoid negative medical outcomes, proper communication with jail medical staff is needed to ensure compliance with medical regimens.

INDETERMINATE HCG: DETERMINED TO DIAGNOSE

Sarah Olofsson[1]; Ricardo Cruz[2]. [1]Internal Medicine, Boston Medical Center, Boston, MA; [2]General Internal Medicine, Boston Medical Center, Boston, MA. (Control ID #3392068)

LEARNING OBJECTIVE #1: Review the differential diagnosis for an abnormal serum bHCG

LEARNING OBJECTIVE #2: Determine appropriate treatment of common sexually transmitted infections (STIs) in pregnant patients

CASE: A 43 year old Haitian female presented to primary care clinic with a 3-month history of irregular periods. She reported bi-monthly heavy bleeding and foul smelling vaginal discharge. She immigrated from Haiti 7 months prior and was sexually active with one new male partner. She denied use of birth control or any previous cervical cancer screening. Exam was notable for a friable, erythematous cervix with mucopurulent discharge, and significant cervical motion tenderness. Based on these findings, the patient was treated for pelvic inflammatory disease (PID) with intramuscular (IM) ceftriaxone and a 14-day course of doxycycline. Labroatory studies included urine HCG which resulted "borderline" and a subsequent quantitative serum HCG of 16 (normal <5, or >202 in pregnant patients 1-20 weeks post last menstrual period). Vaginitis swabs returned positive for chlamydia, bacterial vaginosis (BV) and candida yeast. Given the possbility of active pregnancy, the doxycycline prescription was changed to azithromycin. Metrogel and fluconazole were also prescribed. Subsequent TVUS showed no intrauterine sac, and she was referred to the ER for evaluation by Ob/Gyn out of concern for ectopic pregnancy. Serial HCG testing down-trended to within reference range, and a diagnosis of spontaneous abortion was made.

IMPACT/DISCUSSION: As general internal medicine providers, we have a responsibility to address common gynecologic conditions and recognize when referral to specialized providers is warranted. On initial evaluation of a woman with an elevated HCG, a broad range of diagnoses needs to be considered. Although the result was due to a spontaneous abortion in this case, other causes include early intrauterine or ectopic pregnancy, malignancy (including trophoblastic, ovarian, cervical, and bladder), pituitary secretion, exogenous injection, familial hCG, or false elevations due to certain immunoglobulins. Clinicians must also know safe and effective methods for treating STIs in patients who are or may be pregnant. Although it's quite rare to have PID during pregnancy, it can occur in the first 12 weeks. Doxycycline is a known teratogen so an alternative regimen includes azithromycin in combination with IM cephalosporin. This patient also had BV, which is usually treated with metronidazole. Traditional teaching is that metronidazole may cause fetal harm as it crosses the placenta, however current CDC guidelines no longer discourage its use in pregnancy. BV can increase the risk of preterm birth so it should be promptly treated.

CONCLUSION: A broad differential needs to be considered for a woman presenting with abnormal bleeding and an indeterminate bHCG, including possible malignancy.

As primary care physicians, we should be able to address common gynecologic complaints including appropriate treatment of STIs in pregnant patients.

INFLAMED AND CONSTRAINED: A CASE OF RHEUMATOID INDUCED PERICARDITIS

Esteban N. Mercado-Rodriguez, Robert J. DeGrazia, Ajeetpal Hans, Jennifer N. Goldstein. Internal Medicine, Christiana Care Health System, Newark, DE. (Control ID #3346054)

LEARNING OBJECTIVE #1: Recognize the clinical features related to chronic pericardial inflammation in patients with rheumatoid disease.

LEARNING OBJECTIVE #2: Manage the presentation of constrictive pericarditis in rheumatoid arthritis

CASE: A 50-year-old man with a history of rheumatoid arthritis was admitted with shortness of breath and peripheral edema. He was found to have new-onset atrial fibrillation with RVR as well as clinical features of right-sided heart failure. His past medical history included a right pneumonectomy after failed decortication of a trapped lung following a massive pleural effusion. On presentation, the patient was complaining of a one-month history of progressive dyspnea on exertion, orthopnea, and worsening of peripheral edema. On physical exam patient had 4+ bilateral LE edema as well as scrotal edema, no JVP noted.

Labs: WBC 12.7 / nl; AST 43, ALT 76, ALP 219 UNIT/L; BILT 2.0 mg/dL; pro-BNP 852 pg/mL; UA with no proteinuria.

CXR: right pneumonectomy and new interstitial edema with a small effusion of the left lung. EKG: atrial fibrillation, 127 bpm, right axis deviation, no ischemic changes.

TEE: bi-atrial enlargement with a left ventricular ejection fraction of 65%.

Cardiac MRI: pericardial thickening and calcification over the right and left ventricle, with extension to the AV junction.

MRI findings were consistent with constrictive pericarditis of the ventricles. Thoracic surgery was consulted for possible pericardiectomy; however, the patient opted for medical management of symptoms and immunomodulatory therapy.

IMPACT/DISCUSSION: Constrictive pericarditis is a rare but serious complication of rheumatoid arthritis that can be fatal, thus diagnosis requires a high index of clinical suspicion. Rheumatoid constrictive pericarditis typically presents with symptoms of right-sided heart failure. Prognosis is dependent on underlying etiology, comorbidities and extent of LV dysfunction and can vary greatly between patient populations.

A CT scan of the chest, and/or cardiovascular MR are the gold standard for diagnosis but chest x-ray and echocardiography can support a diagnosis with high clinical suspicion. Patients with confirmed constrictive pericarditis should be evaluated by a thoracic surgeon for possible pericardiectomy. Medical therapy may have an important role particularly in the early effusive period of acute pericarditis.

Early treatment with NSAIDs, low dose corticosteroids, and colchicine can halt the progression to constrictive disease. In the absence of evidence that the constriction is chronic (cachexia, atrial fibrillation, hepatic dysfunction or pericardial calcification) an empiric 2-3 month course of anti-inflammatory medical therapy may be of benefit.

CONCLUSION: - Rheumatoid constrictive pericarditis should be considered in any patient with RA and unexplained systemic venous congestion.

- CT scan of the chest or cardiovascular MR are the gold standards for diagnosis.
- Pericardiectomy is the first-line therapy but in high-risk patients, medical treatment should focus on symptom management.

INSULIN INDUCED EDEMA: A RARE EFFECT OF A COMMON MEDICATION

Megan Karrick, Ahmad O. Aljamal, Danielle L. Heidemann. Internal Medicine, Henry Ford Health System, Detroit, MI. (Control ID #3390695)

LEARNING OBJECTIVE #1: Insulin can cause generalized edema.

CASE: A 75 year old female with type 2 diabetes, hypertension, and chronic kidney disease presented to the clinic for generalized edema. She endorsed associated nausea, but denied chest pain, shortness of breath, and orthopnea. It began after the initiation of insulin glargine for uncontrolled hyperglycemia. Initially, she developed profound swelling in her legs to the thighs, which progressed in two months to involve her upper extremities and torso. She gained 29 pounds in this time. Notably, her previously uncontrolled hypertension improved, allowing discontinuation of many of her anti-hypertensives. Venous duplex ultrasound of her upper and lower extremities showed no superficial or deep vein thrombosis. Computed tomography of pancreas was unremarkable. Renal and liver function testing was normal aside from stable chronic kidney disease and hypoalbuminemia with an albumin of 2. Urine studies showed normal albumin to creatinine ratio and slight proteinuria with urinary protein excretion of 187mg over 24 hours. She had elevated thyroid stimulating hormone of 10.58 but normal free levels, and normal cortisol levels. BNP was normal at 41. She underwent a trans-thoracic echocardiogram which showed an ejection fraction of 67%, with normal diastolic function, high-normal pulmonary artery pressure of 36, and small pericardial and pleural effusions. She was given escalating doses of furosemide therapy, without improvement of her edema.

Her blood sugar improved with dietary restriction, and her insulin requirements gradually decreased and was discontinued. One month later, her edema had resolved. She lost 26 pounds and became increasingly hypertensive, necessitating up-titration of therapy. She was diagnosed with insulin-induced edema.

IMPACT/DISCUSSION: Insulin edema is often overlooked in the setting of edema in patients new to insulin, with only a few cases reported in literature. The pathologic mechanism is unclear. Insulin has been posited to reduce renal sodium excretion and increase albumin excretion. However, our patient showed no hyponatremia and had no evidence of excessive urinary albumin or protein excretion. Commonly treated with diuresis, insulin edema usually resolves with time. Our patient did not respond to diuretic therapy. Interestingly, her uncontrolled hypertension resolved with insulin and immediately returned on stopping therapy.

CONCLUSION: Insulin-induced edema is under-recognized, and may occur more frequently than is reported. Diagnosis of insulin edema should be one of exclusion, with other causes of generalized edema including renal, liver, and cardiac disease ruled out. The timing of insulin initiation and resolution of edema on insulin cessation supports the diagnosis. Most patients respond to diuretic therapy, but some do not, as illustrated in this case. Blood pressure improvement with insulin initiation is another interesting phenomenon observed in our patient, and may suggest the pathophysiology underlying insulin edema.

INTERCEPTING INTUSSUSCEPTION AS A COMPLICATION OF HEREDITARY ANGIOEDEMA IN AN ADULT

Justin B. Roy[1]; Nitasa Sahu[1]; Dhirisha Bhatt[1]; Reshma R. Golamari[3]; Rama R. Vunnam[1]; Rohit Jain[2,1]. [1]Internal medicine, Penn State Hershey, Hummelstown, PA; [2]Medicine, Hershey Medical Center, Cumberland, MD; [3]Internal Medicine, Penn State Health Milton S Hershey Medical Center, Hershey, PA. (Control ID #3385667)

LEARNING OBJECTIVE #1: Evaluate GI manifestations of hereditary angioedema (HAE)

LEARNING OBJECTIVE #2: Review management strategies for HAE

CASE: A 27-year-old male with known HAE type 2 presented due to acute worsening of his abdominal pain that initially began 6 months ago. The patient had been non-compliant with his plasma derived (pd) C1-INH therapy over that time, as it was too expensive. His pain was colicky left lower quadrant pain associated with loose stools. One month prior, he presented to the emergency department for nausea and vomiting and was found to have edema from his gastric antrum to proximal duodenum on CT imaging and was treated with one dose of pd C1-INH prior to leaving against medical advice. In the two weeks prior to presentation, he reported melanic stools; and 3 days prior, reported acute worsening of his abdominal pain.

On presentation, his vital signs were all found to be within normal limits. Physical exam demonstrated a non- distended abdomen with tenderness to both light and deep palpation in the bilateral lower quadrants without rebound or guarding, and hypoactive bowel sounds. Laboratory analysis was significant for a leukocytosis of 13.49k/μL, but otherwise largely unremarkable. CT imagining showed significant intestinal angioedema involving the bladder wall and transverse colon, as well as telescoping of the large bowel at the splenic flexure consistent with intussusception, but non-obstructive. The patient was admitted and administered a total of 3 doses of pd C1-INH at 20mg/kg in the first 24 hours. On hospital day 5, he underwent colonoscopy to rule out malignant lesions, which was notable only for a tortuous colon; no mucosal edema or polyps/masses were appreciated. The patient was discharged with close follow-up with allergy/immunology.

IMPACT/DISCUSSION: HAE is a rare autosomal dominant disease that occurs in three major types affecting the C1 inhibitor protein; quantitative (type 1, 80-85% of cases), qualitative (type 2, 15-20% of cases), and a third type which has been found to affect coagulation factor XII (type 3, < 5% of cases). This leads to activation of the kallikrein-kinin system and release of vasoactive proteins resulting in the characteristic angioedema. The most common GI manifestations include nausea and vomiting, colicky abdominal pain, and diarrhea, but intussusception in an adult is exceedingly rare. CT imaging is the diagnostic test of choice, accurately diagnosing intussusception in 78-100% of patients, whereas ultrasound has been shown to be only 50% accurate. Previously treated with FFP, new medications including C1-INH proteins have been FDA approved for acute HAE episodes. And while intussusception is normally the result of a malignancy in over 75% of adults, in the setting of HAE, treatment of the HAE flare with medical management is often sufficient to avoid invasive interventions.

CONCLUSION: Diagnosis of intussusception is best made with contrast enhanced CT and prompt treatment with pd C1-INH or alternative first line agents for HAE attacks is vital.

INTRAPULMONARY SHUNTS FACILITATING AN ORAL SOURCE OF SEPTIC ARTHRITIS

Yicheng Tang, Allison DeKosky. Internal Medicine, University of Pittsburgh Medical Center, Pittsburgh, PA. (Control ID #3390796)

LEARNING OBJECTIVE #1: Recognize clinical features and complications of hereditary hemorrhagic telangiectasia

LEARNING OBJECTIVE #2: Recognize that intrapulmonary shunts are associated with paradoxical embolic spread of infection to remote sites

CASE: A 28 year old female with no medical history presents with unilateral leg pain, tachycardia, and recurrent epistaxis for one week. CT angiography reveals no embolus, but 3 large pulmonary arteriovenous malformations (AVMs) concerning for new diagnosis of hereditary

hemorrhagic telangiectasia. She then develops knee pain and swelling, with joint aspiration yielding frank pus. She is given antibiotics and taken for surgical management of septic arthritis. Blood and joint cultures initially grow the oral and urogenital bacterium Streptococcus constellatus. She remains stable on parenteral antibiotics over the next week, but surgical culture grows more oral flora – Eubacterium brachy, Parvimonas micra, Prevotella intermedia, and Campylobacter rectus. Brain MRI shows no AVMs but scattered punctate infarcts. Transesophageal echocardiogram shows no vegetations. Formal dental evaluation is unremarkable. She continues to have leg pain, swelling, and elevated inflammatory markers, prompting numerous returns to the operating room for decompression of popliteal and thigh abscesses. These cultures grow more oral flora – Fusobacterium species, Prevotella oris, and Streptococcus anginosus. Further CT imaging of the chest, abdomen, and pelvis reveal no other AVMs or infectious foci. She receives 6 weeks of ceftriaxone and metronidazole per literature reports of bacterial sensitivities, to be followed by repeat MRI of her leg and definitive coil embolization of her pulmonary AVMs.

IMPACT/DISCUSSION: This case represents a highly unusual presentation of a rare genetic disease. The patient develops polymicrobial septic arthritis of a native knee and embolic intracranial infarcts as complications of hereditary hemorrhagic telangiectasia. The proposed mechanism is paradoxical embolization across pulmonary AVMs allowing transient bacteremia of normal oral hygiene to bypass the pulmonary capillary bed's innate filtering ability, as well as its significant pool of marginalized leukocytes. Literature review reveals a handful of cases documenting brain abscesses with oral flora secondary to pulmonary AVMs, but no cases of septic arthritis. In addition to the novelty of the scenario, we also highlight the difficulty in determining timing of embolization. The decision to leave permanent endovascular coils in the setting of ongoing infection is distressing. In patients with pulmonary AVMs, however, closure of the shunts may be required for definitive source control.

CONCLUSION: Suspicion of systemic infectious seeding warrants consideration of paradoxical embolization. In such cases, transient bacteremia alone without a primary source can cause remote infection. Further diagnostic workup may include transthoracic echocardiogram with bubble contrast and pulmonary angiography.

IS HIGH DOSE HYDRALAZINE SAFE TO USE?

Mahmuda Akhter[1]; Khin May Myat[1]; Mahsa Kanzali[2]; Barry Fomberstein[2]. [1]Internal Medicine, Montefiore Medical Center- Wakefield Campus, Astoria, NY; [2]medicine, montefiore medical center, Bronx, NY. (Control ID #3389575)

LEARNING OBJECTIVE #1: Recognize a rare adverse drug reaction of hydralazine.

LEARNING OBJECTIVE #2: Consider an alternate class of antihypertensive before prescribing high dose of hydralazine.

CASE: 63-year-old woman with hypertension treated with 250mg of hydralazine for many years presented with diffuse pruritic rash, nausea and vomiting. She had pink excoriated, painless, itchy rash on the extensor surfaces of upper and lower extremities with hypopigmented atrophic macules coalescing into patches on the trunk. Labs revealed potassium 5.9mEq/L, creatinine of 11.2mg/dl (from 0.8mg/dl 4 months ago) and blood urea nitrogen of 97 mg/dl (from 15mg/dl 4 months ago). Erythrocyte sedimentation rate was >140mm/hr and C-reactive protein was 6.7mg/dl. Further investigations yielded a positive result (>8mU/ml) for anti- myeloperoxidase (MPO) antibody and anti-histone antibody (1U). Tests for proteinase 3 (PR3) antibody, anti- nuclear antibody and complement 3 and 4 (C3, C4) were normal. Renal biopsy showed anti neutrophilic cytoplasmic antibody (ANCA) positive, pauci-immune crescentic glomerulonephritis with associated interstitial inflammation with severe tubular injury. She was diagnosed with hydralazine-associated ANCA positive vasculitis with renal syndrome. Treatment was initiated with cyclophosphamide and hemodialysis.

IMPACT/DISCUSSION: The pathogenesis for hydralazine-induced vasculitis may include its binding to MPO resulting in neutrophil apoptosis, increased neutrophil expression through hydralazine-induced reversal of epigenic silencing of MPO and PR3, and a break in tolerance in slow versus fast acetylators of hydralazine. Based on the study, patient who is on hydralazine for over three years, the incidence ranges from 5.4% in patients on 100mg/day and 10.4% with 200mg/day. Considerable other risk factors include female gender, mean exposure of more than four years, cumulative dose more than 100 mg and thyroid disease. The diagnosis depends mainly on symptoms, exposure to drugs, serological markers such as anti-histone antibody, anti-MPO antibody and/or anti PR3, ANCA and symptoms resolution after discontinuation of the offending agent. For glomerulonephritis due to hydralazine-induced vasculitis, renal biopsy is recommended to determine severity and prognostication. There is no specific guideline for the management of hydralazine induced vasculitis. Treatment depends on age, severity, co-morbidities and renal function. Discontinuation of the offending agent may be enough in mild cases whereas the aggressive treatment with immunosuppressants are warranted in severe cases with renal or pulmonary involvement. Corticosteroids with cyclophosphamide, rituximab and plasma exchange can be considered.

CONCLUSION: Hydralazine induced vasculitis with renal syndrome is associated with cumulative high dose and can be life-threatening. If a patient has refractory hypertension, alternative antihypertensives are suggested to prevent adverse effects.

ISOLATED NON-INFECTIOUS INFLAMMATORY DACTYLITIS

Varshitha Thanikonda[1]; ayesha shaik[1]; Susan Giles[2]. [1]Internal Medicine, Uconn Health, HARTFORD, CT; [2]Rheumatology, St. Francis Hospital, HARTFORD, CT. (Control ID #3374171)

LEARNING OBJECTIVE #1: Differential diagnosis of Isolated dactylitis

LEARNING OBJECTIVE #2: Management of non-infectious isolated inflammatory dactylitis

CASE: A 67-year-old female presented with acute onset of the right second toe swelling without any history of trauma. Interestingly, before her symptoms began, she was treated for uncomplicated urinary tract infection. Also, she received a dose of fremanezumab for her migraine shortly before her symptoms began. She did not have a history of psoriasis, rash, fever, chills, colitis, uveitis, or diarrhea. Her past medical history included ductal carcinoma in situ treated with bilateral mastectomy and radiation; presently, in remission, stable meningioma causing chronic migraine-like headaches and generalized premature osteoarthritis. On exam, her toe was red, swollen, warm to touch, and tender. Initially, due to concern for cellulitis, she completed a course of amoxicillin without improvement. Among the laboratory tests, the erythrocyte sedimentation rate remained elevated at 28mm/h. However, there was no leucocytosis, and C-reactive peptide, rheumatoid factor, anti-cyclic citrullinated peptide antibody were all negative. Magnetic Resonance Imaging of the right foot to further evaluate for osteomyelitis showed bone marrow edema crossing the distal interphalangeal and proximal interphalangeal joints of the second toe along with mild generalized circumferential signal in overlying soft tissue. Subsequently, three-phase bone and indium scans were positive and suggestive of osteomyelitis. However, a bone biopsy and culture were negative for infection. Hence, she got diagnosed with inflammatory dactylitis. As first-line, she was trialed on prednisone 40mg daily with an inadequate response while indomethacin and colchicine provided a

marginal response. Fortunately, following this, she did well on an empiric trial of adalimumab. For insurance reasons, she trialed methotrexate, which made no difference, and finally, she switched to golimumab with further improvement in her symptoms.

IMPACT/DISCUSSION: The common cause of infectious isolated dactylitis is streptococcus, while inflammatory etiology is commonly psoriasis. Interestingly, in this patient's case, she did not have an infection, nor did she have an identifiable inflammatory disorder. Her dactylitis was likely related to a seronegative peripheral spondyloarthropathy. The role of methotrexate in the treatment of psoriasis, which bears a close resemblance to dactylitis, has been questionable. However, biologics, like tumor necrosis factor- alpha inhibitors(TNF-alpha inhibitors), are shown to be effective.

CONCLUSION: In cases of isolated non-infectious inflammatory dactylitis, a trial of TNF-alpha inhibitors warranted as well as vigilance for the emergence of an associated seronegative spondyloarthropathy over time.

IS POST-OP CHEST PAIN ALWAYS AN MI?

Jithu Pradeep[1]; Mahmuda Akhter[2]; Kristin A. Swedish[3]. [1]Internal Medicine, Montefiore Medical Center, Bronx, NY; [2]Internal Medicine, Montefiore Medical Center- Wakefield Campus, Astoria, NY; [3]Department of Medicine, Montefiore Medical Center, Bronx, NY. (Control ID #3391804)

LEARNING OBJECTIVE #1: Recognizing takotsubo cardiomyopathy as a cause of postsurgical chest discomfort.

CASE: A 72-year-old woman with hypertension and hyperlipidemia developed an episode of substernal chest discomfort on post-operative day 1 following left total knee arthroplasty. It was described as a bloating sensation, lasted for few minutes, and resolved on its own. Patient was tachycardic to 107 bpm. Electrocardiography revealed sinus tachycardia without ST or T wave changes. Cardiac biomarkers resulted troponin levels of 0.27 ng/mL and 0.34 ng/mL and creatinine kinase levels of 378 U/L and 472 U/L consecutively. She was initially managed for non-ST elevation myocardial infarction with a heparin drip. Echocardiogram was limited due to tachycardia, but there was akinesia of the antero-septum, apex and distal anterior wall, with an ejection fraction of 44%. In view of recent surgery, the etiology was thought to be due to demand ischemia, but decision was made for cardiac catheterization as her total blood loss during the procedure was minimal. Cardiac catheterization revealed apical hypokinesis and angiographically normal coronaries, suggesting takotsubo cardiomyopathy (TC). She was prescribed a beta blocker and angiotensin converting enzyme inhibitor, and antiplatelet therapy was discontinued. Repeat echocardiogram one month later revealed normal ejection fraction without wall motion abnormality.

IMPACT/DISCUSSION: TC also known as stress cardiomyopathy or apical ballooning syndrome is transient and is typically precipitated by acute emotional stress. It is characterized by transient regional systolic dysfunction of the left ventricle (LV) and is accompanied by reversible LV apical ballooning, mimicking myocardial infarction, but in the absence of angiographic evidence of obstructive coronary artery disease or acute plaque rupture. Pathophysiology of TC includes diffuse catecholamine-induced microvascular spasm or dysfunction or direct toxicity, dynamic mid-cavity or LV outflow tract obstruction. As a physical stress, surgery causes sympathetic stimulation, which can cause catecholamine release.

It is not known why TC disproportionately affects postmenopausal women or why the LV mid-cavity and apex are predominantly affected.

TC commonly presents in a similar manner as myocardial infarction (estimated that 1-2% of suspected acute coronary syndrome). It is always prudent to rule out an ischemic etiology. Patients are treated with thrombolytic agents, which put them at unnecessary risk of bleeding. Undiagnosed TC can present as sudden cardiac death, cardiogenic shock, systemic thromboembolism and congestive heart failure.

CONCLUSION: Having TC as one of the differentials for postsurgical chest discomfort can prevent mismanagement. Although TC is uncommon among post-menopausal female, but of the people who are diagnosed with TC, most are postmenopausal women.

IS THAT THE RIGHT SPLIT? USING THE PHYSICAL EXAMINATION TO DIAGNOSE RIGHT BUNDLE BRANCH BLOCK (RBBB)

Nicole Pohlman, Susan B. Glick. Internal Medicine, Rush Medical College, Chicago, IL. (Control ID #3391795)

LEARNING OBJECTIVE #1: Use the physical examination to diagnose RBBB

LEARNING OBJECTIVE #2: Describe the differential diagnosis of a widely split S1

CASE: A 47-year-old woman presented with 3 unexplained episodes of chest pain. The first episode occurred 6 months prior while she was making dinner. The second occurred 4 months prior while she walked in her home after work. The third occurred 10 days prior to the office visit and woke the patient from sleep. She described the pain as a gripping sensation under her left breast. The pain was pleuritic and resolved after an hour. There was no chest pain with exertion, dyspnea, palpitations, syncope, heartburn or feelings of anxiety or panic.

Past medical history was remarkable for anemia and hypothyroidism. Medications included levothyroxine. Family history was significant for sudden cardiac arrest in her mother and maternal grandfather in their late 60s due to myocardial infarction.

She worked as an attorney, had never smoked, drank 2 drinks per week and did not use drugs.

On physical examination, cardiac exam revealed regular rate and rhythm S1, S2 without murmur rub or gallop, BP 152/78, pulse 64. There was an additional sound following S1, felt to be a widely split first heart sound. The remainder of the examination was normal.

EKG showed sinus bradycardia with heart rate=56 and an incomplete RBBB. Echocardiogram revealed mild tricuspid regurgitation. Stress echocardiogram and lipid profile were normal.

IMPACT/DISCUSSION: Although RBBB is often first identified on EKG, it may also be diagnosed on physical examination. RBBB results in an electrical delay in RV contraction, causing delayed closure of the pulmonary and tricuspid valves. Delayed closure of the pulmonary valve causes splitting of S2 that increases with inspiration and remains auscultable on expiration. Delayed closure of the tricuspid valve results in increased splitting of S1 best heard in the tricuspid region, as was seen in our patient.

RBBB is the most common cause of increased splitting of S1. LV ectopic or paced beats may also present with prominent splitting of S1. Atrial septal defects cause a widely split S1 due to increased blood flow across the tricuspid valve delaying its closure. Ebstein anomaly (associated with RBBB) can also present with wide splitting of S1 due to delayed tricuspid valve closure due to ballooning of the leaflets during systole. Mimickers of a widely split S1 include an S4, ejection sound and systolic click.

Although most patients with incomplete RBBB are asymptomatic, it is important to consider the possibility of underlying cardiac disease, as RBBB may result from structural heart disease, be rate-related or iatrogenic.

CONCLUSION: -RBBB results in wide splitting of S1 and/or S2 on physical examination. These findings may be the only indication of a RBBB in asymptomatic individuals, and may necessitate and EKG.

- PVCs, paced beats, atrial septal defects and Ebstein anomaly are other causes of a widely split S1.
- Mimickers of a widely split S1 include an S4, ejection sound and systolic click.

IS THIS A SPONGY HEART?

Himabindu Boja, Cassie Shaw. Internal Medicine, University of New Mexico, Albuquerque, NM. (Control ID #3392450)

LEARNING OBJECTIVE #1: Early identification of Left Ventricular noncompaction (LVNC) is crucial as it is frequently associated with worse cardiovascular outcomes like fatal arrhythmias, including sudden death. We present a case of a young male who had some of the high-risk features of LVNC.

CASE: A 34-year-old male with a history of Legg-calve Perthes disease, sleep apnea, and gout presented to the hospital with new symptoms of decompensated heart failure. Laboratory testing revealed elevated BNP, normal troponins, and thyroid function. His family history was significant for heart failure in a brother who expired before the heart transplant. His initial electrocardiogram showed sinus tachycardia. His echo indicated that he had severely reduced left ventricular systolic function with an ejection fraction of 18%, grade 3 diastolic dysfunction along with prominent trabeculations. Given his low ejection fraction, the patient underwent a workup for ischemia. It demonstrated normal coronaries along with high pulmonary artery wedge pressure and right atrial pressure. Based on this, a workup for causes of non-ischemic heart failure was pursued, which included normal sedimentation rate, mildly elevated C-reactive protein, normal iron panel. Other workup was negative for Anti-nuclear antibody, HIV, hepatitis C, infiltrative cardiovascular disorders. Cardiac magnetic resonance imaging was suggestive of hyper-trabeculated left ventricular myocardium from the mid chamber to the apex with non-compacted: a compacted ratio of 2.5; meeting threshold criteria for myocardial noncompaction. During his hospital stay, the patient also developed multiple episodes of non- sustained ventricular tachycardia. This patient had multiple risk factors for high-risk phenotype - primary cardiomyopathy with low ejection fraction, family history of heart failure, and the development of arrhythmias. Therefore, he underwent implantable cardiac defibrillator for primary prevention of sudden cardiac death.

IMPACT/DISCUSSION: LVNC is thought to be due to the arrest of myocardial morphogenesis that results in abnormal remodeling of ventricular trabeculae that result in ventricular noncompaction. Some recent studies have shown that around 20-40% of these cases are familial. Genetically, it is heterogeneous and has two modes of inheritance – autosomal dominant and X linked recessive. Clinically, LVNC manifests as heart failure and fatal arrhythmias. The other feature which contributes to the triad of LVNC is systemic embolic events. LVNC is diagnosed with characteristic echo features and cardiac MRI findings. The degree of heart failure and ventricular arrhythmias both serve as strong independent mortality predictors.

CONCLUSION: This case presents to us an exciting opportunity to delve into family history for a patient who presents with new-onset heart failure at a relatively young age.

It also emphasizes the importance of genetic testing of family members.

IS THIS MULTIPLE MYELOMA

Nikhila Thammineni[1]; Apoorva Cheeti[1]; Shashank Cingam[2]. [1]Internal Medicine, University of New Mexico, Albuquerque, NM; [2]Hematology/Oncology, University of New Mexico, Albuquerque, NM. (Control ID #3376050)

LEARNING OBJECTIVE #1: Highlight that several hematologic malignancies can have similar presentation

LEARNING OBJECTIVE #2: Emphasize the significance of integrating findings and avoid treating individual abnormal results

CASE: A 55-year-old man with PMH of asthma, previous smoker was sent to the ED by his PCP for severe anemia. He reported fatigue, exertional dyspnea for a few months, denied fever, recent travel, unintentional weight loss, family history of hematologic malignancies. Medications included prn albuterol inhaler. Initial vitals were normal and examination showed conjunctival pallor. Labs revealed pancytopenia with Hb 4.7, MCV 112, WBC 2200, Platelets 73000, normal B12 and Folate, hyponatremia with a serum(Sr) Na 130 likely associated to paraproteinemia, Sr Cr 1.76, Sr calcium 7.7, AG <6, total Protein 14.5, albumin 2.1, positive IgG cold autoantibody, IgA 18, IgG 10,700, IgM 775, kappa 111, lambda 0.93 with a ratio of 119. Sr Protein electrophoresis showed M spike of 0.74 IgM and 8.71 IgG, urine Protein electrophoresis revealed M component 78 IgG kappa. Peripheral smear revealed normochromic, macrocytic, anisopoikilocytosis with NRBC, few tear drop cells, prominent rouleaux. Skeletal survey was negative. CT chest, abdomen showed splenomegaly with no lymphadenopathy. He received 2 units PRBC which improved Hb to 6.6. He continued to be pancytopenic with elevated Sr Cr and was discharged with an outpatient follow up for initiation of chemotherapy pending BM biopsy results with a presumptive diagnosis of Multiple myeloma(MM).

Later BM biopsy showed low grade B lymphoproliferative disorder with plasmacytic differentiation and a hypercellular marrow. Flow cytometry showed monoclonal B cell and plasma cell colonies. PCR was positive for MYD 88 L265p mutation, cytogenetics showed 6q deletion and isochromosome of 6p and a diagnosis of Lymphoplasmacytic Lymphoma(LPL) with IgG, IgM monoclonal proteins was made.

IMPACT/DISCUSSION: LPL is a low grade B cell tumor and commonly affects the bone marrow and spleen(Swerdlow SH, et al., 2008). 95% of LPL cases are IgM monoclonal gammopathy called Waldenstrom macroglobulinemia(Treon, 2009). However, non IgM LPL has a low incidence and often can be diagnosed preliminarily as a different hematologic malignancy when they have overlapping lymphoplasmacytoid features(Kang, Hong, & Suh, 2018). 4 of 8 non IgM LPL patients included in a study were primitively diagnosed as MM vs 14 of 14 IgM LPL patients who were rightly diagnosed(Kang et al., 2018). Differentiating LPL from MM may not always be possible with clinical presentation and routine work up alone and more sophisticated testing may be needed to arrive at a diagnosis as in our patient.

CONCLUSION: The overall survival and prognosis are poorer in the non IgM LPL compared to the IgM LPL(Kang et al., 2018) and hence it is prudent to include it in the differential when a patient presents with nonspecific symptoms like pancytopenia despite the lower incidence as early recognition helps with early treatment and possible better patient outcomes.

ITCHING FOR THE DIAGNOSIS: A UNIQUE CASE OF AMYLOID LIGHT-CHAIN AMYLOIDOSIS

Isabel C. Guerrido Martinez[1]; Frederick Rozenshteyn[1]; Joan Bosco[2]. [1]Internal Medicine, Mount Sinai Beth Israel, Brooklyn, NY; [2]Internal Medicine, Mount Sinai Beth Israel, New York, NY. (Control ID #3391783)

LEARNING OBJECTIVE #1: Recognize pruritus as a symptom of underlying systemic disease

LEARNING OBJECTIVE #2: Diagnose amyloid light-chain amyloidosis via laboratory tests and biopsy

CASE: A 60 year-old male with no significant past medical history presented with generalized itching and weight loss over the past month. He had no family history of cancer and no history of alcohol, tobacco or drug use. His physical exam was remarkable for multiple diffuse excoriations on the forearms, back, abdomen and legs with no evidence of infection, urticaria, or jaundice. Laboratory tests revealed hyperkalemia of 5.7 mmol/L, BUN of 52 mg/dL, creatinine of 2.14 mg/dL, albumin of 2.2 g/dL, alkaline phosphatase of 2142 U/L, AST of 122 U/L, ALT of 106 U/L and GGT of 3045 U/L. Urinalysis showed proteinuria and hematuria. Serum Protein Electrophoresis (SPEP) was performed and found to be positive for a monoclonal band. Serum Immunofixation test Electrophoresis (sIFE) showed IgG monoclonal lambda in gamma region. MRI showed a noncirrhotic liver with mild hepatomegaly and diffuse hypodensities in liver, spleen and bone marrow. The patient ultimately was evaluated by both gastroenterology and nephrology and underwent kidney and liver biopsies. The biopsies demonstrated amyloid nephropathy with light-chain AL lambda type deposition in both glomeruli and interstitium consistent with amyloid light-chain amyloidosis.

IMPACT/DISCUSSION: Pruritus is a very common complaint in the outpatient setting but can potentially represent an underlying systemic disease. It is important to have a broad differential diagnosis when evaluating patients with symptoms such as pruritus. Basic laboratory tests may help point towards the direction of a possible etiology. Monoclonal light-chains are responsible for a wide array of both renal and hepatic diseases, specifically amyloid light-chain amyloidosis where both kidney and liver involvement is a frequent finding. While amyloid light-chain amyloidosis has a wide spectrum of findings, some key renal manifestations include proteinuria, nephrotic syndrome and progresive renal failure. Ultimately, diagnosis of amyloid light-chain amyloidosis can be made via biopsy of an affected organ and will demonstrate amyloid light-chain deposits.

The prognosis of amyloid light-chain amyloidosis varies and depends on the extent of organ involvement. Therefore, continued follow up with laboratory monitoring and specialist consultation is crucial in managing this challenging disease.

CONCLUSION: 1. Pruritus is a common complaint that can potentially represent an underlying systemic disease. 2. Suspect amyloidosis as a possible diagnosis when both kidney and hepatic disease is present.

ITCHING TO KNOW: AN ELUSIVE CASE OF GENERALIZED ITCHING- SEZARY SYNDROME

Manisha Bhide[1]; Bradley Haverkos[2]. [1]Internal Medicine, University of Colorado Denver, Aurora, CO; [2]Dermatology, University Of Colorado, Aurora, CO. (Control ID #3384732)

LEARNING OBJECTIVE #1: Discuss different causes of common symptom like itching and present a rare case of persistent itching-Sezary syndrome

CASE: 61 year male presented to outpatient clinic with generalized itching of skin and redness all over the body since 3 years. He was frustrated since "I have seen so many doctors. No one can tell me the cause of my itching. I want to know." The itching was so bad that it was interfering with his life and his ability to do his ADLS. He was even contemplating suicide to get rid of the itch. He made many life style modifications to get rid of suspected allergens and had been using moisturizing lotion multiple times, but it was not helping. He complained of diffuse pain associated with skin disease worst in his hands.

Exam revealed a distressed patient with normal vitals who was scratching his body constantly and was unable to sit still. Skin exam showed dry skin with diffuse erythematous macular rash covering > 90 % of body surface area. Systemic exam was otherwise normal.

I evaluated him in the clinic and ordered labs and XR of hands. Labs ruled out polycythemia. Thyroid, ferritin, Liver, kidney function, uric acid was normal. ANA panel was negative. Tryptase which shows mast cell activation was normal. Serum Ig E was normal. HIV, Hepatitis B and C were negative.

XR hands showed mild osteoarthritis. Peripheral smear showed high monocytes to 1.5. (Ref. range0.2 - 0.9 10*9/L) Pt was referred to Hematologist for high monocytes and to dermatologist for biopsy. CT scan chest, abdomen, pelvis showed groin and axillary lymphadenopathy and enlarged liver at 18 cm.

Biopsy showed atypical lymphocytes with epidermotropism. The same clonal population of T-cell identified in the blood were also identified in this skin sampling, supporting the diagnosis of Sezary syndrome.

He was seen by multidisciplinary clinic and started on Targretin and ECP for the newly diagnosed Cutaneous T cell lymphoma.

His rash and pruritis have significantly improved since starting therapy. He is happy that he knows the cause of the itching.

IMPACT/DISCUSSION: The differential diagnosis for generalized chronic itching with erythroderma and exfoliation can be hypothyroidism, diabetes, polycythemia, cirrhosis, renal failure, neurogenic causes, Systemic Sclerosis, hemochromatosis, psoriasis. But in this patient all of those were ruled out with tests. The one that should not be forgotten is a cutaneous T cell lymphoma especially the subtype Sezary syndrome.

CONCLUSION: Mycosis fungoides and the Sezary syndrome (SS) are rare lymphomas of CD4+ helper T cells. There is stage wise progression from patch or plaques to thicker tumor lesions diffuse erythroderma. Blood involvement is a characteristic of Sezary Syndrome. Outcomes are related to the extent of skin, blood, lymph node, and visceral organ involvement. Patients with limited patch and plaque disease are treated with skin-directed therapies. More advanced or refractory disease is treated with skin-directed therapies and oral or systemic immunomodulatory agents.

IT'S GETTING HOT IN HERE: DETERMINING THE CAUSE FOR PERSISTENT FEVER IN AN IMMUNOCOMPROMISED PATIENT

Yili Zhao[1]; Xiaohui Wang[2]; Amy Kwon[2,4]; Alice Tang[3]. [1]Medical Student, Weill Cornell Medicine, New York, NY; [2]Medicine, Weill Cornell Medicine, New York, NY; [3]Medicine, Weill Cornell Medical College, New York, NY; [4]Medicine, OHSU, Portland, OR. (Control ID #3360688)

LEARNING OBJECTIVE #1: Recognize risk factors and morbidity associated with tuberculosis in HIV patients

CASE: A 28-year old Vietnamese man who has sex with men, with recent diagnosis of AIDS, on antiretroviral therapy (ART), presented to the hospital with 1 month of fevers associated with headaches, night sweats, anorexia, and diarrhea. He was born in Vietnam but moved to the United States 2 years prior to presentation for work.

On admission, his vitals were within normal limits, except for a heart rate of 120. Physical exam was notable for clear lung fields, tenderness in the right lower quadrant, and a positive Rovsing sign. HIV viral load was 97 and CD4 count was 63. CT scan revealed diffuse pulmonary nodules in a millet-seed like distribution and a necrotic mass adjacent to the cecum. Sputum smear for acid-fast bacilli and nucleic acid amplification testing confirmed a Mycobacterium tuberculosis infection.

The patient was started on piperacillin-tazobactam for the necrotic abdominal mass and isoniazid, rifampin, pyrazinamide, ethambutol, and levofloxacin for resistant mycobacterium strains. However, he continued to spike daily fevers. Cerebrospinal fluid revealed elevated protein, low glucose, and mononuclear pleocytosis, and MR brain showed leptomeningeal enhancement in the left sylvian fissure and right temporal and occipital lobes, suggestive of TB meningitis. Given his recent initiation on antiretroviral therapy, immune reconstitution inflammatory syndrome (IRIS) was also suspected. Dexamethasone was started and his symptoms abated within 24 hours.

IMPACT/DISCUSSION: This was an AIDS patient with disseminated TB, manifesting with miliary TB, TB meningitis, and a necrotic colonic tuberculoma, with persistent fevers despite broad antimicrobial coverage. Despite exposure to a TB-endemic region, he was not screened for TB at the time of his HIV diagnosis. Screening for latent TB is recommended at the time of initial HIV diagnosis with either tuberculin skin test or interferon gamma release assay. With a CD4 count below 100, he was at increased risk for disseminated TB and TB meningitis, which is associated with severe neurological sequelae and high mortality (up to 41%). He was also at high risk for TB-IRIS given his disseminated TB infection, high HIV viral load at diagnosis, and low CD4 count. There are two forms of TB-IRIS: paradoxical (TB treatment before ART) and unmasking (no TB treatment before ART). Corticosteroids are recommended to treat severe cases of unmasking TB-IRIS, as in our patient. Use of corticosteroids also reduces short-term mortality by nearly a quarter in patients with TB meningitis, although data in HIV patients are limited.

CONCLUSION: The severity and rapid progression of this patient's infection illustrates the importance of TB screening in HIV patients at the time of their HIV diagnosis. AIDS patients are at greater risk for TB meningitis and TB-IRIS, which confer high morbidity and mortality. Corticosteroid administration can decrease mortality in both of these conditions.

IT'S NOT ALWAYS A STRAIN: HIP PAIN DUE TO PSOAS ABSCESS IN A PATIENT WITH CROHN'S DISEASE

Carli Deitel[1]; Ryan Whiting[2]; Caleb Hudspath[3,1]; Allison Bush[3,1]; Anita Bhushan[3,1]. [1]Internal Medicine, Walter Reed National Military Medical Center, Bethesda, MD; [2]Radiology, Walter Reed National Military Medical Center, Bethesda, MD; [3]Gastroenterology, Walter Reed National Military Medical Center, Bethesda, MD. (Control ID #3391620)

LEARNING OBJECTIVE #1: Recognize small bowel Crohn's disease is insidious, and can present as isolated complications of penetrating disease.

CASE: A 45-year-old active duty male soldier with chronic low back pain and history of Crohn's disease, requiring small bowel resection at the time of diagnosis, presented to his primary care physician for right hip pain. The patient was on mesalamine for several years, however, was switched to adalimumab after a flare up last year requiring hospitalization. He had not followed up with his gastroenterologist since starting adalimumab. An initial hip x-ray was negative and he was subsequently treated for a strained hip flexor with physical therapy and dry needling. Three months after his initial visit, he returned to the clinic with persistent hip and low back pain as well as an inguinal hernia. An ultrasound was done to evaluate the inguinal hernia, incidentally showing an inflamed tubular structure in the right hemi-abdomen. A subsequent computed tomography scan showed extensive ileocecal inflammation with fistulization and a 17 cm long right psoas abscess. He was then admitted to the hospital and started on empiric antibiotics and total parenteral feeding.

A magnetic resonance enterogram 4 weeks later showed a resolving psoas abscess and residual stricture of the terminal ileum. The patient underwent an ileocecectomy without complications and has been doing well at post-operative follow up.

IMPACT/DISCUSSION: This case illustrates the complications and insidious nature of small bowel Crohn's disease. While classic symptoms of Crohn's disease remain diarrhea, abdominal pain, weight loss, and fever; penetrating disease is known to fistulize and seed abscesses. Indeed, psoas abscesses are a well- documented complication of Crohn's disease. However, they are often plagued by delayed diagnosis, causing increased morbidity. It is important for primary care providers to recognize isolated hip pain as a presentation of penetrating Crohn's disease complicated by a psoas abscess.

CONCLUSION: Hip pain can be easily overlooked in a primary care clinic inundated with routine musculoskeletal concerns. Therefore, a high index of suspicion must be maintained for complications of penetrating Crohn's disease, such as a psoas abscess presenting as isolated hip pain.

IT'S NOT JUST A YOUNG MAN'S GAME

Nicholas Sassen. Medicine, Tulane University School of Medicine, New Orleans, LA. (Control ID #3391298)

LEARNING OBJECTIVE #1: Recognize the risk factors of E-cigarette or Vaping Associated Lung Injury (EVALI)

LEARNING OBJECTIVE #2: Distinguish patient populations with severe forms of EVALI

CASE: A 71-year-old man presented with 10 days of worsening dyspnea. He experienced fevers, intermittent pleuritic chest pain, nausea, and weight loss of 10 pounds. He had used marijuana for 45 years and 3 years ago began using a THC vaporizer 3-4 times per day. Temperature was 38°C, heart rate was 118 beats per minute, respiratory rate was 35 breaths per minute, and an oxygen saturation was 84% on room air. He was in respiratory distress, using accessory muscles to breathe. Lungs sounds were coarse diffusely with inspiratory crackles. Exam was otherwise normal. He initially required high flow oxygen. A chest CT demonstrated diffuse bilateral ground glass opacities. White blood cell count was 18,000 cells per cubic millimeter but infectious evaluation including respiratory and blood cultures, urine Legionella and Pneumococcal antigen, respiratory viral panel, and HIV screening were negative. Rheumatologic work-up including anti-nuclear antibodies, rheumatoid factor, anti-neutrophilic antibodies were negative. With other plausible etiologies ruled out in the setting of heavy vaporized THC use, he was diagnosed with EVALI. He was treated with high dose steroids and symptoms improved. After 3 weeks, he was discharged on 3 liters of supplemental oxygen and a steroid taper.

IMPACT/DISCUSSION: Vaping products were initially introduced in the U.S. in 2007 and are becoming increasingly popular, particularly among youths. EVALI is an interstitial lung disease related to vape product use. As of October 22, 2019 there have 1,604 cases and 34 deaths in the United States. The majority of patients afflicted by this condition are young white males, with a median age of 25-years-old. The majority of mortality in EVALI cases occurred in older individuals with a median age of 45-years-old. Being over 50-years-old was the worst prognostic indicator

identified with 54% of these individuals requiring intubation and a mean inpatient stay of 15 days. Other groups had an intubation rate of 25% with mean inpatient stay of 8 days. Clinical presentation includes respiratory, gastrointestinal, and constitutional symptoms.

EVALI is mainly associated with THC-containing vape products. Nearly all patients with the condition report use of these products, while only about 10% report use of nicotine-containing products alone. Over 90% of patients obtained THC containing products from unregulated source. There is still no definitive cause of EVALI. A study of patient bronchoalveolar lavage samples showed vitamin E acetate, a thickening agent in THC products, was the only substance detected in all samples.

CONCLUSION: Younger individuals, who are more likely to use this product, are at the highest risk, but older patients tend to demonstrate more severe disease. Preventative counseling is of particular importance given that no definitive treatment has been established for EVALI.

I'VE FORGOTTEN HOW TO WRITE A TITLE

Rebecca Ramm, Hanyuan Shi, Laura Johnson, Jerald L. Taggart. Medicine, Tulane University, New Orleans, LA. (Control ID #3391288)

LEARNING OBJECTIVE #1: Build a differential for rapidly progressive dementia.

LEARNING OBJECTIVE #2: Recognize the diagnostic criteria of sporadic Creutzfeld-Jakob disease.

CASE: A 65-year-old woman presented with status epilepticus and hypertensive emergency. Seizure was aborted and blood pressures lowered. Mental status did not return to baseline. She had been admitted for similar presentations in the last six months with recovery of mental status and blood pressure. Her family also reported progressive forgetfulness and personality changes. She developed akinetic mutism and rigidity in her upper extremities and was found to have an ataxic gait. She had no meningeal signs. Urine drug screen was negative. She had an ESR 119, CRP 8.5, and serum WBC 8.8. Aldosterone/renin ratio was normal. Cerebrospinal fluid (CSF) returned with white blood cells 0, red blood cells 0, glucose 127, and protein 49. CSF paraneoplastic and vasculitis antibody panels, West Nile virus, and VRDL, and culture were negative. EEG exhibited no further epileptiform activity. MRI of the brain revealed evidence of decreased perfusion in the right posterior cerebral artery territory. Her mental status continued to decline. She became less responsive, lethargic, and eventually expired. CSF studies later revealed a tau protein >4000, positive 14-3-3 protein, and negative real time quaking- induced conversion (RTQuIC).

IMPACT/DISCUSSION: Dementia is commonly diagnosed and managed by the general internist. It is normally a slow, progressive process that occurs over many years and treatments aim to delay this decline. Conversely, rapidly progressing dementia (RPD) commonly occurs over the span of several weeks to months. Ongoing atherosclerotic or thromboembolic disease can cause rapid worsening of vascular dementia. Untreated depression can cause of a "pseudo-dementia" symptoms. Recurrent seizure or non-convulsive status epilepticus can contribute to progressive dementia. Deficiencies of B12 or thiamine, autoimmune vasculitis or cerebritis, cancer metastatic to the brain, neurosyphilis, and exposure to toxic substances must also be considered.

The most feared causes of RPD given lack of treatment options are the prion diseases. Prions are neurodegenerative proteins that may be sporadic, inherited, or transmissible. Sporadic Creutzfeld-Jakob disease (CJD) is an example of a prion disease that can cause rapidly progressive dementia. The gold standard in diagnosis of sporadic CJD is neuropathology from brain biopsy, however one of two scenarios outlined below is sufficient to qualify for a clinical diagnosis of sporadic CJD:

1. Neuropsychiatric disorder with positive RTQuIC

2. Progressive dementia PLUS two of four - myoclonus, visual/cerebellar disturbance, pyramidal/extrapyramidal dysfunction, and akinetic mutism PLUS supportive evidence on either EEG, MRI, or CSF 14-3-3.

CONCLUSION: RPD have a limitted differential diagnosis. Systematic investigation may yield the rare diagnosis of CJD.

I'VE GOT YOU UNDER MY SKIN: A CASE OF CHLAMYDIA PNEUMONIAE INDUCED RASH AND MUCOSITIS (CIRM)

Meera Bhakta[2]; Meghana Gadgil[1]. [1]Population Health & Internal Medicine, Dell Medical School, Austin, TX; [2]Internal Medicine, University of Texas at Austin - Dell Medical School, Austin, TX. (Control ID #3387391)

LEARNING OBJECTIVE #1: Recognize newly-described mucocutaneous complications of Chlamydia pneumoniae infection.

CASE: A 19M with no significant PMH presented with a two-week history of progressively worsening intraoral, ocular, and genital ulcerations. The patient had initially developed sinus congestion, rhinorrhea, and bilateral edematous conjunctiva, for which he was prescribed amoxicillin and pseudoephedrine at urgent care. Four days later, he presented to a dentist with swollen lips, intraoral mucosal ulcerations, and odynophagia. Treatment with lidocaine mouthwash, steroids, and trimethoprim-sulfamethoxazole eventualized mild improvement. A week prior to admission, the patient developed daily fevers between 101-103F and had worsening oral ulcerations. The day prior to admission, the patient developed new genital rashes with dysuria. He presented to urgent care, where he was given valacyclovir and fluconazole, but came to our ER when he continued to deteriorate overnight.

Family history was negative for autoimmune disease, and the patient denied tobacco, alcohol, or drug use. He worked as a lifeguard, in a fresh-water and a chlorinated pool. He had one monogamous sexual partner with whom he used condoms consistently. The patient reported his latest sexually activity was two weeks prior to admission. He denied a history of STIs. During admission, the patient's workup was negative for HIV, C. trachomatis, gonorrhea, and HLA-B27. His chest x-ray was unremarkable. Dermatology biopsied an oral lesion, and the patient was started on azithromycin empirically. The patient's HSV-1 IgM was positive, but the vesicular biopsy was negative for HSV by PCR. His respiratory mucosal swab was positive for Chlamydia pneumoniae by PCR. These results led to the diagnosis of Chlamydia pneumoniae induced rash and mucositis (CIRM). The patient was treated with moxifloxacin and discharged home.

IMPACT/DISCUSSION: CIRM is a new syndrome in the international literature that describes the muco- cutaneous sequelae of Chlamydia pneumoniae infection. This is the second reported case of CIRM and the first in an adult. A related entity, Mycoplasma pneumoniae induced rash and mucositis (MIRM), has been recently described as similar to erythema multiforme and Stevens-Johnson syndrome. The pathophysiology of CIRM is thought to involve polyclonal B-cell activation and antibody production. Cases of CIRM have been reported with HSV co-infection, requiring treatment of both pathogens. However, the immune reactivation in CIRM may lead to false positive diagnoses of viral co-infection from immunoassay alone.

This patient had a positive HSV serology, but confirmatory testing with PCR was negative for HSV infection. This case contributes to our understanding of these newly described muco-cutaneous sequelae of C. pneumoniae.

CONCLUSION: CIRM is a newly described syndrome of muco-cutaneous sequelae of Chlamydia pneumoniae infection associated with immune reactivation.

JANE DOE: A VICTIM OF HUMAN TRAFFICKING

Justin B. Roy[1]; Nitasa Sahu[1]; Reshma R. Golamari[2]; Rohit Jain[1]. [1]Internal Medicine, Hershey Medical Center, Hershey, PA; [2]Internal Medicine, Penn State Health Milton S Hershey Medical Center, Hershey, PA. (Control ID #3385078)

LEARNING OBJECTIVE #1: Recognize red flags of a victim of human trafficking once access to medical care is sought

LEARNING OBJECTIVE #2: Identify risk factors for victims of human trafficking

CASE: A presumed 18-year-old African American female was brought in by police after finding her on the corner of a street partially dressed. Initially, the patient only spoke nonsensically to an imaginary being. Upon arrival to the emergency department, basic labs only revealed a very low TSH (<.01) and a positive BHcG. Twin pregnancies were confirmed and she was admitted for further care where she only participated with her name and knew that she was pregnant. The next morning, she had no recollection why she was brought into the hospital and provided inconsistent stories to staff. She also did not know where she was staying as it was paid for by her boss and did not have any ID/phone with her. She did provide details as to where she was employed and two bosses' names that were contacted. As time progressed, more information included a history of sexual trafficking, drug and alcohol use, as well as posttraumatic stress disorder for which she detained details. Resources were contacted for further assistance as well as local and federal authorities to correctly identify the patient and possible involvement in sex/labor trafficking. It was discovered the patient was transported from another state as she was homeless after running away from her family. This company she worked for provided her the opportunity to sell merchandise to make money. The patient was fearful of being discharged without obtaining her belongings, of which she possessed a check that was earned by prostitution because her sales were poor that day. Through a multidisciplinary approach involving the local/federal authorities, social worker, hospital security, and hospital administration, the patient was safely escorted out of the hospital to obtain her belongings and transported to a women's shelter who eventually flew her home to her parents.

IMPACT/DISCUSSION: Human trafficking is forced labor or commercial sex using manipulation into thinking they would have a better life, however, once they oblige to the responsibilities, their identity is removed. Through fear, control and disempowerment, victims find it very difficult to leave the organization. Victims may have posttraumatic stress disorder, paranoia, depression, not know where they are or have any sense of time, show signs of medical neglect, and be reluctant to speak for themselves. Vulnerable victims include those coming from developing countries, resource-poor areas, homelessness, dysfunctional families, have an involvement with substance abuse, and/or have a mental illness.

CONCLUSION: Victims of human traffickers are very difficult to identify unless clinicians deep dive into their social history, physical exam, and work with a multidisciplinary team. Multiple resources exist in reporting any suspicion for human trafficking including the National Human Trafficking Hotline and local community resources.

KEEP AN EYE OUT (AND DOWN) FOR GLUCOSE

Rodolfo Villarreal-Calderon. Internal Medicine, Boston Medical Center, Boston, MA. (Control ID #3392049)

LEARNING OBJECTIVE #1: Evaluate an oculomotor nerve palsy, recognizing multiple etiologies, higher risk features, and prognosis.

LEARNING OBJECTIVE #2: Recognize limited English proficiency Hispanic patients have linguistic and cultural barriers which may lead to poorer diabetic control, especially if with a non-Spanish speaking provider.

CASE: A 50 year-old Spanish-speaking male with hypertension and diabetes type 2 presented to clinic with worsening blurred vision, right sided ptosis and bilateral periorbital headache for the past week. In the emergency department, CBC and BMP were normal except for glucose 429. Computerized tomography angiography (CTA) revealed a 3mm right internal carotid aneurysm.

He denied family history of aneurysm or intracranial hemorrhage. He was unable to recall his prescribed insulin types or antihypertensives. Blood pressure was 163/78 and was neurologically intact except for right pupil-sparing oculomotor nerve palsy (OMNP). C-reactive protein 6.9 and hemoglobin A1c 12.4%. Headache resolved with Acetaminophen. Neurosurgery did not recommend surgical intervention given the small size. His OMNP significantly improved in the next two months and was ascribed to poorly controlled diabetes.

IMPACT/DISCUSSION: Neuropathy is expected as one neurological diabetic manifestation yet cranial nerve palsy is not readily considered. Aneurysm is an urgent condition that can present as cranial nerve palsy, therefore higher risk features are valuable triage tools.

OMNP should first be categorized by pupil involvement. Non-pupil sparing (unopposed dilatation and loss of accommodation) may be an ominous sign, usually attributable to compressive etiologies such as aneurysm or tumor, given the affected pupillomotor fibers are found on the superficial portion of the third cranial nerve. Most pupil-sparing etiologies are from microvascular ischaemic disease—namely diabetes or hypertension. Headache or periorbital pain is not discerning of compression. There is lower threshold for imaging (CTA or magnetic resonance angiography) younger patients (20 to 50 years old) lacking microvascular comorbidities as pre-test probability of aneurysm is increased.

One percent of diabetic patients will have a cranial nerve palsy—approximately 40% as OMNP. Prognosis is favorable, with progressive resolution occurring over 2 to 3 months.

Diabetic control is key and his limited English proficiency (LEP) is of special significance. Cross-sectional studies have found no difference between Hispanic and White populations in glycemic control, but considered language concordance as a possible factor reducing the difference. A retrospective study found glycemic control significantly improved in switching to a Spanish speaking provider.

CONCLUSION: Diabetic neuropathies can involve cranial nerves, resolving in two to three months. Aneurysmal OMNP is more likely to impair the pupil. Providers' ability to speak their patient's language is of value and can have concrete health benefits, such as better controlled diabetes

LESSONS LEARNED FROM CAMP IN NORTH CAROLINA

James D. Baker[1]; Jacob Schulman[1]; Max Harris[1]; Daniel Pohlman[2]; Susan B. Glick[3]. [1]Rush Medical College, Rush University Medical Center, Chicago, IL; [2]Internal Medicine, Rush University Medical Center, Chicago, IL; [3]Internal Medicine, Rush Medical College, Chicago, IL. (Control ID #3391254)

LEARNING OBJECTIVE #1: Recognize the importance of taking a military history

CASE: A 52yo male presented with intermittent fever for 1 year. Fevers occurred with rigors and night sweats 7-9 days each month. He also had headache, rhinorrhea, hearing loss, nausea, and diarrhea. The patient was first seen at a local clinic and worked up for chronic sinusitis. He was referred to an ENT specialist, infectious disease expert, and an oncologist. All could not identify the cause of his fevers.

He had a history of hypercholesterolemia and binge alcohol use, and was on doxycycline. He was a police officer, lived with his wife, and was a veteran. The physician took a military history. The patient had served in the Marines and was stationed at Camp Lejeune from 1985-89.

On exam, he appeared chronically ill. BP 124/80, HR 118, and T 99.3°F. HEENT, cardiac, abdominal, and extremity exams were normal. Neuro exam was significant for bilateral hearing loss. There were no palpable lymph nodes or rashes.

Blood work showed Hgb 12.9, wbc 3.8, platelets 92, Na 125, BUN 23, Cr 1.09. Albumin 3.2, ALT 68, AST 62, LDH 507, ESR 58, CRP 206.3, ferritin 18,499.

He was admitted. CT of the chest revealed enlarged mediastinal and hilar lymph nodes. PET CT revealed diffuse, mild heterogeneous uptake in the skeleton without hypermetabolic nodes. Bone marrow biopsy confirmed Hodgkin Lymphoma.

IMPACT/DISCUSSION: This patient was stationed at MC Base Camp Lejeune in the late 80s. From the 1950s-80s, the water supply at Camp Lejeune was contaminated with several industrial solvents. Exposure to this water has resulted in a variety of cancers and illnesses. The patient had received notice from the Marines about these health risks, but it took over a year until the patient was finally asked about his military history. Using both clinical data and military history, we began to suspect malignancy, ultimately leading to diagnosis.

Veterans are at risk for many health conditions, including hazardous chemical exposures. Recently, sarin gas exposure has been linked to chronic heart disease in Gulf War veterans. Many long-term effects of pollutant exposures are still unknown. Initial symptoms can manifest years after exposure, indicating that a thorough military history is critical for accurate diagnosis.

Due to their complex healthcare needs, identifying patients who are veterans is critical to their care. A common misconception is that veterans only receive care at the VA. However, more than 50% of veterans receive care outside the VA. This number is likely to increase due to the 2014 Veterans Choice Act, which allows veterans more choice in providers. All patients should be asked about military history to ensure all veteran patients are identified.

CONCLUSION: Veterans are at risk for a variety of conditions, including hazardous chemical exposures

A military history can assist with clinical decision making

All patients should be asked about prior military service since many veterans receive care outside the VA

LEUKOCYTOSIS INTERPRETED THREE WAYS: CLL VS B-PLL VS RICHTER'S TRANSFORMATION

Lesley Wu[1]; Lindsay Hammons[1]; Ryan Leibrandt[1]; Bo Wang[2]. [1]Internal Medicine, Mount Sinai Beth Israel, Manhattan, NY; [2]Hematology Oncology, Mount Sinai, New York, NY. (Control ID #3392215)

LEARNING OBJECTIVE #1: Recognize the difference between chronic lymphocytic leukemia and B-cell pro-lymphocytic leukemia

LEARNING OBJECTIVE #2: Anticipate Richter's transformation in a patient with new presentation of leukocytosis

CASE: A 73 year old man with 80 pack year smoking history presented with one month of lower extremity edema and one week of generalized weakness and dyspnea. He had intermittent fevers and mechanical falls.

A few hours after ED visit, he developed septic shock and required vasopressors. Laboratory findings showed WBC 582 K/uL with lymphocytic predominance, hemoglobin 7.5 g/dL, platelets 44 K/uL, and LDH 3,000 U/L. CT chest, abdomen, and pelvis was notable for splenomegaly and para-aortic lymphadenopathy.

Peripheral smear demonstrated 70% immature blastic cells with prominent nucleoli and loose chromatin. Flow cytometry of peripheral blood showed CD20+, CD19+, CD22+, kappa+, FMC7+, CD5+, as well as lambda-, CD10-, CD23-, CD38-, and CD34-, favoring a diagnosis of B-cell prolymphocytic leukemia (B- PLL). Due to the high risk of CNS and pulmonary complications from leukostasis, dexamethasone was initiated followed by hydroxyurea and leukapheresis, resulting in a 90% reduction in WBC to 33 K/uL. He was subsequently able to be weaned off vasopressors.

Bone marrow biopsy revealed two distinct cell types: small lymphocytes with mature clumped chromatin typical for CLL and larger atypical lymphocytes with open chromatin and prominent nucleolus typical of prolymphocytes. Cytogenetics reported interphase FISH consistent with 90% cells showing one copy or loss of TP53 (17p13.1). Overall, the data seemed most consistent with CLL and Richter's transformation (RTF) to B-PLL rather than CLL or B-PLL alone. Rituximab was started but later changed to Ventoclax due to hypotension.

IMPACT/DISCUSSION: CLL is the most common form of adult leukemia in Western countries and is often the initial morphologic impression in cases of leukocytosis. Although CLL has CD5+ and CD23+ co-expression, this case instead showed CD5+, CD23-, and FMC7+ with abnormalities of TP53 gene, which instead favors B-PLL, carrying a poorer prognosis than CLL alone. Bone marrow biopsy that demonstrates two cell types, small CLL lymphocytes and a majority of larger atypical B cell prolymphocytes, suggest a RTF. This involves the development of a post-chronic, secondary aggressive leukemia that is usually less responsive to therapies compared to B-PLL. It is important to note that in cases of acute leukostasis, hydrea followed by leukapheresis can aid in stabilizing hemodynamics.

CONCLUSION: Acute leukocytosis with >55% immature B-cell prolymphocytes, presence of CD23- or CD5- or FMC7+ on flow cytometry, and TP53 gene abnormalities should prompt investigation of B-PLL. Bone marrow biopsy demonstrating two cell lines consisting of small lymphocytes with mature chromatin and large atypical lymphocytes with open chromatin correlates with RTF of CLL to B-PLL, conferring poorer prognosis than either diagnosis separately.

LIFTING THE ANCHOR: HOW RISING LIVER ENZYMES PROMPTED RE-EVALUATION OF AN HIV-ASSOCIATED FUO AND SHATTERED ANCHORING BIAS

Alexandra G. Selby[1]; Jill Allenbaugh[2]. [1]Internal Medicine, Temple University Hospital, Philadelphia, PA; [2]Medicine, Lewis Katz School of Medicine at Temple University, Philadelphia, PA. (Control ID #3383277)

LEARNING OBJECTIVE #1: Define the elements of HIV-associated fever of unknown origin (FUO). **LEARNING OBJECTIVE #2:** Cite the importance of actively seeking additional diagnostic clues to avoid anchoring bias.

CASE: A 34-year-old man with a past medical of HIV/AIDS (CD4+ unknown) on intermittent HAART presented with a 1-week history left sided facial numbness, blurred vision in his left eye, intermittent headaches, and neck stiffness as well as a 1-month history of unintentional weight loss and nights sweats. A CT head with contrast demonstrated no

acute abnormality. A lumbar puncture (LP) was performed and the patient was initiated on empiric antimicrobial therapy due to concern for meningitis. LP results returned the morning after admission with only minimal alterations in glucose and protein, prompting discontinuation of antimicrobial therapy. Within hours, the patient began to develop persistent fevers, at which time antimicrobial therapy was re-initiated and an extensive yet unrevealing infectious workup commenced without resolution of the patient's fevers. After several days of unsuccessful treatment of the presumed infection and continued fevers, rising liver enzymes prompted the team to re-evaluate the full clinical situation and look beyond his HIV status. CT abdomen/pelvis with contrast demonstrated confluent adenopathy concerning for lymphoproliferative disease, and CT chest with contrast noted scattered pulmonary nodules. Percutaneous liver and lymph node biopsies demonstrated non-caseating granulomas, at which time lymphoma and sarcoidosis were moved higher on the differential diagnosis.

IMPACT/DISCUSSION: Infection accounts for ~ 80% of HIV-associated FUOs. As such, practitioners often first consider infectious etiologies as the cause of a patient's HIV-associated FUO, yet malignancy (namely lymphoma) and autoimmune conditions represent important causes of HIV-associated FUOs. These cannot afford to go unrecognized, as the treatment modalities are vastly different. The temporal relationship to the discontinuation of antimicrobial therapy and onset of fevers cemented the anchor that the etiology of the patient's HIV-associated FUO was infectious in nature despite the lack of improvement with antimicrobial therapy. Only on further investigation was the concern for underlying lymphoma or autoimmune conditions such as sarcoidosis carefully considered. This case underscores the importance of actively acknowledging discordant data (in this case, rising liver enzymes) and challenging anchoring bias in an attempt to make a prompt diagnosis and deliver expedient and appropriate therapy.

CONCLUSION: -Infectious etiologies account for the majority of HIV-associated FUOs; however, malignancy and autoimmune conditions are important causes of HIV-associated FUOs that must be carefully considered in the differential diagnosis, as the treatment modalities are vastly different.

-Practitioners must actively seek out additional diagnostic clues to challenge anchoring bias, make a prompt diagnosis, and deliver appropriate therapy.

LITHIUM INDUCED LEUKOCYOTOSIS: A RED HERRING

Ajinkya Kulkarni[1]; Mrunal Kulkarni[1]; Rithikaa Ellangovan[1]; Rajesh Thirumaran[2]. [1]Internal Medicine, Mercy Catholic Medical Center, Yeadon, PA; [2]Mercy Catholic Medical Center, Darby, PA. (Control ID #3391881)

LEARNING OBJECTIVE #1: Lithium has been used for treatment of psychiatric disorders for more than 70 years and has been a cornerstone for long-term treatment of bipolar disorder. Lithium has been associated with diverse hematologic changes, most consistent being leukocytosis. Lack of awareness of these findings may result in unwarranted patient workup and prolonged hospitalization.

CASE: 60 year old male with a past medical history significant for bipolar disorder presented with facial swelling involving almost the entire left side of the face with extension to the external auditory canal. WBC count on admission was 28.6 thou/ul and was attributed to the cellulitis. Patient was started on broad spectrum antibiotics and underwent debridement of external auditory canal. Patient improved clinically. However, WBC count remained elevated greater than 20 thou/uL even though no other source of infection was found. Detailed retrospective review of charts revealed consistently elevated WBC counts on previous admissions in the absence of infection as well. Patient was noted to be on lithium for at least 5 years, and this persistent elevation in WBC count was attributed to the use of lithium.

IMPACT/DISCUSSION: Treatment with lithium has been shown to result in leukocytosis predominantly neutrophilia, increased platelet count and increased circulating CD34+ hematopoietic stem cells. Lithium causes neutrophilia by enhancing the phosphorylation of glycogen synthetase kinase 3 (GSK 3) and increasing hypoxia induced factor-1 (HIF-1). Patients treated with lithium usually have mature granulocytes without a significant shift to the left. WBC elevation occurs by the end of 4 weeks in almost all hematologically normal patients ingesting lithium. Increment in WBC count is not generally proportional to blood lithium levels, however usually noted when serum lithium levels are between 0.4 and 0.7 mmol/l. This leukocytosis is usually self-limiting and should not be treated aggressively. Stopping lithium is not the appropriate step in patients who have been on it chronically and it is recommended that lithium be continued. Lithium has also been successfully used as an augmentation strategy in patients with a partial response to clozapine and to prevent clozapine-associated neutropenia.

CONCLUSION: The take-home message from this case is that, in patients who are chronically on lithium, the presence of a high WBC count alone should be co-related clinically to rule out infection. Lithium therapy should not be abruptly stopped as it can result in worsening of pyschiatric symptoms.

LIVING IN THE CREEKS

Tammy Chuang[1]; Krisha Desai[1]; Bhavin Adhyaru[2]. [1]Internal Medicine, Emory University, Atlanta, GA; [2]General Medicine, Emory Unviersity, Atlanta, GA. (Control ID #3389915)

LEARNING OBJECTIVE #1: Diagnose and treat pathogenic waterborne infections

LEARNING OBJECTIVE #2: Recogize social determinants of health in at-risk patients

CASE: A 53 year-old male presents with left lower leg pain for 1 day. He reported being incarcerated for the past 2.5 years, was released 1 week prior, and was now homeless and living near a creek. He reported bathing in the creek when he felt a sharp pain in his left leg. Past medical history was notable for hypertension, polysubstance use, and decompensated cirrhosis secondary to chronic hepatitis B and alcohol use disorder.

On admission, temperature was 36.7 C, blood pressure was 96/50, heart rate was 107, and oxygen saturation was 97% on room air. His left thigh was edematous, erythematous and tender to touch, and he had pustular bullae to his left foot. Laboratory evaluation revealed a white blood cell count of 9.2 and lactic acid of 4.6. CT of the affected leg revealed extensive soft tissue edema involving the thigh and lower leg suggestive of cellulitis or myositis, devitalized tissue of the left foot, and no drainable abscess. He was treated with vancomycin, piperacillin-tazobactam, and doxycycline for presumed sepsis and he underwent incisional debridement of the foot. Tissue culture revealed *Aeromonas hydrophila* and blood cultures grew *Plesiomonas shigelloides*.

IMPACT/DISCUSSION: Cellulitis is a bacterial skin infection and a condition commonly encountered by internists. β-Hemolytic streptococcus and staphylococcus species are the most common causative organisms. However, in patients with limited access to clean water, rare organisms underlie bacteremia and cellulitis

Plesiomonas shigelloides is a gram-negative bacillus that inhabits aquatic environments like freshwaters and estuaries. It has primarily been linked with gastrointestinal symptoms, especially in those who have consumed raw seafood or are exposed to contaminated water. The most common extra-intestinal manifestation of *Plesiomonas shigelloides* is bacteremia, though it is a rare culprit for septicemia with only about 40 recorded cases,

mostly in patients with underlying HIV, cancer, cirrhosis, or sickle cell anemia. Similarly, *Aeromonas hydrophila*, a gram-negative rod bacterium, is also widely distributed in aquatic environments and most commonly causes diarrheal symptoms after contact with contaminated water, but can have extra-intestinal manifestations as well. Wound infections from *Aeromonas* often lead to cellulitis, and invasive infections are more likely to occur in those with liver cirrhosis, malignancy, or immunocompromised states. Interestingly, there are no recorded cases of soft tissue infections from *Plesiomonas* despite it also being an aquatic pathogen.

CONCLUSION: This case highlights the inextricable link between housing and health outcomes. Lack of housing or clean drinking water made our patient susceptible to these infection with atypical organisms. Addressing health care needs of our patients must address socioeconomic disparities, including access to housing.

LOCKED UP AND LOCKED OUT OF DECISION MAKING

Anna M. Munoa[2,1]; Philip Fung[2,1]; Barbara Statland[2,1]; Erin Ellquist[3]. [1]Internal Medicine, University of Colorado School of Medicine, Denver, CO; [2]Internal Medicine, Denver Health Medical Center, Denver, CO; [3]Denver Health Medical Center, Denver, CO. (Control ID #3363647)

LEARNING OBJECTIVE #1: Understand differences in medical decision-making (MDM) rights for incarcerated patients

LEARNING OBJECTIVE #2: Appreciate complexities of power disparity when incarcerated patients lack medical decision making capacity

CASE: A 72 year old man presents to the hospital after an assault while in custody. Due to the need for a higher level of care patient was transferred to the surgical intensive care unit at our facility with multiple fractures traumatic injuries. Due to his severe injuries including an intracranial hemorrhage and traumatic brain injury he is unable to participate in his care. His correctional records include of next of kin (NOK), however, due to restrictions from the jurisdiction, providers were not given approval for immediate contact. His course was complicated by respiratory failure requiring intubation, tracheostomy, blood transfusions, and multiple surgeries and procedures - all of which require consent. Numerous calls were made to the jurisdiction to try and obtain permission to contact NOK as a possible medical proxy. A provider was told by the jurisdiction that patient needed to be dying in order to contact a proxy decision maker. Several weeks after admission, permission was granted for family meeting and family member to act as a proxy decision maker.

IMPACT/DISCUSSION: In the typical framework for surrogate decision-makers, decision-making authority passes from the patient to surrogates, as needed, when the patient lacks capacity to make medical decisions on their own. When the patient is incarcerated, much of the power to determine things like geographical location is not in the hands of the patient. For example, they cannot choose where they seek medical care, and even if they refuse medical care, they cannot demand to be returned to their correctional facility. In this way, community and correctional health providers, as well as correctional administrators, may take on the role of decision-makers for certain aspects of care. In the case of incarcerated patients that lack medical decision-making capacity, some practical considerations, such as location and security, may come up against the providers' goal of understanding and implementing patient values as they pertain to health care decisions. We review current guidelines for the care of incarcerated incapacitated patients, as well as review some of the more difficult cases encountered at our institution and discuss the tension in the atypical distribution of power in these situations between correctional facility, patient, health care facility, and care team.

CONCLUSION: Competing priorities between providers, jurisdictions security, and patient autonomy complicate surrogacy when incarcerated patients lack MDM capacity. An understanding of the law, correctional standards of care, and medical ethics can guide physicians in the ethical treatment of their incarcerated patients.

LOOK DEEPER! A CASE OF SARCOIDOSIS, THE GREAT IMITATOR

Aretha Boakye-Donkor[2]; Daniel Pohlman[1]. [1]Internal Medicine, Rush University Medical Center, Chicago, IL; [2]n/a, Rush Medical College, Chicago, IL. (Control ID #3388518)

LEARNING OBJECTIVE #1: Recognize the importance of systemic evaluation in a patient with cutaneous sarcoidosis.

LEARNING OBJECTIVE #2: Assess a patient with cutaneous sarcoidosis for extent of systemic involvement

CASE: A 71 year old woman with history of diabetes mellitus, hypertension, left optic neuropathy, GERD, and cutaneous sarcoidosis presented with 3 day history of epigastric pain, nausea, emesis. Pain was tight, epigastric, radiated to bilateral upper quadrants and was sometimes worse with food. No hematemesis, melena, pale colored stool. Granulomatous skin lesions were first diagnosed 2 years prior to presentation. Medications: metformin, chlorthalidone, valsartan, amlodipine, aspirin. No tobacco use.

Exam: BP 148/81, HR 86, T 98.3, R 18. Lungs: no wheezes; Heart: regular rate and rhythm, no murmur; Abdomen: epigastrium mildly tender without guarding or rebound. No masses or hepatosplenomegaly. Skin: hyperpigmented macules on face and neck. Multiple indurated papules on the right forearm, left hand and nose. Labs: Alb 3.5, Ca 10.8, ionized Ca 1.3 (NL), Alk Phos 439, ALT 204, AST 142, Total bili 4.4, Direct bili 3.54, Lipase 71, CA 19-9 73 (elevated), CEA 2.7 (NL). Abdominal ultrasound: Moderate intrahepatic biliary ductal dilation without common bile duct dilation. CT and MRI: 4.2 x 2.8 x 4.7 cm hilar mass predominantly involving the left lobe with extension into central liver with dilated intrahepatic bile ducts, concerning for hilar cholangiocarcinoma; Pathology showed noncaseating granulomas consistent with sarcoid granulomas, negative for malignancy.

IMPACT/DISCUSSION: Sarcoidosis is a multisystem, noncaseating granulomatous disorder of unknown etiology that commonly affects young and middle aged adults. It most frequently involves the lungs, but up to 30% of patients present with extrapulmonary involvement, sometimes mimicking infection or malignancy. Diagnosis typically requires clinicoradiographic findings supported by histopathogic evidence of noncaseating granulomas. Skin is the second most commonly affected organ with involvement in 25-30% of cases. Once diagnosed, evaluation must exclude other causes of granulomatous histopathology, and work-up should attempt to assess extent and severity of organ involvement. Systemic work-up should include detailed history and physical exam (including occupational/environmental history), labs (complete blood count, comprehensive serum chemistries including calcium, liver function tests and creatinine), radiographic evaluation (PAL chest x-ray), PFTs with spirometry and diffusion capacity, ophthalmologic exam, ECG, UA, vitamin D and testing for TB. Additional testing with CT/MRI, echocardiogram and holter monitoring should be considered based upon symptoms or findings. There is growing evidence for the inclusion of PET/CT in the workup of sarcoid, particularly in atypical presentations.

CONCLUSION: Cutaneous sarcoidosis may be the presenting sign of systemic sarcoidosis, and a thorough systemic evaluation is critical to assess for possible life-threatening organ involvement.

LOOKING BEYOND A RARE PRESENTATION OF BETEL NUT USE- AN OPPORTUNITY FOR LESSONS IN GLOBAL HEALTH AND GENDER EQUITY

Riley G. Jones[1,2]; Thomas Park[1,2]; Muhammad Zaman[1]. [1]Internal Medicine, University of Florida, High Springs, FL; [2]Global Health Fellowship, University of Florida, Gainesville, FL. (Control ID #3364255)

LEARNING OBJECTIVE #1: Recognize and interrupt the hidden import and perpetuation of gender-based health disparities.

CASE: A 39-year-old female from South Asia presented with one year of progressive dysphagia, weight loss and trismus. She had no history of facial trauma, radiation, dental abscess, cancer or autoimmune disorders. Since emigrating to the United States at the age of nine she was healthy, took no medications, and denied tobacco use but did endorse daily BN use since early childhood which she continued after immigration through an exotic goods importer in her area; she was never asked or counseled about BN use despite annual primary care visits. Her exam was normal except for sialorrhea, hypophonia, and an inability to retract her jaw greater than 0.9 cm. She had normal electrolytes and a negative autoimmune workup. Computed tomography of the face and neck showed normal temporomandibular joints without masses. Nasopharyngeal endoscopy revealed diffuse thickening of the oral mucosa- biopsies showed squamous mucosa with hyperkeratosis with subepithelial fibrosis and hyperpigmented macrophages without malignancy confirming a diagnosis of BN-associated OSF. She was then taken for brisement surgery and feeding gastrostomy while undergoing long term oral physical therapy.

IMPACT/DISCUSSION: Betel nut (BN) is the fourth most used psychoactive substance used behind caffeine, alcohol, and nicotine with 600 million global users. BN is strongly associated with oral cancer and many other systemic effects including oral submucosal fibrosis (OSF). Its effects may surface long after use posing a diagnostic challenge in caring for an increasingly global diaspora. We present a case of OSF which highlights another aspect of BN use: the enduring effects of gender-based health inequalities. BN is a mild, addictive stimulant consumed in many parts of the world, particularly in south and southeast Asia, which is unregulated by the Food and Drug Administration. Although BN has a strong association with several consequences such as oral cancer, there remains a widespread lack of risk awareness and entrenched social norms permitting BN use in early childhood in endemic areas. Women bear a higher proportion of BN-related disease not only due to limited means of healthcare access but also due to cultural norms that often discourage women from tobacco while encouraging BN use. Here, standard tobacco and cancer screening missed a silent but significant driver of poor health which highlights the importance of a sagacious approach to migrant patients who may have a history of exposure to imported substances and cultural habits of clinical importance, particularly where women may be inadvertently neglected.

CONCLUSION: This case illustrates the enduring effects of gender-based health inequalities and serves to help practitioners recognize their potential in interrupting the occult import and perpetuation of gender disparities which are relevant to the individualized provision of culturally informed, gender equitable care.

LUDWIG'S ANGINA CAN BE LIFE-THREATENING CELLULITIS

Anthi Katsouli. Internal Medicine, Hospitalist, Loyola University Medical Center, South Barrington, IL. (Control ID #3344214)

LEARNING OBJECTIVE #1: Recognizing Ludwig's angina as early diagnosis and immediate treatment planning could be a life-saving procedure

CASE: A 45-year-old female with a past medical history of hypertension, Von Willebrand type 2b who presented to the hospital with swelling of her neck and tongue, some difficulty breathing, dysphagia, odynophagia and change in her voice. The patient started getting left sided tooth pain about a week prior to presentation. She went to her primary and was prescribed Zithromax Z-pak. She presented to dental office a day ago with acute swelling and tooth #18, 19 were extracted and patient was placed on clindamycin. On physical exam, there was firm sublingual and bilaterally submental edema with left submental ecchymosis. The tongue was enlarged and the uvula was not visualized Ear, Nose and Throat (ENT) specialist performed flexible endoscopic nasopharyngolaryngoscopy which confirmed minimally patent airway. Computed tomography of neck was obtained which showed bilateral submental swelling without fluid collection with reactive lymph node enlargement in the neck bilateral. Patient underwent emergent tracheostomy for impending airway obstruction. Oral and maxillofacial surgery (OMFS) consulted who performed incision and drainage (I &D) of bilateral fascial neck and midline neck spaces and dobbhoff feeding tube was placed. The cultures from theI&D and blood were negative. Infectious disease suggested treatment with clindamycin and ciprofloxacin for at least four weeks duration. Patient was going to follow up with both ENT and OMFS to ensure proper response to therapy on physical exam and repeat images. Hematology was also consulted for mild thrombocytopenia in the setting of history of Von Willebrand and recommended aminocaproic acid 1mg twice a day for 3 days after tracheostomy.

IMPACT/DISCUSSION: Ludwig's angina is bilateral infection of the submandibular space that consists of two compartments in the floor of the mouth, the sublingual space and the submylohyoid space. It is an aggressive, rapidly spreading cellulitis without lymphadenopathy with potential for airway obstruction and requires careful monitoring and rapid intervention for prevention of asphyxia and aspiration pneumonia.

CONCLUSION: This case illustrates that we should suspect Ludwig's angina in patients with infection in the floor of their mouth because it is an aggressive cellulitis and can cause airway obstruction. It is a typically a polymicrobial infection involving the flora of the oral cavity but the most common organisms are viridians streptococci. Most abscesses originating from the teeth also harbor oral anaerobes and gram-negative aerobes may also be present in immunocompromised patients.

LUPUS HEPATITIS: AN UNCOMMON PRESENTATION OF THE GREAT IMITATOR

Ravi Patel[1]; Nitasa Sahu[1]; Dhirisha Bhatt[1]; Rezhan Hussein[3]; Reshma R. Golamari[2]; Rama R. Vunnam[1]; Rohit Jain[1]. [1]Internal medicine, Penn State Milton S. Hershey Medical Center, Hershey, PA; [2]Internal Medicine, Penn State Health Milton S Hershey Medical Center, Hershey, PA; [3]Infectious Disease, Penn State Milton S. Hershey Medical Center, Hershey, PA. (Control ID #3387604)

LEARNING OBJECTIVE #1: Identify hepatic dysfunction caused by Systemic Lupus Erythematosus

CASE: A 43-year-old male with history of membranous nephropathy of unknown etiology presented with a 3-day history of gradual onset malaise,

diffuse abdominal pain, myalgias, fever, and headache. Upon presentation he was febrile to 39.1 °C and exam was significant for nuchal rigidity and lower extremity weakness. Labs were significant for a white blood cell count of 2.64 K/μL, platelets of 83 K/μL, acute kidney injury with BUN and creatinine elevated at 40 and 1.77 respectively, transaminitis with ALT of 323 units/L and AST of 375 units/L, and ferritin of 1941 ng/ml. Septic work-up was initiated with blood cultures and a lumbar puncture with CSF studies. CT of the head and abdomen were negative. Patient was admitted and started on broad-spectrum antibiotics for presumed meningitis. However, infectious work-up returned negative and patient continue to have fevers during clinical course with rising LFTs (ALT 1203 units/L, AST 1623 units/L) and ferritin (12,888 ng/ml). Patient underwent more testing with negative toxicology, tuberculosis, HIV, EBV/CMV, hepatitis A/B/C, autoimmune hepatitis, and tick-borne illness serologies. After 1 week of admission with progressive symptoms, patient then exhibited a new rash in malar distribution with positive ANA in a 1:640 cytoplasmic pattern, anti-RNP antibodies, anti-SSA antibodies, as well as low C3 at 56 mg/dL and C4 at 14 mg/dL. Ds-DNA and anti-smith antibodies were negative. He was diagnosed with systemic lupus erythematosus (SLE) and started on glucocorticoids and tacrolimus with remission of fever and abdominal pain, recovery of cytopenias, and improvement of aminotransferase levels to the low 100s. He was thereafter discharged with close follow-up.

IMPACT/DISCUSSION: SLE is a clinically heterogeneous disease, and patients can present in various different ways (1). SLE encompasses a broad spectrum of liver disease including immunologic overlap syndromes, non-immunologic associations, and infrequently damaged induced by itself (2). Bessone et al describe Lupus Hepatitis as an asymptomatic elevation of aminotransferases associated with exacerbations of SLE, which returns to normal values after corticosteroid therapy (3). Furthermore, anti-Ribosomal P antibodies have been correlated to this clinical entity (4). Our case highlights this underreported and uncommon presentation of SLE.

CONCLUSION: Lupus hepatitis is a distinct manifestation of SLE with variable course and prognosis (4). It is important for clinicians to know this association in order to promptly achieve diagnosis and initiate appropriate therapies thereafter.

MAG-NAMINOUS URINE

Priya pal[1]; Alexandra J. Chastant[1]; Catherine Jones[2]. [1]Internal Medicine Residency, Tulane School of Medicine, New Orleans, LA; [2]Internal Medicine, Tulane University SOM, New Orleans, LA. (Control ID #3372788)

LEARNING OBJECTIVE #1: Describe the pathophysiology of hypomagnesemia in patients with alcohol abuse

LEARNING OBJECTIVE #2: Review the consequences of severe hypomagnesemia

CASE: A 61-year-old alcoholic man was admitted to the ICU for management of sepsis, alcohol withdrawal, and hepatic encephalopathy after being found down at home. He required several weeks of renal replacement therapy and subsequently intermittent dialysis until his kidney function recovered from ATN. When renal function improved, he developed hypomagnesemia (0.9 mg/dL) despite daily magnesium repletion and ultimately had to be supplemented with 6 mg IV magnesium and 1200 mg oral magnesium oxide per day. Spot urinary magnesium levels were 25.6mg/dL and 24 hr urinary magnesium level was 803mg/dL confirming a diagnosis of urinary magnesium wasting. Intravenous magnesium was more effective at repleting his magnesium than oral therapy early in his hospital course. Later, he was able to maintain serum magnesium concentrations within normal range without additional IV repletion. Urinary spot magnesium had decreased from 25.6 mg/dL to 6.8 mg/dL.

IMPACT/DISCUSSION: Urinary magnesium wasting is one of many reasons that contribute to hypomagnesemia in alcoholic patients. In a study examining electrolyte abnormalities in alcoholics approximately 30% had hypomagnesemia and of those, 47% were found to be due to urinary magnesium wasting as a consequence of alcohol induced tubular dysfunction. Urinary tubular wasting of magnesium is usually a self-limited process and appropriate urinary absorption recovers in ~4 weeks.

Other mechanisms that contribute to magnesium loss in this patient population are diarrhea, and nutritional deficiencies. Diarrhea is a potent contributor as upper GI secretions have approximately 1mEq Mg/L and lower GI secretions have 15 mEq Mg/L. Medications can also contribute to diminished magnesium loss such as diuretics. Concomitant pancreatitis can also worsen hypomagnesemia as magnesium and calcium are saponified into necrotic fat.

Another unique electrolyte abnormality in patients with alcohol abuse is hypocalcemia. This occurs as a result of hypomagnesemia causing decreased PTH sensitivity as well as renal and skeletal desensitization to the effect of PTH. Hypomagnesemia and hypocalcemia contribute to osteoporosis in these patient populations. These electrolyte derangements can also cause Qt prolongations and increase the risk of ventricular ectopy and torsade de pointes.

CONCLUSION: A general internist frequently encounters alcohol abuse and the the health consequences of excessive drinking. A better understanding of the pathophysiology leading to electrolyte derangement in these patients will result in faster, more appropriate management and limit additional complications.

MAINTAINING THE SICK ROLE AT ALL COSTS: TREATING MEDICAL COMORBIDITIES IN PATIENTS WITH FACTITIOUS DISORDER

Eric Woods, Darlene LeFrancois. Medicine, Montefiore Medical Center, Bronx, NY. (Control ID #3391259)

LEARNING OBJECTIVE #1: Consider optimal strategies for managing patients with factitious disorder presenting with medical comorbidities

LEARNING OBJECTIVE #2: Highlight one of the ethical dilemmas that can arise when treating disease in patients with factitious disorder

CASE: A 38 year-old woman with secondary acute myelogenous leukemia presented after a reported slip and fall. She demanded specific doses of opioids and a cholecystectomy for a "festering gallbladder." Her abdomen had dramatically inconsistent tenderness to light palpation diffusely. Gallstones were absent on CT, however, her spleen was enlarged.

She endorsed many other comorbidities and frequently visited multiple other hospitals to address them. Collateral information from her family and medical record revealed that none of these comorbidities were true and that she had been deceiving people about these diagnoses for decades. At times the patient was willing to acknowledge truths about her medical history, but more often confrontation was met by verbal abuse or feigned sleep.

The patient's desire to remain in a sick role, her refusal to address her undiagnosed psychiatric issues, and her refractoriness to chemotherapy made her a poor candidate for further treatment of her leukemia. She was referred to hospice care where she died after a blast crisis.

IMPACT/DISCUSSION: Patients with factitious disorder (FD) intentionally produce, feign, or exaggerate symptoms of a disease with the motivation of assuming the "sick role." Patients tend to be female, in their mid-30s, employed in the healthcare field, and display signs of a

personality disorder. Due to difficulties with diagnosis, estimates of FD's prevalence among all physician-patient encounters vary widely – from 0.5% to as high as 5%. Reexamining the general internists' management techniques for patients with FD and other comorbidities may result in better patient outcomes and the avoidance of iatrogenic harms.

Many providers choose to confront patients with FD. However, some experts argue against this approach due to the possibility that the patient will become more guarded. They instead suggest using techniques that allow the patient to give up the factitious symptoms without "losing face." The only systematic review looking at these opposing strategies found no significant difference on Global Improvement Scale scores. However, longer lengths of stay, incorporating psychiatric treatment into medical management, and normalizing the patient's reluctance to share painful or embarrassing information is beneficial.

The treatment of this patient's leukemia was hindered by her desire to remain "sick." The vignette highlights the difficulties in balancing the ethical principles of autonomy and beneficence in this particular population.

CONCLUSION: While more research is needed to determine the best techniques for managing patients with comorbid medical conditions and FD, internists should incorporate psychiatric care and empathy into their care plans.

MAJOR DEPRESSIVE DISORDER (MDD) IN ESRD: AN IMPACTFUL COMORBIDITY

Shyam Sundaresh[1]; B. Robert Meyer[2]. [1]Internal Medicine, NewYork-Presbyterian Hospital/Weill Cornell Medical Center, New York, NY; [2]Medicine, Weill Medical College of Cornell University, New York, NY. (Control ID #3392129)

LEARNING OBJECTIVE #1: Appreciate the prevalence of MDD in ESRD patients.

LEARNING OBJECTIVE #2: Recognize the impact that MDD has on outcomes in ESRD patients.

CASE: 37yoAAM with MDD and ESRD secondary to PCKD presented to the ED for syncope and nausea that had been worsening over the last week since his last session of scheduled outpatient hemodialysis (HD). He had recently been permanently discharged from his HD center due to an altercation with a weapon. Vital signs were normal, but examination revealed a lethargic man. Labs were remarkable for K 5.8, BUN 110, SCr 17. The remainder of an extensive inpatient workup, including EKG, CXR, telemetry, and transthoracic echocardiogram, was unremarkable.

Medications:

- none

Psychiatric History:

- remote psychiatric hospitalization for depression during which started on citalopram which was discarded after discharge

- no prior suicide attempts or mania

- prior hydromorphone use, last a year ago and currently no tobacco, illicits, or alcohol

Family History:

- grandfather completed suicide by gun

- brother with bipolar disorder

Social History:

- lives alone with significant housing instability

- identifies as gay, currently no partner

Hospital Course:

He was dialyzed and quickly improved. He disclosed that he had been discharged from numerous HD centers due to irritable altercations. He felt ashamed of his fistula, ugly, and depressed about his illness, no longer able to socialize or sleep. Psychiatry evaluated him and agreed with a diagnosis of MDD with possible borderline traits. He refused psychotherapy and medications.

All attempts at placing him at an HD center failed given a history of a weaponized altercation. He eventually left against medical advice without an HD center and currently pursues emergency-only HD at various emergency departments across the city.

IMPACT/DISCUSSION: Psychiatric disease such as MDD is comorbid in up to 20-30% of ESRD patients. Being mindful of this aids the clinician in diagnosing MDD in ESRD. However, it can be a difficult diagnosis to make in ESRD patients because the symptoms of MDD often overlap with those of chronic uremia. With our patient, the clinical interview elicited feelings of shame unique to MDD. It has been suggested that the interview be the gold standard for diagnosing MDD in ESRD.

It is important to recognize MDD is ESRD, because mortality correlates with severity of comorbid MDD. These patients more often miss HD, utilize the ED, are hospitalized, and require critical care admissions. Much of this applies to our patient who due to MDD now only has access to emergency-only HD, which is inferior to scheduled HD in terms of mortality, ED visits, and hospitalizations.

CONCLUSION: 1. MDD is comorbid with ESRD in 20-30% of patients.

2. Clinical interview may distinguish MDD from chronic uremia in ESRD patients.

3. Mortality correlates with severity of MDD in ESRD.

4. More research is needed on US citizens whose only access to HD is emergency-only, as this is not well- studied in citizens. Outcomes data presented here come from immigrants.

MALIGNANCY-ASSOCIATED REFRACTORY CHYLOTHORAX: WHEN PALLIATIVE MANAGEMENT ISN'T REALLY PALLIATIVE

Kira A. Grush[1]; John M. Cunningham[1,2]. [1]School of Medicine, University of Colorado, Denver, CO; [2]Internal Medicine, Denver Health, Denver, CO. (Control ID #3391265)

LEARNING OBJECTIVE #1: Review options for palliative treatment of chylothorax, including dyspnea and downstream nutritional effects

LEARNING OBJECTIVE #2: Recognize how barriers to care can impact palliative symptom management and quality of life

CASE: A 63-year-old male presented to the ED after a week of progressive dyspnea. Two weeks prior, he was diagnosed with esophageal adenocarcinoma metastasized to the mediastinal and supraclavicular nodes. CT showed bilateral pleural effusions. Thoracentesis revealed milky fluid with triglycerides of 646 mg/dL, meeting criteria for chylothorax (triglycerides > 110 mg/dL). Pleural cytology was negative for malignant cells.

He was treated with diet modification, octreotide, and chemotherapy, yet his effusions rapidly reaccumulated within two weeks. Options for intervention included surgical ligation, lymphatic embolization, pleurovenous shunting, and placement of indwelling pleural catheters (IPC). Given high surgical risk and lack of insurance coverage of alternate procedures, bilateral IPC were placed.

Over the next three months, his tumor burden and oral intake were stable on chemotherapy. However, he averaged 1L of chylous output daily and suffered hypovolemia, 14kg weight loss, and fatigue leading him to transition to hospice care. Despite adequate control of dyspnea, the inability to definitively treat the chylothorax led to progressive symptoms and reduced quality of life, likely due to nutritional losses.

IMPACT/DISCUSSION: Treatment of high output chylothorax in a patient with metastatic esophageal cancer required two key considerations: palliation of dyspnea and management of nutritional complications affecting quality of life. Drainage of the pleural space with IPC or frequent thoracentesis manages dyspnea but poses the risk of nutritional depletion. Procedures such as shunt placement or thoracic duct embolization provide a more permanent solution without risk of nutritional losses.

After conservative treatment failed, we pursued IPC placement based on prior studies that failed to demonstrate significant adverse nutritional outcomes to their use. However, the studied patients experienced spontaneous pleurodesis whereas ours sustained high output over time. Lymphovenous shunting was considered given the patient's high surgical risk and lack of institutional availability of lymphangiography required for thoracic duct embolization. We planned to pursue shunt placement based on positive results reported in case reports; however, the procedure was declined by insurance, limiting treatment options.

CONCLUSION: Managing this patient's chylothorax was complicated given financial barriers to obtaining advanced procedures and limited evidence evaluating treatment options. It is possible that an earlier definitive procedural intervention may have improved quality of life. Though it is unclear whether our approach hastened his decline, it is worth considering how the decisions we make for palliative intent may not be palliative at all.

MANAGEMENT OF SPONTANEOUS MRSA ARTHRITIS IN A PATIENT WITH UNCONTROLLED TYPE 2 DIABETES MELLITUS

Jack Qiu[2,1]; Robert J. DeGrazia[2]; David M. Cohen[2]. [1]Sidney Kimmel Medical College, Philadelphia, PA; [2]Internal Medicine, Christiana Care Health System, Aberdeen, MD. (Control ID #3388349)

LEARNING OBJECTIVE #1: Recognize how community acquired Methicillin-Resistant Staph Aureus (CA-MRSA) septic arthritis can present indolently in patients with minimal predisposing risk factors

LEARNING OBJECTIVE #2: Recognizing the sensitivities of serum tests as surrogate markers for septic arthritis

CASE: A 48-year-old male with a history of uncontrolled diabetes presented with worsening left hip pain over the past 2 months. He denied any history of osteoarthritis or any prior trauma. He noted sharp hip pain that was worse with movement and did not radiate. He had also been taking NSAIDs every day to help his hip pain. The physical exam of the left hip did not reveal any swelling or erythema but was tender to palpation with a full range of motion. X-rays of the hip and ultrasound were normal, however, MRI showed cortical loss of the posterior left acetabulum concerning for septic arthritis and swelling concerning for myositis of the muscles nearby. Vancomycin was started for possible septic arthritis. Blood cultures grew MRSA on the second day in the hospital. Interventional radiology aspirated the left hip joint and the synovial fluid grew MRSA as well. After the positive aspirate, an incision and drainage of the left hip was done in the OR. The patient clinically improved and was discharged with a tunneled catheter for long term IV antibiotics for treating MRSA osteomyelitis.

IMPACT/DISCUSSION: Acute septic arthritis is a medical emergency that requires prompt diagnosis and medical treatment. The typical presentation includes restricted range of motion, joint swelling, pain, and redness. Most septic joint infections are due to methicillin-sensitive Staphylococcus aureus with few reports of MRSA septic joint infections. MRSA septic joint infections are typically seen in patients with prior hospital stays, hardware implantation, or preexisting rheumatic disease. Fortunately, there are only a few cases on septic arthritis secondary to CA-MRSA. This case brings attention to the rising prevalence of CA- MRSA septic arthritis in patients with few predisposing risk factors. Although leukocytosis can be seen with septic arthritis, this patient with a history of uncontrolled diabetes shows how leukocytosis is not a sensitive marker for septic arthritis. Inspection of the synovial fluid and synovial fluid white blood cells, % PMN, and CRP of synovial fluid are more useful clinically. There have been conflicting studies on the sensitivities and specificities of procalcitonin for predicting infectious arthritis. Inflammatory, diabetic, nutritional pathologies should also be recognized as causes of altered biomarkers as this patient's uncontrolled diabetes may have contributed to his normal white blood cell count initially.

CONCLUSION: 1. There are no good serum studies to definitively diagnose septic arthritis, and the gold standard continues to be culturing the presumed infected site.

2. This case reinforces the possible indolent nature of septic arthritis and the need for a high index of suspicion when treating patients with hip pain.

MANAGING MENORRHAGIA MEDICALLY

Chelsea Wiltjer[1]; Lisa B. Bernstein[2]. [1]Internal Medicine, Emory University, Atlanta, GA; [2]Medicine, Emory University, Atlanta, GA. (Control ID #3390378)

LEARNING OBJECTIVE #1: Manage menorrhagia secondary to uterine fibroids in a medically complex patient

CASE: A 44-year-old African American female with severe persistent asthma, unprovoked DVT's requiring life-time anticoagulation and abnormal uterine bleeding due to extensive uterine fibroids presented to the emergency department with chief complaint of severe menorrhagia. Vital signs were normal and admission labs showed a stable microcytic anemia with hemoglobin of 7.1 g/dL and MCV of 75 fL. MRI of her pelvis showed greater than 50 fibroids. Prior treatment for her menorrhagia included use of Provera and uterine artery embolization. Given that she had no further desire to bear children, a hysterectomy was discussed but she was deemed too high a risk for general anesthesia due to poorly-controlled asthma. Medical therapy was determined to be the best option and a long-acting progesterone-only implant was offered.

IMPACT/DISCUSSION: This case highlights a woman battling with a known and common side effect of premenopausal leiomyomata. Menorrhagia can be defined as greater than 80mL of blood loss per cycle, excessive uterine bleeding occurring at regular intervals or prolonged bleeding for more than seven days. Premenopausal uterine fibroids are four times more common in African-American women than in Caucasian women and incidence increases with age. Treatment options for menorrhagia are broad and include oral contraceptive therapy, implantable progesterone therapy, endometrial ablation as well as hysterectomy, novel cryotherapy techniques and uterine artery ablation. The wide range of treatment options allows women and physicians to tailor their treatment on a case-by-case basis. Our case in particular describes a woman in need of medical management for her ongoing menorrhagia as she was deemed not a surgical candidate. This case is important for primary care physicians as menorrhagia and other causes of abnormal uterine bleeding can be effectively managed by internists. In most cases, medical management of menorrhagia is often the preferred initial treatment modality to avoid invasive surgery. The most effective medical treatment shown to reduce menorrhagia is the Levonorgestril-releasing intrauterine system (Mirena). Multiple studies show that internal medicine residents among other primary care specialties lack the training and competency of intrauterine device (IUD) insertion. A formal curriculum for IUD insertion for residents in primary care specialties should be considered given their broad indication for use, including effective treatment of menorrhagia.

CONCLUSION: 1. Menorrhagia and other causes of abnormal uterine bleeding can be effectively managed by internists

2. The most effective medical treatment shown to reduce menorrhagia is the Levonorgestril-releasing intrauterine system

3. Formal training of IUD insertion should be considered for residents in primary care specialties given their broad indication for use

MARCHIAFAVA-BIGNAMI DISEASE: CONNECT THE DISCONNECTED

Kyosuke Seguchi[5]; Tadashi Eguchi[3]; Shohei Harase[1]; Mitsuru Kawamura[2]; Makito Yaegashi[3]; Sandra Y. Moody[4]. [1]Neurology, Kameda Medical Center, Kamogawa-shi, Chiba-ken, Japan; [2]Neurology, Okusawa Hospital and Clinics, Setagaya, Tokyo, Japan; [3]Department of General Internal Medicine, Kameda Medical Center, Kamogawa, Chiba, Japan; [4]Post-Graduate Education/Medicine, Kameda Medica Center & UCSF/SFVAMC, Kamogawa City, Chiba Prefecture, Japan; [5]Post-Graduate Education/Medicine, Kameda Medical Center, Kameda General Hospital, Kamogawa, Chiba, Japan. (Control ID #3390314)

LEARNING OBJECTIVE #1: Recognize the clinical features of Marchiafava-Bignami disease (MBD) including callosal disconnection syndrome in patients with alcoholism and malnutrition.

CASE: 60-year-old right-handed man with a 40-year-plus history of alcohol abuse presented to our hospital with anorexia and difficulty moving. His wife stated that for the past year, he tended to stay at home, refusing social engagements. He also experienced the sensation that his hands were fighting each other when he tried to pick up the remote control for the television. He has hypertension, but has been lost to follow-up for one year. He has consumed 210 grams of alcohol daily for more than 40 years.

On admission, his vital signs were within normal limits. He was oriented to time, place, and person, but his response was slow. Other than being emaciated, his physical examination was unremarkable. His Mini- mental State Examination was 26 out of 30. His serum gamma aminotransferase level was 357 mg/dL, serum albumin 3.4 mg/dL, and vitamin B_1 13 IU/L. Brain MRI showed moderate frontotemporal lobe atrophy, and increased signal intensity in the posterior aspect of the corpus callosum on T2-weighted and FLAIR images, while DWI showed hypointensity in the same area. Diffusion Tensor Imaging (specialized MRI viewing the nerve fibers) showed a deficit of fiber connection in the corpus callosum. Based on the history including alien hand syndrome, the clinical examination indicating callosal disconnection syndrome, and radiological findings, we made a diagnosis of chronic MBD. To confirm this diagnosis, we tested higher-level brain functions based on prior case reports. He exhibited left agraphia (unable to write a sentence with his non- dominant left hand), transfer impairment of right-left symmetrical function (inability to reproduce a hand symbol on both sides with his eyes closed), and frontal lobe dysfunction including apathy, perseveration and inattention. He was treated with high dose vitamins B_1, B_6, and B_{12}. Though his symptoms persisted, they were better managed with home rehabilitation. In addition, he remained abstinent with the help of social workers.

IMPACT/DISCUSSION: In patients with alcoholism and malnutrition who develop neurological symptoms or disorders of higher-level brain functions, not only should Wernicke-Korsakoff syndrome be considered, but also MBD. MBD is a rare disorder of demyelination or necrosis of the corpus callosum that occurs predominantly in malnourished alcoholics. Although callosal disconnection symptoms affect their activities of daily living and quality of life, the diagnosis is often missed. Delay in diagnosis affects outcome and prognosis.

CONCLUSION: MBD is a rare disorder of demyelination or necrosis of the corpus callosum that occurs predominantly in malnourished alcoholics. The clinical features described above could be useful in diagnosing MBD and providing appropriate treatment using a multidisciplinary approach.

MASQUERADING MALIGNANCY PRESENTING AS OBSTRUCTIVE HYPERBILIRUBINEMIA

Dakota Jenneman[1]; Margret Zorc[1]; Holly Hall[2]; Jeffrey Kooper[3,1]. [1]Internal Medicine, University of South Florida, Tampa, FL; [2]Morsani College of Medicine, University of South Florida, Tampa, FL; [3]Internal Medicine, James A. Haley Veterans' Hospital, Tampa, FL. (Control ID #3390450)

LEARNING OBJECTIVE #1: Identify potential causes of obstructive jaundice/hyperbilirubinemia including: choledocholithiasis, cholangitis, malignancy, lymphadenopathy, and biliary stricture.

LEARNING OBJECTIVE #2: Identify common sites of metastases for small cell lung carcinoma.

CASE: A 69-year-old male with past medical history of alcohol abuse, 75 pack-year tobacco smoking history, and untreated anal squamous cell carcinoma presented to hospital with yellowing of his skin for two weeks. He endorsed concomitant right upper quadrant pain in his abdomen described as dull which was not worsened or relieved with meals. He denies history of liver cirrhosis or hepatitis, family history of liver disease, or recent medication changes. Physical exam was significant for widespread jaundice and tenderness to deep palpation of right upper quadrant of abdomen without rebound tenderness or guarding. Laboratory values were significant for aspartate aminotransferase 99, alanine aminotransferase 80, alkaline phosphatase 477, total bilirubin 28.7, and direct bilirubin 19.5. Computed tomography (CT) of the abdomen showed hypodense mass from head of pancreas obstructing and infiltrating the distal portion of the common bile duct (CBD) with associated extra- and intra-hepatic duct dilatation and a low density mass of the right lobe of the liver. CT Thorax and Pancreas revealed mediastinal and hilar lymphadenopathy, large left infrahilar mass, widespread upper abdominal lymphadenopathy, and previously described pancreatic mass not definitely identified, thought to be lymphadenopathy. Patient underwent endoscopic retrograde cholangiopancreatography (ERCP) with biliary stent placement and subsequent downtrend of total bilirubin. Biopsy of mass of right lobe of the liver revealed metastatic small cell carcinoma. Patient was started on palliative chemotherapy with carboplatin and etoposide.

IMPACT/DISCUSSION: This case presents a patient with obstructive hyperbilirubinemia, which has a broad differential diagnosis. This patient has a significant tobacco use history, untreated anal squamous cell carcinoma, and history of alcohol abuse. Considering this patient's past medical and social history, a thoughtful approach to etiology of the obstructive hyperbilirubinemia should be always be sought to consider further treatment options after ERCP and biliary stent placement for decompression.

CONCLUSION: This patient's CT imaging was initially consistent with pancreatic mass with invasion of the CBD, further imaging and a liver biopsy confirmed the diagnosis of small cell lung carcinoma, and obstructive hyperbilirubinemia was secondary to portacaval lymphadenopathy. The most common site of metastases for small cell lung cancer are liver, bone, brain, and lungs. This case highlights the importance of knowing the multiple causes of obstructive hyperbilirubinemia and their treatment, metastatic patterns of malignancies, and further discussion of imaging results with radiologists to narrow the differential diagnosis and predict further treatment plans.

MEMORY LOSS WITH PARKINSONIAN FEATURES: A CASE STUDY

Margot quinn[1]; louisa whitesides[2]; tania alchalabi[2]. [1]Medicine, George Washington School of Medicine and Health Sciences, Washington, DC; [2]geriatrics, george washington university hospital /MFA, Washington, DC. (Control ID #3390824)

LEARNING OBJECTIVE #1: To assess and understand the overlap between parkinsonian features and progressive memory loss.

CASE: We present the case of a 78-year-old woman with three years of worsening memory loss (occurring in a stepwise fashion) and increasingly frequent falls in the same time period. She had difficulty with word finding, naming and recognizing loved ones, and was often disoriented in familiar places. Her weekly falls were attributed to slowed reflexes. The patient denied hallucinations, nightmares, depression, syncope, or urinary incontinence. Family history included Alzheimer's Dementia in her mother.

Her past medical history was complicated by vascular disease, hypertension, upper extremity venous thrombus, and lower extremity neuropathy. Physical exam showed cogwheel rigidity, intention tremor, diffusely hypoactive deep tendon reflexes, and wide based, ataxic gait. Mental status exam was significant for flat affect with masked facies, logorrhea, and disorientation to time and place. MOCA exam score was 12/30, demonstrating difficulty with recall and word finding but with none with clock drawing or attention. Routine labs were within normal limits. MRI showed diffuse cerebral volume loss with signs of chronic microvascular ischemia in the periventricular and subcortical white matter.

IMPACT/DISCUSSION: Parkinson features can present with many underlying pathologies. While many patients who demonstrate both parkinsonian features and memory loss are diagnosed with a movement disorder (Parkinson Disease, Lewy Body Dementia (LBD), Multiple System Atrophy, Progressive supranuclear palsy, and Normal Pressure Hydrocephalus (NPH)), it is important to recognize that these overlapping conditions may be present in other disease processes. Our patient developed memory loss before or simultaneously with falls. Movement disorders that follow this pattern are limited and include: LBD and NPH. Additionally, her past history included vascular disease, and neurological exam was clouded by her notable paucity of memory. Thus, neurology concluded memory loss was unlikely to be related to her other neurological symptoms and the patient did not meet criteria for a specific movement disorder. Lab work demonstrated no other underlying source of her presenting features. Finally, imaging showed marked volume loss and microvascular changes. While initially, this patient appeared to have a movement disorder, with a more thorough, multidisciplinary evaluation, she was ultimately diagnosed with mixed dementia with parkinsonian features.

CONCLUSION: Memory loss and Parkinsonian features are present in multiple disease processes.

While LBD is well documented, few cases of Parkinsonian features in the setting of mixed dementia exist in recent literature.

Evaluation of the overlapping features requires a broad differential of neuropsychiatric diseases. Workup should include separate memory and neurological testing with interdisciplinary collaboration.

MENACING MOBILE MASSES

Dylan M. Baker[1]; Annie Massart[2]; Robin Klein[3]. [1]Internal Medicine, Emory University, Atlanta, GA; [2]Hospital Medicine, Emory University, Atlanta, GA; [3]Internal Medicine, Emory, Atlanta, GA. (Control ID #3390460)

LEARNING OBJECTIVE #1: Review the pathophysiology of tumor emboli.

LEARNING OBJECTIVE #2: Recognize the clinically significant embolic potential of invasive renal cell carcinoma.

CASE: A previously healthy 39 year-old man presents with one week of cough with blood-streaked sputum, left flank pain and hematuria. He reported a 7 kilogram weight loss, night sweats, and fever over the last month.

He was febrile with a temperature of 38.2 degrees, tachycardic with a pulse of 113 bpm and tachypneic with a respiratory rate of 25 bpm. Examination revealed clear breath sounds and abdomen was soft. Laboratory studies revealed white blood cell count of 20.5 $x10^{3}$/uL, creatinine of 1.3 mg/dl, troponin of 0.17 ng/ml, and a urinalysis with 21 white blood cells, 29 red blood cells. CT pulmonary angiogram revealed multiple pulmonary emboli in the bilateral lower lobes and multifocal pulmonary infarcts. CT Abdomen and Pelvis demonstrated a right renal lesion withing the collecting system and right renal vein thrombus extending into the inferior vena cava (IVC).

The patient was treated with heparin and underwent mechanical thrombectomy of the right renal vein and IVC, as well as aspiration thrombectomy of the bilateral pulmonary arteries. Pathology from both sites identified tumor thrombus, confirming the diagnosis of Renal Cell Carcinoma with invasion of the renal vein complicated by pulmonary tumor emboli. He deteriorated after developing additional pulmonary emboli and a hemothorax, and subsequently passed away.

IMPACT/DISCUSSION: Tumor embolism occurs when solid tumors seed the systemic circulation. Manifestations vary from large tumor masses that mimic pulmonary embolism to the more common progressive microvascular obstruction which can progress to pulmonary artery hypertension. While thromboembolism is a commonly encountered phenomena, tumor embolism is relatively rare and often overlooked.

Tumor emboli are often associated with renal cell carcinomas, as up to 10% of these involve local vessel wall invasion of the renal vein or inferior vena cava (1). They are also commonly associated with mucin-secreting adenocarcinomas of the breast, lung and stomach (2). Suspicion for tumor emboli may be raised with a history of malignancy, findings concerning for tumor invasion into the vasculature, or a pattern of numerous bilateral peripheral subsegmental defects. Definitive diagnosis requires sampling and cytological analysis.

This case illustrates an uncommon cause, tumor emboli, of a commonly encountered diagnosis, pulmonary embolism. Physicians should consider tumor emboli in patients at risk especially those presenting with tumors that can invade the vasculature.

CONCLUSION: Renal cell carcinoma has a propensity to invade local vessels and can cause tumor thrombus and emboli.

METASTATIC BASAL-CELL CARCINOMA ASSOCIATED WITH GUNSHOT WOUND TRAUMA

Noah Kojima[1]; Keara Darragh[2]; Brianna J. Cowan[3,4]. [1]Medicine, David Geffen School of Medicine at University of California Los Angeles, Los Angeles, CA; [2]School of Medicine, David Geffen School of Medicine at University of California Los Angeles, Los Angeles, CA; [3]Medicine & Pediatrics, UCLA, Los Angeles, CA; [4]Greater Los Angeles Veterans Affairs Healthcare System, Los Angeles, CA. (Control ID #3392202)

LEARNING OBJECTIVE #1: Recognize features of advanced basal cell carcinoma (BCC) and review treatment options

CASE: A 76-year-old fair-skinned man with a history of chronic homelessness returned to primary care clinic with a 10-centimeter, tender, erythematous, draining left groin mass and chronic left

lower extremity edema. The patient suffered a gunshot wound (GSW) in the left buttock in 1962. Twenty years ago, the patient was diagnosed with BCC of the left groin and underwent resection. Ten years ago, the patient developed a draining surgical site wound. Biopsy showed BCC. The patient's wound was resected with negative margins on pathology; however it is unclear if the site fully healed. He engaged sporadically with the health care system and reported seeking care from outside providers with multiple courses of antibiotics for wound infection without sustained healing.

Three years ago, the patient developed lower extremity edema distal to the wound. Positron emission tomography-computed tomography (PET-CT) identified a large hypermetabolic cutaneous/subcutaneous left inguinal mass with extensive metastases to the lungs, abdomen, and pelvis indicating advanced BCC. The patient started palliative Vismodegib with PET-CT four months later showing reduced metabolic activity and no new lesions. The patient stopped Vismodegib due to side effects including weight loss and ageusia.

Two years later, the patient presented to our clinic and resumed Vismodegib treatment. At initiation, PET-CT showed progression of metastatic BCC with enlargement of the primary groin mass and diffuse involvement of the abdomen, pelvis, retroperitoneum, vertebrae and lungs. The patient again stopped Vismodegib due to side effects. In 2 months, he was hospitalized for sepsis from wound site cellulitis and left femoral DVT, then discharged to a wound care facility. He engaged with homeless services to develop a permanent housing plan, but ultimately chose to relocate. The patient declined additional BCC treatment and ultimately agreed to palliative care in his new location.

IMPACT/DISCUSSION: Common risk factors for BCC are exposures to radiation, including ultraviolet radiation, arsenic, and long-term immunosuppression. BCCs associated with trauma from gunshots are rare but documented. Homelessness and inconsistent primary care engagement were contributors to our patient's advanced BCC.

The majority of BCCs are identified early and treated definitively. Metastatic BCC is uncommon due to slow tumor growth. Vismodegib, a hedgehog pathway inhibitor, is an efficacious treatment of advanced BCC in small trials and for our patient.

CONCLUSION:

-BCC can occur in sites of prior trauma, including GSW. Non-healing wounds should be biopsied to exclude malignancy.

-Providers caring for homeless patients should incorporate comprehensive skin examination into their practice

-Homeless populations benefit from health system mechanisms to promote engagement and maintenance in health care

METASTATIC EMBRYONAL CARCINOMA OF THE TESTICLE PRESENTING AS A COUGH

Jordan Minish, Francesca Gesiotto, Andrew Shychuck. Internal Medicine, Univeristy of Florida, Gainesville, FL. (Control ID #3384467)

LEARNING OBJECTIVE #1: Recognize that symptoms of metastatic disease can be the first presenting symptoms in an undiagnosed malignancy.

CASE: The patient is a 28 year old male with a past medical history of T1DM presenting to his primary care office for a cough. The patient reported a cough x3 weeks that had been minimally productive. On review of systems the patient endorsed intermittent episodes of diaphoresis and heat intolerance as well as "lumps" on his chest underneath his breast tissue and a right sided testicular mass. Denied hemoptysis, chest pain, weight loss, fevers, penile discharge, dysuria and hematuria. On further discussion of the testicular mass he notes that he first noticed it approximately 3 months ago. Family history of maternal grandmother with breast cancer diagnosed in her 40s and mother with recent lymphoma diagnosis. On exam the testicular mass was firm and tender to palpation. His lungs were clear to auscultation bilaterally and there was presence of gynecomastia. An ultrasound of the scrotum was done outpatient and showed irregular intratesticular masses on the right, raising concern for a neoplasm. Follow up CT chest, abdomen and pelvis revealed multiple pulmonary masses and subcarinal, left hilar and retroperitoneal adenopathy all concerning for metastatic disease. Following right radical orchiectomy, pathology showed embryonal carcinoma with lymphovascular invasion.

IMPACT/DISCUSSION: This case of a young man presenting with a common, simple chief complaint of a cough highlights the importance of a thorough review of systems in making an accurate diagnosis. Thorough evaluation can uncover key clues to a diagnosis that the patient believes are unimportant or irrelevant, such as the testicular mass in this case. Ensuring that your review of systems is tailored to rule out the worst case scenarios for common chief complaints will prevent a physician from missing symptoms that could lead to an alternative diagnosis.

It is also important to note that the presenting symptom of many malignancies that patients decide to seek care for can be due to the metastatic lesions and not to the primary tumor. In this case, the lung metastases led to a nagging cough which brought the patient to his PCPs office, where the cough ended up being due to metastatic embryonal carcinoma of the testical. Embryonal carcinoma is a type of nonseminomatous germ cell tumors that is among the most rapidly growing and potentially aggressive testicular tumor types that often first metastasizes to the lungs.

CONCLUSION: Patients do not always recognize symptoms that point to a more nefarious origin, such as the testicular mass in our case report, and instead are bothered by the more nagging symptoms, such as a cough, which can be easily overlooked as benign. It is our responsibility as physicians in the primary care setting to ensure that our evaluations are thorough, as metastatic neoplasms can present with symptoms from the metastases before the patient complains of symptoms from the primary neoplasm.

METASTATIC MALIGNANCY OR SARCOIDOSIS? A DIAGNOSTIC DILEMMA

Isha Dabke, Parth B. Patel. Department of Medicine, Medical College of Georgia, North Augusta, SC. (Control ID #3392127)

LEARNING OBJECTIVE #1: Evaluate different imaging modalities, lab test, and histopathology techniques in distinguishing sarcoidosis from a malignant or infectious cause.

CASE: A 44-year-old African American male presented with an 8-month history of 40-lb. weight loss. He also reported persistent headaches and occasional left eye blurriness. He denied any significant past medical history except a ½ ppd remote smoking history. His review of systems was negative. His physical exam was unremarkable. Due to the weight loss, an abdominal CT was performed which showed multiple hepatic lesions with upper abdominal lymphadenopathy and multiple lucent lesions throughout the bones. These findings were suspicious for a metastatic malignant disease. The patient was admitted for work-up of his hepatic lesions, and lab work demonstrated hyponatremia. Chest CT showed bilateral lymphadenopathy with multiple perilymphatic nodules in the bilateral upper lobes, along with calcified granulomas. Sarcoidosis was considered, however malignancy and tuberculosis could not be ruled out. Serum levels of angiotensin- converting enzyme (ACE) were ordered.

Biopsy of a left iliac bone lesion revealed granulomatous inflammation with giant cell reaction without evidence of malignant cells.

Given the patient's headaches eye blurriness, a brain MRI was performed and revealed diffuse leptomeningeal nodular enhancement of the CNS.

PET scan was necessary to stage the sarcoidosis. PET revealed extensive lymphadenopathy, evidence of skeletal involvement, metabolically active liver lesions, and large left hilar consolidation with bilateral upper lobe nodules.

After explaining the results, the patient was started on Prednisone 80 mg daily for four weeks. The patient's condition improved vastly, and he has been treated continuously since discharge.

IMPACT/DISCUSSION: Sarcoidosis is a multisystemic granulomatous disease of unknown cause. Thought it may affect any organ in the body, pulmonary involvement is the most common. Extrapulmonary involvement is reported in 30% of all cases, but only 5% of these cases show multiple hypodense nodules scattered in the liver such as the case presented here. Additionally, bone involvement in sarcoidosis is rare (7%), and involvement of the vertebrae is even rarer. Disseminated sarcoidosis should be considered as a differential diagnosis when metastatic malignancy or tuberculosis are suspected. Serum levels of ACE, PET scan, and biopsy may be a valuable diagnostic tool of unusual sarcoidosis presentations.

CONCLUSION: Disseminated sarcoidosis present similarly to malignancy and disseminated infections, and these processes need to be ruled out. This case attempted to highlight both the variability in disease presentation and illustrate the utility of several imaging modalities, lab tests, and histopathology techniques in distinguishing sarcoidosis from other cause. We anticipate that this review may be useful for clinicians who face diagnostic dilemmas and management decisions for this complex and variable condition.

METHADONE INDUCED SUDDEN CARDIAC ARREST

Andrea Pagan[1]; Yadis Arroyo[1]; Awa Drame[2]. [1]Internal Medicine, University of South Florida, Tampa, FL; [2]Internal Medicine, University of South Florida, Tampa, FL. (Control ID #3392748)

LEARNING OBJECTIVE #1: Physicians prescribing Methadone Maintenance Therapy should know the risk of methadone induced QT interval prolongation and associated torsades de pointes and weigh the benefits agaist the risks.

LEARNING OBJECTIVE #2: Clinicians should inform patients of arrhythmia risk when they prescribe methadone.

CASE: A case of a 38-year-old male with past medical history of untreated Hepatitis C and polysubstance abuse on methadone maintenance therapy (MMT) was brought to the ED after being found down. Upon examination, the patient was alert and oriented to person and time but did not recall what happened. Labs were pertinent for troponin of 0.27 NG/ML, CPK 3626 U/L, UDS positive for methadone, amphetamines, and cocaine. The ECG on admission was noted to have a QTc of 618ms. A review of the patient's medication revealed that he was on methadone 300 mg/day. In the ED, the patientdeveloped pulseless ventricular tachycardiac followed by ventricular fibrillation requiring ASCLS protocol. Patient regained ROSC after one round. Throughout his hospital course, the patient continued to have multiple episodes of polymorphic ventricular tachycardia requiring isoproterenol drip and a washout period of 11 days to remove the methadone from his system. The discontinuation of methadone was accompanied by normalization of the QTc within 12 days. The patient was started on buprenorphine asan alternative to methadone.

IMPACT/DISCUSSION: Methadone maintenance therapy has shown benefits in reducing the useof illegal substances, has decreased the mortality due to excessive use of drugs, has decreased criminal activity, and reduced the transmission of HIV and viral hepatitis. Methadone-induced QTP and associated TdP is a well- documented side effect of this medication. Methadone causes an inhibition of the cardiac ion channel and causes QTP in a dose dependent manner. The management of an MMT patient presenting with QTP and polymorphic ventricular ectopy or TdP includes magnesium supplementation, isoproterenol, and temporary pacing if arrhythmia persists. Long term treatment includes buprenorphine, naltrexone, or slow-release oral morphine. Other options, such as an implantable cardioverter-defibrillators, have been suggested for MMT patients with symptomatic ventricular arrhythmias, but due to the high procedure-related complications and recurrent shocks, this is often excluded.

CONCLUSION: Methadone is a synthetic opiateand is currently the drug of choice for the treatment of opioid addiction. Side effects of using this medication includes nausea, vomiting, and constipation to more serious adverse effects such as: arrhythmias, QT interval prolongation (QTP), torsade de pointes (TdP), and death. We present a case of a patient with multiple episodes of cardiac arrest secondary to ventricular tachycardia and ventricular fibrillation in the setting of chronic methadone use. Physicians prescribing MMT should weigh the benefits against the increasingly well-documented risk of methadone induced QT interval prolongation and associated TdP.

MEXILETINE INDUCED VISUAL HALLUCINATIONS

Ameer H. Khan, Manishkumar Patel, Victoria Gonzalez. Internal Medicine, Wayne State University, Rochester Hills, MI. (Control ID #3391949)

LEARNING OBJECTIVE #1: Use of Mexiletine, a class IB antiarrhythmic, may lead to the development of rare adverse effects such as visual hallucinations in certain cases

CASE: A 79-year-old male with a past medical history of coronary artery disease status post-CABG, ischemic cardiomyopathy and HFrEF with Dual Chamber ICD which was recently upgraded to CRT-D presented to the ED with visual hallucinations of masked men inside his house trying to rob him for the past 3 weeks. These complex visual hallucinations were corroborated by family members. He reported no other symptoms. His medications were GDMT for CAD and HFrEF. He was also taking amiodarone and mexiletine for refractory ventricular tachycardia. On physical examination, he was awake, alert and oriented. He had no neurological deficits and his vision was intact. Laboratory values and urine drug screen were unremarkable. A CT head showed no acute disease. MRI and EEG were also both unremarkable. The usual causes of visual hallucinations including metabolic encephalopathy, alcohol withdrawal, and drug intoxication were ruled out. Despite extensive investigation, the patient's symptoms continued throughout his hospitalization. Thus, his history and medication list were reviewed again. It was noted that he had just been started on Mexiletine 4 weeks prior due to repeated firing of his AICD for ventricular tachycardia. This medication was thought to be the culprit and therefore it was discontinued. Within one day the patient stopped experiencing visual hallucinations. He was discharged home without this medication and he remained free of visual hallucinations after discontinuing the drug.

IMPACT/DISCUSSION: Mexiletine is a Class IB antiarrhythmic, structurally similar to lidocaine, used frequently for treating ventricular arrhythmias. It acts by inhibiting the inward sodium current, decreasing the rate of rise of phase 0 and, as a consequence, decreases cardiac automaticity, increases refractory periods and slows conduction. Common adverse effects include nausea, vomiting, appetite changes, vision changes, rash, dizziness, dry mouth, and weakness. Even though the GI side effects

are more common, neurological side effects, including visual hallucinations as in our case, may occur.

CONCLUSION: With the initiation of the medication occurring directly prior to the symptom onset and the ceasing of symptoms occurring directly after discontinuation, it is fair to say the medication was the true culprit for the complex visual hallucinations. Extensive investigations for visual hallucinations were also unremarkable. Our literature review revealed no reported cases of visual hallucinations associated with Mexiletine use. If patients report symptoms such as visual hallucinations after starting Mexiletine it is important to have a multi-disciplinary approach including the Cardiology team to balance the risks and benefits of the medication in order to treat refractory ventricular tachycardia.

MICROSCOPIC COLITIS: AN EASILY OVERLOOKED ETIOLOGY OF PERSISTENT DIARRHEA

Abena Kwegyir-Aggrey, Kevin Lam, Bathai Edwards. Department of Medicine, Penn State College of Medicine, Hershey, PA. (Control ID #3391544)

LEARNING OBJECTIVE #1: Recognize the clinical presentation, complications, and workup of microscopic colitis (MC).

LEARNING OBJECTIVE #2: Review the common risk factors for the development of MC and its relationship to autoimmune diseases.

CASE: A 60 year old female presented to the ED with a 3 week history of frequent, watery, non-bloody stools, abdominal pain, and emesis. Past medical history was significant for rheumatoid arthritis and Sjogren's Syndrome, managed with etanercept, and depression, recently started on fluoxetine. She presented 4 days after discharge from an outside hospital with ciprofloxacin for presumed segmental colitis with no resolution of symptoms. Patient noted associated hypotension, oliguria, and lightheadedness. Vitals were temperature of 36.4C, heart rate of 120, and blood pressure of 119/54. Her physical exam was remarkable for diffuse abdominal tenderness to palpation without rebound tenderness or guarding. Labs showed hypovolemic hyponatremia with sodium of 129 mmol/L, metabolic acidosis with pH 7.3, pCO2 of 25, pO2 94, and HCO3 of 14.6 and severe acute renal failure with BUN 27 mg/dL and Cr 3.33 mg/dL. Inflammatory marker results showed ESR of 87mm/hr and CRP 5.69 mg/dl. Non-contrast CT showed fluid throughout the colon. An enteric pathogen panel, C. difficile toxin test, and stool parasite test were negative. Gross findings on colonoscopy were insignificant. However, colonoscopy with biopsy showed new inflammatory cells and intraepithelial inflammation, consistent with lymphocytic microscopic colitis (MC). Gastroenterology recommended treatment with budesonide, leading to clinical improvement.

IMPACT/DISCUSSION: MC is a disease that is poorly understood. MC has two subsets: collagenous colitis and lymphocytic colitis. It is commonly seen in women between the ages of 60-70 and is often associated with autoimmune diseases and medication usage, particularly nonsteroidal anti-inflammatory drugs, PPIs, statins, and SSRIs. Of note, diarrhea is a common adverse effect of these medications. Additionally, smoking is associated with an increased risk of developing MC. MC presents with insidious onset of persistent, non-bloody diarrhea with associated abdominal pain, emesis, and weight loss. It can be difficult to diagnose as these non-specific symptoms are observed in many gastrointestinal pathologies. Hence, the diagnosis of MC is often preceded by a workup that excludes common causes of diarrhea using CBC, electrolyte, stool, and celiac studies. If initial studies are negative, colonoscopy with mucosal biopsy and histological analysis are needed. Paradoxically, colonoscopies often reveal normal gross mucosa, resulting in missed diagnosis as biopsies are deemed unnecessary.

CONCLUSION: This case of MC demonstrates the importance of awareness of an often missed cause of prolonged diarrhea. Obtaining biopsy and histopathological examination are crucial for diagnosis of MC. There should be a high index of suspicion for MC for persistent diarrhea in the setting of new medications and autoimmune diseases.

MIGRAINE, MOOD, OR MARFANS?

Brenden S. Ingraham[1]; Andrew Greenlund[2]. [1]Internal Medicine, Mayo Clinic - Rochester, Rochester, MN; [2]Internal Medicine, Mayo Clinic, Rochester, MN. (Control ID #3371687)

LEARNING OBJECTIVE #1: Recognize bicuspid aortic valve as a risk factor for intracranial aneurysm (9.8% versus 1.1% compared to control group).

LEARNING OBJECTIVE #2: Other conditions associated with intracranial aneurysm formation include coarctation of the aorta, autosomal dominant polycystic kidney disease, glucocorticoid-remediable aldosteronism, Ehlers-Danlos syndrome, and pseudoxanthoma elasticum.

CASE: A 24-year-old male with a history of depression, migraines, tobacco abuse, and bicuspid aortic valve (BAV) presented to clinic with a headache that was sudden in onset while dancing 3 days prior. The pain was primarily left frontal with some pain in the left neck and different from his prior headaches. He reported new vertigo and blurry vision in the left eye without diplopia. No chest pain or mid-scapular pain. The pain was not relieved by acetaminophen, ibuprofen, or sumatriptan. He also reported severe depression with a PHQ-9 score of 20, which had been worsening in prior weeks. Neurological exam was nonfocal. Cardiac exam unremarkable with congruent blood pressures in all extremities. Mild tenderness to manipulation of the neck. Mild joint laxity of the upper extremities. He was sent for non-contrasted CT head and CT angiography (CTA) of the chest, neck, and head. There was no subarachnoid hemorrhage, but CTA revealed sinus of Valsalva dilation at 48 mm and a 6 mm saccular left supraclinoid internal carotid (ICA) aneurysm. No vertebral dissection or stenosis. Lumbar puncture was negative for xanthochromia. He was admitted and evaluated by neurosurgery. He underwent cerebral angiogram with subsequent pipeline embolization of the left ICA aneurysm. He was discharged on clopidogrel and aspirin with plans to deescalate to aspirin monotherapy in 6 months. He was scheduled to see cardiology to address the sinus of Valsalva dilation and consider early intervention as well as genetics to screen for heritable connective tissue disorders.

IMPACT/DISCUSSION: Headaches in young, healthy patients are easy to dismiss as tension headaches or migraines associated with stress, depression, or poor lifestyle. Careful consideration of patient factors and symptoms should guide the diagnostic process to avoid missing intracranial aneurysms (IA) in patients with occult risk factors, like BAV. Other conditions associated with IA include coarctation of the aorta, autosomal dominant polycystic kidney disease, glucocorticoid-remediable aldosteronism, Ehlers-Danlos syndrome, and pseudoxanthoma elasticum. Benefits of screening BAV patients for IA have not been formally evaluated. Many BAV experts have a low threshold to screen, and imaging is certainly warranted if there are clinical signs or symptoms.

CONCLUSION: Intracranial aneurysms are present in approximately 10% of bicuspid aortic valve patients and should be considered when these patients present with headaches.

MILLER FISHER SYNDROME: AN EYE OPENING CASE

Kevin Dyer[2]; Nicole Pohlman[1]; Susan B. Glick[1]. [1]Internal Medicine, Rush Medical College, Chicago, IL; [2]Internal Medicine, Rush Medical College, Chicago, IL. (Control ID #3391893)

LEARNING OBJECTIVE #1: Recognize the symptoms and signs of the Miller Fisher variant of Guillain- Barre Syndrome (GBS)

LEARNING OBJECTIVE #2: Describe the role of GQ1b antibodies in Miller Fisher Syndrome (MFS)

CASE: A 24-yo woman with a history of pseudotumor cerebri presented with numbness, tingling, and weakness throughout her body and diplopia for 1 day. Her prior symptoms of pseudotumor included lightheadedness, diplopia, and headache, but not numbness. She denied recent illness, fever, chills, rash, trauma, headache, blurry vision, and gait instability.

Diamox was discontinued 4 months prior to presentation. Family history revealed only diabetes. She did not use recreational drugs.

On exam, she was awake and alert. Vital signs 111/62-79-14-36.4. HEENT showed blurring of the left optic disc. Neurologic exam revealed impaired eye abduction bilaterally. DTRs were 1+ in the upper extremities and trace in the lower extremities. The remainder of the physical exam including a complete neurologic exam was otherwise normal.

WBC 11, protein 8.5. The remainder of the CBC and CMP were normal. ESR 37, CRP 33.9. CT brain revealed an empty sella without change from the prior CT. MRI of the orbits and brain revealed changes suggestive of intracranial hypertension. LP opening pressure was 37. The CSF was normal. EMG was unremarkable.

Acetazolamide was begun. She developed a change in speech quality and worsening ophthalmoplegia. These findings suggested MFS. She was begun on IVIG and her symptoms improved. Anti-GQ1b then returned positive.

IMPACT/DISCUSSION: MFS, a variant of GBS, is a demyelinating condition characterized by ophthalmoplegia, ataxia and hyporeflexia. Patients may also develop dilated pupils, slurred speech, difficulty swallowing and weakness of the extremities. Like GBS, a viral illness may precede the development of MFS. Immunoglobulins that result from these viruses and share antigenic epitopes with them are thought to target gangliosides (including GM1, GD1a and GQ1b) in nodes of Ranvier, nerve roots and end organs (including the brainstem), causing their demyelination. 85% of patients with MFS possess the GQ1b antibody, which is associated with oculomotor nerve involvement.

Imaging of the brain and spinal cord is usually normal. Nerve conduction studies may demonstrate reduced sensory response without decreased sensory conduction velocity. LP may reveal elevated CSF protein.

Like GBS, treatment for MFS is supportive care, IVIG and plasma exchange. Although most patients do well with recovery beginning 2-4 weeks after symptom onset, some develop respiratory compromise, so patients with MFS are typically hospitalized for observation. Patients most often recover in full within 3 months. Relapses occur rarely.

CONCLUSION: -MFS presents with the unique triad of ophthalmoplegia, ataxia, and areflexia

- GQ1b gangliosides, abundant in the motor nerves of the extraocular muscles, are the targets of the primary antibody that causes this syndrome
- Recurrence rates of MFS are low and are associated with increased anti-GQ1b antibody levels

MISSING THE GUIDE WIRE

Leigh Deshotels[2]; Jerald L. Taggart[1]. [1]Medicine, SLVHCS/Tulane University, New Orleans, LA; [2]Medicine, Tulane University School of Medicine, New Orleans, LA. (Control ID #3391264)

LEARNING OBJECTIVE #1: Describe the emergent treatment options for cardiac tamponade

LEARNING OBJECTIVE #2: Manage patient safety standards under physician and patient duress

CASE: A 68-year-old man with end-stage renal disease was evaluated for hypotension. He was lethargic with systolic blood pressure in the 80s, and a normal heart rate. He had decreased heart sounds, cool extremities but no evidence of jugular venous distention. Echocardiogram revealed a pericardial effusion without right ventricular collapse. Cardiology recommended transfer for a pericardial window. While awaiting transfer, blood pressure remained low despite adequate fluid resuscitation. An emergent central venous catheter (CVC) was placed in the right femoral vein. Afterwards, he had a successful pericardial window placed, and vital signs improved. Following the procedure, a retained guide wire was noted on routine chest x-ray. Interventional radiology was able to remove the catheter and guide wire concurrently. No remnants were identified on post-procedure chest x-ray. The patient experienced no complications.

IMPACT/DISCUSSION: Cardiac tamponade is a medical emergency that happens when fluid in the pericardial sac causes compression of the cardiac chambers leading to shock. When diagnosed, the patient should undergo emergent pericardiocentesis, pericardial window or removal of the pericardium. Fluids and vasopressors are temporizing measures until a more definitive treatment is available, which may require CVC placement.

Insertion of a CVC is a common intervention in the intensive care unit (ICU) with an estimation of 15 million CVC days each year in the United States. Despite preventative efforts, guide wire retention continues to occur, with one study reporting a rate of 1:3291 procedures over 6 years. Loss of the guide wire carries a 20% fatality rate which is usually caused by embolization of guide wire remnants. Standard operating procedures require the guide wire to be held at the tip at all times to avoid loss. This technique can be overlooked due to operator fatigue, inexperience, and/or urgency. The use of multiple central line kits must also be considered. Unfortunately, central lines are commonly done in urgent situations; therefore, it is imperative to find ways to manage patient safety standards in challenging settings. Cases like these may benefit from a post-procedure checklist documented in the medical record with a systematic count of critical items. Several facilities have moved towards requiring post-procedure checklists or reminder stickers. Since guide wire loss is such a rare complication, it is difficult to assess whether this has made any impact.

CONCLUSION: Cardiac tamponade may require insertion of a CVC for vasopressor support while awaiting a more definitive treatment, which includes pericardiocentesis or a pericardial window. CVC insertion carries many risks including retention of the guide wire. This complication may be prevented by standardizing post- procedure checklists.

MONOCLONAL B-CELL LYMPHOCYTOSIS: RECOGNITION AND ASSESSMENT IN PRIMARY CARE

Rachel White, Caroline Flake, Stephen White. Hematology/Oncology, Georgia Cancer Center/University Hospital, Augusta, GA. (Control ID #3390758)

LEARNING OBJECTIVE #1: Recognize the need to assess adult patients with unexplained chronic lymphocytosis with peripheral blood flow cytometry.

LEARNING OBJECTIVE #2: Evaluate the risk of malignant progression of monoclonal B-cell lymphocytosis by clone size.

CASE: A 71-year-old female with a history of HTN, resected DCIS, and osteopenia was found in late 2017 to have a WBC of 9,800 with a differential of 58% lymphocytes (absolute lymphocyte count 5,680), 35% neutrophils, 4% monocytes, 2% eosinophils, and 1% basophils. Review of her medical records revealed a chronic mild lymphocytosis with otherwise normal findings on serial CBCs since at least 2011. She denied fever, drenching night sweats, pruritis, weight loss, LUQ abdominal pain, early satiety, or symptoms of acute or chronic infection. Her physical examination was essentially normal with no palpable cervical, axillary, or inguinal lymphadenopathy or splenomegaly. Additional testing included a normal hemoglobin and platelet count with no LFT, renal, or electrolyte abnormalities. Her peripheral smear revealed a mild predominance of normal appearing lymphocytes with otherwise normal leukocyte, RBC, and platelets. The patient was assessed with peripheral blood flow cytometry revealing a clonal B-cell population with a CLL phenotype (CD5+, CD19+, CD20 dim, CD23+) measuring 3.9 x 109/L. She has since been monitored with annual CBC/differentials demonstrating a stable mild lymphocytosis without concurrent cytopenias. She has not developed symptoms or physical examination findings suggestive of evolving CLL.

IMPACT/DISCUSSION: Monoclonal B-cell lymphocytosis (MBL), a clonal population of peripheral blood B cells measuring < $5X10^9$/L with absent clinical findings of underlying myeloproliferative disease, is detectable in 4-9% of healthy adults. MBL clones are detected, quantitated, and immunophenotypically characterized by peripheral blood flow cytometry. A significant majority of cases of MBL display a CLL immunophenotype with coexpression of CD5 and B-cell markers (CD19, dim CD20, CD23); less commonly, circulating B cells with a marginal zone lymphoma phenotype are detected. The clinical relevance of MBL is largely determined by clone size. Low-count MBL (with a B-cell clone measuring < $0.5x10^9$/L) confers no increased risk of CLL progression. High-count MBL (clone size > $2x10^9$/L) is associated with a 1-2% risk per year progression to CLL requiring treatment.

CONCLUSION: An adult patient with no clinical findings suggestive of underlying lymphoproliferative disease (lymphadenopathy, splenomegaly, cytopenias, unexplained fever, night sweats) and with a peripheral blood lymphocytosis unexplained by secondary causes (infection, autoimmune disease) persisting for more than three months should be assessed by peripheral blood flow cytometry.

If flow cytometry detects a monoclonal B-cell population measuring 2-$5x10^9$/L in this context, annual monitoring with a CBC and clinical assessment is indicated due to a 1-2% yearly risk of progression to symptomatic lymphoproliferative disease.

MORE THAN A FEELING: WHY CHRONIC DYSPNEA SHOUD NOT BE DISCOUNTED

Nicholas Sassen, Marjorie E. Bateman. Department of Medicine, Tulane University School of Medicine, Mandeville, LA. (Control ID #3372809)

LEARNING OBJECTIVE #1: Identify key clinical features of interstitial lung disease

LEARNING OBJECTIVE #2: Distinguish pulmonary sarcoidosis from other etiologies of interstitial lung disease

CASE: A 68-year-old African American woman presented with 1 year of dyspnea on exertion and nonproductive cough. Symptoms had been attributed to deconditioning. She had been taking nitrofurantoin for months as prophylaxis for urinary tract infections and lisinopril for hypertension. She had never smoked and had no family or personal history of autoimmune disease. She had fine bibasilar crackles. Labs were unremarkable. Chest X-ray showed patchy perihilar and diffuse interstitial opacities. Transthoracic echocardiogram was normal. Chest CT demonstrated mediastinal and hilar lymphadenopathy, ground glass opacities, honeycombing, and hypoattenuating splenic lesions. Right heart catheterization revealed pulmonary hypertension with normal pulmonary artery wedge pressure. Lymph nodes were negative for granulomas, but lung tissue demonstrated microgranulomatous foci. She was diagnosed with sarcoidosis and started on methotrexate with significant improvement in her symptoms.

IMPACT/DISCUSSION: Interstitial lung diseases (ILD) are a diverse group of disorders which originate in the interstitium but are associated with disruption of alveolar and airway architecture. They typically present as progressive dyspnea with exertion and nonproductive cough. They are often mistaken for a separate disease (i.e. heart failure, COPD) or attributed to deconditioning, aging, or obesity. Early diagnosis relies on a thorough history of risk factors including family history, medications, and occupational or environmental exposures. Crackles may be observed on exam even before radiographic abnormalities. Digital clubbing is the main extrapulmonary finding. The most common features on imaging include reticular or nodular opacities, while only a few demonstrate hilar/mediastinal adenopathy.

The lifetime incidence of sarcoidosis is under 1% for Caucasians but 2.4% in African Americans. Nearly 25% of patients with sarcoidosis die of respiratory failure, which emphasizes the importance of early diagnosis and treatment. More than half of patients present only with chronic respiratory complaints. Common laboratory findings include cytopenias, eosinophilia, and hypercalcemia. Angiotensin converting enzyme (ACE) is elevated in 40-80% of patients but can be suppressed by ACE inhibitors. Radiographic evidence of intrathoracic disease is present in up to 97% of patients, particularly mediastinal adenopathy. Identification of non-caseating granulomas is a key component of the diagnosis but can also be seen in lymphoma, fungal infections, inhalation-related ILD, drug- induced ILD, and vasculitis.

CONCLUSION: The challenge of diagnosis of sarcoidosis stems from the variable presentation in combination with the lack of a single diagnostic test to confirm or rule out disease. Despite this, a thoughtful clinician can identify when chronic dyspnea is more than a feeling.

MORE THAN A TROPE: HER HEART WILL GO ON

Nicholas Tolat[1]; Marjorie E. Bateman[1]; Jerald L. Taggart[2]. [1]Department of Medicine, Tulane University School of Medicine, Mandeville, LA; [2]Medicine, SLVHCS/Tulane University, New Orleans, LA. (Control ID #3391302)

LEARNING OBJECTIVE #1: Develop a differential diagnosis for an elevated troponin level

LEARNING OBJECTIVE #2: Recognize patient-centered decision making and its impact on delivery of care

CASE: A 54-year-old female phlebotomist requested a troponin be drawn with her routine lab draw. She reported 2 weeks of cough productive of white sputum, sinus congestion, myalgias, and subjective fevers. She denied chest pain and shortness of breath. Her past medical history included myocardial infarction two years prior and Sjogren's syndrome. Her previous myocardial infarction had presented with severe shortness of breath.

Her vitals and exam were within normal limits. Initial troponin was found to be 0.58 ng/ml, which subsequently trended down. A respiratory viral panel returned negative. No ischemic changes were appreciated on EKG, and no acute abnormality was identified on chest x-ray.

Transthoracic echocardiogram revealed an asymmetric septal bulge of the basal and mid septum. Cardiac MRI showed acutely edematous, enhancing mid myocardial septal and lateral walls suggestive of myocarditis. Elevated troponin level was attributed to viral myocarditis.

IMPACT/DISCUSSION: Troponin, a protein expressed only in cardiac muscle, has been used routinely used to determine whether a patient with chest pain is having a myocardial infarction. This is due to the high sensitivity and specificity of the biomarker for myocardial injury. However, the clinician must remain mindful of non-ischemic causes of myocardial injury. An elevated troponin level may also be due to myocarditis, decompensated heart failure, cardiac procedures, cardiotoxic medications, hypertensive emergency, trauma, and demand ischemia. Noncardiac causes like septic shock and pulmonary embolism should also be considered. Presentations of myocarditis may be subclinical, and the etiology can often be identified based on the patient's history. The general internist can utilize the differential diagnosis of elevated troponin and combine it with history and EKG findings to determine if an acute cardiac process is ongoing.

Patient requests for additional testing, referral, or medication are common, occurring in 23% of office visits in one study. These requests are often fulfilled. However, if these requests are not clinically indicated, physician communication with a patient-based perspective is crucial to avoid ordering unnecessary labs or tests. This approach includes exploring the context of the patient's request and providing alternative explanations for their symptoms. Patients may persist on a particular lab or test but providing education or offering a more cost-effective option could be a way to mitigate their ongoing concerns. In doing so, associated current and future healthcare costs would be cut while still providing exemplary patient care.

CONCLUSION: Using a shared decision model in which the patient is involved and exploring their narrative has been shown to lead to greater patient satisfaction and can assist physicians in making a diagnosis.

MORE THAN ONE WAY TO HYPERCAPNIA

Channing G. Brown[2]; Starr Steinhilber[1]; Jeremey B. Walker[1]. [1]Internal Medicine, University of Alabama at Birmingham, Birmingham, AL; [2]Internal Medicine-Pediatrics, University of Alabama at Birmingham, Birmingham, AL. (Control ID #3391957)

LEARNING OBJECTIVE #1: Identify common cognitive diagnostic errors through differential of acute hypercapnic respiratory failure.

LEARNING OBJECTIVE #2: Consider Lambert-Eaton myasthenic syndrome (LEMS) in the differential diagnosis of patients with hypercapnic respiratory failure and long standing smoking history.

CASE: A 72 year-old woman with COPD and tobacco use, presented to the emergency department confused and in respiratory distress. She was recently admitted for two months of progressive vertigo, diplopia, nausea, and weight loss. She was treated for hyponatremia and discharged to a rehabilitation facility due to debility where she had been for 2 weeks prior to this admission. She was unable to provide history due to clinical condition.

On exam the patient was tachycardic to 102, tachypneic to 26, hypertensive and satting 90% on room air. Diffuse pulmonary crackles and respiratory distress were noted along with pitting edema in bilateral lower extremities. EKG revealed atrial fibrillation and chest radiograph revealed bilateral lower lobar infiltrates. Arterial blood gas showed acute on chronic respiratory acidosis. Non-invasive positive pressure ventilation (NIPPV) was initiated and she was admitted to the intensive care unit with treatment for acute exacerbation of COPD and new onset heart failure. She required intubation week 1 and antibiotics were initiated. She failed multiple extubation trials due to recurrent hypercapnia. Week 3 of hospitalization chest CT showed hilar and subcarinal lymphadenopathy. Biopsy of subcarinal nodes confirmed small cell lung cancer (SCLC). Electromyography and nerve conduction studies were diagnostic of postsynaptic neuromuscular junction transmission disorder, consistent with Lambert Eaton Myasthenic Syndrome. Treatment with pyridostigmine and plasma-exchange resulted in improvement and extubation to NIPPV. Anti-P/Q voltage-gated calcium channel (VGCC) antibody returned positive. Oncology initiated a trial of chemotherapy for definitive management of SCLC and LEMS. Despite initial improvement, the patient ultimately died of septic shock.

IMPACT/DISCUSSION: The differential diagnosis of hypercapnic respiratory failure must be considered in order to implement effective treatment. System 1 thinking is necessary in urgent situations where pattern recognition and intuition may allow for prompt treatment of a condition, however it may lead to premature closure which is cited in 74% of diagnostic errors in Internal Medicine. In this case, the differential diagnoses of COPD exacerbation, CHF, and pneumonia were maintained for three weeks prior to evaluation for neuromuscular causes of hypercapnia including LEMS. When treatment of common causes of hypercapnia results in no clinical improvement, utilizing a more analytical system 2 thinking approach with re-evaluation of clinical symptoms and consideration of less common causes of hypoventilation is warranted.

CONCLUSION: Neuromuscular causes of hypercapnia should be considered in patients who fail to respond to initial treatment of common causes.

MORE THAN RECURRENT HYPOKALEMIA

Manuel Endo Carvajal[1]; Mariana Velasquez[3]; Dennys P. Jimenez Hernandez[1]; David Schmit[2]. [1]Internal Medicine, UTHSCSA, San Antonio, TX; [2]Hospital Medicine, UTHSCSA, San Antonio, TX; [3]Antioquia, Universidad CES, Medellin, Colombia. (Control ID #3392086)

LEARNING OBJECTIVE #1: Include thyrotoxic periodic paralysis as part of the differential diagnosis for a patient presenting with recurrent hypokalemia.

LEARNING OBJECTIVE #2: Recognize clinical presentation and diagnose thyrotoxic periodic paralysis.

CASE: A 37-year-old Hispanic man with a past medical history of asthma and recurrent hypokalemia presented to the emergency department (ED) with lower-extremities weakness and myalgias. Upon presentation, the patient denied any other symptom. He was only taking albuterol inhaler as needed for shortness of breath, but he had not used it for the last 3 weeks before presentation.

At arrival patient was hypertensive and tachycardic. Physical exam was just remarkable for decreased motor strength in lower extremities.

Initial laboratory evaluation showed hypokalemia of 2.3 and a suppressed Thyroid stimulating hormone (TSH) with elevated free thyroxine (fT4) levels. Further work-up revealed an elevated free triiodothyronine (fT3) levels, elevated TSH receptor antibodies (Ab), elevated thyroid peroxidase Ab and negative thyroglobulin Ab. The diagnosis of thyrotoxic periodic paralysis (TPP) was made and patient was started on potassium (K) supplementation, propranolol, and methimazole with satisfactory clinical response.

IMPACT/DISCUSSION: Recurrent hypokalemia is a very common medical condition mistreated by internists. Frequently, hypokalemia is empirically treated just with K replacement without an adequate workup.

Hypokalemia can present asymptomatically; however, muscle weakness and cardiac dysrhythmias are common clinical presentations. Hypokalemia can be caused by two mechanism: total body K deficit either due to

decreased oral intake or to gastrointestinal/renal losses; or K shifting into the intracellular space. Thyroid hormone directly stimulates the sodium-potassium adenosine triphosphate (Na-K ATPase) pump causing intracellular shifting of K.

The triad of TPP is acute hypokalemia without total body K deficit, muscle paralysis, and thyrotoxicosis. Paralysis is usually symmetrical and affects more severely the proximal muscles of the lower extremities. Although hyperthyroidism has predominance for females, TPP occurs mostly in young Asian males due to activation of the Na-K ATPase by androgens. Since the clinical presentation is not specific and the symptoms of hyperthyroidism are not always present, the diagnosis of TPP can be challenging and a high index of clinical suspicion is needed.

Because TPP occurs only in the thyrotoxic state, definitive treatment consists in achieving an euthyroid state.

CONCLUSION: -Thyrotoxic periodic paralysis may be the initial presentation of hyperthyroidism, however, in many patients the signs and symptoms are subtle.

- Any young male without a family history of hypokalemic periodic paralysis presenting with neuromuscular symptoms and hypokalemia should be assessed for hyperthyroidism independently of the presence or absence of other thyrotoxic signs or symptoms.

MORPHINE, DON'T LEAVE ME BROKENHEARTED

Allyson Hughes[1]; Stacy Davis[2]. [1]Internal Medicine, UTHSC Nashville, Nashville, TN; [2]Saint Thomas Hospital, Nashville, TN. (Control ID #3391694)

LEARNING OBJECTIVE #1: Recognize the presentation of stress cardiomyopathy.

LEARNING OBJECTIVE #2: Recognize atypical etiologies of stress cardiomyopathy including opiate withdrawal.

CASE: A 69-year-old female with COPD and osteoarthritis managed by chronic opiate use presented with one day of shortness of breath that the patient described as "morphine withdrawal." She takes daily morphine and had not taken morphine for 72 hours. She denied chest pain, jaw pain, palpitations, diaphoresis, and cough. Vital signs were within normal limits. Physical exam noted benign cardiac and pulmonary exams. Initial troponin was 3.05, and repeat was elevated to 12.57. Her urine drug screen was positive for opiates. Other labs were within normal limits. Chest radiograph did not reveal any cardiopulmonary abnormalities. Initial EKG showed normal sinus rhythm and no signs of ischemia; a repeat study 8 hours later revealed sinus rhythm with diffuse T-wave inversion. Echocardiogram revealed LVEF of 34% with grade 1 diastolic dysfunction and extensive akinesis of the apex and surrounding segments consistent with stress cardiomyopathy. Coronary angiography was not performed during hospitalization as she had a normal study 6 months prior with LVEF of 74%. The patient did not report a history of emotional or physical stress. Her home medications of aspirin, lisinopril, and simvastatin were continued during her hospitalization. Morphine was continued at her home dosage in order to prevent worsening cardiomyopathy. She was discharged with a new prescription for beta-blocker therapy and instructions to continue morphine with plans to slowly taper in the outpatient setting in order to avoid withdrawal and cardiac complications. A repeat echocardiogram performed 3 months after hospitalization revealed improved LVEF of 50-55% without signs of apical akinesis.

IMPACT/DISCUSSION: Stress cardiomyopathy, i.e. Takotsubo or Broken Heart Syndrome, is a cardiomyopathy involving regional systolic dysfunction that is transient in nature and mimics acute coronary syndrome. First described in 1990, it now represents up to 2% of patients with troponinemia and suspected ACS. It is theorized that the syndrome is caused by direct toxicity of or induced vascular spasm by catecholamine elevation. Case reports have identified catecholamine elevation as the culprit, citing this syndrome in patients with acute brain injury or pheochromocytoma.

CONCLUSION: While narcotic use/abuse and stress cardiomyopathy are not independently rare, few reports of narcotic withdrawal instigating stress cardiomyopathy exist. Opiate withdrawal leads to a catecholamine surge that can directly or indirectly damage cardiac tissue and ultimately lead to cardiomyopathy. Many reports of stress cardiomyopathy cite a physical trigger (36%), emotional trigger (27.7%), or both (7.8%). Patients with psychiatric or neurologic disease may also be predisposed. Physicians should be aware of possible triggers of stress cardiomyopathy, including opiate withdrawal.

MULTIPLE STROKES IN LATIN AMERICAN PATIENT

Ramez M. Halaseh[1]; Malik Shehadeh[1]; Rachel Marcus[2]. [1]Internal Medicine, Medstar Washington Hospital Center, Washington, DC; [2]Cardiovascular Disease, Medstar Washington Hospital Center, Washington, DC. (Control ID #3392182)

LEARNING OBJECTIVE #1: To recognize Chronic Chagas cardiomyopathy (CCC) as potential cause of stroke in Latin American patients

CASE: A 56-year-old El-Salvadorian male patient without significant prior medical history presented to our hospital with new onset of left sided weakness.

Upon arrival to the hospital, his vitals were unremarkable except for elevated blood pressure. Clinical examination showed 4/5 muscle strength in both left upper and lower extremities. His labs showed LDL of 115 mg/dl with normal hemoglobin A1C.

Brain magnetic resonance imaging (MRI) showed an acute infarct in the right middle cerebral artery along with remote cortical infarcts in the left frontal, parietal and occipital lobes. His electrocardiogram (ECG) showed normal sinus rhythm with right bundle branch block and left anterior fascicular block. Carotid duplex was normal. Both echocardiogram and contrast echocardiogram were limited, but showed low normal left ventricular (LV) systolic function.

Because the patient's clinical presentation was so consistent with Chagas disease, a cardiac MRI was obtained to evaluate for the typical LV apical aneurysm that is associated with this illness. This showed both a focal LV apical aneurysm, which was the most likely source of his cardioembolism, and basal inferolateral scarring which is typical for CCC. A *Trypanosoma Cruzi* serology was obtained and came back positive.

IMPACT/DISCUSSION: Chagas disease is a chronic parasitic infection caused by the protozoan *Trypanosoma Cruzi* that is transmitted to humans through the feces of infected bloodsucking bugs in endemic areas of Latin America. The disease affects about 6 million people in Latin America and is currently considered the most common cause of non-ischemic cardiomyopathy in that region.

Chagas cardiomyopathy typically appears decades after the initial infection and can lead to heart failure, sudden cardiac death, or stroke. The latter is usually attributable to an embolus from an LV apical aneurysm either in the setting of otherwise normal or dilated cardiac chambers and/or atrial fibrillation.

Found in up to 50% of patients with CCC, bifascicular block on ECG is a classic finding for this illness. In a study in Latin American immigrants to the Los Angeles area with this finding on ECG, 18% were found to have Chagas disease. Beyond an ECG, additional evaluation in patients suspected of Chagas-associated cardioembolism should include an echocardiogram to evaluate for focal scarring or LV apical aneurysm. However, if echocardiography is nondiagnostic, a cardiac MRI should be pursued to assess ventricular structure and function. Ultimately, diagnosis

of Chagas disease is based on positive serology for *Trypanosoma Cruzi* IgG, which must be confirmed with additional serologic analysis by the CDC.

CONCLUSION: Ischemic stroke may be the first manifestation of patients with CCC, and should be suspected in any Latin American patient from a Chagas-region with cardioembolism.

MYCOBACTERIUM SHIMOIDEI PRESENTING AS SUSPICIOUS PULMONARY NODULES

Rohit Jain[1]; Ravi Patel[2]; Zainab Shahid[3]; Ricci Kalayanamitra[4]; Dhirisha Bhatt[2]; Rama R. Vunnam[2]; Rezhan Hussein[2]; Nitasa Sahu[2]; Reshma R. Golamari[5,2]. [1]Medicine, Hershey Medical Center, Cumberland, MD; [2]Internal medicine, Penn State Milton S. Hershey Medical Center, Hershey, PA; [3]Internal Medicine, LECOM, Erie, PA; [4]Penn State College of Medicine, Penn State Health, Hershey, PA; [5]Internal Medicine, Penn State Health Milton S Hershey Medical Center, Hershey, PA. (Control ID #3388140)

LEARNING OBJECTIVE #1: Recognize increasing prevalence of non-tuberculous pulmonary infections

LEARNING OBJECTIVE #2: Recognize Mycobacterium Shimoidei as a rare etiology of pulmonary infection.

CASE: A 76 year old male with history of chronic obstructive pulmonary disease, coronary artery disease, hypertension, hypothyroidism, and a 2 month history of night sweats with recent finding of an FDG avid large right upper lobe (RUL) nodule and bilateral pulmonary nodules status post endobronchial ultrasound with biopsy negative for malignancy presented for an elective VATS RUL wedge resection. The procedure was complicated by pneumothorax and persistent air leak with subcutaneous emphysema that was managed with a chest tube and endobronchial valve placement. Pathology from the wedge resection returned with AFB positive necrotizing granulomas consistent with Mycobacterium. This was further analyzed with broad range PCR which returned positive for Mycobacterium Shimoidei. Therapy was thereafter initiated with azithromycin, rifabutin and ethambutol with plan for close follow up.

IMPACT/DISCUSSION: Non-tuberculous mycobacterium (NTM) are organisms ubiquitous in the environment that can cause a wide range of infections, with pulmonary infections being the most frequent.

Mycobacterium shimoidei is a rare subspecies with less than 50 cases reported upon our review of literature. Based on a review of 23 cases by Baird et al the most common symptoms include cough/sputum production, dyspnea, fever/sweats weight loss, and fatigue. With respect to treatment regimens, M. shimoidei is known to be resistant to isoniazid and rifampicin with susceptibilities to ethambutol and rifabutin (2). Therefore accurate diagnosis of this rare isolate is imperative to appropriate treatment and subsequent patient outcome.

CONCLUSION: M. shimoidei is a rare form of non-tuberculous mycobacterium with increasing prevalence and clinical similarities to tuberculous pulmonary disease and primary neoplasms of the lung.

MYOPATHY: A "COLCHIN-ARY" TALE

Vaishnavi Lanka. Internal Medicine, Emory, Atlanta, GA. (Control ID #3349417)

LEARNING OBJECTIVE #1: Recognize renally cleared drugs that induce myopathy

LEARNING OBJECTIVE #2: Motivate clinicians to reconcile medications for appropriate renal dosing

CASE: Pt is a 37yoM with PMH of HTN, ESRD 2/2 cocaine use on PD, HTN, and HFrEF presenting with one week of sharp, left sided abdominal pain, cramping, fevers and fatigue. The pain started in the LLQ and spread to his whole body. He developed progressive weakness and by the end of the week, he was unable to get out of bed. He performed peritoneal dialysis earlier that day prior to admission. Pt was admitted 45 days for pericarditis and discharged on Colchicine 0.6mg BID for 3 months, Ibuprofen 200mg and Protonix 40mg. Physical exam was notable for 3/5 strength in lower extremities and 4/5 strength in upper extremities. Pt was unable to get out of bed without support. Labs pertinent for CPK of 2700, AST of 136 and ALT of 63. Medication reconciliation revealed that the appropriate dosing of colchicine for ESRD was an upper limit of 0.3 daily. Colchicine was discontinued and pt regained function in a couple of days.

IMPACT/DISCUSSION: Colchicine-induced myopathy has been reported in several previous case studies. In this case colchicine, a medication with known side-effects of myopathy, was dosed inappropriately in an ESRD patient. This patient has been getting four times the appropriate amount of colchicine for more than a month before presentation. There have been many adverse patient outcomes due to inappropriate dosing in CKD patients. A study from 2009 show that 21.9% of prescriptions were nonadherent to renal dosing guidelines and there were adverse drug events (ADE) 21.3% of the time. Pharmacy guided dosing decreased the ADE to 16%. In the outpatient setting, approximately 25% of patients with CKD were receiving inappropriately dosed prescriptions. Moreover, discrepancies between sources makes it difficult for clinicians to identify renally dosed medications. One article studied five pharmaceutical databases and concluded that there was only slight agreement among the sources with poorly defined qualitative data and lack of consistency in quantitative values.

Signs of myopathy include myalgias, hyperkalemia, weakness and myogloninuria. Anticholesterol (statins), antirheumatic (D-penicillamine, colchicine), immunosuppressive (steroids, tacrolimus) and antinucleoside analogues are classically associated with myopathy. Illicit substances including cocaine, heroin, amphetamines, PCP and alcohol have also been known to cause myopathy. Particularly, colchicine, simvastatin, gemfibrozil, D-penicillamine, Cyclosporine, Tacrolimus and Zidovudine are myopathy-inducing medications that need to be dose-adjusted or are contraindicated in ESRD.

CONCLUSION: Physicians must be more vigilant when prescribing renally cleared medications to avoid adverse events, especially in ESRD patients. It is vital to conduct a thorough medication reconciliation on ESRD patients both in the inpatient and outpatient setting to diagnose symptomatology and prevent adverse events.

NAVIGATING THE MAZE OF AUTOIMMUNE ENCEPHALITIS FOR THE INTENIST

Patricia Machado[1]; Manuel Endo Carvajal[2]; Rebecca S Romero[1]; Elena Jimenez Gutierrez[2]. [1]UT Health San Antonio, San Antonio, TX; [2]Department of Medicine, The University of Texas Health Science Center at San Antonio, San Antonio, TX. (Control ID #3391741)

LEARNING OBJECTIVE #1: Recognize clinical scenarios in which the internist should suspect autoimmune encephalitis (AE).

LEARNING OBJECTIVE #2: Diagnose AE early in the clinical course to avoid irreversible neuronal loss.

CASE: A 36-year-old man with childhood epilepsy, not on antiepileptic therapy, and hydrocephalus requiring ventriculoperitoneal (VP) shunt six years ago presented with one week of confusion and increased muscle tone with bilateral hand tremors. He was febrile, tachycardic and

tachypneic. Physical exam was notable for disorientation to time, paucity of speech, impaired short-term memory, increased muscle tone, bilateral resting tremors of upper extremities, and hyperreflexia. Labs demonstrated elevated inflammatory markers, but normal lactate and white cell count. Broad spectrum antibiotics were started. Electroencephalogram showed shaking spells without electrical correlate. Magnetic resonance imaging of the brain revealed a right frontal VP shunt without acute abnormality. Cerebrospinal fluid (CSF) studies revealed <5 nucleated cells per microliter with 88% lymphocytes, presence of oligoclonal banding, elevated protein, low glucose, and elevated angiotensin-converting enzyme. Infectious workup including urine and blood cultures; CSF bacterial, fungal and acid-fast bacilli cultures; meningitis PCR panel, HIV, syphilis, and chest x-ray were negative. Thus, the diagnosis pointed towards autoimmune causes and empiric intravenous steroids were started. Serum AE panel revealed elevated titers of acetylcholine receptor ganglionic neuronal and glutamic acid decarboxylase 65 antibodies, but CSF antibody panel was negative. A dedicated work up for systemic sarcoidosis was negative as well. AE was diagnosed and patient underwent plasma exchange (PLEX) with symptomatic improvement.

IMPACT/DISCUSSION: AE is a challenging diagnosis given the diverse clinical presentation. A high index of suspicion is needed and even empiric initiation of immunotherapy with further assessment of clinical response plays an important role in the diagnostic process. Since many patients with AE do not present with a well-defined syndrome, the detection of serum and CSF antibodies is a crucial step for definitive diagnosis.

However, access to these panels is limited and results are often not available early during the clinical course. Given that some antibodies in the AE panel have been found in asymptomatic patients and that many other autoimmune diseases with CNS involvement may respond to steroids/PLEX, these diagnostic steps are not completely specific. Nonetheless the patient presented with a compatible clinical presentation and positive serology, the diagnosis was confirmed with response to steroids and PLEX.

CONCLUSION: Internists should include AE in the differential for patients presenting with unspecified encephalopathy in which infective causes have been ruled out.

A low threshold for ordering AE panels is recommended for early initiation of specific therapy preventing irreversible neuronal loss.

NECK PAIN AS THE CHIEF COMPLAINT FOR INFECTIVE ENDOCARDITIS

Sarah Godfrey. Medicine, Columbia University Medical Center, New York, NY. (Control ID #3387848)

LEARNING OBJECTIVE #1: Recognize signs of epidural abscess on physical exam

LEARNING OBJECTIVE #2: Diagnose neurological complications of infective endocarditis

CASE: Male, 66, with coronary artery disease s/p quadruple vessel CABG, aortic stenosis s/p surgical AVR, hypertension, insulin-dependent diabetes mellitus, severe diverticulitis s/p partial colectomy, degenerative spine disease, obstructive sleep apnea, and hypothyroidism who was referred to the emergency department for hypoxemia. Two weeks prior to presentation, he developed severe left-sided neck pain worse than his chronic pain. He went to his primary provider, who prescribed tinazidine and soft neck collar. The pain continued to worsen until he presented to an urgent care where he was found to be hypoxic. He was admitted to the general medicine service, and physical exam revealed 2/6 systolic ejection murmur over the RUSB, bibasilar crackles, and exquisite tenderness over the left trapezius with only 20 degrees of neck motion. Blood cultures were positive for *Streptococcus bovis*. Chest x-ray showed pulmonary edema, and EKG had new atrial fibrillation in the 140s. A TTE was largely unremarkable, but TEE revealed a 1.6cm vegetation on the posterior mitral valve leaflet with mild mitral regurgitation, in addition to severe bioprosthetic aortic stenosis. MRI spine showed C4-5 discitis/osteomyelitis with epidural abscess. While undergoing operative planning, the patient developed difficulty typing phone numbers on his cellphone, and neurological exam revealed normal cranial nerves, strength, and sensation but subtle difficulties with right hand coordination. Emergent MRI revealed acute right occipital and cerebellar infarctions secondary to septic emboli. The patient underwent emergent aortic and mitral valve replacement, and during surgery, he was found to have a large mitral vegetation extending into the left atrium and ventricle with an associated aortic root abscess. He was ultimately discharged on a 6-week course of ceftriaxone.

IMPACT/DISCUSSION: The patient initially presented to his outpatient physician with worsening neck pain and limited range of motion. He was prescribed a muscle relaxant, but upon admission to the hospital, he was diagnosed with *Streptococcus bovis* bacteremia, likely secondary to his severe diverticulitis, with associated epidural abscess and infective endocarditis. While musculoskeletal complaints are one of the most common presentations in the outpatient setting, careful physical exam can reveal alarm symptoms that warrant inpatient evaluation. Further, subtle changes in his inpatient neurological exam were the first sign of an acute neurological complication. This highlights the importance of careful daily physical exam of patients with infective endocarditis to monitor for life-threatening complications.

CONCLUSION: Internists should be comfortable with assessing musculoskeletal complaints for alarm symptoms for severe infections and familiar with manifestations of complications of infective endocaritis to initiate appropriate management.

NECROTIC SCALP ESCHAR AND NECK LYMPHADENOPATHY WITH SEPSIS

Ellen M. Ribar[1]; Saloni Kapoor[3]; Dustin McCurry[3]; Alfred Shoukry[2]. [1]School of Medicine, University of Pittsburgh, Pittsburgh, PA; [2]Internal Medicine, UPMC, Pittsburgh, PA; [3]Internal Medicine, University of Pittsburgh Medical Center, Pittsburgh, PA. (Control ID #3361544)

LEARNING OBJECTIVE #1: Recognize possible infectious causes of eschars in the U.S.

CASE: A 25-year-old man presented in June with a painful black eschar on his scalp for 3 days with 1 day of fever and chills. He had a bilateral retroorbital headache. He had no shortness of breath, cough, changes in vision, or neck stiffness. Six days prior to presentation, he visited a state park, spending time outdoors in grassy areas and swam in a pond. He checked himself for ticks and did not find any. He has two cats, one of which goes outdoors and is not given flea/tick prevention. He had no recent out of state travel. He had no past medical history and did not take any medications. On physical exam, he was febrile to 38.2C and tachycardic to 130 bpm. There was a 5cm black eschar on the occiput, with surrounding erythema. A 1cm, tender, right occipital lymph node was present. Diagnostic studies showed a WBC count of 16.8×10^9/L. The patient was admitted for sepsis management and infectious work-up. A tick- or flea-borne exposure was presumed based on his time outdoors. Given this and the systemic response, ulceroglandular tularemia was considered most likely. The lack of rash and uncommon regional presentation made a rickettsial etiology such as rickettsialpox from Rickettsia akari less likely. Y. Pestis was also considered less likely as it is not endemic to the region. Cutaneous anthrax was unlikely given the scarcity in the U.S., lack of farm animal exposure, and negative blood cultures. Scrub typhus is not found in the U.S. Other tick-borne diseases are not

typically associated with eschars and present with rash, myalgias, GI symptoms, or hematologic abnormalities. The patient received gentamicin and doxycycline. His vitals normalized after the first day of antibiotics, and the eschar decreased in size, so the patient was discharged with a ten-day course of doxycycline and ciprofloxacin.

Tissue testing, including Bartonella stain was negative. Follow-up at the infectious disease clinic 4 weeks later demonstrated resolution of the eschar. No repeat antibodies or cultures turned positive.

IMPACT/DISCUSSION: Eschar causing infections including cutaneous anthrax and scrub typhus are extremely uncommon or non-existent in the U.S. Ulceroglandular tularemia is a much more common cause of eschars in the U.S. and most commonly reported in the month of June, particularly in males. Of note, the CDC reports the incidence of ulceroglandular tularemia between 2007 and 2017 was 0.02 per 100,000 in Pennsylvania, with no reported cases in Southwest Pennsylvania making this case unusual.

CONCLUSION: Ulceroglandular tularemia should be considered in patients in the U.S. with risk factors such as potential tick bite or animal exposure and present with fever, an eschar and lymphadenopathy.

NEOPLASTIC FEVER: A CHALLENGING DIAGNOSIS

Joseph Ibrahim, Rachel Vanderberg. Internal Medicine, University of Pittsburgh Medical Center, Pittsburgh, PA. (Control ID #3378901)

LEARNING OBJECTIVE #1: Recognize Clinical Indicators of Neoplastic Fevers

LEARNING OBJECTIVE #2: Distinguish neoplastic fever from other etiologies of fever

CASE: 71yo male with recently diagnosed metastatic pancreatic adenocarcinoma with extensive liver metastases presented with intermittent fevers for two weeks. He endorsed a sore throat, loss of appetite and fatigue for a week. He denied chest pain, dyspnea, vomiting, headaches, rash, dysuria, increased frequency, diarrhea, myalgias, medication changes, sick contacts, travel, indwelling catheters or lines, or tick/insect bites. On presentation, T 36.2, BP 97/63, HR 115 and SaO2 99%. Labs were remarkable for WBC 28.8 (84% neutrophils), AST 46, ALT 58, & Alk phos 225. CXR was unremarkable. CT C/A/P with contrast demonstrated an enlarging pancreatic mass and multiple enlarging hepatic mets compared to previous CT. Empiric antibiotics were started; however, they were discontinued when RUQ US returned negative for biliary obstruction and blood cultures remained negative autoimmune and thromboembolic etiologies seemed unlikely based on history and physical exam. Drug fever was felt to be unlikely as patient had not started chemotherapy. Fevers were felt to be secondary to malignancy and patient elected to go home with hospice

IMPACT/DISCUSSION: Clinical manifestations of neoplastic fevers differ slightly from those of infectious fevers. Fever correlated to infection is often associated with chills, tachycardia and sometimes altered mental status. However, neoplastic fevers often are associated with diaphoresis and warmth but not chills or mental status changes.

Fevers of infectious etiologies are often constant lasting the duration of the infection and resolve with source control. Meanwhile, neoplastic fevers are often intermittent. Cyclical fever patterns can indicate neoplastic origin, but this finding is often rare and not sensitive to neoplastic fever.

Another important clinical indicator is suppression by naproxen (naproxen test). A small study demonstrated neoplastic fevers defervesced after the administration of naproxen in 14 out of 15 patients while 5 patients with infectious fevers saw no resolution. In a follow-up study of 68 cancer patients with FUO, the naproxen test had a sensitivity of 92% (95% CI, 80–97%), specificity of 100% (95% CI, 78–100%), positive predictive value of 100% (95% CI, 90–100%), and the negative predictive value of 82% (95% CI, 59–94%) for neoplastic fever.

Lastly, recognizing common culprits of neoplastic fevers including hodgkin's and non-hodgkin's lymphoma, renal cell carcinoma, hepatocellular carcinoma, AML, hairy cell leukemia, glioblastoma multiforme, atrial myxoma and ovarian cancer can be helpful in the diagnostic evaluation.

CONCLUSION: Malignancy induced fever is one of the most challenging diagnoses due to its overlapping presentation with other causes of fever. The discussed clinical manifestations can only be helpful in raising suspicion for the diagnosis when utilized in conjunction with the clinical presentation and history of the patient.

NEW-ONSET RAYNAUD'S PHENOMENON IN A 50-YEAR-OLD MALE WITH UNDERLYING LIMITED SCLERODERMA

Scott K. Hetzel. Internal Medicine, University of Wisconsin Hospital and Clinics, Middleton, WI. (Control ID #3392251)

LEARNING OBJECTIVE #1: Recognize the clinical findings that may distinguish primary from secondary etiologies of Raynaud's phenomenon

LEARNING OBJECTIVE #2: Determine the appropriate diagnostic evaluation of secondary etiologies

CASE: A 50-year-old Caucasian man with GERD, HTN, and HLD presents with episodic, triphasic discoloration of bilateral fingers with associated discomfort. His symptoms began two years ago and are notably worse during the winter months, although can occur anytime his hands are cold. He denies any digital ulceration, but feels like episodes are becoming more frequent. There have been no new skin rashes, muscle weakness, fatigue, joint discomfort, or dyspnea. GERD has been well controlled. No family history of Raynaud's. His only medication is lisinopril. Physical exam without any digital calcinosis, sclerodactyly, pitting, or ulcerations. 2+ radial artery pulse bilaterally. There were mild telangiectasias present over the upper chest. Heart RRR and lungs CTAB with normal work of breathing on room air. A screening ANA returned with high titers (1:640) in centromere pattern. Anti-centromere antibodies also positive. These findings were consistent with limited scleroderma. Additional work-up included normal spirometry. He was initiated on nifedipine ER 30 mg once per day with successive reduction in pain episodes.

IMPACT/DISCUSSION: This case represents when to explore secondary etiologies of Raynaud's phenomenon. The majority of clinical Raynaud's will be benign, but being aware of clinical features of secondary etiologies is key to avoid missing the correct diagnosis while avoiding excessive work-up.

CONCLUSION: Raynaud's phenomenon has a prevalence of 5-15% within the general population. The majority of these cases, 80-90%, are classified as primary Raynaud's phenomenon and are due to spontaneous arterial vasospasm. Secondary etiologies may include systemic sclerosis, mixed connective tissue disease, SLE, Sjogren's syndrome, dermatomyositis, or rheumatoid arthritis. Additionally, certain drugs like vasoactive agents, trauma, arterial disease, or hematologic disorders can result in finger discoloration. Certain clinical features are more frequently associated with secondary etiologies and include: asymmetrical involvement, more frequent and painful episodes, digital ulcerations, male gender, age > 35, or manifestations of autoimmune/connective tissue disorders. The presence or absence of these clinical features can help with clinical decision-making and extent of evaluation. In this case, a screening ANA titer should be obtained. This test has high sensitivity and good negative predictive value for rheumatologic disorders. The specificity increases with the higher the titer. An ANA centromere pattern is highly associated with limited scleroderma, along with an anti-centromere antibody. Also known as CREST syndrome, exam findings may include digital

Calcinosis, Raynaud's phenomenon, Esophageal dysmotility, Sclerodactyly, and Telangiectasias. PFT monitoring is important due to risk for pulmonary fibrosis.

NIPPLE DISCHARGE WITHOUT A PALPABLE MASS DIAGNOSED AS MALE BREAST CANCER (MBC)

Justin Durland, Karan Ramakrishna, Amit S. Dhamoon. Medicine, SUNY Upstate Medical University, Syracuse, NY. (Control ID #3392702)

LEARNING OBJECTIVE #1: Recognize male breast cancer does not always present as a palpable mass.

LEARNING OBJECTIVE #2: Recognize the clinical significance of unilateral nipple discharge in men.

CASE: An obese 69-year-old African-American male without a history of breast pathology or family history of breast cancer presented to his primary care physician with one year of clear, intermittent unilateral nipple discharge without an evident palpable mass on physical exam. His laboratory findings were significant for mild hyperprolactinemia at 28.9ng/mL (reference range 4.0 – 15.2 ng/mL). The diagnostic evaluation included right-sided mammography, breast ultrasound, and excisional biopsies. Histology revealed both grade II ductal carcinoma in situ and papillary carcinoma that were strongly estrogen and progesterone positive (ER+/PR+). Genetic testing for a gene panel containing the 9 most high-risk genes associated with breast cancer was negative. The patient was treated with a right total mastectomy and placed on adjuvant hormonal therapy with tamoxifen. About 1.5 months after starting therapy, tamoxifen was discontinued due to adverse side effects. The patient remained without signs of recurrent disease 4 months from initiation of treatment.

IMPACT/DISCUSSION: Male breast cancer (MBC) constitutes less than 1% of all breast cancer cases. The prognosis of MBC is based on staging at diagnosis. Nipple discharge without a palpable mass presents in as few as 1 - 12% of all MBC cases, making it easy to overlook the significance of this finding. Being able to recognize this uncommon presentation may allow clinicians to make an earlier diagnosis and, therefore, improve outcomes. A review of literature shows 22 - 57% of men with nipple discharge have underlying cancer. Prolactin has been involved in the pathogenesis of breast cancer in animal studies, but no definitive causal relationship has been established in humans. Since our patient presented with hyperprolactinemia, we discuss evidence that prolactin may impact MBC by both binding prolactin receptors and elevating total estrogen levels. This case adds to literature highlighting the importance of recognizing nipple discharge in men. It also adds to the few reports of MBC presenting in the presence of hyperprolactinemia.

CONCLUSION: MBC may present as nipple discharge without a palpable mass. Nipple discharge in men shows a strong association with MBC. Hyperprolactinemia may be invovled in the pathogenesis of MBC.

NO APPETITE FOR ERROR: ANOREXIA AND ALTERED MENTAL STATUS IN A PATIENT WITH ANOREXIA NERVOSA

Neil R. Lim, Tanping Wong. Internal Medicine, New York Presbyterian Hospital– Weill Cornell, New York, NY. (Control ID #3366689)

LEARNING OBJECTIVE #1: Recognize the danger of anchoring bias in misdiagnosis of patients with psychiatric comorbidities

LEARNING OBJECTIVE #2: Review the limitations of imaging in diagnosing cirrhosis

CASE: A 37-year-old woman with anorexia nervosa (AN) and depression was brought to the ED by family for months of worsening appetite and binging/purging behavior. She had been diagnosed with AN at 14 and briefly followed with psychiatry, but was lost to follow up and never treated. She drank 3 glasses of wine daily for 15 years.

Exam revealed BMI 15, cachexia, hepatomegaly, and flat affect. Labs showed: WBC 15, Hgb 10, Plt 331, K 2.7, AST 180, ALT 35, alk phos 174, albumin 1.8, INR 1.4. Ultrasound, MRCP, and CT A/P revealed hepatomegaly, steatosis, trace perihepatic ascites, and small paraesophageal varices. Hepatitis, lipid, autoimmune, and iron panels were normal.

Psychiatry diagnosed worsening AN. She was admitted for nutritional support, but her course was complicated by fluctuating altered mental status (AMS). MR brain, infectious workup, vitamin b12, folate, TSH, RPR, and CSF were normal. Ammonia was mildly elevated at 51, but her AMS was attributed to delirium from malnutrition.

She also had recurrent bleeds, including oral bleeding, post-lumbar puncture subdural hematoma, and hematochezia; colonoscopy showed rectosigmoid ulcers. During colonoscopy prep, her AMS improved.

Rifaximin and lactulose were started for presumed hepatic encephalopathy (HE), and her mental status and appetite greatly improved. Liver biopsy revealed cirrhosis and likely alcoholic steatosis. Hematology found her bleeds secondary to dysfibrinogenemia from cirrhosis. Psychiatry re-evaluated her anorexia as secondary to cirrhosis/HE, and she was discharged to alcohol rehabilitation.

IMPACT/DISCUSSION: The diagnosis of cirrhosis should be suspected in patients with sequelae of liver disease/portal hypertension. The diagnosis of HE should likewise be entertained in patients with AMS and stigmata of cirrhosis. In this case, anchoring—a bias in which too much weight is placed on initial information—delayed both diagnoses despite evidence of coagulopathy, varices, ascites, and alcohol abuse. Misdiagnosis in patients with psychiatric comorbidities is common: a study of 658 psychiatric patients found that 9% had actual somatic disorders, treatment of which resolved their symptoms. Another found that 46 of 100 psychiatric inpatients had a somatic illness that caused/exacerbated their psychiatric illness. Psychiatric symptoms should portend somatic disease until proven otherwise.

The diagnoses were also obfuscated by imaging that did not identify frank cirrhosis. However, imaging alone is not sensitive for cirrhosis. Studies show that ultrasound carries only a 65-95% sensitivity, while CT/MR have sensitivities of 77-84%. Thus, the absence of cirrhosis on imaging should not prompt its exclusion.

CONCLUSION: Misdiagnosis of psychiatric patients is common and can be facilitated by anchoring bias. The absence of cirrhosis on imaging alone should not prompt its exclusion.

NON KETOTIC HYPERGLYCEMIA: FOCAL SEIZURES AS A SYMPTOM OF TYPE 2 DIABETES MELLITUS

Noah S. Rosenberg[1,2]; Mat Kladney[2,1]. [1]Department of Medicine, NYU School of Medicine, New York, NY; [2]Internal Medicine, Bellevue Hospital, New York, NY. (Control ID #3342606)

LEARNING OBJECTIVE #1: Recognize the acute neurologic manifestations of non-ketotic hyperglycemia in adults with type 2 diabetes.

LEARNING OBJECTIVE #2: Management of chronic disease in non-English speaking patient populations with low health literacy.

CASE: 44 year old Mandarin speaking male with a history of hypertension and type 2 diabetes (DM2) presented with five days of intermittent episodes of involuntary right arm movement associated with urinary incontinence. Episodes occurred at least ten times daily and were not associated with alteration of consciousness. Of note, he was diagnosed with DM2 in the past year, but had limited understanding of the disease and was not taking any medications.

The patient takes no medication. He has no family history of seizures or other neurological problems. He smokes rarely and does not drink alcohol or use drugs.

On presentation he had stable vital signs and physical exam revealed no focal neurological deficits and was otherwise normal. Labs including a blood count, hepatic panel, urine toxicology, and metabolic panel were normal apart from a glucose at 616 mg/dL with a HbA1C at 14.1%. After a normal non-contrast head CT, these episodes were confirmed as focal seizures on EEG and were refractory to 1500mg levetiracetam twice daily. He was placed on a basal-bolus regimen of insulin, with improvement of his glucose and cessation of his seizures with no further abnormal activity on EEG.

Before discharge, the patient was counseled on his diagnosis of DM2 with culturally appropriate, Mandarin based educational materials as well as individual teaching on glucose monitoring and insulin administration using an interpreter.

IMPACT/DISCUSSION: Non-ketotic hyperglycemia (NKHG) is a complication of DM2, and often is triggered by metabolic stressors. Classically, this presents as polyuria, polydipsia, lethargy, confusion, and ataxia. Other neurologic findings such as increased motor tone, hemiparesis, or focal seizures are rare.

The pathophysiology of focal seizures in NKHG is not fully understood. Hypertonicity is unlikely to be the cause as these seizures are not present in diabetic ketoacidosis, and serum osmolarity is normal during these seizures. A prominent theory is that there may be increased metabolism of the neurotransmitter GABA, decreasing the seizure threshold. Managing these focal seizures is often difficult due to delay in diagnosis and treatment. Focal seizures tend to be refractory to antiepileptic drugs, and phenytoin can worsen these seizures by reducing insulin secretion. Management of focal seizures in NKHG is control of the hyperglycemic state, with insulin and rehydration.

CONCLUSION: In our patient, treatment of hyperglycemia was successful in terminating seizure activity, representing a rare case of focal seizures presenting as a symptom NKHG. In addition, usage of culturally and language specific educational materials is vital for the proper management of chronic conditions such as DM2, in order to prevent further complications of chronic disease.

NON-NECROTIZING GRANULOMAS IN THE BONE MARROW OF A PATIENT WITH A HISTORY OF ANGIOIMMUNOBLASTIC T-CELL LYMPHOMA (AITL) AND A REMOTE HISTORY OF TUBERCULOSIS PRESENTING WITH FEVERS

Jeong Min Yu[1]; Tanyalak Parimon[2]; Andrew Siref[2]; Ronald Paquette[2]. [1]Internal Medicine, Cedars-Sinai Medical Center, West Hollywood, CA; [2]Cedars-Sinai Medical Center, Los Angeles, CA. (Control ID #3391281)

LEARNING OBJECTIVE #1: Recognize that AITL can present with fever, generalized lymphadenopathy, and granulomas that makes it a diagnostic challenge to differentiate from active tuberculosis.

CASE: An 87-year-old man with a history of AITL treated most recently with Brentuximab with complete response on prior PET-CT had recurrent high fevers daily up to 104 °F for several months without obvious etiology on multiple infectious workups, and fevers were attributed to recurrence of AITL. Repeat PET-CT came back negative for metabolic lymphadenopathy, and patient was admitted to undergo further workup for infection and occult lymphoma in the bone marrow. Patient was started on broad spectrum antibiotics for neutropenic fever. Bone marrow biopsy was performed which revealed multiple non-necrotizing granulomas, etiology for which was non-diagnostic for AITL with flow cytometric analysis and immunohistochemical analysis. Patient was known to have a remote history of tuberculosis (TB) that was treated in 1960s. Although the granulomas were nonnecrotizing, given the history, there was a high index of suspicion for tuberculous infiltration of the bone marrow and patient was started on multidrug-resistant TB treatment regimen. Chest CT demonstrated bilateral pleural effusions with new left and right upper lobe infiltrates.

Thoracentesis revealed transudative fluid with no growth in cultures and negative AFB smear. Bronchoscopy and lavage revealed CMV pneumonitis and aspergillus pneumonia and patient was started on appropriate treatment. Repeat bone marrow biopsy confirmed AITL involvement but was also positive for auramine– rhodamine stain concerning for TB. Patient continued to have high fevers throughout the hospital course and became hypotensive, requiring ICU care. Workup of CSF and paracentesis fluids were unrevealing. Patient's life expectancy was expected to be weeks from AITL without chemotherapy, and patient was deemed not a candidate for further chemotherapy. Patient was transitioned to inpatient hospice care and soon thereafter expired. The etiology of death was attributed to bone marrow infiltration of AITL and TB.

IMPACT/DISCUSSION: AITL is a type of peripheral T cell lymphoma that often leads to immunodeficiency and increased risk for opportunistic infections. Patients typically present with systemic B symptoms, generalized lymphadenopathy, and advanced disease with bone marrow involvement. Rarely, granuloma formation has been implicated leading to a diagnostic challenge in patients with multiple risk factors for granuloma formation. This case illustrates that AITL can lead to fever and granuloma formation that can be challenging to differentiate from TB. Obtaining a thorough past medical history and social history can shed light to appropriate differential and management.

CONCLUSION: AITL can be challenging to differentiate from TB. Obtaining a thorough past medical history and social history can shed light to appropriate differential and management.

NON-UREMIC CALCIPHYLAXIS: A CHARACTERISTIC LESION WITH AN EXTENSIVE WORK UP

Babak Tehrani, Amy Mathew, Kimberly Babb. Internal Medicine, Brown University, Providence, RI. (Control ID #3390844)

LEARNING OBJECTIVE #1: To consider the broad etiologies and work up of calciphylaxis

LEARNING OBJECTIVE #2: To recognize the classic appearance of calciphylaxis

CASE: The patient is a 72 year old female that spent the better part of two months at separate outside hospitals before being transferred for a second opinion regarding her acute encephalopathy, and for ENT evaluation. Prior to transfer, her course was complicated by encephalopathy, sepsis, acute renal failure, GI bleed, anemia, Type 2 NSTEMI, atrial fibrillation, thrombocytopenia, and concern for mastoiditis. On presentation, several extensive non-painful lesions were seen on the patient's lower extremities. The wounds were necrotic appearing encircled by a ring of erythema. Per the family, the wounds had developed over the past 1-2 months while hospitalized. Dermatology, hematology, rheumatology, nephrology, and surgery were all consulted for further evaluation and wound treatment. The diagnosis of calciphylaxis was made based on classic wound appearance and x-ray imaging displaying fine reticular calcifications in the lower extremities, as biopsies taken were inconclusive. The etiology, however, was never fully understood. Calcium and phosphate were within normal limits, Vitamin D levels were minimally decreased and PTH was mildly elevated. Hypercoagulable workup was notable for low protein C and antithrombin III. The patient's renal function had recovered such that she no longer required hemodialysis. Expansive autoimmune and vasculitis testing was negative. Initiation of sodium thiosulfate (STS) treatment was

discussed with the patient and family, but was not started given concern for adverse effects and limited benefits of therapy in the setting of multiple medical comorbidities.

IMPACT/DISCUSSION: Calciphylaxis is a rare condition with a high rate of morbidity and mortality.

While usually associated with end-stage renal disease, it is also associated with warfarin use, connective tissue disease, systemic corticosteroid use, liver disease, hypercoagulable states, as well as calcium and phosphate derangements. Outside of wound care, sodium thiosulfate (STS) is considered a mainstay of treatment. However, STS has questionable efficacy. This case illustrates the characteristic appearance and extensive evaluation required for those presenting with non-uremic calciphylaxis, as well as the current limitations in treatment.

CONCLUSION: - Being able to recognize the classic appearance of calciphylaxis is an important first step in work up and possible treatment without delay.

- When considering the etiology of calciphylaxis, it is important to maintain a broad differential. Although end-stage renal disease is the most recognized cause, it is important to consider other possibilities when renal failure is not present.

NON-UREMIC CALCIPHYLAXIS: A RARE AND DECEPTIVE ADVERSE EFFECT OF WARFARIN

Xavier Candela. Medicine, Penn State College of Medicine, Hershey, PA. (Control ID #3391896)

LEARNING OBJECTIVE #1: Recognize the history and physical exam findings for calciphylaxis.

LEARNING OBJECTIVE #2: Differentiate classic uremic calciphylaxis from warfarin-associated non- uremic calciphylaxis.

CASE: An 88-year-old woman with history significant for type II diabetes, hypertension, atrial fibrillation on warfarin, and CKD stage III was transferred from an outside hospital for a severely painful, progressively worsening left calf wound. Prior to presentation, the wound was unresponsive to serial debridement and antibiotic therapy. Pertinent positives on exam included a 11x17cm well demarcated left leg ulceration with Achilles tendon exposed; ulcer was clean appearing with no areas of purulence. Pertinent labs included a Cr of 1.7 mg/dL, GFR 33 mL/min, PT 20.9 secs, INR 1.8, Ca 8.6 mg/dL, PO^4 2.4 mg/dL, and a Mg of 2.2 mg/dL. Further workup included ultrasound, which did not show any evidence of a DVT. ABI was consistent with mild to moderate peripheral artery disease. CT scan and x-rays showed mild arterial calcifications with no signs of infection. Tissue biopsy was obtained, and pathology showed subcutis calcific stippling of fat lobules and calcification of the walls of small and rare medium-caliber vessels. Biopsy results in conjunction with the patient's clinical presentation led to the diagnosis of warfarin-associated non-uremic calciphylaxis. The patient's warfarin was discontinued, and she was discharged to inpatient rehab with wound care, sodium thiosulfate, and outpatient follow up with nephrology.

IMPACT/DISCUSSION: Classic uremic calciphylaxis is a rare condition characterized by vascular calcifications that occlude microvessels in the subcutaneous adipose tissue and dermis resulting in intensely painful, ischemic skin lesions. Initial skin manifestations may include a nodule or induration that expands with dusky discoloration, reticular areas of erythema, and progression to malodorous ulcers with black eschars.[1] Risk factors for calciphylaxis include obesity, diabetes mellitus, female sex, hemodialysis, and end stage renal disease. There are currently no FDA approved therapies for calciphylaxis but clinical trials for sodium thiosulfate and vitamin K are underway. Non-uremic calciphylaxis is defined as histopathologic evidence of calciphylaxis without severe kidney disease (creatine >3mg/dL), GFR <15ml/min, dialysis, or renal transplant. Warfarin increases chances of calcification 10-fold, and the mortality of non-uremic calciphylaxis is 17% compared to the staggering 50-80% in classic calciphylaxis. Non-uremic calciphylaxis occurs an average of 32 months after warfarin initiation.[2]

CONCLUSION: Warfarin-associated calciphylaxis presents in the absence of ESRD as this case highlights and the diagnosis can be delayed due to this complication arising years after warfarin initiation.

NO SIGN IS NOT A GOOD SIGN: ATYPICAL PRESENTATION OF ACUTE CHOLECYSTITIS

Eunice Chen[2]; Aditya Pisupati[2]; Korey Bartolomeo[1]; Joan Cullen[1]; Ronaldo Panganiban[1]. [1]Internal Medicine, Penn State Health, Hershey, PA; [2]College of Medicine, Penn State Health, Hershey, PA. (Control ID #3377003)

LEARNING OBJECTIVE #1: Recognize clinical features and risk factors that distinguish acute cholecystitis (AC) and gangrenous cholecystitis (GC) in older adults

LEARNING OBJECTIVE #2: Identify the significance of a negative sonographic Murphy's sign in GC

CASE: An 82-year-old gentleman with dementia presented with severe right upper quadrant (RUQ) abdominal pain of 12 hours duration. He was acutely encephalopathic at presentation, which was worse than his baseline. On exam, his abdomen was mildly distended and soft with RUQ tenderness and abdominal guarding. Labs showed leukocytosis at 10.8 K/μL, which worsened to 22.8 K/μL by the afternoon. However, a contrast-enhanced CT and bedside RUQ ultrasound showed a mildly distended gall bladder with no wall thickening, cholelithiasis, or pericholecystic fluid. A sonographic Murphy's sign was also not elicited. He was admitted and empirically started on ampicillin-sulbactam for possible sepsis from an undetermined gastrointestinal source. Emergency General Surgery (EGS) was consulted and recommended a HIDA scan. This scan showed a non-filling gallbladder consistent with a cystic duct obstruction concerning for acute cholecystitis. Emergent laparoscopic cholecystectomy was performed that evening. A necrotic, tensely filled gallbladder covered by adherent omentum was found. Needle aspiration removed purulent fluid, and the gallbladder burst with gentle manipulation and spilled more fluid and a stone. Pathology showed necro- inflammatory fluid consistent with GC. He tolerated the surgery without complications and was discharged home 3 days later.

IMPACT/DISCUSSION: AC is defined as inflammation of the gallbladder, commonly due to ductal obstruction. This disease typically presents with RUQ pain, nausea and vomiting, and fever. GC is a complication of AC, where transmural inflammation of the gallbladder wall causes ischemia and subsequent necrosis. Risk factors of GC include age >45, male, leukocytosis, history of diabetes mellitus or cardiovascular disease, and increased time from admission to OR. Our patient's initial equivocal imaging findings and negative sonographic Murphy's sign belied his underlying disease. His worsening abdominal exam the following day is what triggered emergent surgical intervention. However, literature review suggests that a negative sonographic Murphy's sign should actually increase the suspicion of GC, due to necrotic denervation of the gallbladder. Additionally, our patient had multiple risk factors. It should be noted that our patient was acutely encephalopathic at admission; this likely impacted the description of his symptoms and duration of pain resulting in increased the time until surgical intervention.

CONCLUSION: - A negative sonographic Murphy's sign in an elderly patient with risk factors should increase suspicion for GC, even with bland imaging findings.

- Sonographic Murphy's sign positive in >95% of acute cholecystitis but in only 33% of gangrenous cholecystitis.

NOT EVERY HOT, TENDER, INFLAMED JOINT IS INFECTED (OR GOUT)

Angela Gupta[1]; Etleva Bejko[2]; Maya Mattar[2]; James R. Anderson[3]; Charles Malemud[2]. [1]Internal Medicine, University Hospitals Cleveland Medical Center, Cleveland, OH; [2]Rheumatology, University Hospitals Cleveland Medical Center, Cleveland, OH; [3]Orthopedic Surgery, University Hospitals Cleveland Medical Center, Cleveland, OH. (Control ID #3392092)

LEARNING OBJECTIVE #1: Diagnose calcific tendinitis in an atypical anatomical location

LEARNING OBJECTIVE #2: Recognize the clinical features of calcific tendinitis

CASE: A 36-year-old physician without any significant medical history presented with right thumb pain for two days. The pain was throbbing and localized to the thumb's interphalangeal (IP) joint. She tried Tylenol, Ibuprofen, and immobilization of the thumb without relief. She denied fevers, chills, night sweats, skin rashes, and other joint pain. She also denied trauma and strenuous activity.

On exam, the right thumb was swollen, held in extension, and erythematous on the volar aspect of the IP joint. The skin around the thumb and nail were intact. There was warmth and severe tenderness on palpation of the IP joint. Active and passive flexion of the IP joint was limited due to pain, but extension was intact.

X-ray of the right hand was unremarkable. It was thought patient had an infection of the first right IP joint and she was given antibiotics. Despite antibiotic use, symptoms progressed. The patient saw an orthopedic hand surgeon, who recommended urgent exploratory surgery for possible flexor tenosynovitis of the thumb. The patient then went to another orthopedic hand surgeon for a second opinion and another x-ray was done. This x-ray provided a better lateral view of the thumb and showed flexor pollicis longus tendon calcification. The patient was started on a Medrol dose pack and used Ibuprofen for pain. Her symptoms improved within the first twenty-four hours and full range of motion was achieved in three weeks.

IMPACT/DISCUSSION: Calcific tendinitis is a rare condition that classically involves the rotator cuff. In fact, calcific tendinitis is considered a painful "shoulder disorder." Our case is noteworthy, as it describes calcific tendinitis in an uncommon location: the flexor pollicis longus of the thumb. Onlly isolated case reports exist of the disease affecting other anatomical locations.

Our patient's presentation was similar to the typical presentation seen in acute calcific tendinitis of the shoulder: sudden onset of pain unassociated with trauma. Nevertheless, diagnosis upon presentation was unclear. In the absence of trauma, gout and infection were also considered. Calcific tendinitis is best diagnosed by imaging—plain radiography and ultrasound are both helpful for detecting calcifications. In our case, diagnosis was confirmed with plain radiography after visualizing calcifications. The diagnosis of calcific tendinitis in the hand has a higher rate of missed or delayed diagnosis, as its presentation shares features of other conditions, and there is a lack of familiarity with its presentation.

CONCLUSION: Calcific tendinitis should be on the differential diagnosis for acute musculoskeletal pain— even pain not at the rotator cuff.

Pain that is associated with a tender, inflamed joint can be more than either infection or gout.

It is important to recognize calcific tendinitis as a potential diagnosis, as this could prevent unnecessary interventions and therapy.

NOT FOR THE FAINT OF HEART: SPONTANEOUS CORONARY ARTERY DISSECTION AFTER FIRST TIME COCAINE USE

Daniel Chu. Medicine, Baylor College of Medicine, Houston, TX. (Control ID #3388229)

LEARNING OBJECTIVE #1: Understand the importance of obtaining a thorough social history in assessing young women presenting with chest pain.

LEARNING OBJECTIVE #2: Recognize spontaneous coronary artery dissection in a young woman with no traditional cardiac risk factors.

CASE: A 35-year-old woman with no past medical history presented with two hours of unremitting chest pain. She never experienced pain like this in the past. She described the pain as severe, pressure-like, and substernal. It woke her from sleep and was not relieved with anything. She denied any triggers, including recent emotional or physical stress, or upper respiratory illness. She also initially denied drug use, however when alone, admitted to first time intranasal cocaine ingestion 24 hours prior to presenting. Her EKG showed nonspecific ST-T segment changes. Troponin was initially 0.4 ng/mL and peaked at 14.2 ng/mL. Given the patient's presentation and lab findings, she was taken urgently to the cardiac catheterization laboratory. Coronary angiography revealed 99% occlusion of the third obtuse marginal artery due to spontaneous coronary artery dissection. No coronary intervention was performed, and she was managed conservatively with close outpatient follow-up.

IMPACT/DISCUSSION: Though our patient initially denied substance use, when questioned alone without her mother she admitted to using cocaine for the first time the day prior. Cocaine is known to cause sympathetic activation, vasoconstriction, and hypercoagulability and is known to be associated with SCAD. This proved to be a crucial part of the history, as her acute presentation was surely related. As SCAD patients generally have few traditional cardiac risk factors, they are at risk of being discharged early on in their clinical course. High initial suspicion is thus very important and a thorough social history can be of great clinical utility.

Since the first description of SCAD in 1931, our understanding of the disease has expanded significantly. Thought to initially be a rare entity that almost always resulted in death, recent studies have shown it to be more common than previously believed, occurring in up to 2% of all acute coronary syndrome cases, especially in young women. Conditions associated with SCAD include fibromuscular dysplasia, connective tissue disorders, systemic inflammatory disease, and substance use.

In regard to treatment, more work needs to be done to determine the best course of action. Multiple studies have demonstrated a higher rate of complications in SCAD patients that undergo percutaneous coronary intervention. At present, observational studies at least suggest that conservative management is prudent in a hemodynamically stable patient, as 70-97% of SCAD lesions may actually heal.

CONCLUSION: Spontaneous coronary artery dissection is more likely in young women and should be considered in these patients, especially in the setting of cocaine use.

NOT JUST ANOTHER CASE OF KIDNEY STONES

Eva Waite[1]; Rachel Solomon[2]. [1]General Medicine, Mount Sinai, New York, NY; [2]Medicine, Mount Sinai Medical Center, New York, NY. (Control ID #3390026)

LEARNING OBJECTIVE #1: Include cancer in the diffential of hematuria, even in pateints under 35 yr.

LEARNING OBJECTIVE #2: Identify patients who may be at risk for renal medullary carcinoma.

CASE: 27 yr. AA male with no PMH presented with episodic right flank pain over 4 months and 2 weeks of hematuria. On ROS he described a 5 kg weight loss, night sweats, and new cough and dyspnea. He smoked marijuana daily, but no tobacco. FH was notable for sickle cell trait in his father and brother. In the preceding 2 weeks, he had sought ER care 3 times for escalating symptoms. He first received tamsulosin and percocet for presumed nephrolithiasis; then, 4 days later, ciprofloxacin and referral to urology for worsening pain, blood clots, and right sided hydronephrosis on US. A week later, CT scan of abdomen/pelvis showed an enlarged, right kidney with possible mass, small right pleural effusion and bilateral peribronchial opacities. On arrival to clinic, vitals were stable, lungs clear, no mass was palpated, and there was no CVA tenderness. Labs included urinalysis with moderate blood, creatinine 1.33 (baseline 0.9), nl CBC, and negative HIV. Imaging of chest/abdomen/pelvis confirmed an infiltrative mass with diffuse lymphadenopathy and likely metastases to bilateral lungs. The patient was admitted for further evaluation with bronchoscopy and biopsy. Pathology confirmed renal medullary carcinoma (RMC). The patient died of respiratory failure two months after diagnosis.

IMPACT/DISCUSSION: Renal medullary carcinoma is a rare and highly aggressive form of renal cancer almost exclusively found in young people of African descent with sickle cell trait or, less commonly, sickle cell disease. Men are 2x as likely as women to be affected. Median age at onset is early 20's (range 10-40). Our patient screened negative for sickle cell disease, but otherwise fits a high-risk profile. He presented with dyad of hematuria and flank pain. While RMC remains poorly understood, studies consistently suggest that, as in our patient, most disease is right sided and metastatic at the time of diagnosis (generally to lymph nodes, lung, liver and/or contra-lateral kidney). RMC is poorly responsive to treatment. Median survival from time of diagnosis is under 8 months. If caught early and localized, treatment of choice is radical nephrectomy. Platinum based chemotherapy has shown benefit in case studies; but overall, RMC has proven relatively resistant to most chemotherapeutic and biologic agents. Referral to clinical trials remains essential to better elucidate effective treatment. Further research should also be targeted to possible screening for this "seventh sickle cell nephropathy."

CONCLUSION: Gross hematuria associated with weight loss is unlikely to be benign stone disease. Clinicians should have a low threshold to consider RMC in patients with SCD or SCT presenting with hematuria and/or flank pain. Further investigation is needed to identify more effective treatments for this highly aggressive disease associated with poor prognosis (young AA men).

NOT SIMPLY A HEPARIN BRIDGE

Abigail Phelps[2]; William B. Rothwell[1]. [1]Internal Medicine & Pediatrics, Tulane University School of Medicine, New Orleans, LA; [2]Medicine, Tulane University School of Medicine, New Orleans, LA. (Control ID #3391397)

LEARNING OBJECTIVE #1: Develop an approach to the evaluation of thrombocytopenia

LEARNING OBJECTIVE #2: Recognize the importance of prompt diagnosis and treatment of thrombotic thrombocytopenic purpura

CASE: A 39-year-old woman presented with 1-day headache and blurry vision. Symptoms were similar to presentation of previous strokes, however MRI and MRV of the brain did not reveal any evidence of acute stroke, and symptoms resolved spontaneously. Prior medical history included previous ischemic strokes and systemic lupus erythematosus (SLE). INR was found to be 0.9 so heparin infusion was initiated. No new focal neurologic deficits, petechiae, bruising, or lymphadenopathy was appreciated. Hemoglobin level returned at 8.7g/dl with an MCV 86fL and the platelet count was 30k/uL. Peripheral blood smear revealed 4+ schistocytes per high power field. A D dimer 2.4mcg/mL, fibrinogen 470mg/dL, reticulocytes 1.3%, haptoglobin 24, lactate dehydrogenase 400 on admission which increased to 554mg/dL on repeat, negative direct and indirect Coombs test, Creatinine 1.1mg/dL, and a negative pregnancy test.

With unexplained neurologic deficits, evidence of microangiopathic hemolytic anemia (MAHA) on peripheral blood smear, and a PLASMIC score of 6, clinical suspicion was high for thrombotic thrombocytopenic purpura (TTP), and plasma exchange was promptly started. Additional therapy also included high dose steroids and rituximab. On admission day four, ADAMTS13 activity resulted < 2% and ADAMTS13 antibody was detected, confirming diagnosis of TTP.

IMPACT/DISCUSSION: An internist needs a methodical approach to determining the cause of thrombocytopenia as it is mportant to distinguish between life threatening causes that require prompt treatment. In any patient with unexplained thrombocytopenia and anemia, a peripheral blood smear should be obtained to evaluate for MAHA diagnosed by presence of schistocytes. Once MAHA is confirmed, systemic disorders that can manifest these findings should be excluded and work up including coagulation assay of PT/PTT/INR, D dimer, fibrinogen, haptoglobin, lactate dehydrogenase, Coombs test, indirect bilirubin, BUN, creatinine, pregnancy test, ADAMTS13 should be collected.

TTP must be treated promptly with plasma exchange as mortality rate is high (90% prior to plasma exchange). TTP is a severe deficiency of the protease ADAMTS13 (activity level <10%), which cleaves large von Willebrand multimers. Deficiency of ADAMTS13, which can be hereditary or acquired, promotes formation of micro thrombi leading to MAHA and thrombocytopenia. In our patient with SLE, the ADAMTS13 deficiency was acquired, caused by autoantibodies. As ADAMTS13 activity level and antibody test can take days to result, the PLASMIC score can be used to estimate the likelihood of severe ADAMTS13 deficiency with a sensitivity of 91%.

CONCLUSION: TTP should be considered in any patient with MAHA, thrombocytopenia, and any other clinical indicators including unexplained neurologic findings and minimal to no acute kidney injury.

NOT SO SWEET jennifer zakko. Internal Medicine, Rush University Medical Center, Chicago, IL. (Control ID #3392051)

LEARNING OBJECTIVE #1: Review Diagnostic Criteria for Sweet Syndrome and Differentiate Classical, Malignancy-Associated, and Drug-Induced Sweet Syndrome

LEARNING OBJECTIVE #2: Recognize Dermatologic and Extradermal Manifestations of Sweet Syndrome

CASE: A 72 year-old man with relapsing polychondritis on chronic prednisone and recent leflunomide presented with an acute-onset visual defect in his left eye after 2 weeks of bilateral scleritis. Rash and fever began 3 days prior to presentation.

He was febrile to 103.3 on arrival. Erythematous papular and vesicular rash was noted on the trunk, face, and extremities. C-reactive protein was 193.5. He was pancytopenic with hemoglobin 9, platelets 114, and absolute neutrophil count 550. Given fever and prednisone use, broad spectrum antimicrobial drugs were started including acyclovir for presumed disseminated varicella zoster. Ophthalmology diagnosed central retinal artery occlusion. Stroke workup was unremarkable. Skin lesion biopsy showed dense, diffuse dermal neutrophilic infiltrate consistent with Sweet syndrome. Fevers slowly improved on prednisone. C-reactive protein decreased to 73.9 by day 10 of admission. Bone marrow biopsy and age-appropriate malignancy workup were normal.

IMPACT/DISCUSSION: Acute febrile neutrophilic dermatosis, or Sweet syndrome, is a rare cause of febrile rash in hospitalized patients. Major diagnostic criteria are rapid-onset of erythematous plaques or nodules with dense neutrophilic infiltration. Minor criteria include fever, elevated erythrocyte sedimentation rate or C-reactive protein, and leukocytosis with over 70% neutrophils.

Classical Sweet syndrome is idiopathic and often preceded by respiratory infections. Drug-induced Sweet syndrome is most often seen with granulocyte-stimulating factors. 21% of Sweet syndrome is malignancy-related, usually with acute myeloblastic leukemia or adenocarcinoma of the breast, gastrointestinal, or genitourinary organs. Therefore, age appropriate cancer screening is warranted as well as risk assessment for asymptomatic hematologic malignancies. Given his negative malignancy work-up and lack of causative drug exposure, our patient met criteria for Classical Sweet syndrome.

Skin lesions may appear vesicular given edema of the papillary dermis, making biopsy crucial for accurate diagnosis. Extradermal manifestations like malaise, arthralgias, and ocular involvement may occur. Our patient had scleritis, then developed central retinal artery occlusion shortly after onset of skin rash. Anterior ocular inflammation such as scleritis or conjunctivitis is common in Sweet syndrome. Posterior inflammation such as retinal vasculitis is rarer, presenting as blurred or otherwise impaired vision. Retinal vasculitis requires urgent assessment as it may lead to retinal ischemia with permanent visual impairment if the underlying cause is not treated promptly.

CONCLUSION: Biopsy is crucial for correct diagnosis: lesions may vary in appearance

Age-appropriate cancer screening is imperative

Visual impairment requires urgent fundoscopic examination

NOT SO SWEET: EUGLYCEMIC DIABETIC KETOACIDOSIS AND SGLT2 INHIBITORS

Michael G. Simonson[1,2]; Sina Salehi Omran[1,2]. [1]University of Pittsburgh School of Medicine, Pittsburgh, PA; [2]UPMC Presbyterian-Shadyside, Pittsburgh, PA. (Control ID #3374399)

LEARNING OBJECTIVE #1: Diagnose diabetic ketoacidosis in patients presenting with euglycemia

LEARNING OBJECTIVE #2: Identify SGLT-2 inhibitors as a risk factor for development of diabetic ketoacidosis

CASE: A 61-year-old man with hypertension and diabetes was admitted for evaluation of obstructive jaundice and 3 cm pancreatic mass in the setting of nausea and abdominal pain progressing over 3 days. His medications were hydrochlorothiazide, lisinopril, metformin, and ertugliflozin. On exam he was hemodynamically stable with dry mucus membranes, scleral icterus, and moderate epigastric tenderness. Labs revealed Na 133, K 4.5, Cl 105, HCO3 7, sCr 1.1, glucose 196, tBili 9.9, AST 356, ALP 920, gGTP 1410, lipase 255, lactate 0.9, and acetone 37. Arterial pH was 7.28. Ethanol and toxic alcohols were not detected. Urinalysis was notable for 3+ ketones and >1000 glucose. A diagnosis of diabetic ketoacidosis (DKA) without hyperglycemia was made and the patient was started on glucose and insulin infusions. Over the next 24 hours the anion gap resolved and the patient had resolution of abdominal pain. Work up for the obstructive jaundice included an ERCP with biopsies consistent with pancreatic adenocarcinoma.

IMPACT/DISCUSSION: Sodium-Glucose Transport Protein 2 inhibitors (SGLT2i) are increasingly being prescribed for patients with type 2 diabetes due to their beneficial effects on glycemic control, cardiovascular mortality, weight loss, and blood pressure. The primary mechanism of action is via inhibition of SGLT2 in the proximal renal tubule, leading to glycosuria and decreased serum glucose levels. As their use becomes more common, physicians must be aware of the potential for adverse reactions.

DKA is classically defined by the triad of hyperglycemia, elevated ketones, and acidosis (pH<7.3 and HCO3<18). Rarely, DKA may occur without hyperglycemia; this has been reported with increasing frequency for patients taking SGLT2i. The mechanism for DKA in patients taking SGLT2i is not completely understood but likely multifactorial: SGLT2i likely decrease endogenous insulin production as serum glucose levels decrease, directly stimulate glucagon production by islets alpha-cells, and possibly increase renal tubular absorption of ketone bodies. As insulin falls and ketones increase, ketoacidosis can occur.

Use of SGLT2i was a likely precipitant of DKA in this patient. There were no signs of infection and other etiologies of elevated anion gap (lactic acidosis) and ketosis (alcohol and toxins) were ruled out. Testing for autoantibodies was negative and a C-peptide level was detected but low, arguing against latent autoimmune diabetes of adults or misdiagnosed type 1 diabetes. In the presence of the new pancreatic mass, diabetes type 3c was considered but much less likely given the absence of any other symptoms of pancreatic exocrine function.

CONCLUSION: Euglycemic DKA should be considered in patients with anion gap metabolic acidosis when glucose levels are not elevated. SGLT2i increase risk for euglycemic DKA through multiple mechanisms.

NOT SWEET'N LOW: A CASE OF SEVERE HYPOGLYCEMIA WITH COMBINED CIPROFLOXACIN AND GLIMEPIRIDE

Tina Y. Hu[1,3]; Robert J. DeGrazia[1]; David M. Cohen[2]. [1]Internal Medicine, Christiana Care, Newark, DE; [2]Christiana Care, Newark, DE; [3]Nemours/Alfred I. duPont Hospital for Children, Wilmington, DE. (Control ID #3388328)

LEARNING OBJECTIVE #1: Recognize that glimepiride in addition to glyburide and glipizide as sulfonylureas can cause severe hypoglycemia due to interactions with fluoroquinolones, specifically, ciprofloxacin

CASE: An 80-year-old male with a history significant for pancreatic cancer status post Whipple procedure on chemotherapy, bladder cancer, and non-insulin dependent diabetes type 2 presented after being found unresponsive at home. Patient was in a state of chronic debility with poor appetite; intermittent nonbloody, nonbilious emesis; and daily, chemotherapy - induced diarrhea. He was admitted two months prior for *Pseudomonas* bacteremia secondary to a UTI and continued on ciprofloxacin for asymptomatic bacteriuria. Medications also included glimepiride with daily compliance. Upon EMS arrival, the patient had blood glucose of 27 mg/dL and given one amp of D50 with improvement in mental status. In the hospital, he was given one dose of octreotide with D5NS drip and two ¼ amps of D50 rescue during the first four hours. The patient had subsequent improvement in his mental status and remained normoglycemic for 48 hours. Of note, hemoglobin A1c decreased from 9.0 to 5.2% over the preceding 3 months and glimepiride was discontinued along with transition of ciprofloxacin to cefepime.

IMPACT/DISCUSSION: This illustrates the importance of reviewing medication interactions in cases of severe hypoglycemia. Although this patient had diminished intake, this was chronic and unchanged, reflected in his last hemoglobin A1c of 9.0%. The interaction between fluoroquinolones and sulfonylureas may be complicated by hypoglycemia, which can be severe. Of the sulfonylureas, glyburide and glipizide have been identified, and with specific interactions with ciprofloxacin. This case is notable as the second published case of glimepiride and ciprofloxacin use associated with severe hypoglycemia. These interactions should be appreciated as prescriptions of antimicrobials and sulfonylureas are common and can cause

substantial morbidity with high costs to the healthcare system. Fluoroquinolones potentiate the sulfonylurea's effects on glucose by inhibiting ATP K+ channels in pancreatic B-cells; this causes overstimulation of pancreatic islet cells, excessively high levels of insulin and C-peptide, and subsequent hypoglycemia. It is important to note that fluoroquinolones are not initiators by itself, but solely enhancers of insulin secretion. Treatment involves octreotide with a central role in severe sulfonylurea-induced hypoglycemia by inhibiting further insulin secretion along with dextrose infusion.

CONCLUSION: This case expands existing literature as the second reported case to highlight the potential danger of the combination of glimepiride and ciprofloxacin as a cause of severe, symptomatic hypoglycemia. Octreotide is a safe and effective tool to restore normal glucose rapidly in drug-induced disease. Lastly, provider review of all potential drug-drug interactions is an essential tool to promote safe, value-based medical care.

NOT YOUR AVERAGE HYPERTENSION: DIAGNOSING AND TREATING POSTPARTUM PREECLAMPSIA IN PRIMARY CARE

Brittney Frankel[1]; Pamela Charney[2]. [1]Internal Medicine, New York Presbyterian-Cornell, New York, NY; [2]Internal Medicine, Weill Cornell Medical College, New York City, NY. (Control ID #3388408)

LEARNING OBJECTIVE #1: Distinguish postpartum preeclampsia (PPE) from chronic hypertension in period after birth

LEARNING OBJECTIVE #2: Review management of PPE

CASE: A 26 year-old African American woman G2P2002 with preeclampsia in her first pregnancy presented 7 weeks postpartum. She was normotensive during pregnancy with an uncomplicated vaginal delivery. One day postpartum, her blood pressure was 160/90. She was started on nifedipine 30 mg XL and discharged home where her blood pressure was persistently elevated. She denied headache, blurred vision, abdominal pain, nausea/vomiting, chest pain, shortness of breath, and edema. Her obstetrician thought her postpartum recovery was normal and recommended followup with her PCP for chronic hypertension.

OB history

1 prior pregnancy 2016 – uncomplicated preeclampsia

FH

Mother age 50, brother age 30 - hypertension

Labs

CMP and CBC normal. UA 100 protein (had been normal in pregnancy)

PE

Vitals normal except BP 170/90

BMI 24

Normal physical exam

Based on the above, the patient was diagnosed with PPE. Her nifedipine was increased to 60mg XL with home blood pressure monitoring and 1-week followup.

IMPACT/DISCUSSION: PPE is underdiagnosed and associated with significant morbidity. Up to ¼ of eclamptic seizures occur 48 hours to 6 weeks postpartum. Intracerebral hemorrhage and stroke are other devastating sequelae. PPE risk factors are similar to preeclampsia's, including preeclampsia in prior pregnancy, being black or Latino, age > 40, obesity, multiparity and gestational diabetes. The American College of Obstetricians and Gynecologists (ACOG) defines preeclampsia as blood pressure > 140/90 and one of the following: proteinuria, thrombocytopenia, renal insufficiency, abnormal liver function, pulmonary edema or cerebral/visual symptoms. PPE is the onset of these criteria > 48 hours postpartum. PPE generally presents < 6 weeks postpartum although some cases are reported up to 3 months after birth. In contrast, ACOG defines chronic hypertension as predating pregnancy. Given this patient had history of preeclampsia, no previous hypertension, and new proteinuria, she was diagnosed with PPE.

After immediate blood pressure control, maintenance therapy is selected based on comorbidities and breastfeeding. All antihypertensives pass into breast milk, albeit in negligible amounts. Similar to during pregnancy, beta/alpha blockers, calcium channel blockers, methyldopa and hydralazine are considered safe, well-studied and thus favored. Unlike in pregnancy, ACE inhibitors are safe postpartum but may cause hypotension in breastfed neonates; ARBs have never been studied. Diuretics theoretically reduce milk production but studies of hydrochlorothiazide demonstrate safety during lactation; furosemide also has never been studied.

This case demonstrates that patients at risk for PPE should be identified based on their history, monitored closely for PPE and treated promptly.

CONCLUSION: PPE risk factors and diagnostic criteria are similar to preeclampsia. Treatment should be selected based on comorbidities and breastfeeding.

NOT YOUR COMMON ATHLETIC HEART PROBLEM

Padma Shenoy[1]; Taher M. Tayeb[2]; Pedro Covas[3]; Nardos Temesgen[4]; Cynthia Tracy[1]. [1]Cardiovascular Disease, Internal Medicine, George Washington University Hospital, Washington, DC; [2]Internal Medicine, The George Washington University, Arlington, VA; [3]Internal Medicine, George Washington University, Washington, DC; [4]Internal Medicine, The George Washington University Hospital, Washington, DC. (Control ID #3383602)

LEARNING OBJECTIVE #1: Diagnose SCAD through non-invasive methods such as coronary CTA

LEARNING OBJECTIVE #2: Recognize that SCAD can present with complications such as LV thrombus.

CASE: A 19 year old healthy male collegiate athlete presented with typical anginal symptoms for one month. Vitals and physical exam were unremarkable. Labs included a troponin of 0.12 ng/ml which peaked at 17.7 ng/ml and CK-MB of 28.1 ng/ml. EKG demonstrated diffuse biphasic T waves.

IMPACT/DISCUSSION: For young patients presenting with an NSTEMI, clinical suspicion should be raised for SCAD, myocarditis, or pericarditis. Our patient received a coronary Computed Tomography (cCTA) which demonstrated a 1.5 cm dissection in the LAD with a 1.9x1.8cm attenuation defect consistent with a thrombus. Subsequent coronary catheterization confirmed SCAD of the left anterior descending. Transthoracic echocardiogram demonstrated wall motion abnormalities in the region of the dissection along with a 1.4x0.7cm apical left ventricular thrombus. Patient was medically managed with warfarin and a beta blocker.

CONCLUSION: Spontaneous coronary artery dissection, although confirmed through invasive measures, could be reliably diagnosed through non-invasive methods such as a coronary CTA. Thorough investigation of every patient with ACS for intra-cardiac thrombi should be considered, even in younger populations.

NOT YOURE AVERAGE PE: A CASE OF ANTIPHOSPHOLIPID SYNDROME IN A MAN WITH RECURRENT CLOTS

Samantha J. Allen, Sophie Clark. Internal Medicine, University of Colorado, Denver, CO. (Control ID #3392154)

LEARNING OBJECTIVE #1: Diagnose and treat antiphospholipid syndrome

LEARNING OBJECTIVE #2: Identify indications for and recognize limitations of thrombophilia testing

CASE: A 22-year-old man presented with dyspnea and was diagnosed with a pulmonary embolus. He also had an unprovoked deep venous thrombosis five months prior. He was taking warfarin, but his INR was subtherapeutic. Plans were made to discharge him on a direct oral anticoagulant (DOAC) given his difficulty with warfarin adherence; however, review of his lab findings prompted further testing that changed his management. He had a remarkably low albumin of 2.4. Subsequent urinalysis revealed nephrotic-range proteinuria; creatinine was normal. Kidney biopsy showed lupus nephritis class five. He was started on prednisone and cyclophosphamide.

His recurrent clots and new diagnosis of systemic lupus erythematosus suggested a diagnosis of antiphospholipid syndrome, so he was restarted on warfarin therapy instead of a DOAC and provided additional support to ensure adherence. The diagnosis of antiphospholipid syndrome was later confirmed on outpatient labs.

IMPACT/DISCUSSION: This diagnosis significantly altered our patient's care. For most patients with venous thromboembolism, DOACs are effective treatment. However, warfarin remains the treatment of choice for antiphospholipid syndrome because it decreases the risk of clot in comparison to rivaroxaban.

Most cases of unprovoked clots warrant lifelong anticoagulation. Thus, hypercoagulability testing is generally irrelevant, as the results would not change management. There are, however, situations where testing may provide useful information or guide treatment decisions. Patients with a personal and family history of clots should be tested, as it may influence family members, particularly women of childbearing age. Furthermore, in patients with arterial clots or recurrent venous thromboembolism, testing for antiphospholipid syndrome should be considered, as the results will affect the choice of anticoagulation. Additionally, patients with clots in unusual locations, such as cerebral or splanchnic veins, should be evaluated further.

Antiphospholipid syndrome is diagnosed based on clinical and laboratory findings. Clinical criteria include venous or arterial clots and pregnancy complications. Lab criteria include antibody-based tests for anticardiolipin and anti-β_2-glycoprotein, which are reliable regardless of whether the patient is on anticoagulation, and a clot-based assay for lupus anticoagulant, which can be falsely positive if the patient is on anticoagulation. Hence, testing should be performed while off of anticoagulation, or otherwise interpreted with caution. Positive tests must be confirmed on repeat testing after at least 12 weeks.

CONCLUSION: This case exemplifies one of a few situations in which thrombophilia testing changes management. While DOACs are a convenient alternative to warfarin, clinicians should be aware of the diagnoses, including antiphospholipid syndrome, for which warfarin is the treatment of choice.

NOT YOUR HALLMARK CASE: AN UNUSUAL PRESENTATION OF ANAPLASTIC LARGE CELL LYMPHOMA

Audrey Ready[1]; Luke Mantle[2]; Jasmine Paadam[1]. [1]Internal Medicine, Baystate Medical Center, Springfield, MA; [2]Baystate Medical Center, Springfield, MA. (Control ID #3389267)

LEARNING OBJECTIVE #1: Recognize lactic acidosis as a sign of underlying hematologic malignancy, in this case anaplastic large cell lymphoma

LEARNING OBJECTIVE #2: Identify Anaplastic large cell lymphoma that typically presents as a rapidly progressive T-cell lymphoma with peripheral lymphadenopathy, fevers, night sweats and weight loss

CASE: A 73-year-old female with a history of cirrhosis secondary to non-alcoholic steatohepatitis, gastric antral vascular ectasia (GAVE), heart failure with preserved ejection fraction, and type II diabetes mellitus presented to the hospital with melena after an elective endoscopy. She offered only complaints of fatigue. On exam, she was hemodynamically stable and was unremarkable except for mild left upper quadrant tenderness to palpation. Review of initial laboratory work revealed a leukocytosis of 23,000, thrombocytopenia of 137,000, INR of 1.5, AST 100, ALT 2.3, and a lactic acidosis measured at 12.6. A lactate measured one- month prior was 2.1. A CT angiogram of the abdomen and pelvis was performed that ruled out mesenteric ischemia, overt GI bleed or lymphadenopathy. During her hospitalization her lactate and white cell count continued to rise. Ultimately, flow cytometry revealed a clonal population positive for CD30, CD43, and CD2. Morphologic evaluation of the cells demonstrated large atypical cells with highly pleomorphic nuclei with convoluted and lobulated nuclear contour and multiple prominent nucleoli. Scattered hallmark cells were also seen. The pathology favored a diagnosis of ALK-negative anaplastic large cell lymphoma (ALCL). The patient and her family decided to pursue comfort focused care, and she passed away ten days after presentation.

IMPACT/DISCUSSION: This case, an example of type B lactic acidosis in the setting of leukocytosis, should raise suspicion of underlying malignancy, as the prognosis in this population is poor and often rapidly fatal. Type B lactic acidosis is seen in the absence of tissue hypoperfusion and can be caused by a large variety of etiologies, including diabetic ketoacidosis, medication including metformin and certain anti- retroviral agents, liver and kidney dysfunction and others. Elevated lactate in malignancy has been coined the Warburg effect and refers to the preference of cancer cells to metabolize pyruvate to lactate. ALCL is a rare T-cell hematologic malignancy that often presents with peripheral lymphadenopathy, fevers, night sweats and weight loss and has never been described in the literature as being associated with elevated lactate.

CONCLUSION: Lactic acidosis with no evidence of hypoperfusion is known as a type B lactic acidosis. Type B lactic acidosis in malignancy is known as the Warburg effect, where malignant cells favor anaerobic respiration over normal glycolysis even when oxygen is abundant. ALCL typically presents with peripheral lymphadenopathy, fevers and night sweats but should be considered in any patient with a rapidly progressive leukocytosis and type B lactic acidosis.

NOT YOUR REGULAR RASH: A RARE CASE OF AMYOPATHIC DERMATOMYOSITIS

Sana Hyder[1]; Naga Vaishnavi Gadela[1]; Frank Santoro[2]. [1]Internal Medicine, University of Connecticut, Hartford, CT; [2]Dermatology, University of Connecticut, Hartford, CT. (Control ID #3391781)

LEARNING OBJECTIVE #1: To differentiate amyopathic dermatomyositis from dermatomyositis.

LEARNING OBJECTIVE #2: To understand the risks of undiagnosed amyopathic dermatomyositis.

CASE: Our patient is a 42-year-old female with no significant past medical history, who presented with a pruritic rash for several months. The rash involved the dorsal hands, thighs, chest, and upper back. The patient denied any inciting event or the use of new medications. She had photosensitivity. along with non- specific joint pain in the bilateral wrists and interphalangeal joints, without stiffness or swelling. She denied muscle pain or weakness. On examination, there was a malar rash involving the nasolabial folds, Gottron's papules, and reddened area over the upper chest in a shawl-like pattern. Labs revealed a normal erythrocyte sedimentation rate, C-reactive protein, eosinophil counts, muscle enzymes, and complement levels. Infectious workup was negative for

Lyme's disease, hepatitis, and sexually transmitted diseases. Myositis panel was negative for muscle-specific antibodies except for anti-signal recognition peptide antibody. Skin biopsy revealed perivascular lymphocytes, sub-epidermal melanophages and dermal mucin deposition consistent with dermatomyositis. She was diagnosed with amyopathic dermatomyositis(ADM) and started on hydroxychloroquine as a steroid-sparing agent.

IMPACT/DISCUSSION: ADM is characterized by the presence of cutaneous dermatomyositis(DM) with normal muscle enzymes and no significant muscle weakness with debilitating fatigue. A population-based survey of ADM revealed that overall age and sex-adjusted incidence is 2.08 per 1 million, predominantly in middle-aged women. It has been proposed that amyopathic and myopathic forms exist as a continuum, and a proportion of amyopathic patients transform into a myopathic state. It is characterized by the presence of typical skin lesions like Gottron's papules, heliotrope rash, pink rash on the face, neck, and forearms. Diagnosis can be established by classical skin findings, negative electromyography findings, normal muscle enzymes, and skin biopsy demonstrating inflammatory changes consistent with DM. The presence of anti- MDA5 antibodies can serve as an important biomarker to predict prognosis in patients with inflammatory muscle diseases. A few cases have been associated with malignancies, delayed onset of DM, and fatal interstitial lung diseases. Some cases of ADM have been reported in association with breast cancer, lymphoma, and ovarian cancer. Hence, it is essential to classify these patients, as they may have prognostic significance. Although no specific guidelines exist, it is usually treated with steroids, antimalarial agents, immunosuppressive agents, or immunoglobulins.

CONCLUSION: Patients with ADM should undergo age-appropriate malignancy screening. Fatigue and rash are commonly overlooked in the outpatient setting. Hence, it is essential to have a broad differential to identify and manage such conditions.

NO WOMAN NO CRYO

Deep Sangani[1]; Celeste Newby[2]. [1]Internal Medicine, Tulane University, New Orleans, LA; [2]Internal Medicine, Tulane University Hospitals, New Orleans, LA. (Control ID #3391215)

LEARNING OBJECTIVE #1: Discuss evluation of extreme leukocytosis in the hospitalized patient

LEARNING OBJECTIVE #2: Recognize myelodysplastic/myeloproliferative overlap neoplasms (MDS/MPN) as a rare form of myeloid malignancy

CASE: A 58-year-old man presented with a leukocytosis of 40 x 10 9 /L after one month of an intravenous antibiotic course for presumed osteomyelitis of the feet. He had a history of hepatitis C and cirrhosis. A purpuric rash was appreciated on the arms, and diffuse swelling was present in all extremities and dependent areas. Leukemia was suspected; however, no blasts were identified on blood smear and BCR-ABL returned negative. MRI of the feet revealed possible osteomyelitis, but ESR/CRP levels were normal and he had received adequate treatment with the extended antibiotic course prior to arrival. Cryoglobulinemia was considered with a positive cANCA, but C3 and C4 were low-normal. He was diagnosed with HCV-associated cutaneous vasculitis (non-cryoglobulinemic) and corticosteroid treatment was initiated, but the leukocytosis and thrombocytosis persisted. A core bone marrow biopsy returned with hypercellular marrow (80-90% cellularity) and negative cytogenetic studies, fitting the diagnostic criteria for myelodysplastic/myeloproliferative neoplasm, unclassifiable (MDS/MPN-U).

IMPACT/DISCUSSION: When a patient presents with a severe leukocytosis, causes can be categorized broadly as non-malignant and malignant etiologies. Regarding non-malignant causes of severe leukocytosis, the most common etiology is typically an infection. Other non-malignant causes of severe leukocytosis include a catecholamine- induced demargination of WBCs - which can be seen in the stress-inducing situations including surgery, exercise, or trauma – as well as medication reactions, namely to corticosteroids. Vasculitis can be considered but a lack of response to empiric treatment may prompt further investigation. Bone marrow biopsy should be considered to determine underlying malignancy as a cause of severe leukocytosis. A peripheral blood smear may reveal signs of leukemia but in this case, the bone marrow biopsy was crticial to the diagnosis.

Myelodysplastic (MDS)/myeloproliferative (MPN) neoplasm, unclassifiable diagnosis is a rare and distinct group of myeloid neoplasms with features of both MDS and MPN, and the unclassifiable diagnosis makes up 5% of all myeloid neoplasms. MDS/MPN neoplasms are predominantly diagnosed by findings in the bone biopsy. A number of somatic mutations need to be considered in order to improve diagnostic precision, including SF3B1, SETBP1, TET2, SRSF2, and ASXL1. Treatment includes hypomethylating, immunomodulatory, or cytoreductive therapies; however specific therapies for MDS/MPN overlap symptoms have not yet been developed.

CONCLUSION: When encountering marked leukocytosis, an internist may consider non-malignant or malignant etiologies. Through a systematic approach and testing, the correct diagnosis can be uncovered.

NUTRITIONALLY VARIANT STREPTOCOCCAL ENDOCARDITIS - A CASE SERIES

Suman Pal[1]; Luis Lantigua-Tatem[2]; Sejal Gandhi[2]. [1]Internal Medicine, Westchester Medical Center, Tarrytown, NY; [2]Westchester Medical Center, Valhalla, NY. (Control ID #3390750)

LEARNING OBJECTIVE #1: Recognize nutritionally variant streptococcus as a rare cause of infectious endocarditis.

CASE: Case 1- A 44 year old gentleman presented with slurred speech, right leg weakness and low back pain for 2 months. He reported intermittent fever with night sweats, and joint pain. Medical co-morbidities included hypertension and bicuspid aortic valve with aortic insufficiency. His examination revealed scanning speech with word finding difficulty. Bilateral upper and lower extremity motor strength was preserved. MRI brain showed acute-subacte infarcts in left parietal region. Multiple blood cultures subsequently grew Granulicatella adiacens. A presumptive diagnosis of endocarditis with septic emboli was made and patient was started on IV vancomycin. A transthoracic echo showed bicuspid aortic valve with dilated aortic root and severe aortic insufficiency with severely dilated LV. He underwent AVR. Tissue cultures from aortic valve were positive for Granulicatella adiacens confirming diagnosis. Patient improved on Vancomycin and was discharge to rehab with six weeks of planned IV vancomycin therapy.

Case 2 -A 58 year old gentleman presented with fever, headaches with photophobia and neck pain for 2 days. Medical co-morbidities included hypertension. Lab investigations revealed leukocytosis and elevated ESR. Lumbar puncture was performed for suspected meningitis which showed elevated WBC count with 70% PMNL, low glucose and elevated protein suggestive of bacterial meningitis. He was started on IV vancomycin, ceftriaxone and ampicillin empirically. Subsequently, MRI brain showed multiple acute infarcts suggestive of septic emboli. Blood cultures grew Granulicatella adiacens. Antibiotic regimen was switched to only IV vancomycin. A TEE showed 12 x 25mm vegetation on anterior leaflet of mitral valve and 6 x 5 mm vegetation on aortic valve. Patient underwent mitral valve replacement and aortic valve repair and was discharged with planned 4 weeks of IV vancomycin therapy.

IMPACT/DISCUSSION: NVS are gram positive cocci that have fastidious growth requirements – growing as satellite colonies around other microorganisms or in complex media enriched with sulfhydryl compounds.

First identified in 1961, NVS is currently estimated to cause 3-5% of all streptococcal endocarditis. It has an indolent course, but diagnosis is often delayed due to difficulty isolating and culturing the organism. This leads to higher rates of complications such as heart failure, septic embolization, and death. It is interesting to note that both our patients presented with neurological symptoms secondary to septic emboli. Whether this reflects a specific feature of NVS endocarditis remains to be seen. AHA recommends treatment of NVS endocarditis with penicillin MIC $\geq$0.5 μg/mLwith Ampicillin and Gentamicin combination, though if Vacomycin is used, addition of Gentamicin is not recommended.

CONCLUSION: Nutritionally variant streptococcus (NVS) should be considered early in differential of infective endocarditis.

NXP2 DERMATOMYOSITIS WITH ABDOMINAL PAIN AND SEVERE CALCINOSIS

Bradley Rockwell[1]; Darlene LeFrancois[2]. [1]Internal Medicine, Montefiore Medical Center, Bronx, NY; [2]Medicine, Montefiore Medical Center, Bronx, NY. (Control ID #3392492)

LEARNING OBJECTIVE #1: Recognize a typical presentation of dermatomyositis

LEARNING OBJECTIVE #2: Recognize a phenotypic variant of dermatomyositis associated with the NXP2 autoantibody characterized by significant calcinosis

CASE: 72 year-old woman with dermatomyositis (DM) diagnosed by muscle biopsy in 2008 presented with dysuria and left lower quadrant abdominal pain for 2 weeks that had proven refractory to outpatient treatment for presumed urinary infection. Of note, patient had a recent admission for severe lower GI bleed treated with middle colic artery embolization, and a 2cm stomach ulcer in 2009. Physical exam revealed extensive calcinosis cutis, no significant muscle weakness, and mild Gottron papules. She had left sided abdominal tenderness. CT abdomen/pelvis showed diffuse wall thickening of the colon consistent with pancolitis, present on multiple prior studies. Colonoscopy findings were most consistent with regeneration of ischemic colitis. MRI of bilateral lower extremities showed no active myositis. Given the significant calcinosis and pancolitis in this known DM patient, myositis specific autoantibodies (MSA) were sent, revealing a positive nuclear matrix protein-2 (NXP2) antibody, consistent with this rare variant of DM. Patient was scheduled for initiation of treatment with intravenous immunoglobulin.

IMPACT/DISCUSSION: DM is an inflammatory myopathy typically presenting with proximal muscle weakness, and various skin manifestations. Several MSA have been identified and are causal to the disease, characterized histologically by perifascicular atrophy and perivascular inflammation. In addition, an increased rate of malignancies, specifically breast, lung, GI, and nasal malignancies, is seen in DM patients in comparison with the general population. NXP2-DM, which our patient had, has been associated with a phenotype that includes more severe muscle weakness, calcinosis cutis but otherwise milder skin disease, and gastrointestinal (GI) manifestations when compared to those without the NXP2 antibody. GI manifestations include abdominal pain, and gastrointestinal hemorrhage and/or ulcerations from vasculitis, more frequently seen in juvenile NXP2-DM patients. Adults with NXP2 autoantibodies may also present with dysphagia. Our patient had severe calcinosis and GI involvement (pancolitis and history of hemorrhage and ulceration), giving her two distinct manifestations of NXP2-DM. It is important to recognize that patients with DM do not always present with a classic rash, phenotype varies depending on the MSA associated.

CONCLUSION: - DM is caused by autoantibodies against muscle fibers yielding the presentation of muscle weakness and inflammation on biopsy.

- NXP2-DM is an unusual variant of DM characterized by calcinosis cutis, more severe muscle weakness, milder skin disease, and GI tract involvement.

OCCULT PERIVALVULAR ABSCESS: A TELL-TALE PROLONGATION

Anna Apostolopoulou, Chad Kosanovich. Internal Medicine, UPMC, Pittsburgh, PA. (Control ID #3387568)

LEARNING OBJECTIVE #1: Recognize a new PR prolongation in a patient with a bloodstream infection as a sign of complicated endocarditis with perivalvular abscess.

CASE: A 39-year-old man with a history of end-stage renal disease on hemodialysis (HD) and an *Enterococcus faecalis* catheter-related bloodstream infection complicated by native aortic valve endocarditis and severe aortic regurgitation requiring mechanical aortic valve replacement 3 months prior presented for one episode of fever at his nursing facility. Besides low-grade temperature and tachycardia, he had no localizing infectious signs or symptoms - including no new cardiac murmur upon admission. He had a right chest temporary dialysis catheter (TDC) in place for HD which did not appear infected. His two initial sets of peripheral blood cultures grew methicillin-resistant *Staphylococcus epidermidis* and *Corynebacterium jeikeium*. He was started on vancomycin and his cultures cleared within 48 hours. In light of his extremely poor vascular access, his TDC was initially exchanged over a wire instead of replaced. However, he was noted to have a first-degree atrioventricular block with a PR interval of 360 mm, new as of this admission. This prompted a transesophageal echocardiogram (TEE), which showed no vegetation but was remarkable for a perivalvular abscess associated with the aortic prosthesis. His TDC was subsequently removed and he was taken to the operating room for a homograft root replacement.

IMPACT/DISCUSSION: In patients with a diagnosis of endocarditis, we tend to vigilantly monitor their EKGs for development of a heart block suggesting the formation of a perivalvular abscess. This case demonstrates how careful interpretation of an EKG in a patient with bacteremia and no other overt signs of endocarditis completely changed clinical management by revealing an occult perivalvular abscess. Given his rapid clinical improvement upon initiation of antibiotics, the abscess might have been undiagnosed if the EKG was overlooked, possibly leading to a poor outcome.

CONCLUSION: Perivalvular abscess is a well-known complication of infective endocarditis, especially when affecting the aortic valve given its proximity to the native conduction system. Extension of an abscess cavity into the atrial septum leads to conduction delay, including bundle branch blocks and first-degree AV block. Therefore, any new conduction delay on EKG should prompt further evaluation with TEE, which has a much better diagnostic yield compared to transthoracic echocardiography. This is important given the significant morbidity and mortality of patients with untreated cardiac abscesses including further degradation of the cardiac conductive system and other major structural emergencies.

OCULAR SYPHILIS IN AN HIV-INFECTED PATIENT

Rachel Dajani[1]; Pamela Tsing[2,3]. [1]Internal Medicine, UCLA Medical Center, Los Angeles, CA; [2]David Geffen School of Medicine at UCLA, Los Angeles, CA; [3]West Los Angeles VA Medical Center, Los Angeles, CA. (Control ID #3386011)

LEARNING OBJECTIVE #1: Identify, diagnose, and treat neurosyphilis with ocular involvement in an HIV-infected patient.

LEARNING OBJECTIVE #2: Recognize the risks posed by lack of adequate healthcare access in HIV- infected patients.

CASE: A 43-year-old male with a history of HIV and recent incarceration presented to HIV clinic with vision changes. He reported progressive blurred vision and floaters in his field of vision over the past few months. The patient was previously on antiretroviral therapy (ART); however, he was released from a one- month-long incarceration three months prior to this visit and had been off of ART since that time. Eye exam was notable for decreased visual acuity bilaterally and he was urgently referred to ophthalmology. In ophthalmology clinic, retinal exam was notable for optic nerve swelling and retinal pigment epithelium hyperreflectances, which were specifically concerning for syphilis. The patient was admitted for expedited work-up.

Magnetic resonance imaging of the brain was obtained and notable for subtle leptomeningeal enhancement, which raised concern for several infectious etiologies including neurosyphilis. Labs on admission were notable for serum RPR of 1:1024 and CD4 cell count of 47 cells/mm^3. CSF analysis revealed lymphocytic pleocytosis, positive VDRL, and elevated protein. Empiric treatment for neurosyphilis with intravenous penicillin was initiated immediately after lumbar puncture. VDRL of the CSF returned positive at 1:8, confirming the diagnosis of neurosyphilis with ocular involvement. Additional infectious work-up was negative. The patient completed a 14-day course of intravenous penicillin G. Repeat RPR six months later had appropriately decreased to 1:16 and the patient reported improved vision.

IMPACT/DISCUSSION: Neurosyphilis is diagnosed by CSF analysis demonstrating positive VDRL, elevated protein, and lymphocytic pleocytosis. Ocular syphilis is one manifestation of neurosyphilis, although ocular syphilis without central nervous system involvement is also an entity. Treatment of neurosyphilis and ocular syphilis is identical, typically consisting of a 10-14 day course of intravenous penicillin G 4 million units every 4 hours.

Neurologic manifestations of syphilis may be seen earlier in HIV-infected patients than in non-HIV-infected patients. The patient described in this case had multiple risk factors for the development of neurosyphilis including male gender, CD4 count under 350 cells/mm^3, and RPR titer greater than 1:128. The patient's recent incarceration may have contributed to his exposure to syphilis and progression to neurosyphilis. Among HIV-infected patients, recent incarceration has been associated with detectable HIV viral loads and lower CD4 counts.

CONCLUSION: 1. Ocular syphilis is a manifestation of neurosyphilis and should be considered HIV-infected patients with vision disturbances.

2. Recent incarceration has been associated with poorer health outcomes in HIV-infected patients.

OH SCHISTOCYTES! ALCOHOL-RELATED HEMOLYTIC ANEMIA

Bethina Liu[2]; Julian Waksal[1]; Alexis Vien[1]. [1]Internal Medicine, Weill Cornell Medicine, New York, NY; [2]Weill Cornell Medical College, New York, NY. (Control ID #3341260)

LEARNING OBJECTIVE #1: To recognize Zieve syndrome

LEARNING OBJECTIVE #2: To identify risk factors and opportunities for alcohol use screening and counseling for transgender patients

CASE: A 45 year-old transgender woman on estrogen therapy with history of unhealthy alcohol use presents with acute onset RUQ abdominal pain which began soon after consuming 6 alcoholic beverages. She also notes weekly marijuana and methamphetamine use. On exam, she was hemodynamically stable with scleral icterus and RUQ tenderness. Labs were notable for transaminitis (AST/ALT 346/340), indirect bilirubinemia (3.9), and hyperproliferative macrocytic anemia (Hgb 10.0, MCV 102, retic 5.3%). A broad hepatitis workup was unrevealing. MRCP revealed cholelithiasis without cholecystitis or biliary dilatation. Anemia workup was concerning for acute intravascular hemolysis. Coombs antibody and G6PD were negative. Given the patient's alcohol use history, a unifying diagnosis for her presentation is Zieve syndrome (ZS), a condition that manifests as a triad of jaundice, Coombs-negative hemolytic anemia, and hyperlipidemia secondary to alcohol-induced liver injury that frequently presents with abdominal pain. Because ZS was not on the differential until late in the patient's hospital course, a lipid panel was not obtained to confirm the diagnosis.

IMPACT/DISCUSSION: ZS was first described in 1958. With only 120 reported cases published mostly in non-English literature, ZS is an under recognized and frequently undiagnosed or misdiagnosed. In addition to the clinical triad described above, features of ZS include abdominal pain, which was present in all 20 cases reported by Dr. Zieve, as well as nausea, vomiting, and constitutional symptoms. Hyperlipidemia was present in 50% of the patients from the same study. Patients presenting without hyperlipidemia are described to have atypical ZS. Symptoms typically resolve within several weeks of illness onset, though fatal cases have been reported. Accurate and timely diagnosis of ZS is important in allowing appropriate management and provision of alcohol use counseling to prevent recurrence.

This case also demonstrates the importance of recognizing opportunities for screening for substance use and counseling for transgender patients. Unmet treatment need for substance use disorder is thought to be disproportionately high among transgender populations given unique barriers they may encounter in accessing healthcare.

CONCLUSION: Zieve syndrome is an under recognized cause of acute hemolysis in patients with a history of unhealthy alcohol use. The syndrome presents as a triad of jaundice, hyperlipidemia, and Coombs-negative hemolytic anemia and can be accompanied by abdominal pain. Treatment of Zieve syndrome involves supportive care and abstinence from alcohol.

It is important to recognize opportunities for alcohol use counseling for LGBT patients, particularly transgender patients, who may be at higher risk of developing unhealthy alcohol use and may face greater barriers in accessing medical care.

ONCE BITTEN: A CASE OF SEPSIS, THROMBOCYTOPENIA, AND PURPURA FROM CAPNOCYTOPHAGA CANIMORSUS BACTEREMIA

Sarah Wachtel[1,2]; Jeff Zoucha[1,2]; Nicholas Scaletta[1,2]. [1]Hospital Medicine, Denver Health Medical Center, Denver, CO; [2]Medicine, University of Colorado School of Medicine, Aurora, CO. (Control ID #3392208)

LEARNING OBJECTIVE #1: Recognize the importance of obtaining an exposure history in cases of infection of unknown source

LEARNING OBJECTIVE #2: Recognize the key role of molecular lab tests in diagnosing Capnocytophaga canimorsus

CASE: A 75 year-old woman with a remote history of breast cancer and macrocytic anemia presented to the Emergency Department with malaise and a painful bilateral lower extremity rash for 3 days. Her vital signs were within normal limits and examination was notable for non-blanching scattered purpuric macules of her lower extremities. She was admitted to the hospital after being found to have platelets of 28,000 and serum

creatinine of 3.4 mg/dL (both values were normal one week prior). She had no evidence of hemolysis on her labs.

Her creatinine normalized with intravenous fluids. However, she developed a new fever to 39° C along with nausea and encephalopathy. A chest X-ray, urinalysis and head CT where normal. Blood cultures were drawn, and, due to concern for meningitis, empiric antibiotic coverage with cefepime, vancomycin, ampicillin, and acyclovir was started after unsuccessful attempts at lumbar puncture.

By hospital day 6, fever and encephalopathy resolved, and blood cultures from 72 hours prior became positive for anaerobic gram negative rods (GNRs). A detailed exposure history revealed that she had sustained several bites from a new kitten at home the week prior to admission. Over the ensuing days, her antibiotics were narrowed to ampicillin-sulbactam, and she remained afebrile with normalization of her labs. One week later, the identification of the anaerobic organism from her initial blood cultures performed via MALDI-TOF mass spectrometry assay returned as Capnocytophaga canimorsus.

IMPACT/DISCUSSION: Capnocytophaga canimorsus is an anaerobic GNR that is a part of the normal oral flora of cats and dogs, and is usually transmitted by bites or scratches. It is a fastidious organism, and the laboratory should be alerted if Capnocytophaga is suspected so that enriched agar can be used. In many cases, even with a culture environment tailored to growth of Capnocytophaga, culture data alone will be insufficient, and specialized molecular testing is necessary.

Infection with Capnocytophaga canimorsus can cause severe sepsis often accompanied by disseminated purpura, encephalopathy and AKI, and is associated with a high mortality rate, with immunocompromised patients at greatest risk of infection. This patient was potentially immunocompromised from suspected underlying myelodysplastic syndrome as the cause of her macrocytic anemia.

CONCLUSION: This case emphasizes the importance of obtaining an exposure history and continually reframing the differential diagnosis based on evolving clinical data. Having a high clinical suspicion for Capnocytophaga canimorsus is necessary to ultimately secure the diagnosis given the need for specialized lab testing. In this case, the positive zoonotic exposure along with developing fever, purpuric rash, AKI, and thrombocytopenia ultimately led to a correct diagnosis.

ONE IN A MILLION ...

Hasan Ahmad Hasan Albitar[1]; Nadia Akhiyat[1]; Aleshia Magee[1]; Robert Kraft[1]; David Raslau[2]. [1]Internal Medicine, Mayo Clinic, Rochester, MN, Rochester, MN; [2]General Internal Medicine, Mayo Clinic, Rochester, MN. (Control ID #3392460)

LEARNING OBJECTIVE #1: Describe the features of the choriocarcinoma syndrome

LEARNING OBJECTIVE #2: Recognize choriocarcinoma syndrome as a medical emergency that warrants urgent oncologic consultation

CASE: A 29-year-old male presented to the emergency department with dyspnea and hematuria of 2-week duration. On further questioning, the patient reported left testicular swelling and hematospremia of 4-month duration. Medical and surgical histories were negative and family history was noncontributory. On physical examination, left testicular swelling with scrotal nodularity was noted in addition to diffuse lung crackles. Laboratory evaluation was significant for mild anemia with hemoglobin of 11.7 and urinalysis showed significant hematuria without red blood cell casts. Testicular ultrasound showed solid mass containing micrcalcifications measuring 3.4 x 4.9 x 5.4 cm. Chest/abdomen/pelvis CT scan showed large right-sided pleural effusion with near total collapse of the right lung, innumerable pulmonary masses, and multiple enlarged lymph nodes in the chest and abdomen. The patient underwent pigtail catheter placement in the right pleural space which drained bloody pleural effusion. Further laboratory tests showed significantly elevated LDH at 767 U/L (122-222), alpha-fetoprotein at 362 ng/ml (<6) and beta-hCG at 94482 IU/L (<1.4). Brain MRI was performed and showed 4 hemorrhagic cerebral metastases, the largest of which measures 11 mm. The diagnosis of choriocarcinoma syndrome was confirmed. Urgent oncologic consultation was placed and the patient was immediately started on BEP (bleomycin, etoposide, paclitaxel-cisplatin) chemotherapy even without tissue confirmation of the underlying choriocarcinoma. The patient tolerated his first cycle of chemotherapy and was discharged for outpatient ongoing treatment.

IMPACT/DISCUSSION: Testicular choriocarcinoma is and aggressive form of non-seminoma germ cell tumors that typically presents with elevated hCG and diffuse metastases. The choricocarcinoma syndrome is diagnosed in the presence of rapid hematologic spread of the tumor with diffuse hemorrhagic pulmonary metastases, hemorrhagic brain metastases, in the presence of beta-hCG level > 50,000. Spontaneous tumor lysis syndrome and hyperthyroidism can also occur but are not required for the diagnosis. It is considered a medical emergency due to the high mortality rate and patients need to be started on chemotherapy immediately even without tissue diagnosis as the diagnosis can be established using the aforementioned criteria. It is exceedingly rare with estimated prevalence of 0.1/100,000.

CONCLUSION: Choriocarcinoma syndrome is diagnosed in patients presenting with diffuse hemorrhagic metastases (pulmonary and brain) in addition to markedly elevated beta-hCG (> 50,000). The diagnosis is established using this criteria without the need for tissue diagnosis. It is considered a medical emergency and chemotherapy must be started immediately due to the high mortality rates.

ONE OF THE HEREDITARY DISEASES CAN BE DIAGNOSED BY THE PRESENTATION OF INTUSSUSCEPTION AT AN ATYPICAL AGE OF ONSET

Ryutaro Nagaya[1]; Takamasa Tanaka[2]; Hidekazu Takahashi[3,4]; Nobuhiro Haruki[4]; Mitsunori Iwase[5]. [1]Division of integrated medicine, Toyota memorial hospital, Toyota-city, Aichi prefecture, Japan; [2]Internal medicine, Toyota memorial hospital, Toyota-city, Aichi prefecture, Japan; [3]Gastroenterology, Toyota memorial hospital, Toyota-city, Aichi prefecture, Japan; [4]Gastrointestinal Surgery, Toyota memorial hospital, Toyota-city, Aichi prefecture, Japan; [5]Cardiology, Toyota Memorial Hospital, Toyota, Aichi, Japan. (Control ID #3392268)

LEARNING OBJECTIVE #1: Peutz-Jeghers syndrome which is one of the hereditary diseases may miss until intussusception occurs.

LEARNING OBJECTIVE #2: Brown spots on the lips may be clues for diagnosis of Peutz-Jeghers syndrome.

CASE: The patient was a 16-year-old woman with Iron deficiency anemia. She presented to our emergency room with intermittent abdominal pain that suddenly developed on the day of consultation. There were no melena or black stools. Her blood pressure was 120/97 mmHg, the pulse rate was 90 beats/min, and the body temperature was 36.8 degrees. She had tender throughout the abdomen, especially from the navel to the upper right abdomen. Brown spots were observed on the lips and fingers. She had previously visited a dermatologist for the brown spots but had been diagnosed as just nevuses. Blood tests showed increase the levels of WBC ($12\times10^3/\ \mu L$) and the levels of AST, Alt, ALP, γGTP and CRP were normal. Abdominal enhanced CT showed intussusceptions at the hepatic flexure and small bowel and a tumor in the sigmoid colon. She was admitted to be conducted emergency CS and the intussusception at the hepatic flexure was released. Her abdominal pain improved temporarily. However, the abdominal symptoms recurred the next day. Re-examined abdominal CT showed the small bowel intussusception was

unchanged. Then, laparoscopic small bowel resection was performed for the small bowel intussusception and laparoscopic colon resection and polypectomy in the sigmoid colon were also performed. After the surgery, her condition improved and she was discharged on the 14th day without any symptoms. Pathological examination didn't reveal a malignant tumor but found out hamartomatous lesions which were consistent with pathological features of Peutz-Jeghers syndrome (PJS).

IMPACT/DISCUSSION: PJS is a rare, but life-threatening, autosomal dominant disease characterized by melanocytic macules of the lips and toes and multiple hamartomatous polyps on the entire gastrointestinal tract except the esophagus. The estimated incidence of PJS is about 1/200,000.

The polyposis can cause intussusception by enlargement. PJS patients initially have only brown spots and is often diagnosed only after developing an intussusception. The median age of first intussusception due to PJS is around 16 years and almost all cases are performed bowel resection, whereas the common age of intussusception on childhood is less than 2 years and non-invasive reduction such as endoscopic reduction is selected in 70-90% cases. In this regard, the treatment policies differ greatly betwen an intussusception due to PJS and an ordinal one. Although PJS is a rare disease, we should consider brown spots on the lips tell diagnostic clues for PJS and intussusception can occur at atypical ages due to it, as in this case.

CONCLUSION: PJS is rare and often missed until intussusception occurs. If we meet a intussusception at an atypical age of childhood, bowel resection surgery must be considered to treat it whereas ordinally intussusception is treated by non-invasive reduction.

ONE STROKE WITH BILATERAL SYMPTOMS: ACUTE BILATERAL PARAMEDIAN MEDULLARY INFARCTION

Syed Muhammad Ibrahim Rashid, Crystal Jobson, Ava Liberman. Internal Medicine, Montefiore Medical Center, Bronx, NY. (Control ID #3392388)

LEARNING OBJECTIVE #1: Recognize the clinical features of acute bilateral paramedian medullary stroke

LEARNING OBJECTIVE #2: Diagnose and treat acute bilateral paramedian medullary stroke

CASE: A 76-year-old man woke up with new bilateral arm and leg weakness as well as numbness throughout his entire body. He was transferred to our hospital two days after symptom onset without a definitive diagnosis for care escalation. On neurological examination he had severe dysarthria, mild weakness of both arms (4/5), moderate right leg weakness (4-/5), and mild left leg weakness (4/5) in all muscle groups. With his eyes closed, he could not identify where his limbs were in space but with eyes open had no dysmetria; sensation was intact to light touch and pinprick with diminished vibration throughout all extremities. Vessel imaging demonstrated diffuse intracranial and extracranial atherosclerotic disease with a complete occlusion of the left vertebral artery in the V3 segment. Brain MRI showed a bilateral paramedian medullary infarct. He was started on aspirin, clopidogrel, and atorvastatin for secondary stroke prevention and received a PEG tube for dysphagia. He was discharged to acute rehab.

IMPACT/DISCUSSION: Bilateral paramedian medullary infarcts are challenging to diagnose as, unlike many acute ischemic stroke syndromes, deficits are bilateral. These infarcts typically present with acute onset quadriparesis (78.4%), bulbar weakness with dysarthria (48.4%), hypoglossal palsy (40.5%), and sensory, specifically proprioceptive, deficits (43.2%). This presentation can easily be confused for many neuromuscular diseases, such as Guillain-Barre syndrome (GBS), myasthenia gravis, botulism, tick paralysis, as well as spinal cord infarction and brain stem encephalitis. Early diagnosis of this stroke syndrome is challenging with high rates of morbidity and mortality.

Rates of false negative stroke diagnosis (stroke chameleons) in the emergency setting are roughly 9%. Delay in stroke diagnosis can lead to adverse patient outcomes precluding time-sensitive thrombolysis. Key features to that may distinguish bilateral paramedian stroke from other neurological symptoms are: acute symptom onset, occurrence in patients with cerebrovascular risk factors, and an upper motor neuron pattern of cranial nerve involvement associated with motor weakness. A heart-shaped infarction on brain MRI is pathognomonic for bilateral paramedian medullary infarct most commonly due to atherosclerosis of the vertebral artery with artery to artery embolism affecting the small perforating arteries of the medulla or the anterior spinal artery.

CONCLUSION: Acute bilateral paramedian medullary infarcts present with a stroke syndrome that can be difficult to diagnose given the bilaterality of clinical signs. Physicians must have a high clinical degree of suspicion to pursue a brain MRI to diagnose this rare but devastating stroke subtype to reduce morbidity and mortality.

OPENING A CAN OF WORMS: ANISAKIASIS FOLLOWING RAW FISH CONSUMPTION

Susan C. Mirabal[1]; Poy Theprungsirikul[1]; Samantha Zullow[2]; Stephanie Sterling[2]; James Kim[2]. [1]Internal Medicine, NYU Langone, Brooklyn, NY; [2]NYU Langone, New York, NY. (Control ID #3386749)

LEARNING OBJECTIVE #1: To discuss the need for a broad differential for abdominal pain

LEARNING OBJECTIVE #2: To define the clinical features of anisakiasis, the diagnostic criteria and current treatment options

CASE: A 49-year-old female with an unremarkable medical history, presented to the Emergency Department (ED) with acute onset abdominal pain associated with non-bilious, non-bloody emesis, fevers, and decreased appetite that started 4 days after eating fresh, cured Alaskan salmon and poke-style raw tuna from Alaska. Physical exam was remarkable for mild abdominal distension with guarding. Labs showed eukocytosis to 19.9 K/Lwith 1% eosinophils and 17.3K/LANC. An abdominal CT showed severe diffuse gastric wall thickening with perigastric varices, adenopathy, and surrounding fat stranding with infiltrative changes of the omentum, concerning for lymphoma or gastric cancer as well as small volume ascites and moderate free fluid in the pelvis. An esophagogastroduodenoscopy (EGD) visualized nematodes in the gastric body and antrum, burrowed in the gastric wall. Results revealed as Pseudoterranova decipiens. The patient was subsequently treated with Albendazole 400mg twice daily for 21 days. Stool studies showed moderate white blood cells but were negative for ova or parasites.

IMPACT/DISCUSSION: Our patient presented with non-specific abdominal symptoms, initially concerning for malignancy. However, a broad differential diagnosis helped us zero in on her recent exposure to raw fish. In all, the signs and symptoms were typical for the invasion of the gastric mucosa including severe abdominal pain, nausea, vomiting following ingestion.

Four major syndromes, characterized by site-specific symptoms, have been identified as part of anisakiasis infection: gastric, intestinal, ectopic and allergic disease. Intestinal anisakiasis starts 5-7 days following infection and presents with abdominal pain, ascites and/or peritoneal signs. The ectopic syndrome arises following mechanical penetration of the larvae into the stomach resulting in extensive chronic infection with mesenteric masses. Severe allergic reactions have also been reported.

Definite diagnosis of anisakiasis is made by direct visualization of larvae via EGD. Obtaining a detailed diet history as well as an anti-A simplex Immunoglobulin E can aid in diagnosis. Delayed endoscopy may result in

lack of visualization of worms. Treatment includes surgical and/or endoscopic gastric or intestinal removal as well as 400-800mg of Albendazole daily for 6 to 21days. Anisakids are resistant to freezing, microwaving, heating, and salting.

CONCLUSION: This is the case of a middle aged woman presenting with acute onset diffuse abdominal pain, nausea, vomiting, and anorexia following consumption of salt-cured salmon and raw tuna. We stress the need to consider a broad differential diagnosis for abdominal pain, as well as describe the clinical features of anisakiasis, the diagnostic criteria and treatment options to date.

OPIOID-INDUCED SECONDARY ADRENAL INSUFFICIENCY (SAI)

Haihua Zhang. Internal Medicine, Tufts Medical Center, Boston, MA. (Control ID #3386102)

LEARNING OBJECTIVE #1: Raise level of awareness that chronic opioid therapy can induce SAI

LEARNING OBJECTIVE #2: Recognize SAI can present with normal cosyntropin test as adrenal glands are not completely atrophied

CASE: A 48-year-old female with past medical history of ovarian carcinoma, Crohn's disease on chronic methadone and oxycodone, complicated by rectovaginal fistula status post subtotal colectomy 3 months ago, further complicated by inferior STEMI on POD1, was admitted to the hospital for progressive diffuse abdominal pain since the surgery. On admission, vitals were notable for blood pressure 75/51. Exam was significant for diffuse abdominal pain without rebound tenderness. Lab results revealed normal electrolytes and no leukocytosis. Our differential diagnosis included sepsis, right heart failure and adrenal insufficiency. CT abdomen/pelvis was obtained, and results were consistent with post-operative changes without acute pathology. Blood cultures on admission did not show growth. An echocardiogram was performed which showed normal biventricular function without wall motion abnormalities. Given high suspicion for adrenal insufficiency, a stress dose dexamethasone was initiated while waiting for confirmative consyntropin stimulation test. Adrenal functions were evaluated, which revealed low morning cortisol (1.1 μg/dL), low morning ACTH (<5 pg/mL), and borderline cosyntropin stimulation test (19.7 μg/dL 60 minutes after 250 μg IV cosyntropin). MRI of the head with contrast revealed normal pituitary and hypothalamus. She was then transitioned to stress dose hydrocortisone with which blood pressure significantly improved. Subsequently, abdominal pain resolved shortly. She was discharged on oral hydrocortisone.

IMPACT/DISCUSSION: This case demonstrates SAI induced through chronic narcotic use. The most common etiologies of SAI include exogenous glucocorticoid therapy, brain surgery, and infiltrative disease to pituitary. Multiple case reports demonstrated the association between SAI and chronic opioid use by suppressing HPA axis; however, opioid induced SAI is not well recognized. Given the opioid endemic in America, clinicians should raise level of awareness about it.

SAI can be difficult to diagnose due to the low sensitivity of cosyntropin stimulation test (57%) secondary to incompletely atrophied adrenals, which should be used to rule in rather than rule out SAI. If clinical suspicion is high, glucocorticoid treatment should be administered. Dexamethasone is preferred considering the lack of mineralocortical component and minimal interference with cosyntropin test.

CONCLUSION: Chronic narcotic use can induce secondary adrenal insufficiency by suppressing HPA axis

Diagnosis is rendered difficult due to the low sensitivity of the cosyntropin test. If clinical suspicion is high for SAI, glucocorticoid should be administered immediately.

Dexamethasone is preferred prior to consyntropin test

OUTPATIENT MANAGEMENT OF ORTHOSTATIC HYPOTENSION AS A CHRONIC COMPLICATION OF UPPER SPINAL CORD INJURY

Samuel G. Ruchman[1]; Alexis Tchaconas[1]; Joseph Truglio[2]. [1]Internal Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; [2]Internal Medicine, Pediatrics and Medical Education, Icahn School of Medicine at Mount Sinai, Maplewood, NJ. (Control ID #3390851)

LEARNING OBJECTIVE #1: Recognize patterns of autonomic dysfunction as complications of spinal cord injury.

LEARNING OBJECTIVE #2: Describe the management approach to chronic orthostatic hypotension in the outpatient setting.

CASE: AL is an 18-year-old man with a history of incomplete tetraplegia following traumatic cervical spinal cord injury (SCI), complicated by orthostatic hypotension (OH), neurogenic bladder, and neuropathic pain, who presented to the clinic to establish care. He reported chronic episodes of pre-syncope and diaphoresis several times daily with no loss of consciousness, provoked by rapid positional changes and partially alleviated by leaning forward. Pre-syncopal episodes had persisted despite treatment with 5 mg midodrine twice daily for OH since inpatient admission 14 months prior. On exam, AL's blood pressure was 96/64, wearing an abdominal binder. Cardiovascular auscultation was unremarkable. The dose of midodrine was increased to 10 mg in the morning and afternoon. At follow up, AL reported subjective improvement and denied adverse effects including symptoms of hypertension, such as headache, flushing or blurred vision.

IMPACT/DISCUSSION: SCI superior to the T6 vertebra can cause autonomic dysfunction resulting in hypertension or hypotension. Resting hypotension and OH in upper SCI patients occurs due to impairment of sympathetic cardiovascular inputs, which leaves vagally mediated parasympathetic pathways unopposed. In one study, nearly 75% of SCI patients demonstrated OH during postural changes, but fewer than 60% of individuals were symptomatic. Pre-syncopal episodes are disruptive to daily activities, can limit participation in rehabilitation, and pose a fall risk during positional transfers. Unaddressed, dramatic blood pressure fluctuations may also contribute to long-term cognitive impairment in SCI patients through effects on cerebral vasculature.

A recent systematic review found that among pharmacologic agents used to control OH in SCI patients, only midodrine, a selective alpha-adrenergic agonist, had evidence from a randomized controlled trial (pilot study, n=4) to support its use. Outpatient practitioners can initiate midodrine at low doses (2.5 or 5 mg in the morning and afternoon) and rapidly uptitrate. Twice daily dosing may be preferable to avoid an evening dose, which can predispose patients to supine hypertension. Home blood pressure monitoring complements subjective reporting of symptoms. Fludrocortisone, a mineralocorticoid, is commonly initiated prior to midodrine for management of OH in general, but its use lacks rigorous evidence in SCI patients specifically. Physical interventions such as abdominal binders, compression stockings, and increased fluid and salt intake are also common but lack specific evidence in SCI patients.

CONCLUSION: Patients with upper SCI can experience chronically recurring OH, disrupting daily activities and rehabilitation. Outpatient providers can initiate and rapidly uptitrate midodrine to mitigate OH.

OVERCOMING COGNITIVE BIAS IN PRIMARY CARE CLINIC BY UTILIZING A REVIEW OF SYSTEMS: A CASE OF COMMON COLD OR CANCER?

Anne Wagstaff. Internal Medicine, University of Alabama at Birmingham, Birmingham, AL. (Control ID #3392078)

LEARNING OBJECTIVE #1: Cognitive bias impacts clinical decision making, and a thorough review of systems is a checklist physicians can implement to examine their daily heuristics in the primary care setting.

CASE: A 72 year-old white male with hypertension and hyperlipidemia presented to the walk-in resident clinic complaining of a sore throat ongoing for 2 weeks in October. The clinic had seen a plethora of common cold cases recently, so the history focused on relevant questions. The patient denied rhinorrhea, nasal congestion, sinus headache, cough, shortness of breath, fevers, chills, or sick contacts. Given the lack of associated infectious symptoms, a more comprehensive review of systems was taken to expand the differential. This revealed unilateral, left-sided throat soreness, dysphagia, and weight loss. This prompted questions that revealed a 50 pack-year smoking history and significant previous alcohol consumption. Physical exam showed cachexia and a left submandibular, hard, immobile nodule approximately 1 x 3 cm in size. His exam along with his history was concerning for malignancy, so a CT of his neck was done promptly. This showed an epiglottic mass and a biopsy showed squamous cell carcinoma. A PET scan revealed metastatic spread to lymph nodes and the lungs, and he was diagnosed with Stage IVa squamous cell carcinoma. He received a PEG to assist with nutrition and established care with hematology with plans to start cisplatin.

IMPACT/DISCUSSION: Diagnostic accuracy is central to the practice of medicine but is impaired by cognitive bias. Approximately 5% of patients in the outpatient setting will experience a diagnostic error every year. Due to time constraints, physicians rely on heuristics to make quick medical decisions, but this is prone to cognitive biases. Two examples of cognitive bias are premature closure (deciding on a diagnosis before all the information is considered) or availability bias (believing a patient has a diagnosis because another patient with similar symptoms recently had this diagnosis). Studies show the utilization of checklists is one strategy in overcome cognitive bias. Medical students learn to take a review of systems as part of a medical history, a checklist of sorts to ensure important symptoms are not missed. This patient presented with a sore throat to clinic during common cold season. Availability bias and premature closure could have easily influenced clinical reasoning. However, a thorough review of systems revealed the essential clues of weight loss, dysphagia, and a substantial smoking and alcohol history that questioned the common cold heuristic and led to a diagnosis of cancer.

CONCLUSION: The review of systems is often an overlooked component of the medical history but can serve as a checklist to reevaluate one's initial diagnostic heuristic to avoid cognitive bias in making clinical decisions.

OVERDOSE RISK DURING A ROCKY REENTRY: A TALE OF SECOND CHANCES

Benjamin Bovell-Ammon, Davis N. Bradford. Internal Medicine, Boston Medical Center, Boston, MA. (Control ID #3391722)

LEARNING OBJECTIVE #1: Assess the overdose risk factors that are common among justice-involved patients with opioid use disorder (OUD)

LEARNING OBJECTIVE #2: Recognize critical touch points for engaging these high-risk, hard-to-reach patients in addiction care

CASE: A 33-year-old man with multiple substance use disorders (opioid-predominant) and depression was brought to the emergency department (ED) after an accidental polysubstance overdose. He has a long history of contact with the criminal justice system, and most of his prior experiences with health care occurred while in prison. He current lacks stable housing and employment. Due to outstanding warrants, he was recently arrested and detained in the local county jail for 5 days. His overdose, which was his first, occurred when he resumed intranasal heroin use upon release. Emergency medical services found him unconscious in a public space. He was successfully resuscitated in the field with intranasal naloxone.

Upon arrival to the ED, he had normal vital signs and was awake and lucid, though mildly distressed at first. There were no other notable findings on physical exam. Hepatitis A vaccination was administered, an intranasal naloxone kit was provided, and a peer navigator with the hospital's addiction outreach team met with the patient. He was accompanied to the low-barrier addiction medicine clinic on campus and initiated buprenorphine therapy that day.

IMPACT/DISCUSSION: This patient's overdose following release from jail demonstrates a missed opportunity. Individuals recently released from criminal justice institutions have an exceptionally high risk of opioid overdose due to an array of factors: lost tolerance to opioids, lack of or interruptions in medical and behavioral health care, social isolation, unstable housing and other forms of material insecurity, and psychological stress. Despite the demonstrated efficacy of medications for opioid use disorder to prevent overdoses in both general and justice-involved populations, few prisons and jails in the US provide them during incarceration or at release.

While neither the criminal justice nor the health care system offered him this care at the time of release, his survival provided a second chance. Justice-involved patients face many barriers to outpatient health care, so an ED admission for a non-fatal overdose serves as another critical touch point. This case highlights the success of targeted outreach, accompaniment, and low-barrier addiction services in engaging this high-risk and hard-to-reach patient population.

CONCLUSION: 1. Recently incarcerated patients with substance use disorder have an elevated overdose risk and face many barriers to care in the community.

2. Targeted outreach and low-barrier treatment services are effective ways to engage this population, especially at key touch points such as post-incarceration reentry and acute medical presentations.

PACEMAKER IMPLANTATION IN A PATIENT WITH CHALLENGING VASCULAR ACCESS

Malik Shehadeh[2]; Chantal Chahine[1]; Vijaywant Brar[1]; John Costello[1]; Nebu Alexander[1]; Cyrus Hadadi[1]; Susan O'Donoghue[1]; Zayd Eldadah[1]; Seth Worley[1]. [1]Section of Cardiac Electrophysiology, MedStar Washington Hospital Center, Washington, DC; [2]Internal Medicine, MedStar Washington Hospital Center, Washington, DC. (Control ID #3391790)

LEARNING OBJECTIVE #1: To manage and treat patients with poor upper extremity vascular access who need pacemaker implantation.

CASE: A 78-year-old female patient with medical history significant for superior vena cava occlusion and heart failure with reduce ejection fraction due to nonischemic cardiomyopathy presented to our hospital with a 1-month history of multiple presyncopal episodes.

Upon arrival to the hospital, her vitals were unremarkable. Labs showed normal thyroid function. Her electrocardiogram showed normal sinus rhythm with first degree block, right bundle branch block and left anterior fascicular block. Echocardiogram showed left ventricular ejection fraction of 35% without evidence of valvular disease. Carotid duplex was negative except for moderate stenosis in the left proximal internal carotid artery. Her symptoms were attributed initially to dehydration and orthostatic hypotension, which she was treated with fluids.

While in the hospital, her telemetry showed high-grade atrioventricular block during which she was symptomatic. A decision was made to proceed with biventricular pacemaker implantation. During the procedure, multiple unsuccessful attempts were made using upper extremity vasculature to access the central circulation. Procedure was aborted to allow patient recovery from contrast load.

Subsequently, patient underwent a repeat attempt using femoral vein access with leads advanced successfully through the right iliac vein. The implanted leads were connected to the pacemaker generator that was secured to the anterior abdominal wall. The patient was discharged in good condition and continues to do well.

IMPACT/DISCUSSION: Pacemakers are medical devices that generate electrical impulses transmitted via electrodes to regulate the electrical activity of the heart. The most common indications for permanent pacemaker implantation are sinus node dysfunction and high-grade atrioventricular block.

Typically, pacemakers are placed in the left upper chest with leads advanced through the left upper extremity vasculature. However, in patients with anatomic abnormality or difficult vascular access, alternate options should be searched.

Here we are reporting a rare case of a patient with complete occlusion of the superior vena cava who underwent successful pacemaker implantation via the right iliac vein.

CONCLUSION: Iliac vein lead delivery and supra-inguinal device placement is a viable strategy for pacemaker implantation in patients who lack upper body vascular access.

PAIN IN THE LEGS: LOOK UP!

Amanda H. Ceravolo[1]; Christopher Babu[1]; Pamela Charney[2]. [1]Weill Cornell Community Clinic, Weill Cornell Medicine, New York, NY; [2]Internal Medicine, Weill Cornell Medical College, New York City, NY. (Control ID #3390761)

LEARNING OBJECTIVE #1: Recognize the value of a primary care intervention on identifying and treating emergent clinical situations in uninsured patients.

LEARNING OBJECTIVE #2: Recognize the clinical features of cervical myelopathy and identify back pain as symptom of cervical myelopathy

CASE: A 59-year-old uninsured Mandarin speaking political scholar with a history of bladder cancer treated with chemotherapy and surgery in remission, cervical stenosis, HTN, HLD, T2DM presented to a student-run free clinic with two months of lower back pain radiating down his left leg and multiple falls over the last couple months secondary to his left leg "giving out". ROS positive for shoulder pain and bilateral arm numbness in ulnar distribution likely secondary to the patient's known cervical stenosis. Given his history of cancer, we obtained an MRI lumbar and thoracic spine showing moderate thoracic spinal stenosis most pronounced at T10-11, no lumbar stenosis, foraminal stenosis, or cord compression. He was treated with a course of NSAIDs and physical therapy referral. Due to lack of improvement, we obtained a cervical spine MRI that significantly changed management. The patient was urgently referred to a public hospital for surgical consultation where he had a C4-6 laminectomy and fusion with significant improvement in his leg and arm symptoms.

Initial Exam: negative straight leg test, 4+/5 left hip flexion, decreased sensation to light touch bilateral 4^{th} and 5^{th} fingers and medial forearms, toes upgoing bilaterally, normal gait

Labs: BMP: Na 135 otherwise normal, HgA1c: 7.1%, B12: normal

MRI: C5-6 herniation with significant cord compression and effacement of the spinal canal
