Supplementary Figure 1. Pairwise associations

Risks of developing a subsequent later disorder among persons with versus those without a prior disorder

Each panel shows the pairwise association between prior disorders and later disorders. Estimates were obtained via Cox proportional hazards regression model adjusting for age-cohort, sex, and country (Model A – purple circles in the plot), with further adjustment for type and number of mental disorders with onset preceding the prior disorder (Model B –orange triangles in the plot). Results were displayed in the form of Hazard ratios (HRs) and 95% confidence intervals (CIs). A vertical line at $x = 1$ representing “null effect” is also plotted in each panel. If the confidence intervals for the estimates overlap with this line, we have no evidence against the null hypothesis that the risk of developing a subsequent later disorder are the same among persons with prior disorder compared to those without. Estimates were not shown for disorder pairs with less than 30 cases due to unstable estimates. Abbreviations: Major Depressive Episode – MDE; Generalized Anxiety Disorder – GAD; Attention Deficit Hyperactivity Disorder (ADHD); Obsessive Compulsive Disorder (OCD); Post-Traumatic Stress Disorder (PTSD); Separation Anxiety Disorder (SAD); Intermittent Explosive Disorder (IED); Oppositional Defiant Disorder (ODD).

Supplementary Figure 2. Sex-specific pairwise associations

Risks of developing a subsequent later disorder among persons with versus those without a prior disorder, by sex

The following figures show pairwise hazard ratios, estimated separately for men (blue triangles in the plot) and women (pink circles in the plot). The prior disorders are listed at the top of each panel and later disorders listed on the Y-axis. Estimates were obtained via Cox proportional hazards regression model adjusting for age-cohort, sex, and country with further adjustment for type and number of mental disorders with onset preceding the prior disorder (Model B). A vertical line at $x = 1$ representing “null effect” is also plotted in each panel. Estimates were not shown for disorder pairs with less than 30 cases due to unstable estimates. Abbreviations: Major Depressive Episode – MDE; Generalized Anxiety Disorder – GAD; Attention Deficit Hyperactivity Disorder (ADHD); Obsessive Compulsive Disorder (OCD); Post-Traumatic Stress Disorder (PTSD); Separation Anxiety Disorder (SAD); Intermittent Explosive Disorder (IED); Oppositional Defiant Disorder (ODD).

Supplementary Figure 3. Lagged associations

Lagged associations between prior disorders and subsequent later disorders

Each panel shows the risk of developing a subsequent later disorder conditioned on the time since onset of prior disorder. Estimates were obtained via Cox proportional hazards regression model adjusting for age-cohort, sex, and country (Model A – purple circles), with further adjustment for type and number of mental disorders with onset preceding the prior disorder (Model B – orange triangles). Results were displayed in the form of Hazard ratios (HRs) [shown in a log scale] and 95% confidence intervals (CIs). A horizontal line at $y = 1$ representing “null effect” is also plotted in each panel. The reference category is those without the specific prior disorder. Estimates with less than 30 cases were not shown. Later disorders are listed at the top of each panel. Abbreviations: Major Depressive Episode – MDE; Generalized Anxiety Disorder – GAD; Attention Deficit Hyperactivity Disorder (ADHD); Obsessive Compulsive Disorder (OCD); Post-Traumatic Stress Disorder (PTSD); Separation Anxiety Disorder (SAD); Intermittent Explosive Disorder (IED); Oppositional Defiant Disorder (ODD).

Supplementary Figure 4. Absolute risks (overall estimate)

Absolute risk of later disorders after the initial onset of a prior disorder

Each panel shows the overall absolute risks (solid orange line) and 95% confidence interval (shaded area) of developing a subsequent later disorder after the onset of prior disorder. The label for each later disorder is shown at the top of each panel. The horizontal axis shows the time since onset of prior disorder. The vertical axis shows the cumulative incidence proportions per 100 persons (and 95% CI). Abbreviations: Major Depressive Episode – MDE; Generalized Anxiety Disorder – GAD; Attention Deficit Hyperactivity Disorder (ADHD); Obsessive Compulsive Disorder (OCD); Post-Traumatic Stress Disorder (PTSD); Separation Anxiety Disorder (SAD); Intermittent Explosive Disorder (IED); Oppositional Defiant Disorder (ODD).

Supplementary Figure 6. Absolute risks (time-specific estimate)

Absolute risk of later disorders after the initial onset of a prior disorder (time-specific estimates)

Each panel shows the overall absolute risks and 95% confidence interval (shaded area) of developing a subsequent later disorder after the onset of prior disorder estimated separately by the age-of-onset for prior disorder ('< 20 years' - blue line in the plot), ('20-40 years' - pink line in the plot), and ('> 40 years' - orange line in the plot). The label for each later disorder is shown at the top of each panel. The horizontal axis shows the time since onset of prior disorder. The vertical axis shows the cumulative incidence proportions per 100 persons (and 95% CI). Abbreviations: Major Depressive Episode – MDE; Generalized Anxiety Disorder – GAD; Attention Deficit Hyperactivity Disorder (ADHD); Obsessive Compulsive Disorder (OCD); Post-Traumatic Stress Disorder (PTSD); Separation Anxiety Disorder (SAD); Intermittent Explosive Disorder (IED); Oppositional Defiant Disorder (ODD).

Additional methods

In most countries, internal subsampling was used to reduce respondent burden and average interview time by dividing the interview into two parts. Part 1 of the interview, administered to all respondents, evaluated core mental disorders (depression, mania, panic disorder, specific phobia, social phobia, agoraphobia, GAD and substance-use disorder). Part 2 of the interview, included more information related to correlates and disorders of secondary interest and this was administered to the respondents reporting any core mental disorder and a probability sample of part 1 respondents who did not meet criteria for any core disorder. Sample sizes of these surveys ranged from 2,357 (Romania) to 12,790 (New Zealand). A total of 145,990 respondents completed part 1 of the interview and 80,190 completed part 2 of the interview with an average weighted response rate of 69.5%. Part 2 responses were weighted by the inverse of their probability of selection into part 2 sample to adjust for any differential sampling. Additional weights were used to adjust for differential probabilities of selection within households, nonresponse, and to match the samples to population sociodemographic distributions. Thus, the weighted estimates shown below are representative of the original sampling frame. Further details of the construction of the analyses weights are provided elsewhere (Kessler et al. 2018). Due to concerns about recall failure among adults in the assessment of childhood and adolescence disorders, Oppositional Defiant Disorder, Conduct Disorder, Attention Deficit Hyperactivity Disorder and Separation Anxiety Disorder were assessed only among the part 2 respondents aged 18-44 or 18-39. We did not quantify the association between (a) prior substance dependence and later substance abuse, and (b) prior adult separation anxiety disorder and subsequent child separation anxiety disorder as the first disorder over-rides the later disorder. Estimates were not quantified for disorder pairs with less than 30 cases due to unstable estimates. The WMH surveys assessed age of onset of disorders in whole years, and respondents may report occurrences of two or more disorders in any given year (i.e. presence of ties). In a time-to-event framework, these ties would lead to under-reporting of comorbidity between disorders that occur in the same year. In keeping with our previous analyses (Plana-Ripoll et al. 2019), we broke these ties by randomly reassigning a proportion of those with same year of onset to having the prior disorder a year earlier. Before estimating each pairwise association, we calculated the proportion of respondents that had to be randomly reassigned in the total sample by dividing the number of respondents that developed 'prior disorder' before 'later disorder' by the number of respondents with both 'prior disorder' and 'later disorder' excluding those with ties. This proportion was multiplied with the number of respondents with ties (i.e. two disorders with the same year of onset) to obtain the number to be randomly assigned to having the prior disorder a year earlier.
