

Supplementary Materials

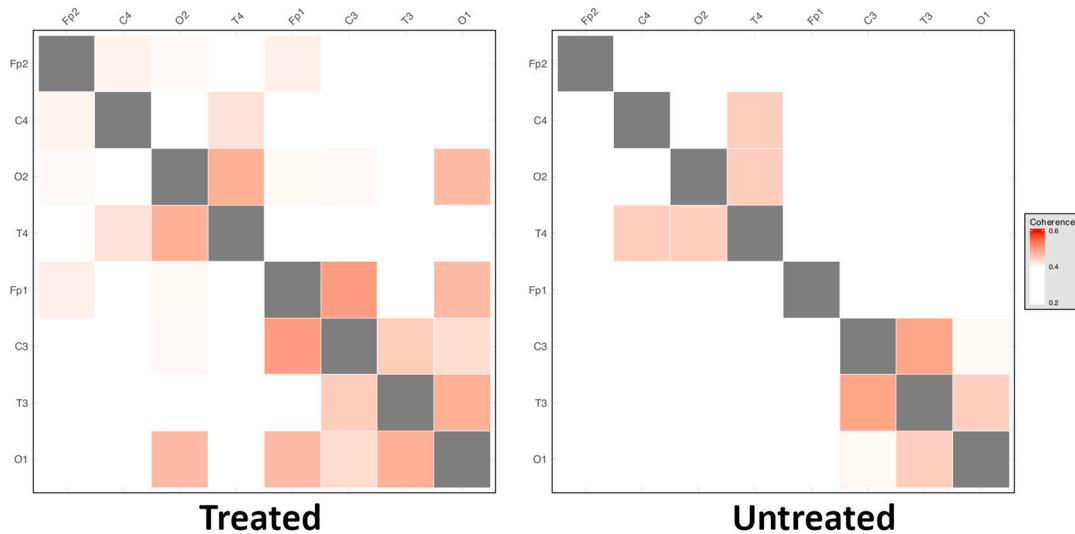

Figure S1. Heatmap demonstrating distribution of coherence between individual electrode pairs, treated vs. untreated at baseline. There are statistically significant differences between a number of long-range electrode pairs, suggesting differences in network connectivity at baseline.

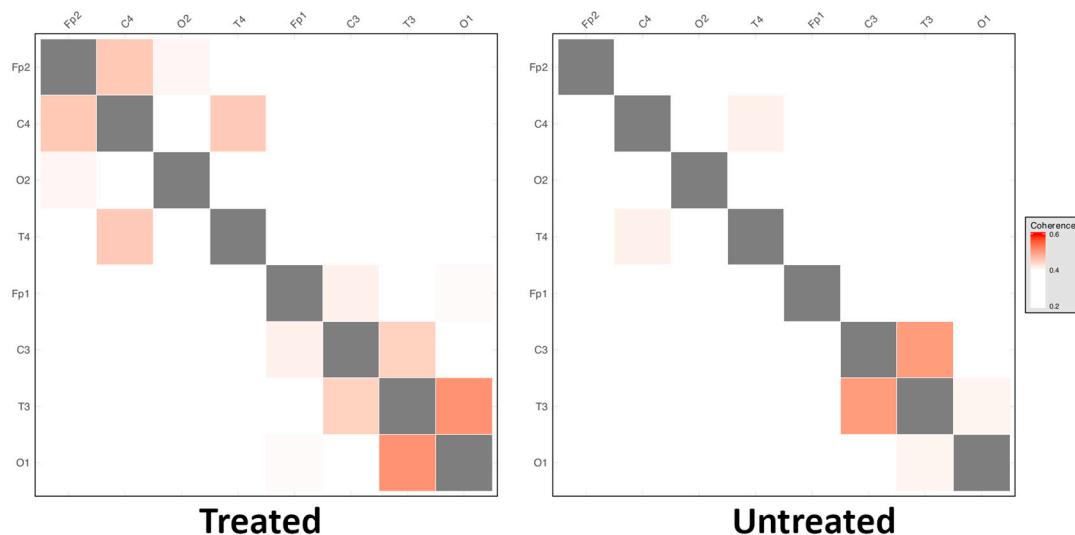

Figure S2. Heatmap demonstrating distribution of coherence between individual electrode pairs, treated vs. untreated at twelve months. There were no statistically significant differences between any individual electrode pairs, suggesting a change in connectivity following treatment.

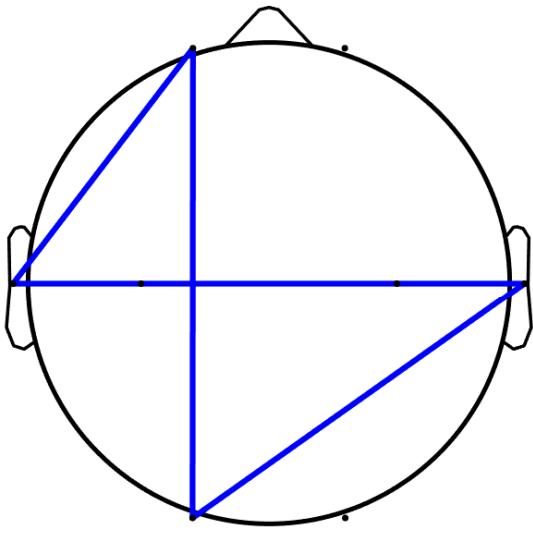

Figure S3. Schematic of differences network architecture at baseline, treated vs. untreated groups. Lines join channels with a statistically significant difference in coherence between groups at baseline ($p < 0.05$). The differences in network features were predominantly driven by long-range connections.

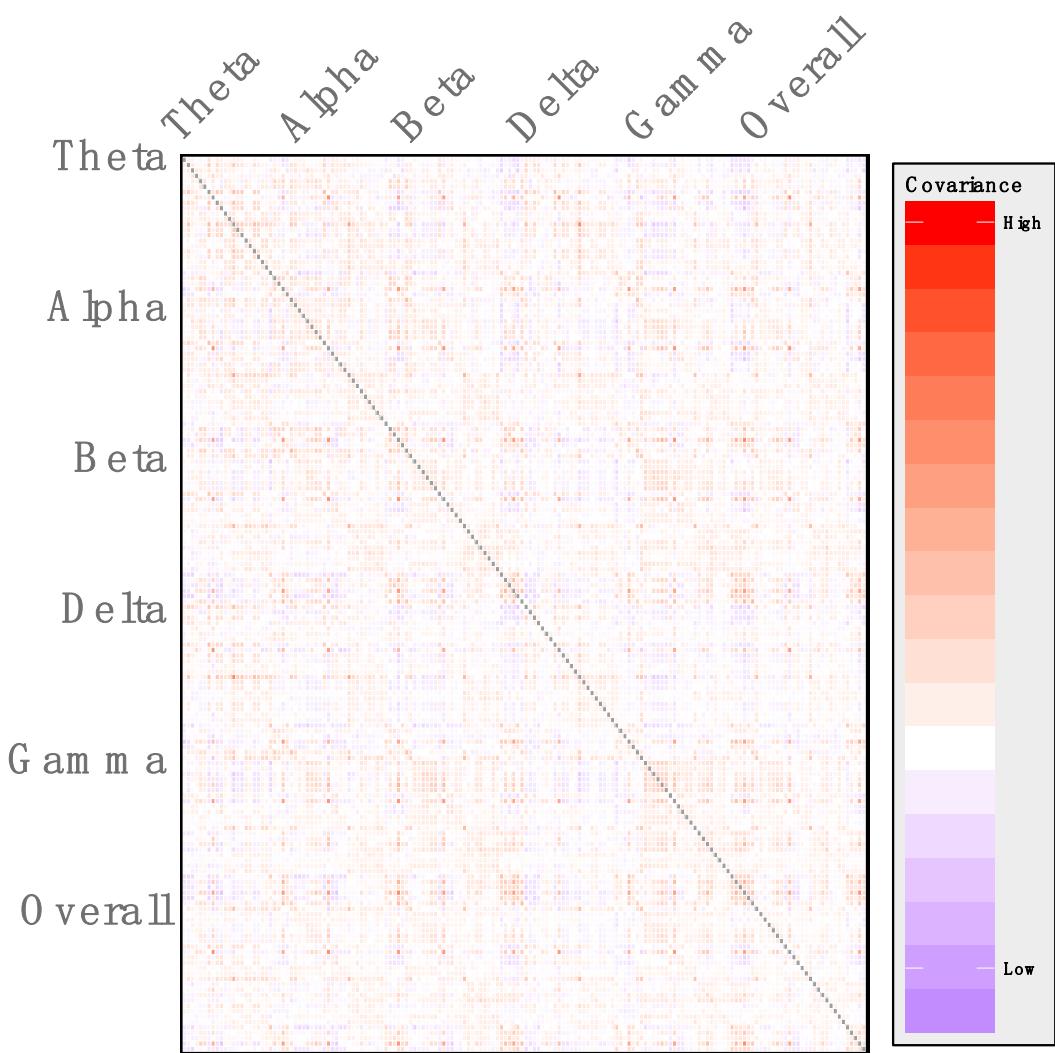

Figure S4. Covariance matrix of network measures, treated patients at baseline. There were statistically significant differences in network loadings at baseline between treated and untreated groups, suggesting that network-level differences may exist that were not apparent on clinical assessment. This may have implications for targeting treatment.

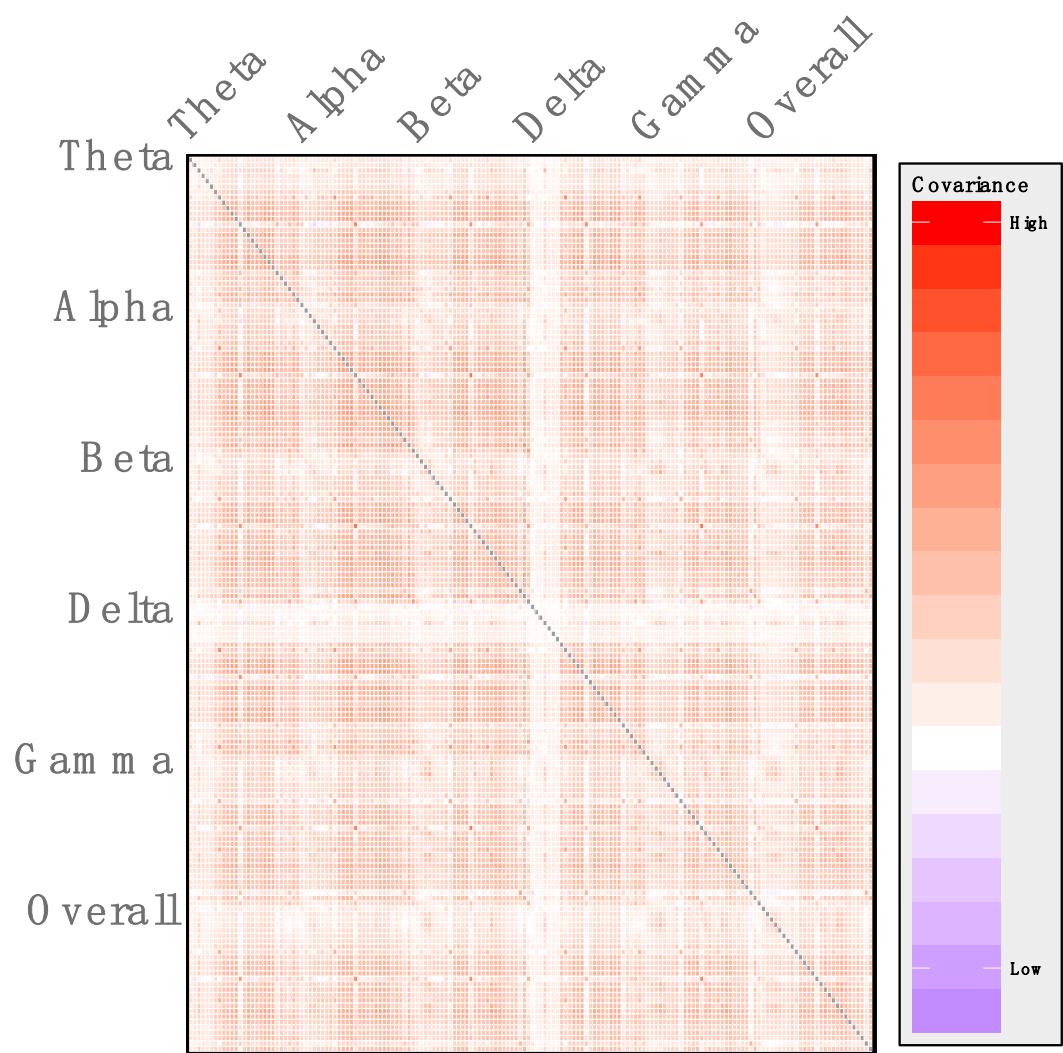

Figure S5. Covariance matrix of network measures, untreated patients at baseline. There were statistically significant differences in network loadings at baseline between treated and untreated groups, suggesting that network-level differences may exist that were not apparent on clinical assessment. This may have implications for targeting treatment.

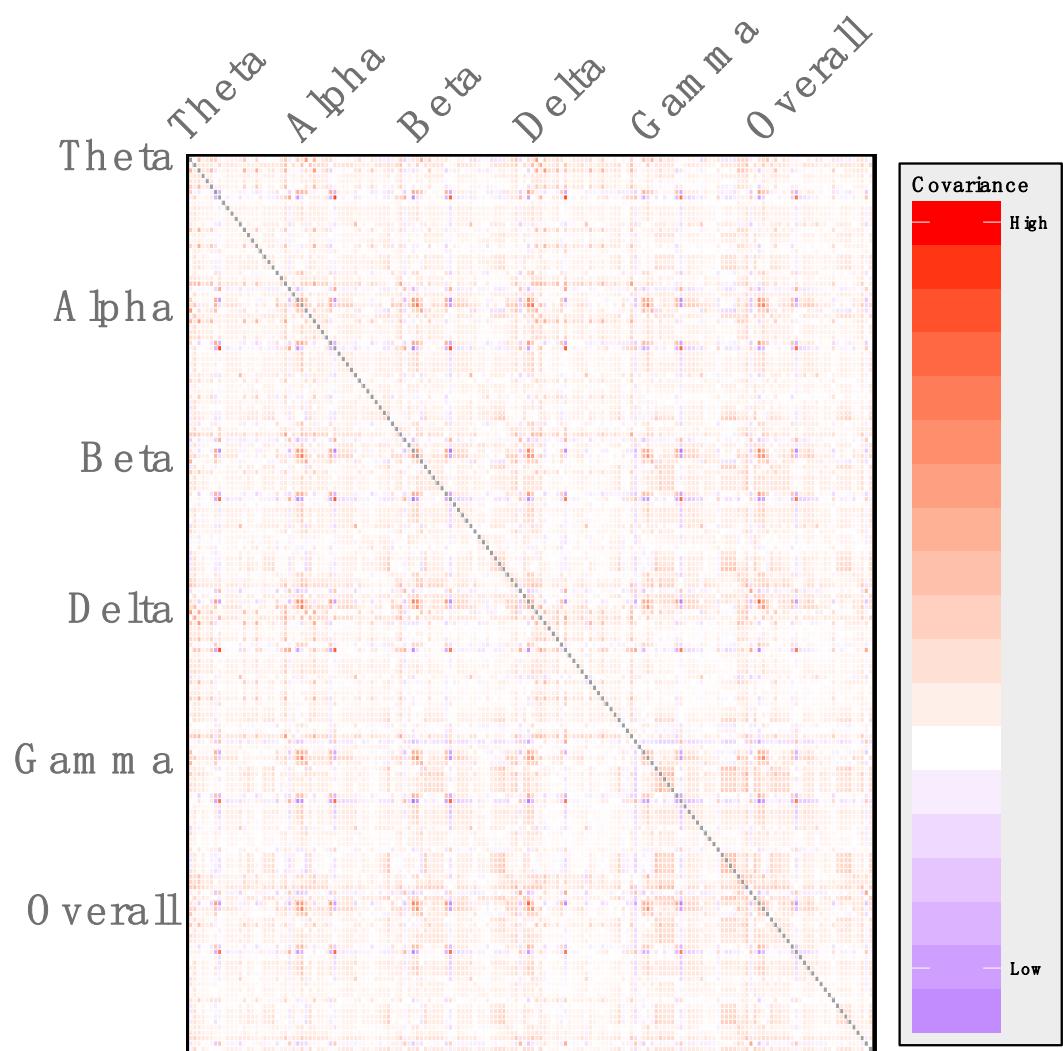

Figure S6. Covariance matrix of network measures, treated patients at 12 months. There was a statistically significant effect of treatment group & time on network loadings, suggesting that treatment with IGF-1 caused alterations in cortical electrophysiology. This underlines the emerging importance of network electrophysiology in Rett Syndrome and its treatment and may have implications for targeting treatment based on electrophysiological biomarkers.

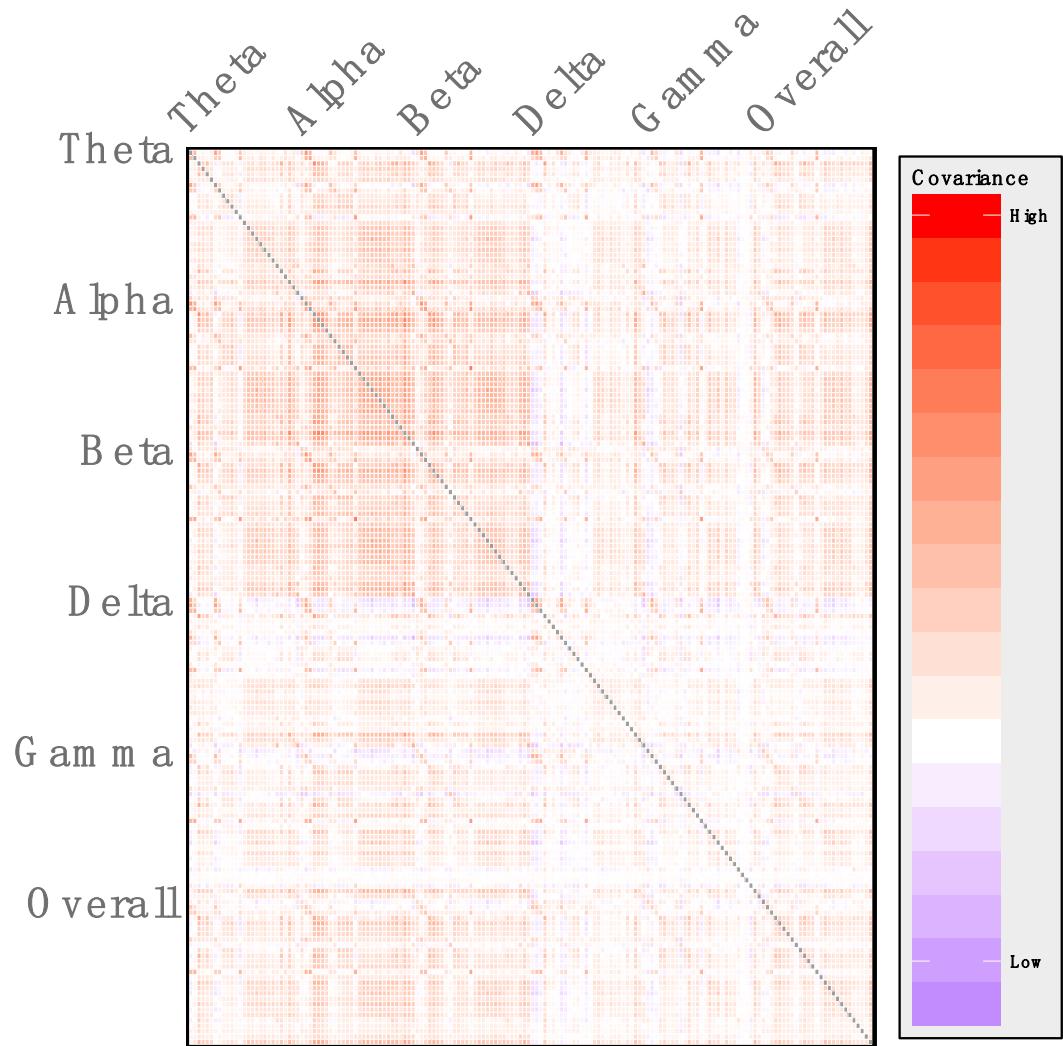

Figure S7. Covariance matrix of network measures, untreated patients at 12 months. There was a statistically significant effect of treatment group & time on network loadings, suggesting that treatment with IGF-1 caused alterations in cortical electrophysiology. This underlines the emerging importance of network electrophysiology in Rett Syndrome and its treatment and may have implications for targeting treatment based on electrophysiological biomarkers.

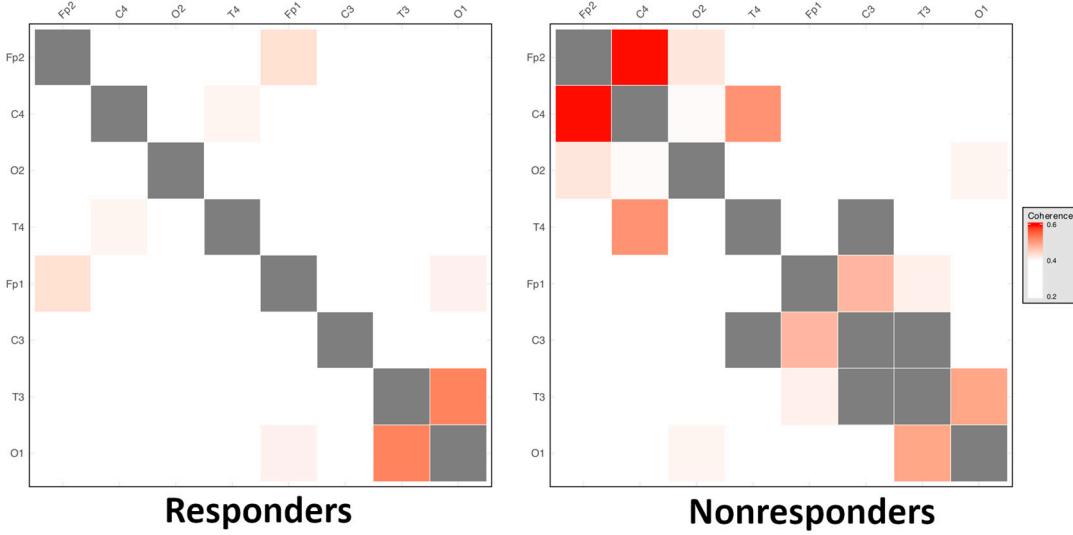

Figure S8. Heatmap demonstrating the distribution of coherence measures at individual electrode pairs, responders vs. nonresponders at twelve months. There were no statistically significant differences in coherence between individual electrodes, suggesting that observed differences in overall network architecture are due to an overall pattern change, rather than differences at individual channel pairs.

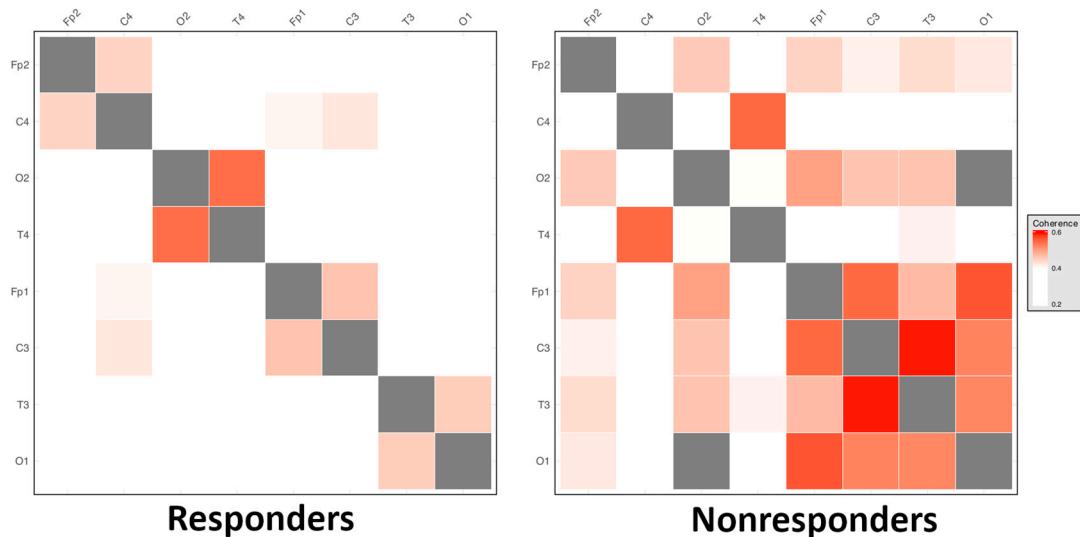

Figure S9. Heatmap demonstrating coherence measures at individual electrode pairs, responders vs. nonresponders at baseline. There are a number of statistically significant differences between measures at baseline, suggesting network-level differences between responders and non-responders prior to treatment. These are predominantly long-range pairs.

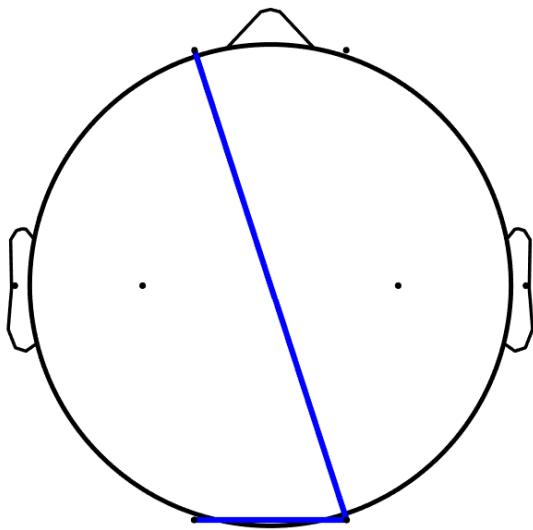

Figure S10. Schematic of differences network architecture at baseline, responders vs. nonresponders. Lines join channels with a statistically significant difference in coherence between groups at baseline ($p < 0.05$). The differences in network features were predominantly driven by long-range and occipital interhemispheric connections.

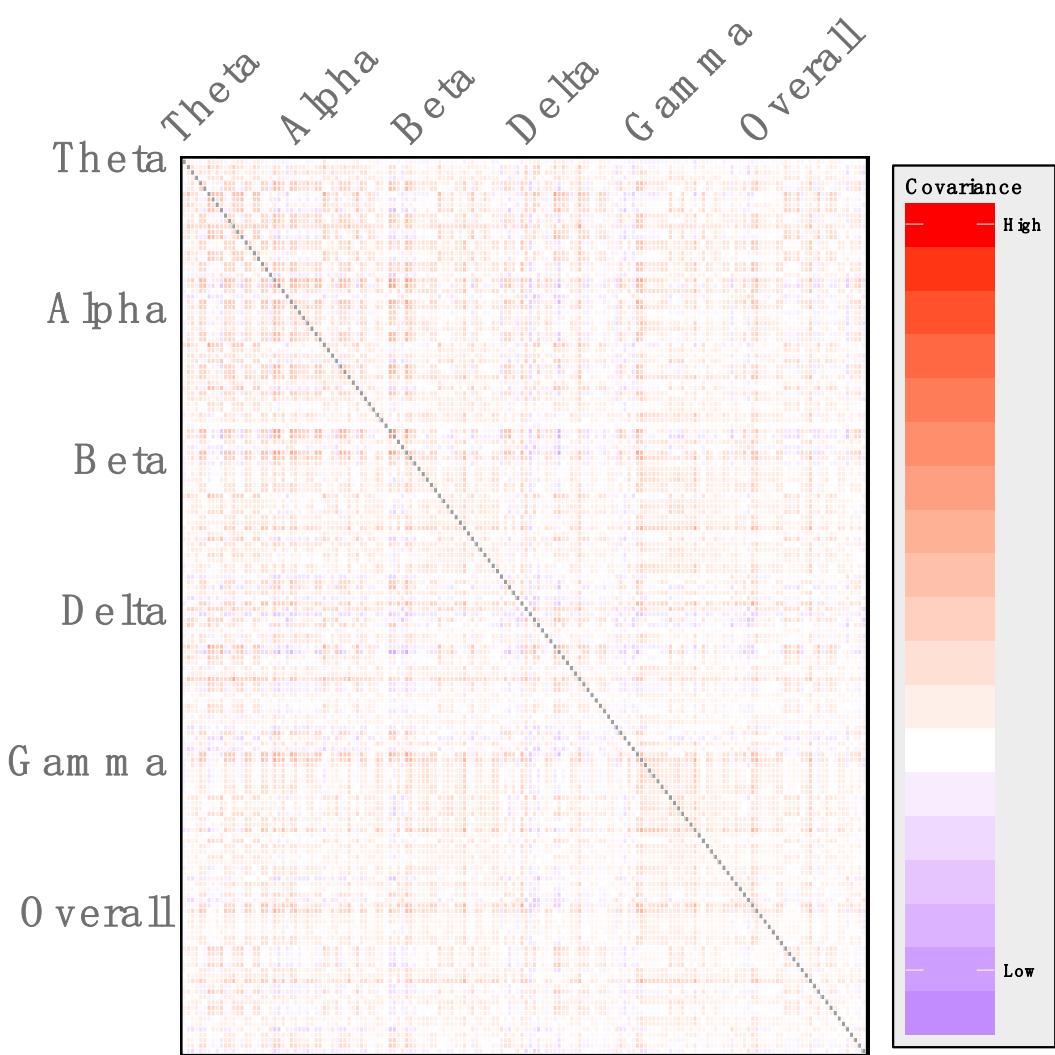

Figure S11. Covariance matrix of network measures, responders at baseline. There were statistically significant differences in network loadings at baseline between responders and nonresponders, suggesting that network-level differences may identify those likely to benefit before treatment is initiated. This may have implications for targeting treatment.

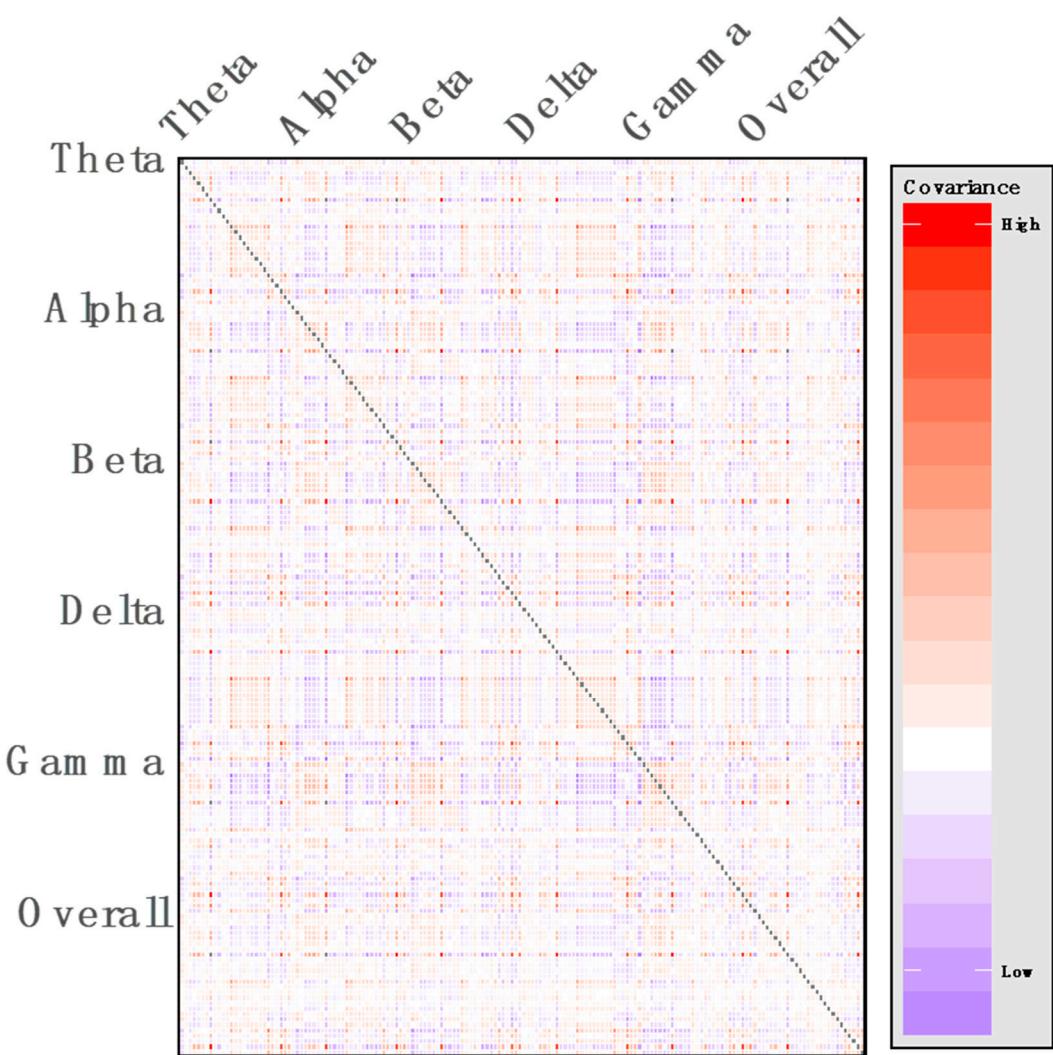

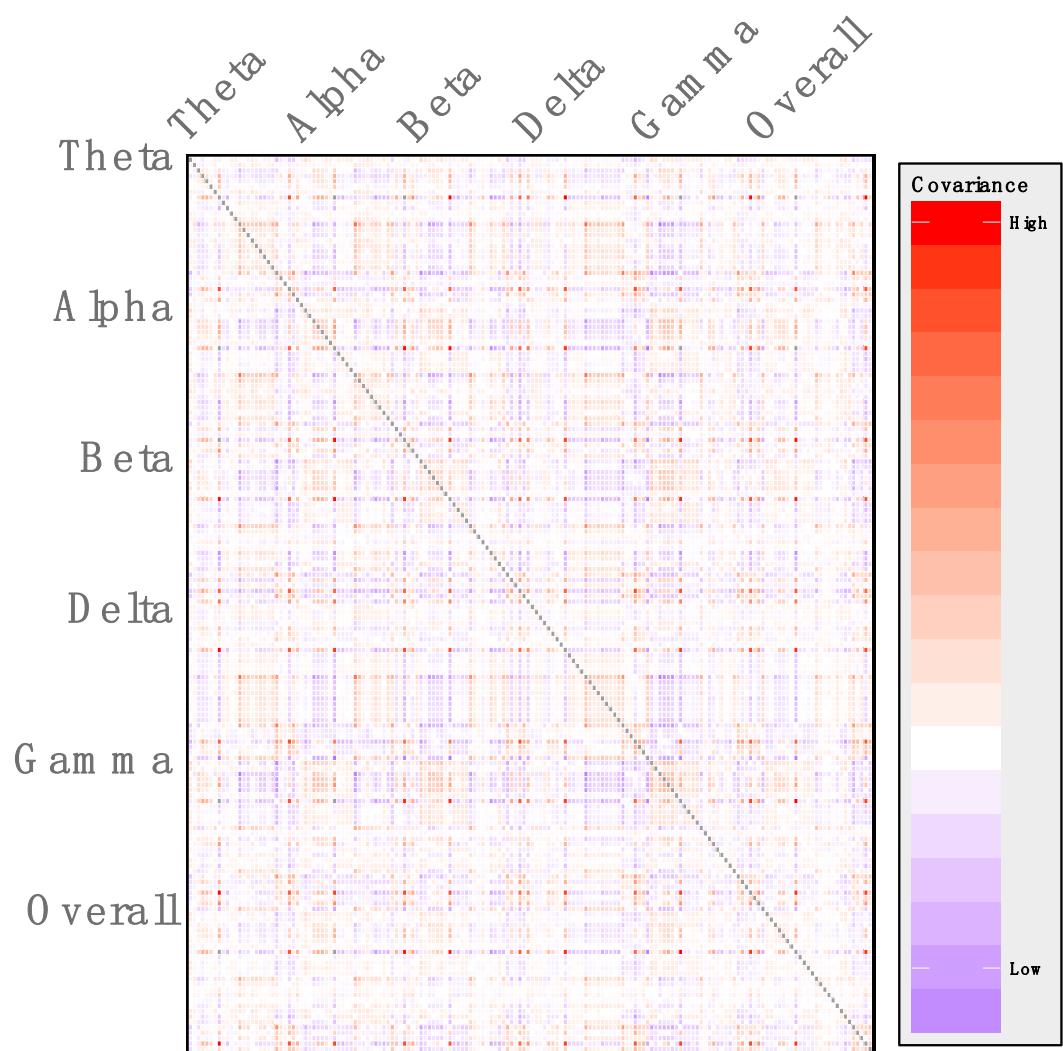

Figure 12. Covariance matrix of network measures, nonresponders at baseline. There were statistically significant differences in network loadings at baseline between responders and nonresponders, suggesting that network-level differences may identify those likely to benefit before treatment is initiated. This may have implications for targeting treatment.

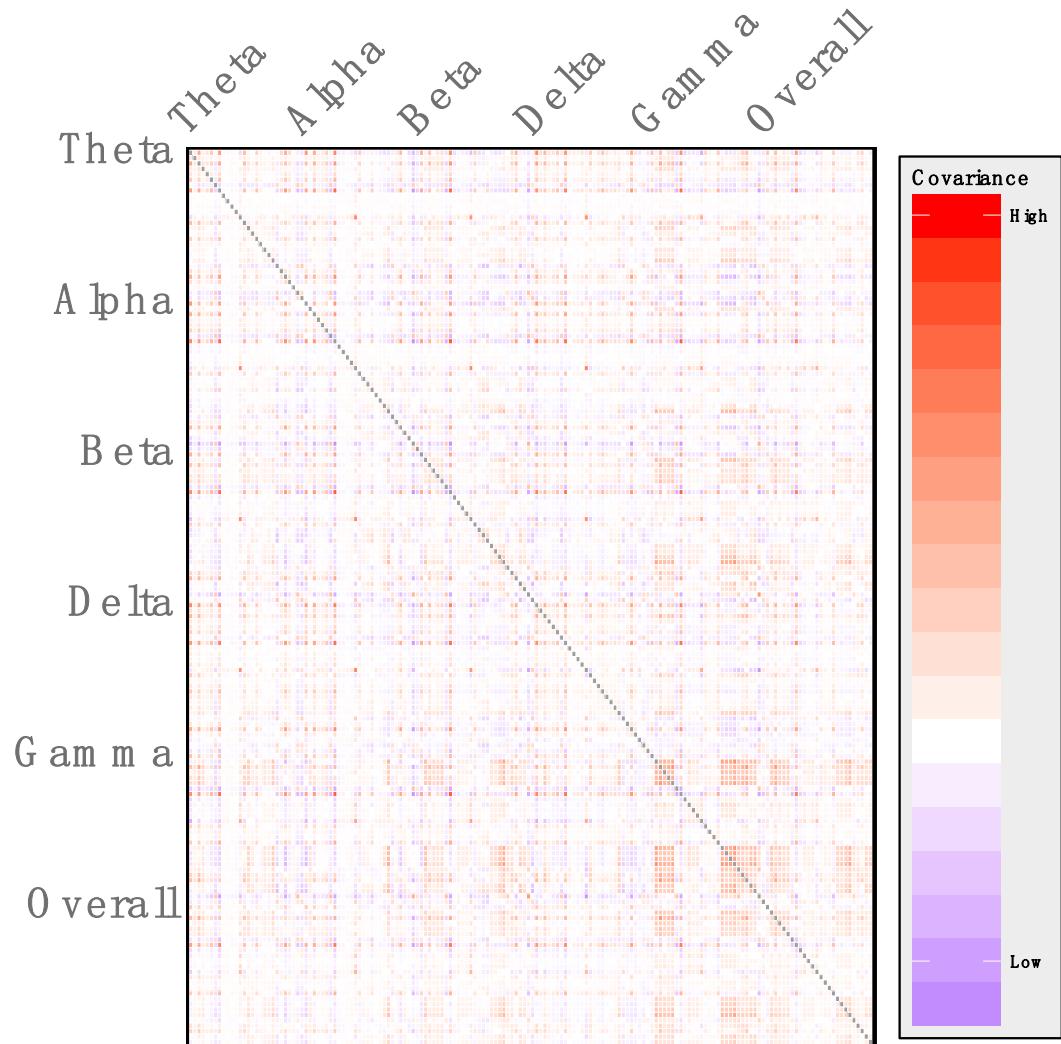

Figure S13. Covariance matrix of network measures, responders at 12 months. There was a statistically significant effect of treatment group & time on network loadings, suggesting that there were specific alterations in cortical electrophysiology in those that responded clinically to treatment with IGF-1. This underlines the emerging importance of network electrophysiology in Rett Syndrome and its treatment and may have implications for targeting treatment based on electrophysiological biomarkers.

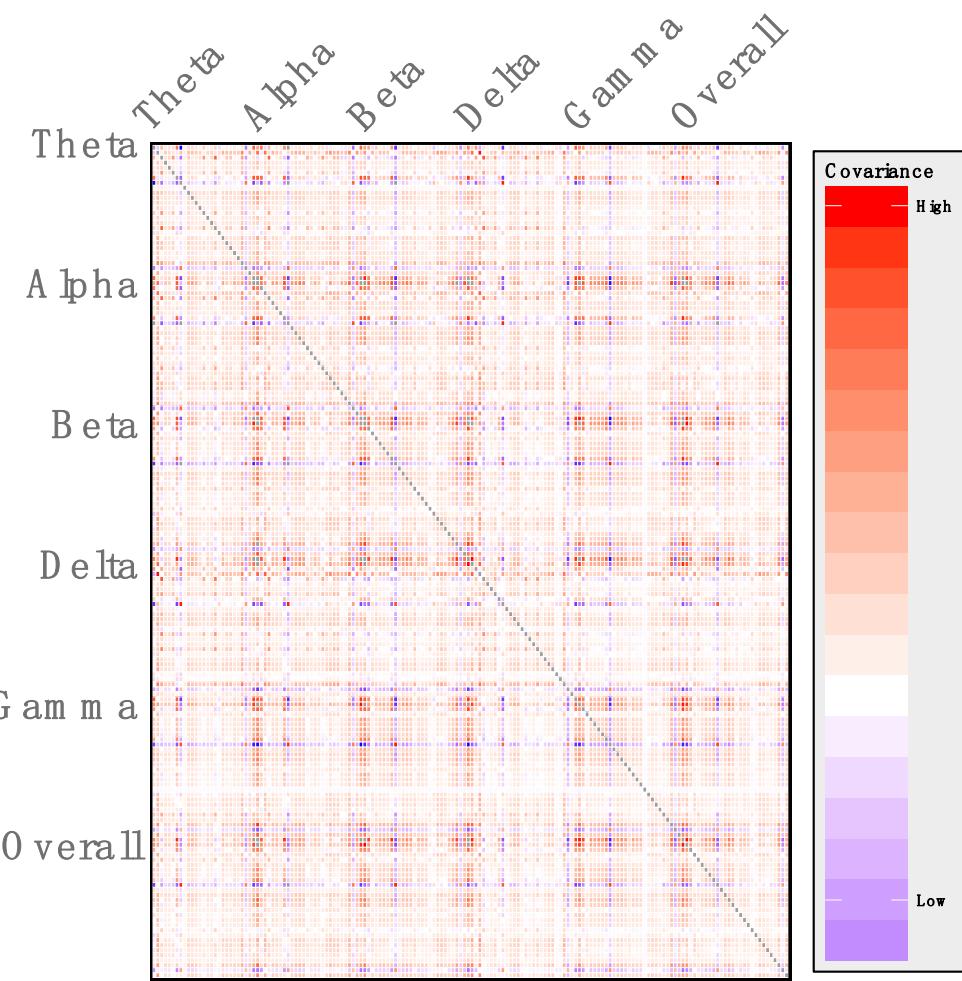

Figure S14. Covariance matrix of network measures, nonresponders at 12 months. There was a statistically significant effect of treatment group & time on network loadings, suggesting that there were specific alterations in cortical electrophysiology in those that responded clinically to treatment with IGF-1. This underlines the emerging importance of network electrophysiology in Rett Syndrome and its treatment and may have implications for targeting treatment based on electrophysiological biomarkers

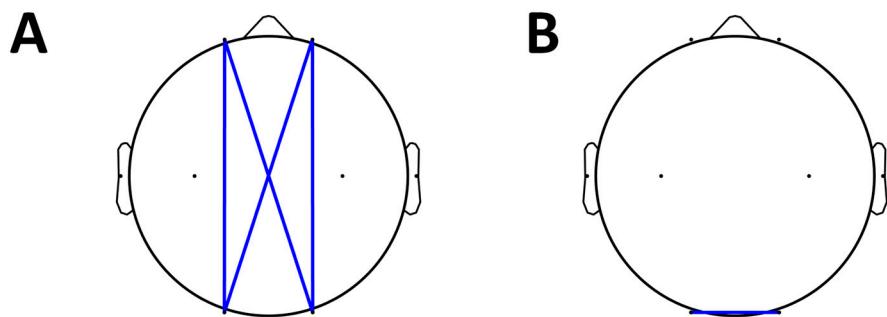

Figure S15. Schematic of channels included in prediction model. (A) shows channel pairs included in long-range coherence measure, (B) demonstrates the occipital interhemispheric channel. These channels showed a promising ability to predict treatment response to IGF-1.

Table S1. Overall power and power within each band at each electrode location, treated vs. untreated at baseline.
