1. Data Selection and Curation

Experimental data for building models of quantitative structure-activity relationships were downloaded from ChEMBL database (version 24) and then analyzed. Data containing about 50 thousand entries were derived from scientific literature turned out to be highly heterogeneous having different experimental conditions and various ligand efficiency indices were measured (Ki, IC50, percent of inhibition etc.). The curation process was realized according to the pipeline (Figure 1). It corresponds to the “Best QSAR practice” (Tropsha,A., et al. *Molecular Informatics*, 2010, 29, 476; Fourches,D., et al. *Journal of Chemical Information and Modeling*, 2016, 56, 1243).

Figure 1. Data curation process pipeline.

The process could be subdivided to two parts – chemical data curation and biological data curation.

Chemical data curation:

- Deletion of incomplete and insufficient entries;
- Deletion of inorganics, metallorganics, rare atom compounds;
- Mixture and salt compounds processing and standartzition;
- Invalid structures recovery;
- Standartzition of structures kekulization;
- Chemical groups normalization;
- Tautomeric data handling;
- Enantiomeric and stereomeric data inspection.

Biological data curation:

- Deletion of entries for mutants, drug-resistant stamps and invalid targets;
- Data split basing on experimental protocols;
- Potential duplicates were checked either for equal compounds with different activity values or for coumpounds having the same set of descriptors. Basing on each case the entries were deleted or the median value was calculated;
- External laboratory error estimation;
- Handling activity cliff data

In addition, the data validity was verified by analysis of the information presented in the original publications. Curated data were used to create training sets for HIV targets.

2. Selected Descriptors

The modelling was accomplished using two types of descriptors – Multilevel Neighborhoods Atoms (MNA) and Quantitative Neighborhoods of Atoms (QNA) descriptors.

MNA descriptors are based on the molecular structure representation, which includes the hydrogen atoms according to the valences and partial charges of other atoms and does not specify the types of bonds. MNA descriptors are generated as recursively defined sequence:

- zero-level MNA descriptor for each atom is the mark A of the atom itself;

any next-level MNA descriptor for the atom is the sub-structure notation $A(D_1, D_2, \dots, D_i, \dots)$, where D_i is the previous-level MNA descriptor for i -th immediate neighbor's of the atom A .

The mark of atom may include not only the atomic type but also any additional information about the atom. In particular, if the atom is not included into the ring, it is marked by «-». The neighbor descriptors $D_1, D_2, \dots, D_i, \dots$ are arranged in unique manner, e.g., in lexicographic order. Iterative process of MNA descriptors generation can be continued covering first, second, etc. neighborhoods of each atom.

Descriptors for each molecule are generated on the basis of connectivity matrix \mathbf{C} and table of atoms types A . Connectivity matrix contains data on the covalent bonds in a molecule. Various bond types are not specified (topological approximation). All hydrogens based on valences and partial charges of atoms are taken into account. The types of atoms are specified according to the data presented in Table 1.

Table 1. Classification of different atom types used in calculation of descriptors

Class name	Elements
H	H
C	C
N	N
O	O
F	F
Si	Si
P	P
S	S

MNA descriptors for phenol.
MNA/0, MNA/1, MNA/2 - zero, first and second levels
of MNA descriptors.

Figure 2. MNA descriptors of 0, 1, 2 level calculated for an example structure.

QNA descriptors are calculated based on the connectivity matrix \mathbf{C} and the standard values of ionization potential IP and electron affinity EA of atoms in a molecule. For any given atom i QNA descriptors are calculated as follow:

$$P_i = B_i \sum_k \left(\text{Exp} \left(-\frac{1}{2} \mathbf{C} \right) \right)_{ik} B_k \quad (1)$$

$$Q_i = B_i \sum_k \left(\text{Exp} \left(-\frac{1}{2} \mathbf{C} \right) \right)_{ik} B_k A_k \quad (2)$$

where

$$A_k = \frac{1}{2} (IP_k + EA_k) \quad B_k = \frac{1}{2} (IP_k - EA_k)^{-\frac{1}{2}}$$

The values of EA and IP collected from many different sources and used in this work are represented in Table 2.

Table 2. Electron affinity (EA) and first ionization potential (IP), electron volts, and atomic radius (AR), angstroms.

Though the value $\mu(P - Q)$ can be considered by convention as the partial atomic charge, where μ is the chemical potential, in general, the P and Q values are not the estimate of partial atomic charges, hardness or so forth.

QNA describes each of the atoms in a molecule, and, at the same time, each of the P and Q values depends on the whole composition and structure of a molecule (Figure 3).

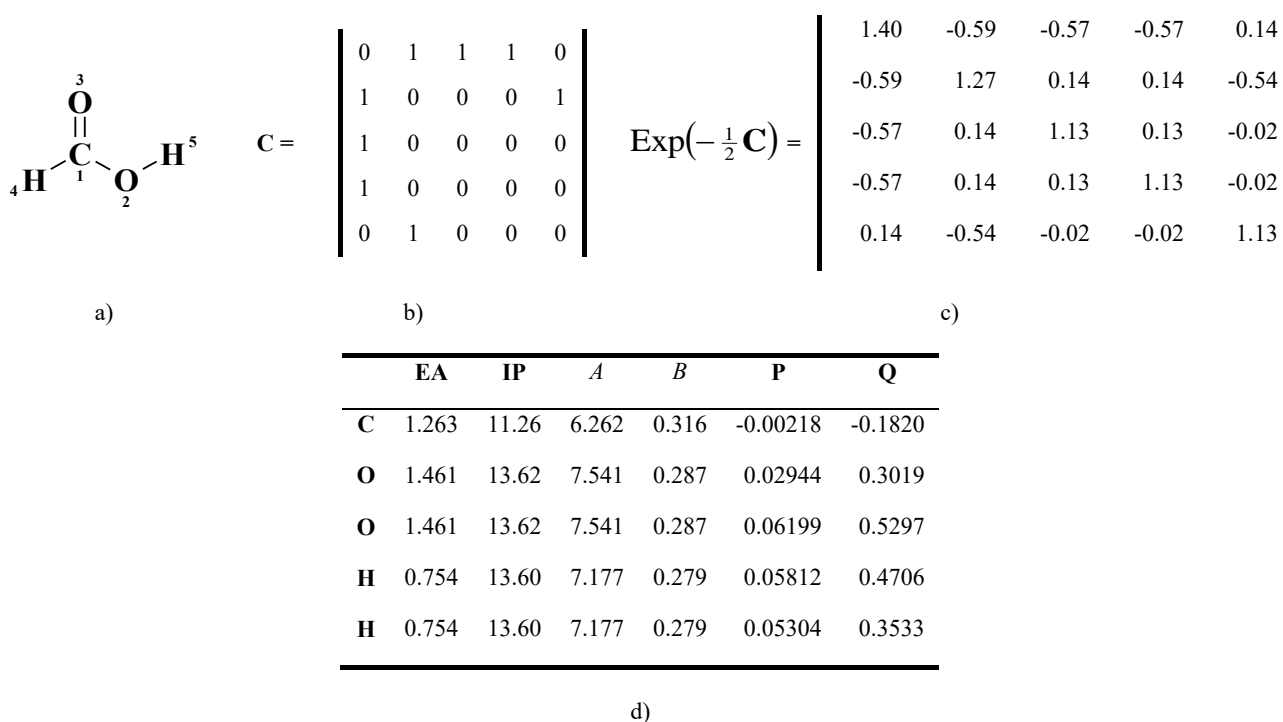

Figure 3. Example of QNA description of *formic acid*: (a) structure diagram; (b) connectivity matrix; (c) exponent of the connectivity matrix; (d) electron affinities, ionization potentials, variables of equations (1) and (2), P and Q values for each atom of *formic acid* molecule.

From Figure 3c it is clear that any atom influences the others, though the influence decreases with the increase of the distance between them; *e.g.* components of matrix $\text{Exp}\left(-\frac{1}{2}\mathbf{C}\right)$ for atom 1 (C) are: 1.40 for atom 1 itself, -0.59 for its immediate neighbor atom 2 (O), -0.57 for atoms 3 (O) and 4 (H), and 0.14 for atom 5 (H).

The algorithm of QNA descriptor calculation is quite simple due to uselessness of the matrix $\text{Exp}\left(-\frac{1}{2}\mathbf{C}\right)$ itself, only product of $\text{Exp}\left(-\frac{1}{2}\mathbf{C}\right)$ by vector is necessary, and that matrix \mathbf{C} consists of 0 and 1 only.

3. QSAR Modeling Using GUSAR Program

QNA describe each particular atom of a molecule, at the same time, each P or Q value depends on the total molecule composition and structure. To use this molecule structure representation we have proposed to calculate each $f_i(S)$ function of the structure of a molecule as the average value of $g_i(P, Q)$ function of P and Q variables for those m atoms in a molecule, which have two or more immediate neighbors:

$$f_i(S) = \frac{1}{m} \sum_k g_i(P, Q) \quad (3)$$

$$y_{pred} = a_0 + \sum_i a_i \frac{1}{m} \sum_k g_i(P, Q) \quad (4)$$

According to the equation (4) the estimate y_{pred} for molecule can be interpreted as an average of values predicted for particular atoms in a molecule. Formally, QNA descriptors represent a molecule structure by two descriptors only (P and Q), in contrast to numerous traditional descriptors used in QSAR. Since P and Q values have different scales (standard deviations are 0.023 and 0.208, respectively), we made the normalization to optimize a family of functions $g_i(P, Q)$.

Normalization has been performed by calculation of the average values (E_P and E_Q), standard deviations (D_P and D_Q) and correlation between P and Q values (R_{PQ}):

$$P' = \frac{P - E_P}{D_P} \quad Q' = \frac{Q - E_Q}{D_Q} \quad (5)$$

$$U = \frac{P' + Q'}{\sqrt{2(1 + R_{PQ})}} \quad V = \frac{P' - Q'}{\sqrt{2(1 - R_{PQ})}} \quad (6)$$

The orthonormal U and V have zero mean, unit variance and they are uncorrelated.

Chebyshev polynomials were chosen as the family of functions $g_i(P, Q)$, and the orthonormal U and V values have been additionally transformed by using hyperbolic tangent, so, the “normalized QNA” vary from -1 to 1. After this, the functions $g_i(P, Q)$ in equation (4) are represented using Chebyshev polynomials as:

$$g_i(P, Q) = T_{uv}(P, Q) = \text{Cos}(u * \text{ArcCos}(\text{TanH}(U))) * \text{Cos}(v * \text{ArcCos}(\text{TanH}(V))) \quad (7)$$

where the integer numbers $u, v = 0, 1, 2 \dots$ define 2-dimensional Chebyshev polynomial degree. The final equation for estimate y_{pred} using QNA descriptors is:

$$y_{pred} = \frac{1}{m} \sum_k \left(a_0 + \sum_{uv} a_{uv} T_{uv}(P, Q) \right) \quad (8)$$

QNA descriptors and their polynomial transformations (5)-(7) do not provide information on the shape and volume of a molecule although this information may be important for determination of the structure-activity relationships. Therefore, these parameters were added to QNA descriptors. Topological length of a molecule was calculated as the maximal distance between any two atoms and the volume of a molecule – as the sum of each atom’s volume,

$\frac{4}{3}\pi R^3$, where R is the atomic radius (see Table 2 (AR)).

The Chebyshev polynomials are arranged in ascending order of their degrees $u + v$. For $u + v = 1$ they are $T_{1,0}$, $T_{0,1}$; for $u + v = 2$ they are $T_{2,0}$, $T_{1,1}$, $T_{0,2}$ etc. The first, second and third power of topological length and volume

of a molecule were used. The number of initial variables equals to the number of Chebyshev polynomials plus the number of the first, second and third power of topological length and volume of a molecule.

The number of initial variables depends on the number of compounds in the training set. If the number of compounds in the training set less than 25, then the initial variables are 24. If the number of compounds in the training set varied from 25 to 100, then the initial variables depends on the following equation:

$$A = (\ln(B) \times 18.755) - 36.37,$$

where A – initial variables and B – the number of compounds in the training set. If the number of compounds in the training set varied from 100 to 2000, then the number of initial variables equal to one-half of the number of compounds in the training set. If the number of compounds in the training set exceeds 2000, then the initial variables are 1000.

GUSAR algorithm uses three procedures described below for generation of different QSAR models based on QNA descriptors.

- 1) U and V values from (7) are multiplied by value, which are randomly chosen from 0.98 to 1.09.
- 2) Coefficient before matrix \mathbf{C} is randomly chosen from -0.1 to -0.9.
- 3) Calculation of QNA descriptors is randomly chosen from two cases. First case is when P and Q values are calculated for all atom types. Second case is when P and Q values are calculated for each atom, which has connection with more than one carbon.

All these procedures are used for creation of each QSAR model based on QNA descriptors. These procedures allow obtaining the different QNA models.

Self-Consistent Regression (SCR)

The classical MLR has a number of limitations. Particularly, the number of objects in the training set should significantly exceed the number of independent variables, and it is important to use the non-collinear variables only. To overcome these limitations, we have employed the approach based on statistical regularization of ill-posed problems. It has resulted in the regularized least-squares method:

$$\mathbf{a} = \text{ArgMin} \left[\sum_{i=1}^n \left(y_i - \sum_{k=0}^m (x_{ik} a_k) \right)^2 + \sum_{k=1}^m (v_k a_k^2) \right] \quad (9)$$

where \mathbf{a} is the regression coefficient, n is the number of objects, y_i is the response value of i^{th} object, m is, here and below, the number of the independent variables, x_{ik} is the value of k^{th} independent variable of i^{th} object, a_k is the k^{th} value of the regression coefficients, v_k is the k^{th} value of the regularization parameters. Equation (9) has the following solution:

$$\mathbf{a} = \mathbf{TX}^T \mathbf{y}, \quad \mathbf{T} = (\mathbf{X}^T \mathbf{X} + \mathbf{V})^{-1}$$

where \mathbf{X}^T is the transposed regression matrix \mathbf{X} , \mathbf{V} is a diagonal matrix of the regularization parameters. The best regularization \mathbf{V} satisfies to the equations:

$$v_k (a_k^2 + s^2 t_k) = s^2, \quad k = 1, \dots, m$$

where s is the standard deviation of residuals, t_k is the k^{th} diagonal element of matrix \mathbf{T} .

Use of Nearest Neighbours

Algorithm of GUSAR allows using nearest neighbours for improvement of prediction value obtained from regression model. The corrected value is estimated by taking an average of the three chemicals values in the training set that are the most similar to the chemical under study. Similarity of the any pair of chemical

compounds is estimated as Pearson's coefficient calculated in the space of independent variables obtained after SCR. This function usually increases the prediction accuracy for the external test sets for QSAR models created on the basis of training sets with 500 and more structures. Sometimes the use of this function may lead to decrease of accuracy prediction, which depends on the quality of the training sets.

Consensus method

The predicted value is estimated by taking into account a weighted average of the predicted values from the obtained QSAR models (QSAR models provide the predictions that are within the respective applicability domains). Prediction obtained from each developed model is weighted on its applicability domain values (AD). GUSAR algorithm calculates the similarity value; leverage value and estimation of three nearest neighbours' accuracy of prediction for the applicability domain assessment (see AD description, page 70). Weighting of the predicted value is performed using similarity and leverage values only.

If all predicted values from the obtained QSAR models exceed the similarity threshold and leverage threshold, then the consensus prediction value is calculated from similarity weighted predicted values. If all predicted values from the obtained QSAR models are less than the leverage and similarity thresholds, then the consensus prediction value is calculated from leverage weighted predicted values. If the predicted values from the obtained QSAR models exceed similarity and is less than leverage thresholds, then the consensus prediction value is calculated as average from leverage weighted predicted values and similarity weighted predicted values. If the predicted values from the obtained QSAR models are less than similarity and exceed the leverage thresholds, then the consensus prediction value is calculated as average from all weighted predicted values.

Similarity

Three nearest neighbours from the training set are calculated for each chemical compound under study using similarity estimation. Similarity of the pair of chemical compounds is estimated as Pearson's coefficient calculated in the space of independent variables obtained after SCR. The average similarity of three nearest neighbours is used for assessment of the applicability domain (AD) of the model. If the average similarity exceeds the threshold, then the studied chemical compound falls in AD of the model and vice-versa. The higher value of the threshold was selected, the more similar compounds fell in AD of the model.

Leverage

Hat value of leverage was used for domain applicability assessment. Hat values from the leverage matrix representing the "distance" of the molecule to the model structural space were calculated as:

$$Leverage = x^T (\mathbf{X}^T \mathbf{X})^{-1} x$$

where x is a vector of descriptors of a query compound, and \mathbf{X} is a matrix formed with rows corresponding to the descriptors of molecules from the training set. Hat value of leverage was calculated for each compound of the training set and then a distribution of the obtained values was estimated.

A warning level of hat value was considered as percentile. The end-user could select 99th, 95th and 90th percentile. Therefore, if a chemical compound from the external test set has hat value exceeded this warning level, then this compound is considered as being out of the applicability domain.

Accuracy of three nearest neighbours' predictions

For the assessment of this type of the applicability domain the following equation is used:

$$AD_{value} = \frac{RMSE_{3NN}}{RMSE_{train}}$$

where AD_{value} is the applicability domain value, $RMSE_{3NN}$ is root mean square error of prediction of three most similar compounds from the training set, $RMSE_{train}$ is root mean square error of predictions for the training set.

Three nearest neighbours from the training set are calculated for each studied chemical compound using similarity value. Similarity of the two chemical compounds is estimated as Pearson's coefficient calculated in the space of independent variables obtained by SCR.

If the AD_{value} is less than the threshold, then the studied chemical compound falls into AD of the model and vice-versa. Therefore, any chemical compound, whose three nearest neighbours are predicted worse than the prediction accuracy of the whole training set, is considered as being out of the applicability domain.

Leave-Many-Out procedure

This procedure is used for assessment of external prediction accuracy. The initial data is randomly divided onto the training and the external test sets. End-user could select the following proportions:

10% for the external test set and 90% for the training set;

20% for the external test set and 80% for the training set;

30% for the external test set and 70% for the training set;

50% for the external test set and 50% for the training set.

For obtaining the objective assessment of predictive accuracy and robustness of the developed models each splitting should be repeated many times. End-user could select the following number of repeats: 1, 5, 10 and 20.

Y-randomization procedure

This procedure allows to be ensuring that the developed models do not have the overfitting. In this procedure the dependent-variable vector, Y vector, is randomly shuffled and new QSAR model is developed using the original independent-variable matrix. It is expected that the resulting models should generally have low Q^2 values. This procedure could be repeated many times for each model, and then the average Q^2 value is calculated.

4. PASS (Prediction of Activity Spectra of Substances) Method

In PASS biological activities are described qualitatively (active or inactive). Any property of chemical compounds, which is determined by their structural peculiarities, can be used for prediction by PASS. It is clear, that the applicability of PASS is broader than the prediction of biological activity spectra.

The MNA descriptors (both for predicting the activity spectrum of the compound and for adding substances to SAR Base) are generated only if molecular structure corresponds to the following criteria:

- each of the atoms in a molecule must be presented by atom symbol from the periodic table. Symbols of unspecified atom A, Q, *, or R group labels are not allowed;
- each of the bonds in a molecule must be covalent bond presented by single, double or triple bond types only;
- molecular structure must include three or more carbon atoms;
- molecular structure must include only one component. Single atom parts like HCl, Cl-, OH-, Na+, etc., (hydrogen atoms do not take into account) are excluded from MNA descriptors generation;
- structure (main part, see the previous sentence) must be uncharged;
- the absolute molecular weight of a substance must be less than 1250 Da.

A relevant error will be generated whenever a molecular structure does not correspond to these criteria or input data contains some other errors.

The PASS training sets for HIV-associated comorbidities include about 240,000 thoroughly selected data records about structure and biological activity of organic compounds from the general PASS training set. The knowledgebase SAR Base is created in process of training on the basis of the PASS training set.

The PASS estimations of biological activity spectra of new compounds are based on the Structure-Activity Relationships knowledge-base (SAR Base), which accumulates the results of the training set analysis. SAR Base includes a biological activities dictionary and MNA descriptors dictionary, data and knowledge on the "structure – biological activity" relationships, the database of structure of compounds from the training set with their biological activity spectra. The structure of the compound represented as a set of MNA descriptors. Unfortunately, it is currently impossible to make a large collection of biologically active compounds using only publicly available sources, for which assay results for all types of biological activity were known.

Algorithm of activity spectrum prediction description may be done easy using well known Bayesian approach. For the chemical compound C , which molecular structure is represented by the set $\{D_1, \dots, D_m\}$ of m MNA descriptors, estimate the probability $P(A|C)$ that the compound C has an activity A . According to the Bayes formula:

$$P(A|C) = \frac{P(A)P(C|A)}{P(C)} \quad (9)$$

where $P(A)$ is the activity A prior probability; $P(C|A)$ is the conditional probability of compound C providing that it has activity A ; $P(C)$ is the compound C prior probability.

On the assumption that descriptors D_1, \dots, D_m are independent one can write the probability $P(C|A)$ as the product of conditional probabilities for particular descriptors:

$$P(C|A) \cong P(D_1, \dots, D_m|A) = \prod_{i=1}^m P(D_i|A)$$

This expression is approximately true since the MNA descriptors are a fortiori dependent due to their generation method. However, we have not acceptable alternatives, and we cannot forget about the approximation of obtained formulas.

After simple transformations, we obtain the expression for the log-likelihood ratio of the conditional probabilities $P(A|C)$ for activity A and $P(B|C)$ for activity B as:

$$\ln \left[\frac{P(A|C)}{P(B|C)} \right] \cong \ln \left[\frac{P(A)}{P(B)} \right] + \sum_{i=1}^m \left\{ \ln \left[\frac{P(A|D_i)}{P(B|D_i)} \right] - \ln \left[\frac{P(A)}{P(B)} \right] \right\}$$

In a particular case, where B is the lack of activity A , we obtain:

$$\ln \left[\frac{P(A|C)}{1 - P(A|C)} \right] \cong \ln \left[\frac{P(A)}{1 - P(A)} \right] + \sum_{i=1}^m \left\{ \ln \left[\frac{P(A|D_i)}{1 - P(A|D_i)} \right] - \ln \left[\frac{P(A)}{1 - P(A)} \right] \right\}$$

The implication of the expression is quite clear: the logarithm of the posterior likelihood ratio is the sum of the logarithm of the a priori likelihood ratio and the sum of individual descriptors contributions. And, if the activity is not dependent on this descriptor, then $P(A|D_i) = P(A)$ and the such descriptor has no affect on the results and its contribution to the sum is zero. This is the classical result of the probabilistic approach. But, apart from the already marked proximity, this result has another significant, well-known disadvantage: the contribution of some descriptors is too large and suppresses all other terms of the sum for which the conditional probability of activity is too close to 0 or 1, when its present in the structure. The most pronounced effect could be in the situation, when for probabilities $P(A|D_i)$ used frequency estimates based on analysis of the training set and the values 0 and 1 are the rule rather than the exception.

To overcome this problem one can offer many different approaches and they were tested in the PASS development. The best result was obtained by using of so-called Fischer $ArcSin(2p - 1)$ conversion instead of $\ln[p/(1 - p)]$: its shape coincides with the shape of $\ln[p/(1 - p)]$ for almost all values of p , but $ArcSin(2 - 1)$ values are bounded by the values $\pm\pi/2$. The accuracy of prediction also improved after changing the sum of descriptor contributions by the their average value, that apparently compensates for the assumption of descriptors independence. Logarithm of the a priori likelihood ratio has little information about a specific predicted organic compound and can be omitted.

Bayesian approach described above explains why PASS prediction algorithm based on the following specific statistics: on the basis of a molecular structure represented by the set $\{D_1, \dots, D_m\}$ of m MNA descriptors, the B_k values are calculated for each activity A_k :

$$B_k = \frac{S_k - S_{0k}}{1 - S_k \cdot S_{0k}}$$

$$S_k = \text{Sin} \left[\sum_i \text{ArcSin}(2P(A_k|D_i) - 1)/m \right]$$

$$S_{0k} = 2P(A_k) - 1$$

For each kind of activity, if for all descriptors of molecule $P(A_k|D_i) = 1$, then $B_k = 1$; if for all descriptors of molecule $P(A_k|D_i) = 0$, then $B_k = -1$; if the relationship between descriptors of molecule and activity A_k does not exist and $P(A_k|D_i) \approx P(A_k)$, then $B_k \approx 0$.

The PASS prediction algorithm uses the following data on the "structure-activity" relationships:

N is the total number of compounds in the SAR Base;

N_i is the number of compounds contained descriptor D_i in the structure description;

N_k is the number of compounds contained the activity A_k in the activity spectrum;

N_{ik} is the number of compounds contained both the activity A_k and the descriptor A_k .

The simplest frequency estimations of probabilities $P(A_k)$ и $P(A_k|D_i)$ are given by:

$$P(A_k) = \frac{N_k}{N}, \quad P(A_k|D_i) = \frac{N_{ik}}{N_i}$$

Estimation of PASS prediction accuracy and dependency required for calculation probabilities Pa and Pi on the basis of B statistics, are the end result of the training procedure, which consists in the following. According to the SAR Base, formed on the basis of the training set, for each kind of activity A_k , for each N_k active, and for each $N - N_k$ inactive compound, B statistics values are calculated. Calculations are carried out in the Leave-One-Out Cross-Validation (LOO CV), i.e., after the "exclusion" of the compound from SAR Base, for what is enough to not include it in sum. Smooth estimations of the distribution functions $Pa(B)$ and $Pi(B)$ are based on the obtained sets of B statistics.

The probabilities Pa and Pi are both the measures of belonging to subsets of "active" and "inactive" compounds, and the probabilities of the 1st and 2nd kinds of prediction error, respectively. These two interpretations of the probabilities Pa and Pi are equivalent and can be used for understanding the results of prediction. It allows constructing different criteria for analyzing the results of prediction corresponding to the solution of specific practical problems.

An important feature of the PASS prediction algorithm is its robustness to the imperfection of information on the structure and biological activity spectrum of organic compounds in the training set. In a special study was showed that halving the actual well-known information about the structure or activity of organic compounds in the training set only slightly reduces the accuracy of prediction in cross-validation. There's demonstrated that the accuracy base on a LOO CV is even more rigid than for cross-validation.

5. Qualitative Characteristics of the (Q)SAR Models

Here we summarize the information on developed quantitative models for HIV-1 protease, reverse transcriptase, integrase, REV and classification model for TAT.

Number of structures in the training sets, cross-validated determination coefficient (Q^2) and root-mean-square-errors (RMSE) for quantitative models and sensitivity, specificity values are shown in Table 3.

Table 3. QSAR models developed in GUSAR program for HIV-1 targets.

Training set	Structures	Q ²	RMSE
HIV-1 Protease pIC50:	1440	0.81	0.64
HIV-1 Reverse transcriptase pIC50:	1393	0.68	0.60
HIV-1 Integrase pIC50:	1436	0.83	0.56
HIV-1 REV pIC50:	105	0.55	0.34
Training set	Structures	Sensitivity	Specificity
HIV-1 TAT:	2566	0.79	0.82

The following Predicted versus Observed plots (Figures 4-8) correspond to each model. Plots visualize Q^2 and RMSE values and show the studied p(IC50) prediction range and adequate homoscedasticity of prediction results.

Figure 4. Observed versus Predicted plot for pIC50 activities of HIV-1 protease

Figure 5. Observed versus Predicted plot for pIC50 activities of HIV-1 reverse transcriptase

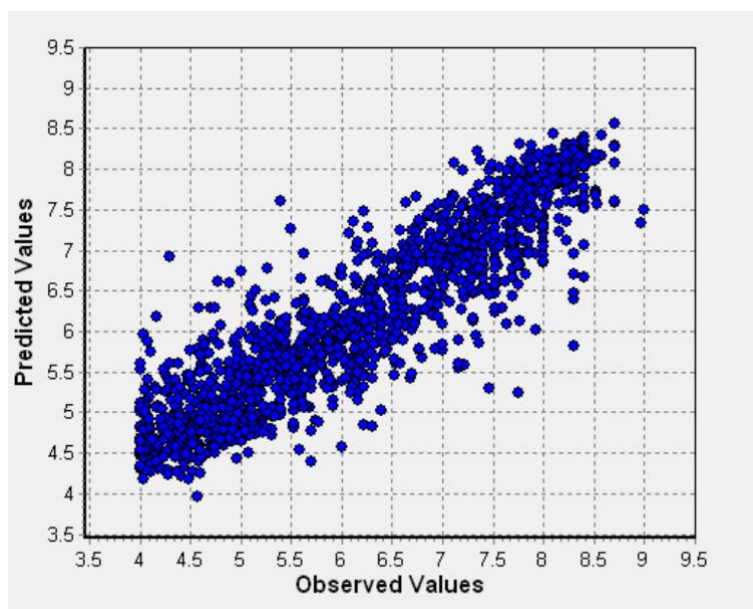

Figure 6. Observed versus Predicted plot for pIC50 activities of HIV-1 integrase

Figure 7. Observed versus Predicted plot for pIC50 activities of HIV-1 REV

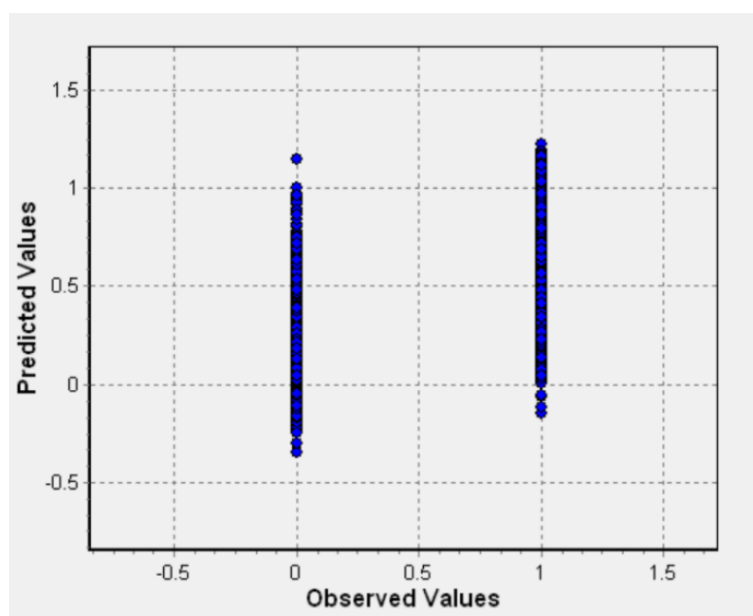

Figure 8. Observed versus Predicted plot for pIC50 activities of TAT (classification model)

6. List of Predicted Activities

List of 81 activities associated with treatment of HIV-associated disorders and diseases is represented in Table 4. For each activity the number of compounds in the training set (N) and invariant accuracy of prediction (IAP) is given (IAP equivalent to AUC ROC value).

Table 4. Activities associated with treatment of HIV-associated disorders and diseases.

HIV-associated comorbidity	N	IAP
Alzheimer's disease treatment	2639	0.9
Amyotrophic lateral sclerosis treatment	463	0.94
Analgesic	16272	0.88
Antiamyloidogenic	284	0.92
Antianorexic	102	0.96
Antiarthritic	13767	0.87
Antidepressant	11164	0.92
Antidiabetic	21403	0.89
Antidiabetic (type 2)	3182	0.94
Antifungal	5074	0.93
Antiinflammatory	9804	0.86
Antileprosy	82	0.94
Antileukemic	5109	0.94
Antimigraine	2172	0.95
Antineoplastic (bladder cancer)	378	0.9
Antineoplastic (brain cancer)	1008	0.9
Antineoplastic (breast cancer)	5668	0.92
Antineoplastic (colorectal cancer)	5740	0.94
Antineoplastic (endocrine cancer)	236	0.88
Antineoplastic (gastric cancer)	635	0.92

Antineoplastic (hematological cancer)	80	0.75
Antineoplastic (liver cancer)	412	0.9
Antineoplastic (lymphocytic leukemia)	2813	0.96
Antineoplastic (lymphoma)	992	0.94
Antineoplastic (melanoma)	1714	0.93
Antineoplastic (multiple myeloma)	208	0.88
Antineoplastic (myeloid leukemia)	133	0.81
Antineoplastic (non-Hodgkin's lymphoma)	83	0.85
Antineoplastic (non-small cell lung cancer)	965	0.91
Antineoplastic (ovarian cancer)	2047	0.95
Antineoplastic (pancreatic cancer)	360	0.89
Antineoplastic (renal cancer)	547	0.9
Antineoplastic (sarcoma)	331	0.92
Antineoplastic (small cell lung cancer)	211	0.87
Antineoplastic (solid tumors)	778	0.88
Antineoplastic antibiotic	1697	0.98
Antineurogenic pain	1162	0.92
Antiobesity	12280	0.91
Antiprotozoal (Leishmania)	1988	0.95
Antismoking	220	0.97
Antiviral (Hepatitis B)	449	0.96
Antiviral (Hepatitis C)	6807	0.97
Antiviral (Papilloma)	77	0.95
Atherosclerosis treatment	4552	0.89
Attention deficit/hyperactivity disorder treatment	676	0.97

Autoimmune disorders treatment	8944	0.88
Biliary tract disorders treatment	97	0.9
Cachexia treatment	265	0.96
Cancer associated disorders treatment	51	0.87
Cocain dependency treatment	235	0.96
Cognition disorders treatment	11383	0.9
Cystic fibrosis treatment	622	0.94
Dependence treatment	2076	0.94
Dermatologic	7173	0.9
Diabetic neuropathy treatment	61	0.81
Endocrine disorders treatment	16	0.84
Female sexual dysfunction treatment	129	0.97
Gastric emptying disorders treatment	99	0.96
Gastrointestinal disorders treatment	305	0.93
Gynecological disorders treatment	1084	0.98
Heart failure treatment	1632	0.94
Immunomodulator	2776	0.91
Immunostimulant	1135	0.92
Immunosuppressant	4252	0.89
Inflammatory Bowel disease treatment	2987	0.91
Lipoprotein disorders treatment	4667	0.95
Macular degeneration treatment	256	0.94
Multiple sclerosis treatment	3001	0.92
Myelodysplastic syndrome treatment	52	0.75
Neuropathy treatment	26	0.89

Pancreatic disorders treatment	400	0.97
Preneoplastic conditions treatment	8	0.87
Prostate cancer treatment	2944	0.93
Psychotropic	32069	0.87
Renal disease treatment	1788	0.95
Rheumatoid arthritis treatment	1925	0.9
Scleroderma treatment	22	0.84
Sickle-cell anemia treatment	55	0.93
Sleep apnea treatment	79	0.95
Sleep disorders treatment	2425	0.96
Wound healing agent	638	0.94

7. Examples of Predictions for the Widely Used Antiretroviral Drugs

Prediction results for FDA approved protease, integrase and non-nucleotide reverse transcriptase inhibitors is represented below. All values are p(IC₅₀) values for molar concentrations (e.g. for p(IC₅₀) = 7.742 IC = 18.11 nM). Prediction results for these inhibitors are close to the average experimental values (even for those which are not in applicability domain).

Protease inhibitors

Amprenavir	8.751	in AD
Atazanavir	7.351	in AD
Darunavir	8.342	in AD
Indinavir	9.035	in AD
Fosamprenavir	8.491	in AD
Lopinavir	7.741	in AD
Nelfinavir	8.074	in AD
Ritonavir	8.946	in AD
Tipranavir	7.158	in AD

NN Reverse transcriptase inhibitors

Efavirenz	7.289	in AD
Etravirine	7.246	not in AD
Delavirdine	6.666	in AD
Doravirine	6.403	not in AD
Nevirapine	6.715	in AD
Rilpivirine	7.095	not in AD

Integrase inhibitors

Dolutegravir	8.522	in AD
Elvitegravir	6.257	in AD
Raltegravir	7.33	in AD

An example of HIV-1 activity prediction for Saquinavir, one of the FDA approved HIV-1 protease inhibitors, is given in Figure 9. The prediction for protease inhibiting activity is close to yje experimental values. The high p(IC₅₀) value for reverse transcriptase inhibiting activity could be ignored because prediction does not correspond to the applicability domain. Prediction of integrase inhibiting activity reflects that Saquinavir is not integrase inhibitor.

HIV TARGETS PREDICTION RESULTS

Targets	Value	Prediction	Applicability Domain
Protease (HIV-1):	p(IC ₅₀)	8.977	in AD
Reverse Transcriptase (HIV-1):	p(IC ₅₀)	7.404	not in AD
Integrase (HIV-1):	p(IC ₅₀)	4.604	not in AD

Figure 9. Saquinavir prediction with AntiHIV-Pred.

An example of activity spectra of HIV-1 comorbidities for Lamivudine, one of the FDA approved HIV-1 nucleotide analogue reverse transcriptase inhibitors, is given in Figure 10. The prediction shows four possible activities: antineoplastic, against myelodysplastic syndrome, antiviral (hepatitis B), antileukemic. It was experimentally confirmed that Lamivudine have some activity against hepatitis B (Nabuyuki, T., et al. Hepatology Resarch, 2002, 24, 34).

HIV COMORBIDITIES ACTIVITY SPECTRA

Comorbidity	Pa	Pi
Antineoplastic (myeloid leukemia)	0.777	0.007
Myelodysplastic syndrome treatment	0.768	0.005
Antiviral (Hepatitis B)	0.71	0.002
Antileukemic	0.607	0.009

Figure 10. Lamivudine prediction with AntiHIV-Pred.
