Appendix 1: Data sources

Data inclusion and exclusion

Data sources were included in NCD-RisC database if:

- measured data on height, weight, waist circumference, or hip circumference were available;
- study participants were five years of age and older;
- data were collected using a probabilistic sampling method with a defined sampling frame;
- data were representative of the general population at the national, subnational, or community level;
- data were collected in or after 1950;
- data were from the countries and territories listed in Appendix Table 1.

We excluded all self-reported data because they are subject to bias. We also excluded data sources on population subgroups whose anthropometric status may differ systematically from the general population, including:

- studies that had included or excluded people based on their health status or cardiovascular risk;
- ethnic minorities;
- specific educational, occupational, or socioeconomic subgroups of the population; and
- those recruited through health facilities, with the exception noted below.

We used school-based data in countries where secondary school enrolment was 70% or higher, and used data whose sampling frame was health insurance schemes in countries where at least 80% of the population were insured. In addition, we used data collected through general practice and primary care clinics in high-income countries with universal insurance, because in these

settings contact with the primary care systems tends to be at least as good as response rates for population-based surveys. No studies were excluded based on the level of BMI. In this paper, we used BMI data on data from the NCD-RisC database for years 1975 through 2014, and among participants aged 18 years and older.

Primary data access

We used multiple routes for identifying and accessing data. We accessed publicly available population-based multi-country and national measurement surveys (e.g., Demographic and Health Surveys, and surveys identified via the Inter-University Consortium for Political and Social Research and European Health Interview & Health Examination Surveys Database) as well as the World Health Organization (WHO) STEPwise approach to Surveillance (STEPS) surveys. We requested, via WHO and its regional offices, from ministries of health and other national health agencies to identify and access population-based surveys. Requests were also sent via the World Heart Federation to its national partners. We made a similar request to the NCD Risk Factor Collaboration (NCD-RisC), a worldwide network of health researchers and practitioners working on NCD risk factors. To identify major sources not accessed through the above routes, we searched and reviewed published studies, as detailed below, and invited all eligible studies to join NCD-RisC.

Anonymised individual record data from sources included in NCD-RisC were re-analysed by the Pooling and Writing Group or by data holders according to a common protocol. All re-analysed data sources included mean BMI and prevalences for the BMI categories listed in Methods section of the main paper, in standard age groups (18 years, 19 years, 20-29 years, followed by

10 year age groups and 80+ years), as well as sample sizes and standard errors. Before calculating means and prevalences, we dropped participants with implausible BMI levels, defined as BMI < 10 kg/m² or BMI > 80 kg/m² (<0.2% of all subjects). All analyses incorporated appropriate sample weights and complex survey design when applicable. To ensure summaries were prepared according to the study protocol, the Pooling and Writing Group provided computer code to NCD-RisC members who requested assistance. We also recorded information about the study population, period of measurement, sampling approach, and measurement methods. This information was used to establish that each data source was population-based, and to assess whether it covered the whole country, multiple subnational regions, or one or a small number of communities, and whether it was rural, urban, or combined. All submitted data were checked by at least two independent members of the Pooling and Writing Group. Questions and clarifications were discussed with the Collaborating Group members and resolved before data were incorporated in the database.

Finally, we obtained data not accessed through the above routes by extracting from published reports all additional national health surveys identified through the above-described strategies, three subnational STEPS surveys, and six MONICA sites. We also extracted data compiled for a previous global pooling.¹¹ These sources had information on only some of our quantities of interest, e.g., only on mean and/or some prevalences. We used data that had all of the relevant quantities of interest (mean BMI as well as all the above-mentioned prevalences) to develop regression equations for predicting the missing metrics from those available. These regression equations are described in Appendix 2 and their coefficients are provided in Appendix Table 3.

We identified duplicate data sources by comparing studies from the same country and year. Additionally, NCD-RisC members received the list of all data sources in the database and were asked to ensure that the included data from their country met the inclusion criteria and that there were no duplicates. Data sources used in the analysis are listed in Appendix Table 2.

Secondary search for additional data sources

To identify any major sources not accessed through the above routes, we searched Medline (via PubMed) for articles published between 1st January 1950 and 12th March 2013 using the search terms “body size”[mh:noexp] OR “body height”[mh:noexp] OR “body weight”[mh:noexp] OR “birth weight”[mh:noexp] OR “overweight”[mh:noexp] OR “obesity”[mh] OR “thinness”[mh:noexp] OR “Waist-Hip Ratio”[mh:noexp] or “Waist Circumference”[mh:noexp] or “body mass index” [mh:noexp]) AND (“Humans”[mh]) AND (“1950”[PDAT] : “2013”[PDAT]) AND (“Health Surveys”[mh] OR “Epidemiological Monitoring”[mh] OR “Prevalence”[mh]) NOT Comment[ptyp] NOT Case Reports[ptyp]. Articles were screened according to the inclusion and exclusion criteria described above. The number of articles identified and retained is summarised in Appendix Figure 1. As described above, we contacted the corresponding authors of all eligible studies and invited them to join NCD-RisC. We did similar searches for other cardio-metabolic risk factors including blood pressure, serum cholesterol, and blood glucose. All eligible studies were invited to join NCD-RisC and were requested to analyse data on all cardio-metabolic risk factors.

Appendix 2: Converting among mean BMI and prevalences of different BMI categories

As described in the main text, we estimated mean BMI as well as prevalences of the following BMI categories: $<18.5 \text{ kg/m}^2$, $18.5 \text{ to } <20 \text{ kg/m}^2$, $20 \text{ to } <25 \text{ kg/m}^2$, $25 \text{ to } <30 \text{ kg/m}^2$, $30 \text{ to } <35 \text{ kg/m}^2$, $35 \text{ to } <40 \text{ kg/m}^2$, $\geq 40 \text{ kg/m}^2$. In 19.4% of our data points, those extracted from published studies or from a previous global pooling, data were available for a subset of these outcomes, and/or were available for prevalences of other BMI ranges. In order to use these data, we developed conversion (or cross-walking) regressions to estimate all of our outcome variables from the available data. All sources of uncertainty in the conversion, including the sampling uncertainty of the original data, the uncertainty of the regression coefficients and random effects, and the regression residuals, were carried forward by using repeated draws from their respective distributions. We accounted for the correlation among the uncertainties of regression coefficients and random effects, by drawing from their joint posterior distribution.

Estimating prevalences for BMI categories from mean BMI

15.9% of all data used in the analysis had information on mean BMI but not on some or all of the prevalence outcomes. For these data, the cross-walking regressions used information on mean to estimate the missing prevalences. The dependent variable in each of the seven regressions for estimating prevalences of BMI categories from mean BMI was prevalence, fitted using generalised linear mixed models with a probit link; the independent variables were mean BMI (transformed as detailed in Appendix Table 3 to provide better fit to data), age, sex, year of data, and natural logarithm of per-capita gross domestic product (GDP). There were also statistical interactions between mean BMI and age and sex. The regression also included random effects for regions, to allow for the possibility that at each mean BMI level, prevalences of various BMI

categories may vary across regions. The coefficients of these regressions were estimated from the 80.6% of data for which all outcomes of interest were available, excluding data points for which there were fewer than 25 subjects. The regression coefficients and number of data points used in estimating the coefficients are shown in Appendix Table 3.

Estimating mean BMI from prevalences of various BMI ranges

3.5% of our data had information on prevalences of only selected BMI categories, some of which overlapped with our outcomes of interest (e.g., BMI of 25 to $<30 \text{ kg/m}^2$) and others that were different from those for which we made estimates (e.g., BMI $\geq 30 \text{ kg/m}^2$). We first converted these data to mean BMI, which was then used to estimate the prevalences used in our analysis as described above. The dependent variable in these regressions was the inverse of mean BMI; the independent variables were the probit-transformed prevalence, age, sex, year and $\ln(\text{GDP})$. We used this specification because the relationship between inverse mean BMI and the probit of prevalence was found to be closer to linear than relationships between other functions of mean BMI and prevalence. There were also statistical interactions between probit-transformed prevalence and age and sex. As above, the regressions also included random effects for regions.

Appendix 3: Validation of statistical model

We tested how well our statistical model, which is described in the main text, predicts missing data in two different tests. In Test 1, we held out all data from 10% of countries with data (i.e., created the appearance of countries with no data where we actually had data). The countries whose data were withheld were randomly selected from the following three groups: data-rich (6 years or more of data for women and 5 years or more for men, with at least one year of data after 2000), data-poor (2 years of data for women and 1 year for men), and average data availability (3 to 5 years of data or 6 years or more of data with no data after 2000 for women, and one fewer year of data for men). In total, there were 66 data-rich countries for women and 72 for men; 52 data-poor countries for women and 48 for men; and 68 countries for women and 58 for men had average data availability.

We fitted the model to the data from the remaining 90% of countries and made estimates of the held-out observations. In Test 2, we assessed other patterns of missing data by holding out 10% of our data sources, again from a mix of data-rich, data-poor, and average-data countries, as defined above. For a given country, we either held out a random one third of the country's data or all of the country's 2000-2014 data to determine, respectively, how well we filled in the gaps for countries with intermittent data and how well we estimated in countries without recent data. We fitted the model to the remaining 90% of the dataset and made estimates of the held-out observations. We repeated each test five times, holding out a different subset of data in each repetition. In both tests, we calculated the differences between the held-out data and the estimates. We also checked the 95% CrIs of the estimates; in a model with good external predictive validity, 95% of held-out values would be included in the 95% CrIs.

The estimates of mean BMI were unbiased as evidenced by median errors that were very close to zero globally, and less than $\pm 0.13 \text{ kg/m}^2$ in every subset of withheld data except for those in relation to age group in Test 1 where median errors ranged from -0.63 to 0.17 kg/m^2 (Appendix Table 6). Even the 25th and 75th percentiles of errors rarely exceeded $\pm 0.8 \text{ kg/m}^2$. The 95% credible intervals of estimated mean BMIs covered 94-98% of true data, which implies good estimation of uncertainty; among subgroups of data, coverage was rarely $< 90\%$. Median errors for prevalences of different BMI categories were also small, and ranged between -0.24 percentage points (BMI 18.5 to $< 20 \text{ kg/m}^2$ in men) to 1.95 percentage points (BMI 20 to $< 25 \text{ kg/m}^2$ in men). Median absolute errors ranged from 0.15 to 6.33 percentage points. Estimates for women had slightly larger errors than those for men, possibly because there is more variation in female BMI within and across regions (see below) making it harder to estimate missing country-years. For comparison, median absolute differences for the same BMI categories between pairs of nationally representative surveys done in the same country and in the same year ranged 0.9 - 5.4 percentage points, indicating that our estimates perform as well as running two parallel surveys in the same country and year. Coverage for different prevalence categories ranged between 56% and 99% , and was generally smaller at the tails of the distribution, because some age-sex groups had zero prevalences of extreme categories; the estimates, and their CrIs, can become very close to zero but not precisely zero.

Appendix Table 1: List of analysis regions and “super-regions”, and countries in each region. The hierarchical structure of the statistical model consisted of country, region, super-region, and world.

We did not have data on population by age group for American Samoa, Bermuda, French Polynesia, Greenland and Tokelau. Country-specific estimates were made but were not used in calculation regional and global prevalences because the latter requires weighting by age-specific population.

Super-region	Region
Sub-Saharan Africa (48)	Central Africa (6): Angola, Central African Republic, Congo, DR Congo, Equatorial Guinea, Gabon
	East Africa (17): Burundi, Comoros, Djibouti, Eritrea, Ethiopia, Kenya, Madagascar, Malawi, Mauritius, Mozambique, Rwanda, Seychelles, Somalia, Sudan, Tanzania, Uganda, Zambia
	Southern Africa (6): Botswana, Lesotho, Namibia, South Africa, Swaziland, Zimbabwe
	West Africa (19): Benin, Burkina Faso, Cabo Verde, Cameroon, Chad, Cote d'Ivoire, Gambia, Ghana, Guinea, Guinea Bissau, Liberia, Mali, Mauritania, Niger, Nigeria, Sao Tome and Principe, Senegal, Sierra Leone, Togo
Central Asia, Middle East and North Africa (28)	Central Asia (9): Armenia, Azerbaijan, Georgia, Kazakhstan, Kyrgyzstan, Mongolia, Tajikistan, Turkmenistan, Uzbekistan
	Middle East and North Africa (19): Algeria, Bahrain, Egypt, Iran, Iraq, Jordan, Kuwait, Lebanon, Libya, Morocco, Occupied Palestinian Territory, Oman, Qatar, Saudi Arabia, Syrian Arab Republic, Tunisia, Turkey, United Arab Emirates, Yemen
South Asia (6)	South Asia (6): Afghanistan, Bangladesh, Bhutan, India, Nepal, Pakistan
East and South East Asia (16)	East Asia (4): China, China (Hong Kong SAR), North Korea, Taiwan
	South East Asia (12): Brunei Darussalam, Cambodia, Indonesia, Lao PDR, Malaysia, Maldives, Myanmar, Philippines, Sri Lanka, Thailand, Timor-Leste, Viet Nam
Oceania (17)	Polynesia and Micronesia (13): American Samoa, Cook Islands, French Polynesia, Kiribati, Marshall Islands, Micronesia (Federated States of), Nauru, Niue, Palau, Samoa, Tokelau, Tonga, Tuvalu
	Melanesia (4): Fiji, Papua New Guinea, Solomon Islands, Vanuatu
High-income Asia Pacific (3)	High-income Asia Pacific (3): Japan, Singapore, South Korea
Latin America and Caribbean (35)	Andean Latin America (3): Bolivia, Ecuador, Peru
	Caribbean (18): Antigua and Barbuda, Bahamas, Barbados, Belize, Bermuda, Cuba, Dominica, Dominican Republic, Grenada, Guyana, Haiti, Jamaica, Puerto Rico, Saint Kitts and Nevis, Saint Lucia, Saint Vincent and the Grenadines, Suriname, Trinidad and Tobago
	Central Latin America (9): Colombia, Costa Rica, El Salvador, Guatemala, Honduras, Mexico, Nicaragua, Panama, Venezuela
	Southern Latin America (5): Argentina, Brazil, Chile, Paraguay, Uruguay
High-income Western countries (27)	High-income English-speaking countries* (6): Australia, Canada, Ireland, New Zealand, United Kingdom, United States of America
	North Western Europe (12): Austria, Belgium, Denmark, Finland, Germany, Greenland, Iceland, Luxembourg, Netherlands, Norway, Sweden, Switzerland
	South Western Europe (9): Andorra, Cyprus, France, Greece, Israel, Italy, Malta, Portugal, Spain
Central and Eastern Europe (20)	Central Europe (13): Albania, Bosnia and Herzegovina, Bulgaria, Croatia, Czech Republic, Hungary, Macedonia (TFYR), Montenegro, Poland, Romania, Serbia, Slovakia, Slovenia
	Eastern Europe (7): Belarus, Estonia, Latvia, Lithuania, Moldova, Russian Federation, Ukraine

* Although high-income English-speaking countries are geographically separated, they exhibit remarkably similar trends in cardio-metabolic risk factors and outcomes. They were therefore grouped together so that the statistical model shares information amongst them more than it does with other countries that are geographically closer but epidemiologically more distinct. This similarity is also seen in results, e.g., in Figure 2 in the main paper.

* National studies for the 3 years prior to 1975 were assigned to 1975 so that they can inform the estimates in countries with older national data.

† This research uses data from China Health and Nutrition Survey (CHNS). We thank the National Institute of Nutrition and Food Safety, China Center for Disease Control and Prevention, Carolina Population Center (5 R24 HD050924), the University of North Carolina at Chapel Hill, the NIH (R01-HD30880, DK056350, R24 HD050924, and R01-HD38700) and the Fogarty International Center, NIH for financial support for the CHNS data collection and analysis files from 1989 to 2011 and future surveys, and the China-Japan Friendship Hospital, Ministry of Health for support for CHNS 2009.

Appendix Table 3: Coefficients of regressions to estimate the prevalences of different BMI categories when information was available on mean BMI. The dependent variables in all regressions were prevalences, fitted using a generalised linear mixed model fitted with a probit link. For each regression, 11,595 data points were used to fit the model.

BMI <18.5 kg/m²	
Variable	Coefficient (95% CI)
Intercept	-7.38 (-7.49, -7.26)
Inverse mean BMI	121.0 (120.0, 122.0)
Mean age of age group	-0.00061 (-0.00144, 0.00023)
Male sex	-0.79 (-0.82, -0.76)
Study mid-year (per one more recent year since 1975)	0.00091 (0.00075, 0.00107)
Natural logarithm of per-capita gross domestic product (GDP)	0.074 (0.071, 0.077)
Inverse mean BMI * mean age of age group	0.078 (0.059, 0.097)
Inverse mean BMI * male sex	14.4 (13.8, 15.1)

Traditional R^2 is not clearly defined for mixed-effect models. The pseudo- R^2 for the model, which describes the proportion of variance explained by both fixed and random factors, was 0.90.

18.5 ≤ BMI <20 kg/m²	
Variable	Coefficient (95% CI)
Intercept	-0.40 (-0.44, -0.35)
Inverse (mean BMI – 19.25)	-90.7 (-91.6, -89.8)
Mean age of age group	-0.0030 (-0.0031, -0.0028)
Male sex	0.155 (0.150, 0.161)
Study mid-year (per one more recent year since 1975)	0.00027 (0.00013, 0.00040)
Natural logarithm of per-capita gross domestic product (GDP)	0.0134 (0.0108, 0.0160)
[Inverse (mean BMI – 19.25)] * mean age of age group	-0.054 (-0.071, -0.036)
[Inverse (mean BMI – 19.25)] * male sex	-26.3 (-26.9, -25.7)

Traditional R^2 is not clearly defined for mixed-effect models. The pseudo- R^2 for the model, which describes the proportion of variance explained by both fixed and random factors, was 0.87.

20 ≤ BMI <25 kg/m²	
Variable	Coefficient (95% CI)
Intercept	0.46 (0.42, 0.50)
Inverse (mean BMI – 22.5)	-58.3 (-59.2, -57.4)
Mean age of age group	0.00049 (0.00041, 0.00057)
Male sex	0.144 (0.142, 0.147)
Study mid-year (per one more recent year since 1975)	-0.0024 (-0.0025, -0.0023)
Natural logarithm of per-capita gross domestic product (GDP)	-0.020 (-0.022, -0.018)
[Inverse (mean BMI – 22.5)] * mean age of age group	-0.69 (-0.71, -0.67)
[Inverse (mean BMI – 22.5)] * male sex	-25.7 (-26.2, -25.1)

Traditional R^2 is not clearly defined for mixed-effect models. The pseudo- R^2 for the model, which describes the proportion of variance explained by both fixed and random factors, was 0.85.

25 ≤ BMI <30 kg/m²	
Variable	Coefficient (95% CI)
Intercept	-0.41 (-0.45, -0.38)
Inverse (mean BMI – 27.5)	-120.0 (-121.0, -120.0)
Mean age of age group	0.00089 (0.00079, 0.00100)
Male sex	0.290 (0.287, 0.293)
Study mid-year (per one more recent year since 1975)	-0.00025 (-0.00036, -0.00013)
Natural logarithm of per-capita gross domestic product (GDP)	0.022 (0.020, 0.024)
[Inverse (mean BMI – 27.5)] * mean age of age group	0.44 (0.43, 0.46)
[Inverse (mean BMI – 27.5)] * male sex	-36.2 (-36.6, -35.7)

Traditional R^2 is not clearly defined for mixed-effect models. The pseudo- R^2 for the model, which describes the proportion of variance explained by both fixed and random factors, was 0.91.

30 ≤ BMI <35 kg/m²	
Variable	Coefficient (95% CI)
Intercept	-0.74 (-0.78, -0.70)
Inverse (mean BMI – 32.5)	-97.2 (-98.2, -96.2)
Mean age of age group	0.0021 (0.0019, 0.0023)
Male sex	0.158 (0.152, 0.165)
Study mid-year (per one more recent year since 1975)	0.0028 (0.0026, 0.0030)
Natural logarithm of per-capita gross domestic product (GDP)	0.022 (0.019, 0.025)
[Inverse (mean BMI – 32.5)] * mean age of age group	-0.20 (-0.22, -0.18)
[Inverse (mean BMI – 32.5)] * male sex	-25.7 (-26.3, -25.1)

Traditional R^2 is not clearly defined for mixed-effect models. The pseudo- R^2 for the model, which describes the proportion of variance explained by both fixed and random factors, was 0.91.

35 ≤ BMI <40 kg/m²	
Variable	Coefficient (95% CI)
Intercept	-1.07 (-1.13, -1.00)
Inverse (mean BMI – 37.5)	-85.4 (-87.0, -83.7)
Mean age of age group	0.0047 (0.0042, 0.0051)
Male sex	-0.167 (-0.181, -0.152)
Study mid-year (per one more recent year since 1975)	0.0051 (0.0048, 0.0054)
Natural logarithm of per-capita gross domestic product (GDP)	0.022 (0.017, 0.027)
[Inverse (mean BMI – 37.5)] * mean age of age group	-0.61 (-0.64, -0.57)
[Inverse (mean BMI – 37.5)] * male sex	-4.89 (-6.01, -3.77)

Traditional R^2 is not clearly defined for mixed-effect models. The pseudo- R^2 for the model, which describes the proportion of variance explained by both fixed and random factors, was 0.86.

BMI \geq40 kg/m²	
Variable	Coefficient (95% CI)
Intercept	1.16 (1.02, 1.29)
Inverse mean BMI	-97.4 (-99.9, -94.8)
Mean age of age group	0.0068 (0.0047, 0.0090)
Male sex	-0.66 (-0.73, -0.59)
Study mid-year (per one more recent year since 1975)	0.0060 (0.0056, 0.0064)
Natural logarithm of per-capita gross domestic product (GDP)	0.042 (0.036, 0.048)
Inverse mean BMI * mean age of age group	-0.295 (-0.352, -0.238)
Inverse mean BMI * male sex	9.74 (7.98, 11.50)

Traditional R^2 is not clearly defined for mixed-effect models. The pseudo- R^2 for the model, which describes the proportion of variance explained by both fixed and random factors, was 0.81.

Appendix Table 4: Age-standardised mean BMI by sex and country in 1975, 1985, 1995, 2005, and 2014. Numbers in brackets show 95% credible intervals. Estimates for all countries and years can be downloaded from www.ncdrisc.org.

[†] Estimated values minus held out values.

* p-values for model error comparisons were calculated using the non-parametric Wilcoxon signed-rank test for paired data. The p-values are calculated assuming independence of the held-out observations. They should therefore be interpreted as an approximation because there is some dependence among the held-out observations, within each of the five repetitions for example.

Test 1: Men, BMI < 18.5 kg/m²

[†] Estimated values minus held out values.

* p-values for model error comparisons were calculated using the non-parametric Wilcoxon signed-rank test for paired data. The p-values are calculated assuming independence of the held-out observations. They should therefore be interpreted as an approximation because there is some dependence among the held-out observations, within each of the five repetitions for example.

Test 1: Men, BMI 35 to <40 kg/m²

[†] Estimated values minus held out values.

* p-values for model error comparisons were calculated using the non-parametric Wilcoxon signed-rank test for paired data. The p-values are calculated assuming independence of the held-out observations. They should therefore be interpreted as an approximation because there is some dependence among the held-out observations, within each of the five repetitions for example.

Test 1: Women, BMI 20 to <25 kg/m²

[†] Estimated values minus held out values.

* p-values for model error comparisons were calculated using the non-parametric Wilcoxon signed-rank test for paired data. The p-values are calculated assuming independence of the held-out observations. They should therefore be interpreted as an approximation because there is some dependence among the held-out observations, within each of the five repetitions for example.

[†] Estimated values minus held out values.

* p-values for model error comparisons were calculated using the non-parametric Wilcoxon signed-rank test for paired data. The p-values are calculated assuming independence of the held-out observations. They should therefore be interpreted as an approximation because there is some dependence among the held-out observations, within each of the five repetitions for example.

Test 2: Men, BMI 30 to <35 kg/m²

[†] Estimated values minus held out values.

* p-values for model error comparisons were calculated using the non-parametric Wilcoxon signed-rank test for paired data. The p-values are calculated assuming independence of the held-out observations. They should therefore be interpreted as an approximation because there is some dependence among the held-out observations, within each of the five repetitions for example.

Test 2: Women, BMI < 18.5 kg/m²

[†] Estimated values minus held out values.

* p-values for model error comparisons were calculated using the non-parametric Wilcoxon signed-rank test for paired data. The p-values are calculated assuming independence of the held-out observations. They should therefore be interpreted as an approximation because there is some dependence among the held-out observations, within each of the five repetitions for example.

Test 2: Women, BMI 35 to <40 kg/m²
