Figure S1 shows the AFM images with profiles from white lines. The drop-cast sample consists of nanodroplets up to 50 nm high. On the contrary, sublimated samples resulted in the formation of microcrystals hundreds of nanometers high.

Figure S1. AFM images from drop-cast and sublimated samples at 75 °C and 265 °C.

Figure S2 shows a weak signal from Co 2p found on the surface after drop-cast. The right side of the image shows the fit in the CasaXPS program with a weak Co 2p peak detected.

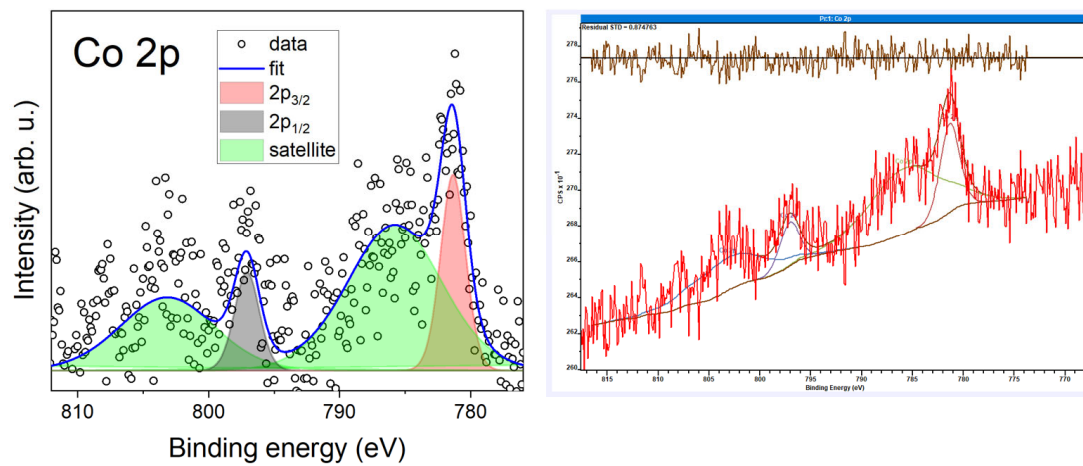

Figure S2. Weak Co 2p peak from the drop-cast sample.

Figure S3 illustrates the semi-empirical quantitative analysis of elemental composition for the studied complex of powder taken from crucible after sublimation at 75 °C and 265 °C. The red line denotes the calculated ideal percental amount of each element from the compound $\text{CoC}_{38}\text{H}_{32}\text{Cl}_2\text{N}_4\text{O}_4$. Histograms illustrate that cobalt and chlorine content increases as the sublimation temperature rises; this means that cobalt stays in the crucible and supports the observation of no cobalt detected on the surface of microcrystallites after thermal sublimation.

Figure S3. Elemental percentage of atoms in powder from crucible after thermal sublimation at 75 °C and 265 °C.
