22 **3. Supplemental figures**

23

24 **1. Experimental procedures**

25 **Source of inoculum.** Lake Matano is a metal-rich, ancient ocean analog with an active Mn cycle
26 (1, 2). Organic carbon in Lake Matano is mostly mineralized via methanogenesis (3). A 15-cm
27 sediment core from 200 m water depth in Lake Matano, Sulawesi Island, Indonesia
28 ($02^{\circ}26'27.1''\text{S}$, $121^{\circ}15'12.3''\text{E}$; *in situ* sediment temperature $\sim 27^{\circ}\text{C}$) was sampled in November
29 2014 and sub-sampled at 2.5-cm increments. Sediments were sealed in gas-tight Mylar bags with
30 no headspace (4) and stored at 4°C for ~ 1 year.

31

32 **Inoculation of enrichment cultures.** Mylar bags containing sediment samples were opened in
33 an anoxic chamber (97% N_2 and 3% H_2 ; Coy Laboratory Products, Grass Lake, MI, USA).
34 Sediments from each 2.5 cm subsample were transferred to 160 mL serum bottles, diluted 1:2
35 with minimal media, and pre-incubated for 45 days at 30°C in 100% N_2 headspace to deplete
36 endogenous organic carbon, electron donors, and electron acceptors. Sediments from the top 5
37 cm were subsequently mixed together and transferred to defined medium at a 1:20 dilution
38 (transfer 1, day 45) amended with Mn(III) and a headspace of $\text{CH}_4:\text{N}_2$ (50:50) or N_2 . Subsequent
39 transfers were carried out in the same way (transfer 2, day 91; transfer 3, day 183; transfer 4, day
40 230) for CH_4 headspace cultures, with heat-killed and substrate controls generated each time
41 using the newly transferred culture (10% v/v dilution). By day 210, enrichments appeared to be
42 sediment-free, except for microparticles. The fifth transfer (day 245) inoculated using non-
43 labeled methane, was used entirely for metaproteomic analysis after visual confirmation of active
44 Mn(III) reduction in the live enrichment bottles (see **Figs. 1, S1**). Two 100 mL bottles were
45 pooled together to obtain 200 mL duplicates for each treatment, centrifuged ($10,000 \times g$, 30

46 min, 4°C) and supernatant-free pellets were stored at -80°C until protein extraction and
47 metaproteomic sequencing.

48 Defined medium consisted of modified artificial freshwater medium lacking nitrate and
49 sulfate, developed based on the pore water composition of Lake Matano sediments as described
50 in prior work (5). The medium contained 3 mM NaHCO₃, 825 μM MgCl₂, 550 μM CaCO₃, 225
51 μM NH₄Cl, 5 μM Na₂HPO₄, 3.5 μM K₂HPO₄, and a trace metal solution (1 nM CuCl₂, 1.5 nM
52 Na₂MoO₄, 2.5 nM CoCl₂, 23 nM MnCl₂, 9 nM FeCl₃, 4 nM ZnCl₂, 0.091 μg/L vitamin B₁₂,
53 0.091 μg/L biotin, and 18.18 μg/L thiamine. Vitamins were filter-sterilized and added after
54 autoclaving. Bottles were stoppered with sterile black bromobutyl stoppers (Geo-Microbial
55 Technologies, Ochelata, OK, USA; pre-boiled in 0.1 N NaOH), and crimped with aluminum
56 seals. An acetate-free 10 mM stock of Mn(III)-pyrophosphate was prepared using solid Mn₂O₃
57 (99% purity, 325 mesh powder, Sigma Aldrich) instead of Mn(III)-acetate (6) and filter-
58 sterilized. Mn(III)-pyrophosphate was added at a final concentration of 1 mM. Bottles were
59 purged with 99.9% N₂ for 20 min, and were appropriate, CH₄ was injected with a 50% headspace
60 volume of CH₄ at a 1:1 labeled to unlabeled ratio (99.9% CH₄ and 99% ¹³CH₄; Cambridge
61 Isotope Laboratories, Tewksbury, MA, USA). Heat-killed controls were autoclaved prior to
62 Mn(III) or CH₄ addition. All treatments were duplicated, and bottles were incubated in the dark
63 at 30°C.

64 **Substrate utilization.** The benzidine method was used to measure Mn(III) consumption
65 (7) throughout the transfer 4 enrichment. Methane (¹³CH₄) oxidation was monitored by
66 measuring ¹³C enrichment in dissolved inorganic carbon as described in (5).

67 **16S rRNA gene amplicon sequencing.** To identify the dominant microbial community
68 members, we analyzed the microbial community composition of samples taken at the end of each

69 enrichment period by sequencing 16S rRNA gene amplicons as described previously (5). Reads
70 were analyzed using Mothur (8) following its MiSeq standard operating procedure
71 (https://www.mothur.org/wiki/MiSeq_SOP, accessed November 2017). Merged reads were
72 dereplicated and aligned to the ARB SILVA SSU database release 123 (July 23, 2015).
73 Homopolymers longer than 8bp were filtered out. Reads were then clustered into OTUs at 97%
74 similarity based on uncorrected pairwise distance matrices. OTUs were classified using the ARB
75 SILVA SSU reference taxonomy database release 123.

76 **Metagenome (DNA) sequencing and assembly.** Community DNA was processed using
77 the Nextera XT DNA Sample Prep kit and sequenced using a paired-end Illumina MiSeq 600 kit.
78 Raw reads were submitted to NCBI. The accessions for the study and samples in the submission
79 are PRJNA489678, LakeMatanoMn3_Enrichment (SAMN10343573). The accession numbers
80 for the N₂ headspace experiment and run are LM_Mn(III)_2018 (SRX5007804) and
81 LakeMatano_11_NoMethane_R1.fastq.gz (SRR8188020), and the accession numbers for the
82 CH₄ headspace experiment and run are LM_Mn(III)_CH4_2018 (SRX5007805) and
83 LakeMatano_9_Methane_R1.fastq.gz (SRR8188019).

84 Barcoded sequences were de-multiplexed, trimmed (length cutoff 100 bp), and filtered to
85 remove low quality reads (average Phred score <25) using Trim Galore!
86 (http://www.bioinformatics.babraham.ac.uk/projects/trim_galore/). Forward and reverse reads
87 were assembled using SPAdes (9) with the ‘meta’ option. Metagenomic reads were deposited in
88 NCBI. Contigs \geq 500 nt were organized into MAGs based on tetranucleotide frequency and
89 sequence coverage using MaxBin 2.0 (10). MAG completeness and contamination were
90 estimated by lineage-specific marker genes using CheckM (11). We obtained one
91 *Betaproteobacteria* metagenome-assembled genome (MAG; *Rhodocyclales* bacterium GT-UBC,

92 NCBI accession QXPY01000000) with 99.53% completeness, 0.02% contamination, 60.9% GC
93 content, and 4,555 protein-coding genes. We provisionally classified *Rhodocyclales* bacterium
94 GT-UBC as a new species within the *Dechloromonas* genus, which we named “*Candidatus*
95 *Dechloromonas occultata*” sp. nov.; etymology: *occultata*; (L. fem. adj. ‘hidden’), based on its
96 resistance to cultivation. We also obtained one *Deltaproteobacteria* MAG (*Desulfuromonadales*
97 bacterium GT-UBC; NCBI accession RHLS01000000) with 99.36% completeness, 0.64%
98 contamination, 59.9% GC content, 3,617 protein-coding genes, and 80% ANI to *Geobacter*
99 *sulfurreducens*. We provisionally named *Desulfuromonadales* bacterium GT-UBC “*Candidatus*
100 *Geobacter occultata*” sp. nov.

101 **Comparative genomic analysis.** The “*Ca. D. occultata*” MAG was annotated using
102 RAST. Metabolic pathways were identified in RAST (12-14), and manually checked for
103 completeness in PATRIC (15), following pathways reported in KEGG
104 (<https://www.genome.jp/kegg/>) and MetaCyc (<https://metacyc.org/>) and confirming potential
105 new variants in the literature (references where appropriate throughout the manuscript). For
106 incomplete pathways, the three other genomes of isolated *Dechloromonas* strains (*D. aromatica*,
107 *D. denitrificans*, and *D. agitata*) in PATRIC were searched for missing proteins. Central
108 metabolic and secondary pathways were compared among *Dechloromonas* spp. and other metal-
109 cycling species using the RAST subsystems option, searching for specific annotated proteins
110 with RAST, and within PATRIC using the Compare Region Viewer and its heatmap options.
111 Proteins of interest were characterized *in silico* based on conserved domains and homology
112 searches with BLAST and NCBI tools. Localization of proteins was predicted using PSORTb
113 model ECSVM (16). The synteny of gene clusters containing functional genes of interest were
114 analyzed using Simple Synteny (<https://www.dveltri.com/simplesynteny/cfinder.html>), last

115 accessed July 2018). Putative multiheme *c*-type cytochromes (≥ 3 Cxx(x)CH motifs) were
116 identified using a previously reported Python script (<https://github.com/bondlab/scripts>, (17)).

117 **Phylogenetic analysis.** The evolutionary history of functional genes was inferred using
118 MEGA7 (18) with the Maximum Likelihood method based on the JTT matrix-based model (19).
119 After all gaps were eliminated, initial tree(s) for the heuristic search were obtained automatically
120 by applying Neighbor-Join and BioNJ algorithms to a matrix of pairwise distances estimated
121 using a JTT model, and then selecting the topology with superior log likelihood value. The trees
122 were drawn to scale, with branch lengths measured in the number of substitutions per site and
123 bootstrap values based on 500 replicates. The synteny of selected genes was determined using
124 Simple Synteny (20). The evolutionary history of selected whole genomes of Proteobacteria was
125 reconstructed using GToTree (21) with genomic NCBI IDs as input, retrieved manually. Single-
126 copy genes (SCGs) were identified from a set of 74 single-copy genes. GToTree uses
127 concatenated alignments of identified SCGs to build the phylogenomic tree with FastTree. The
128 final tree was viewed and edited in FigTree V1.4.4 (22).

129 **Protein digestion and desalting.** To solubilize oxidized metal precipitants and
130 precipitate proteins, 100 μ L of 20% trichloroacetic acid (4°C) was added to each sample and
131 incubated on ice for 1 hour. Bacterial cells and soluble proteins were pelleted at 10,000 x g (1 hr,
132 4°C). Cells were then resuspended in 100 μ L of 6 M urea in 50 mM NH_4HCO_3 and lysed using a
133 sonicating probe (3 watts; 15s, 5 times), alternating in dry ice in ethanol to keep the sample cold.
134 Sonication, digestion, and desalting proceeded as previously described (23). Briefly, after
135 sonication and protein quantification using the Bradford assay (Bio-Rad, Hercules, CA), tris(2-
136 carboxyethyl)phosphine (TCEP) was added to reduce samples (1 hr, 37°C), and iodoacetamide
137 was used as the alkylating agent (1hr, in dark, RT). NH_4HCO_3 and HPLC-grade methanol were

138 added to each sample to dilute the urea to allow the trypsin digestion to proceed. Trypsin was
139 added in a 1:20 ratio and incubated overnight at RT. The digestion was stopped by adding small
140 aliquots of 10% formic acid until a pH < 2 was achieved. Prior to desalting the peptides, samples
141 were dried down and reconstituted in 5% acetonitrile with 0.1% trifluoroacetic acid. Desalting
142 was carried out with MicroSpin C18 columns following the manufacturer's instructions (The
143 Nest Group). Peptides were dried and reconstituted in 5% ACN with 0.1% formic acid to achieve
144 concentrations of 2 $\mu\text{g } \mu\text{L}^{-1}$.

145 **LC-MS/MS.** The mass spectrometry analysis was performed on a QExactive at the
146 University of Washington Proteomics Resource (Seattle, WA). Samples were separated and
147 introduced into the mass spectrometer (MS) by reverse-phase chromatography using a
148 Manufactured PicoTip fused silica capillary column (30 cm long, 75 μm i.d.) packed with C18
149 particles (Dr. Maisch ReproSil-Pur; C18-Aq, 120 \AA , 3 μm) fitted with a 3 cm long, 100 μm i.d.
150 precolumn (Dr. Maisch ReproSil-Pur; C18-Aq, 120 \AA , 3 μm). Peptides were eluted using an
151 acidified (formic acid, 0.1% v/v) water-acetonitrile gradient (5–35% acetonitrile in 90 min) and
152 mass spectrometry was performed on a Thermo Fisher (San Jose, CA) QExactive (QE). The top
153 20 most intense ions were selected for MS2 acquisition from precursor ion scans of 400–
154 1200 $\text{m } z^{-1}$. Centroid full MS resolution data was collected at 70,000 with AGC target of 1E6
155 and centroid MS2 data was collected at resolution of 35,000 with AGC target of 5E4. Dynamic
156 exclusion was set to 15 seconds and +2, +3, +4 ions were selected for MS2 using data dependent
157 acquisition mode (DDA). Quality control (QC) peptide mixtures were analyzed every fifth
158 injection to monitor chromatography and MS sensitivity. Skyline was used to determine that QC
159 standards did not deviate >10% through all analyses (24). The mass spectrometry data were
160 deposited to the ProteomeXchange Consortium via the PRIDE partner repository with the dataset

161 identifier PXD011642.

162 **Protein identification and data analyses.** Peptide identifications from mass
163 spectrometry data were completed using Comet (25). The protein database used for correlating
164 spectra with protein identifications was generated from the metagenome by Prokka (26), and
165 from each individual bin using RAST (13) and included the MAGs to improve peptide spectra
166 correlations (15). This was then combined with 50 common contaminants and the QC peptides.
167 Comet parameters included: reverse concatenated sequence database search, trypsin enzyme
168 specificity, cysteine modification of 57 Da (resulting from the iodoacetamide) and modifications
169 on methionine of 15.999 Da (oxidation). Concatenated target–decoy database searches were
170 completed and minimum protein and peptide thresholds were set at $P > 0.95$ on ProteinProphet
171 and $P > 0.99$ on PeptideProphet (27). Protein identifications from the whole-cell lysates were
172 accepted by ProteinProphet if the above mentioned thresholds were passed, two or more peptides
173 were identified (PeptideProphet), and at least one terminus was tryptic (27). Calculated false
174 discovery rates (FDR) were <0.01 . Resulting data files were combined and normalized spectral
175 abundances were calculated in QPROT with Abacus (28). Abacus parameters include initial
176 probability threshold of 0.5 on peptides, and a minimum protein probability of 0.8. Abacus
177 provides consistent protein inferences across biological and technical replicates. Abacus spectral
178 abundance outputs were analyzed with QSpec, a statistical framework within QPROT, to
179 determine log fold changes between treatments. Log fold change in protein abundances
180 calculated using QSpec were accepted if ≥ 0.5 and Zstatistic score ≥ 2.0 (increased abundance
181 across all replicates) or ≤ -0.5 and Zstatistic score ≤ -2.0 (decreased abundance across all
182 replicates) (28). Peptide counts were normalized to total peptide counts for each treatment.
183 Averages of normalized technical replicates were used to compare treatments with and without

184 methane. A two-tailed paired t-test was carried out using Excel to test the null hypothesis of no
185 differential expression among treatments and determine the p-value associated with each change.

186 **Cultivation attempts.** Isolation strategies were designed considering the metabolic potential of
187 “*Ca. D. occultata*” but failed to isolate the targeted organism. Samples from highly enriched
188 cultures were inoculated with acetate for denitrification or microaerobic Fe(II) oxidation. For
189 Fe(II) oxidation, samples were inoculated into two-layered FeS vs. O₂ gradient tubes (29), with 1
190 mM acetate in the top layer. There was no Fe(II) oxidation in Mn(III)-amended treatments. With
191 O₂ addition, visual evidence for Fe(II) oxidation was observed, and a *Comamonas* spp. with
192 closest hits to environmental sequences from lake sediment was isolated. With acetate and
193 Mn(III), a *Comamonas aquatica* strain was isolated.
