19 **Supplemental Figure 1: Reported illnesses did not differ significantly between CTX-T and**  
20 **CTX-N infants during the study period.**

21 Comparison of reported **A.** all cause illness and **B.** gastrointestinal specific illness during the study  
22 period. TRUE indicates that an illness was reported and FALSE indicates no reported illness. Red  
23 bars correspond to counts for CTX-T infants and blue bars correspond to counts for CTX-N infants.  
24 Fisher's exact test was used to determine if either group was significantly more likely to report  
25 illness.

**CTX-****CTX+****A****microbial taxa****B****functional pathways****C****resistance genes****D****dfr/sul genes**

26 **Supplemental Figure 2: Resistance gene Shannon Diversity ( $\alpha$ -diversity) increases over**  
27 **time in CTX-T infants, but is stable for CTX-N infants**

28 Points represent Shannon diversity values for individual samples and boxes show median values  
29 (dark middle line) and 1<sup>st</sup> and 3<sup>rd</sup> quartiles (lower and upper lines). x-axis groups for each plot are  
30 the times of collection and y-axis for each plot is richness. Paired Wilcoxon tests (signed rank)  
31 were used to compare the latter two collections (timepoints B and C) to the first collection  
32 (timepoint A) and p-values are reported above the graph with black lines depicting the  
33 comparisons. Graphs on the left show CTX-N infants (blue, CTX-) and on the right show CTX-T  
34 infants (red, CTX+). Shannon diversity was calculated for **A.** microbial taxa, **B.** functional  
35 pathways, **C.** resistance genes, and **D.** *dfr/sul* genes.

**A****B**

36 **Supplemental Figure 3: Maternal CD4 cell count does not significantly change microbiota  $\alpha$ -**  
37 **diversity**

38 **A.** Relationship between maternal CD4 count and HEU infant microbial taxa  $\alpha$ -diversity.  
39 Microbial taxa  $\alpha$ -diversity is on the y-axis and maternal CD4 count is on the x-axis. Maternal CD4  
40 count was sampled once and is independent of infant sampling time separated by columns. Sample  
41  $\alpha$ -diversity is given for Shannon index above and richness below. Red dots correspond to CTX-T  
42 infants and blue dots are CTX-N infants. The black solid line is fitted to all points in the panel with  
43 the formula  $\alpha$ -diversity  $\sim$  maternal CD4 count. Grey shaded area is the 95% CI for this line. Red  
44 and blue dashed lines are similarly fitted to CTX-T infants and CTX-N infants respectively. **B.**  
45 Expected (null) slope distribution from 1000 permutations compared to observed slope for  
46 relationship between maternal CD4 count and HEU infant microbial taxa  $\alpha$ -diversity. Red vertical  
47 lines show the observed Estimate (slope) value for the panels in Supplemental Figure 3A and black  
48 histograms show the expected slope value under a null distribution based on linear models from  
49 1000 permutations of the data in Supplemental Figure 3A. P-values calculated from the z-score  
50 are given in white for the deviation of the observed slope from the expected slope.

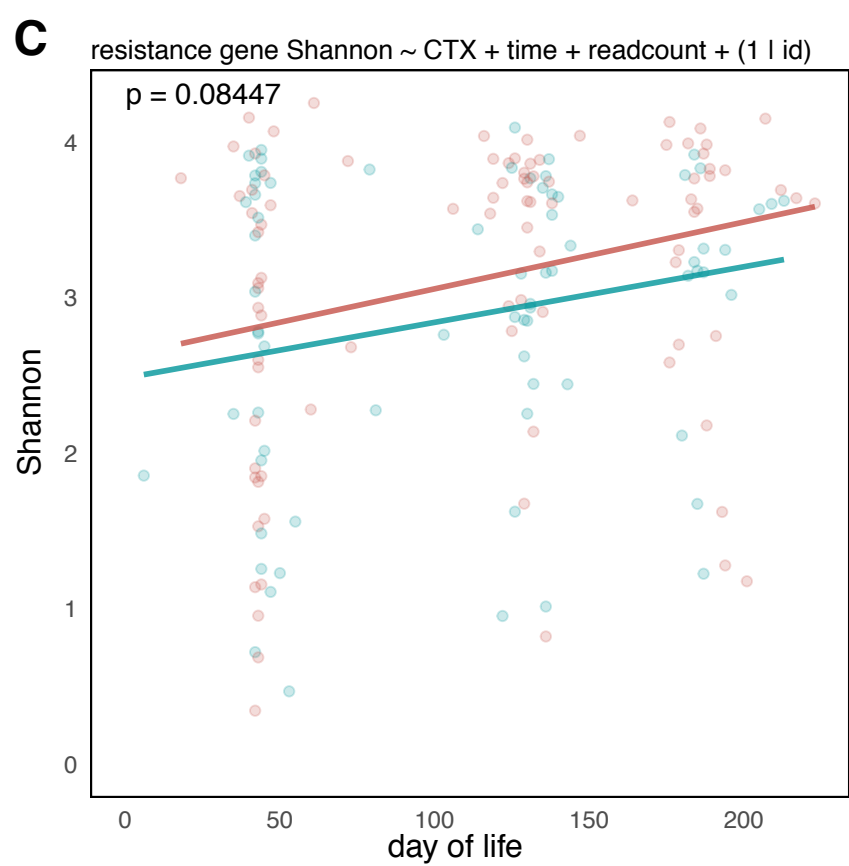

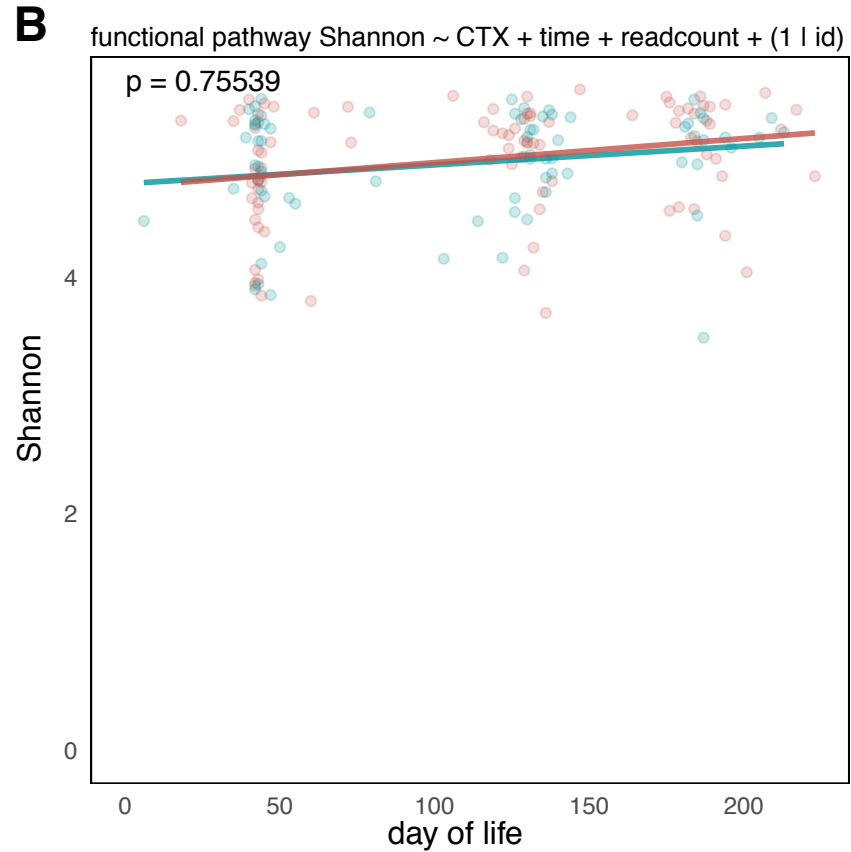

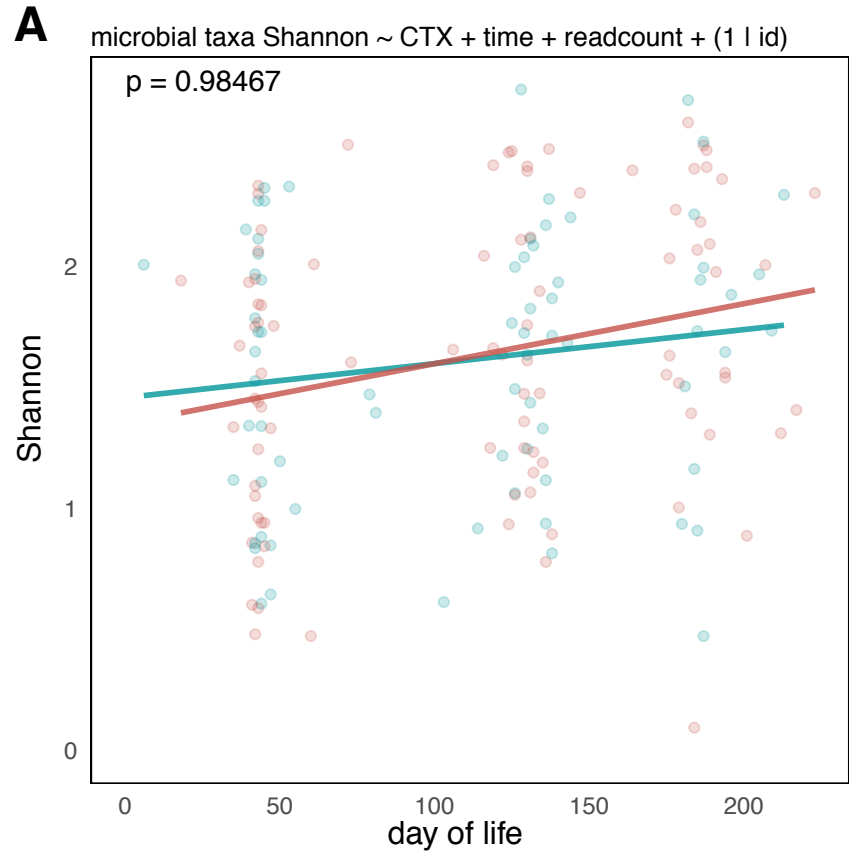

51 **Supplemental Figure 4:  $\alpha$ -diversity does not vary by all cause reported illnesses.**  
52 Points represent individual patient samples colored by treatment group (red for CTX-T infants and  
53 blue for CTX-N infants). Circular points are samples where no illness was reported, and diamond  
54 points with black outlines are samples where illness was reported. The x-axis for each plot is the  
55 day of life for each infant calculated from their day of birth. Y-axis is Shannon diversity for **A.**  
56 microbial taxa, **B.** resistance genes, **C.** functional pathways, and Richness for **D.** microbial taxa,  
57 **E.** resistance genes, **F.** functional pathways.

58 **Supplemental Figure 5:  $\alpha$ -diversity does not vary by all cause reported gastrointestinal**  
59 **symptoms.**

60 Points represent individual patient samples colored by treatment group (red for CTX-T infants and  
61 blue for CTX-N infants). Circular points are samples where no gastrointestinal illness (diarrhea or  
62 vomiting) was reported, and diamond points with black outlines are samples where gastrointestinal  
63 illness was reported. The x-axis for each plot is the day of life for each infant calculated from their  
64 day of birth. Y-axis is Shannon diversity for **A.** microbial taxa, **B.** resistance genes, **C.** functional  
65 pathways, and Richness for **D.** microbial taxa, **E.** resistance genes, **F.** functional pathways.

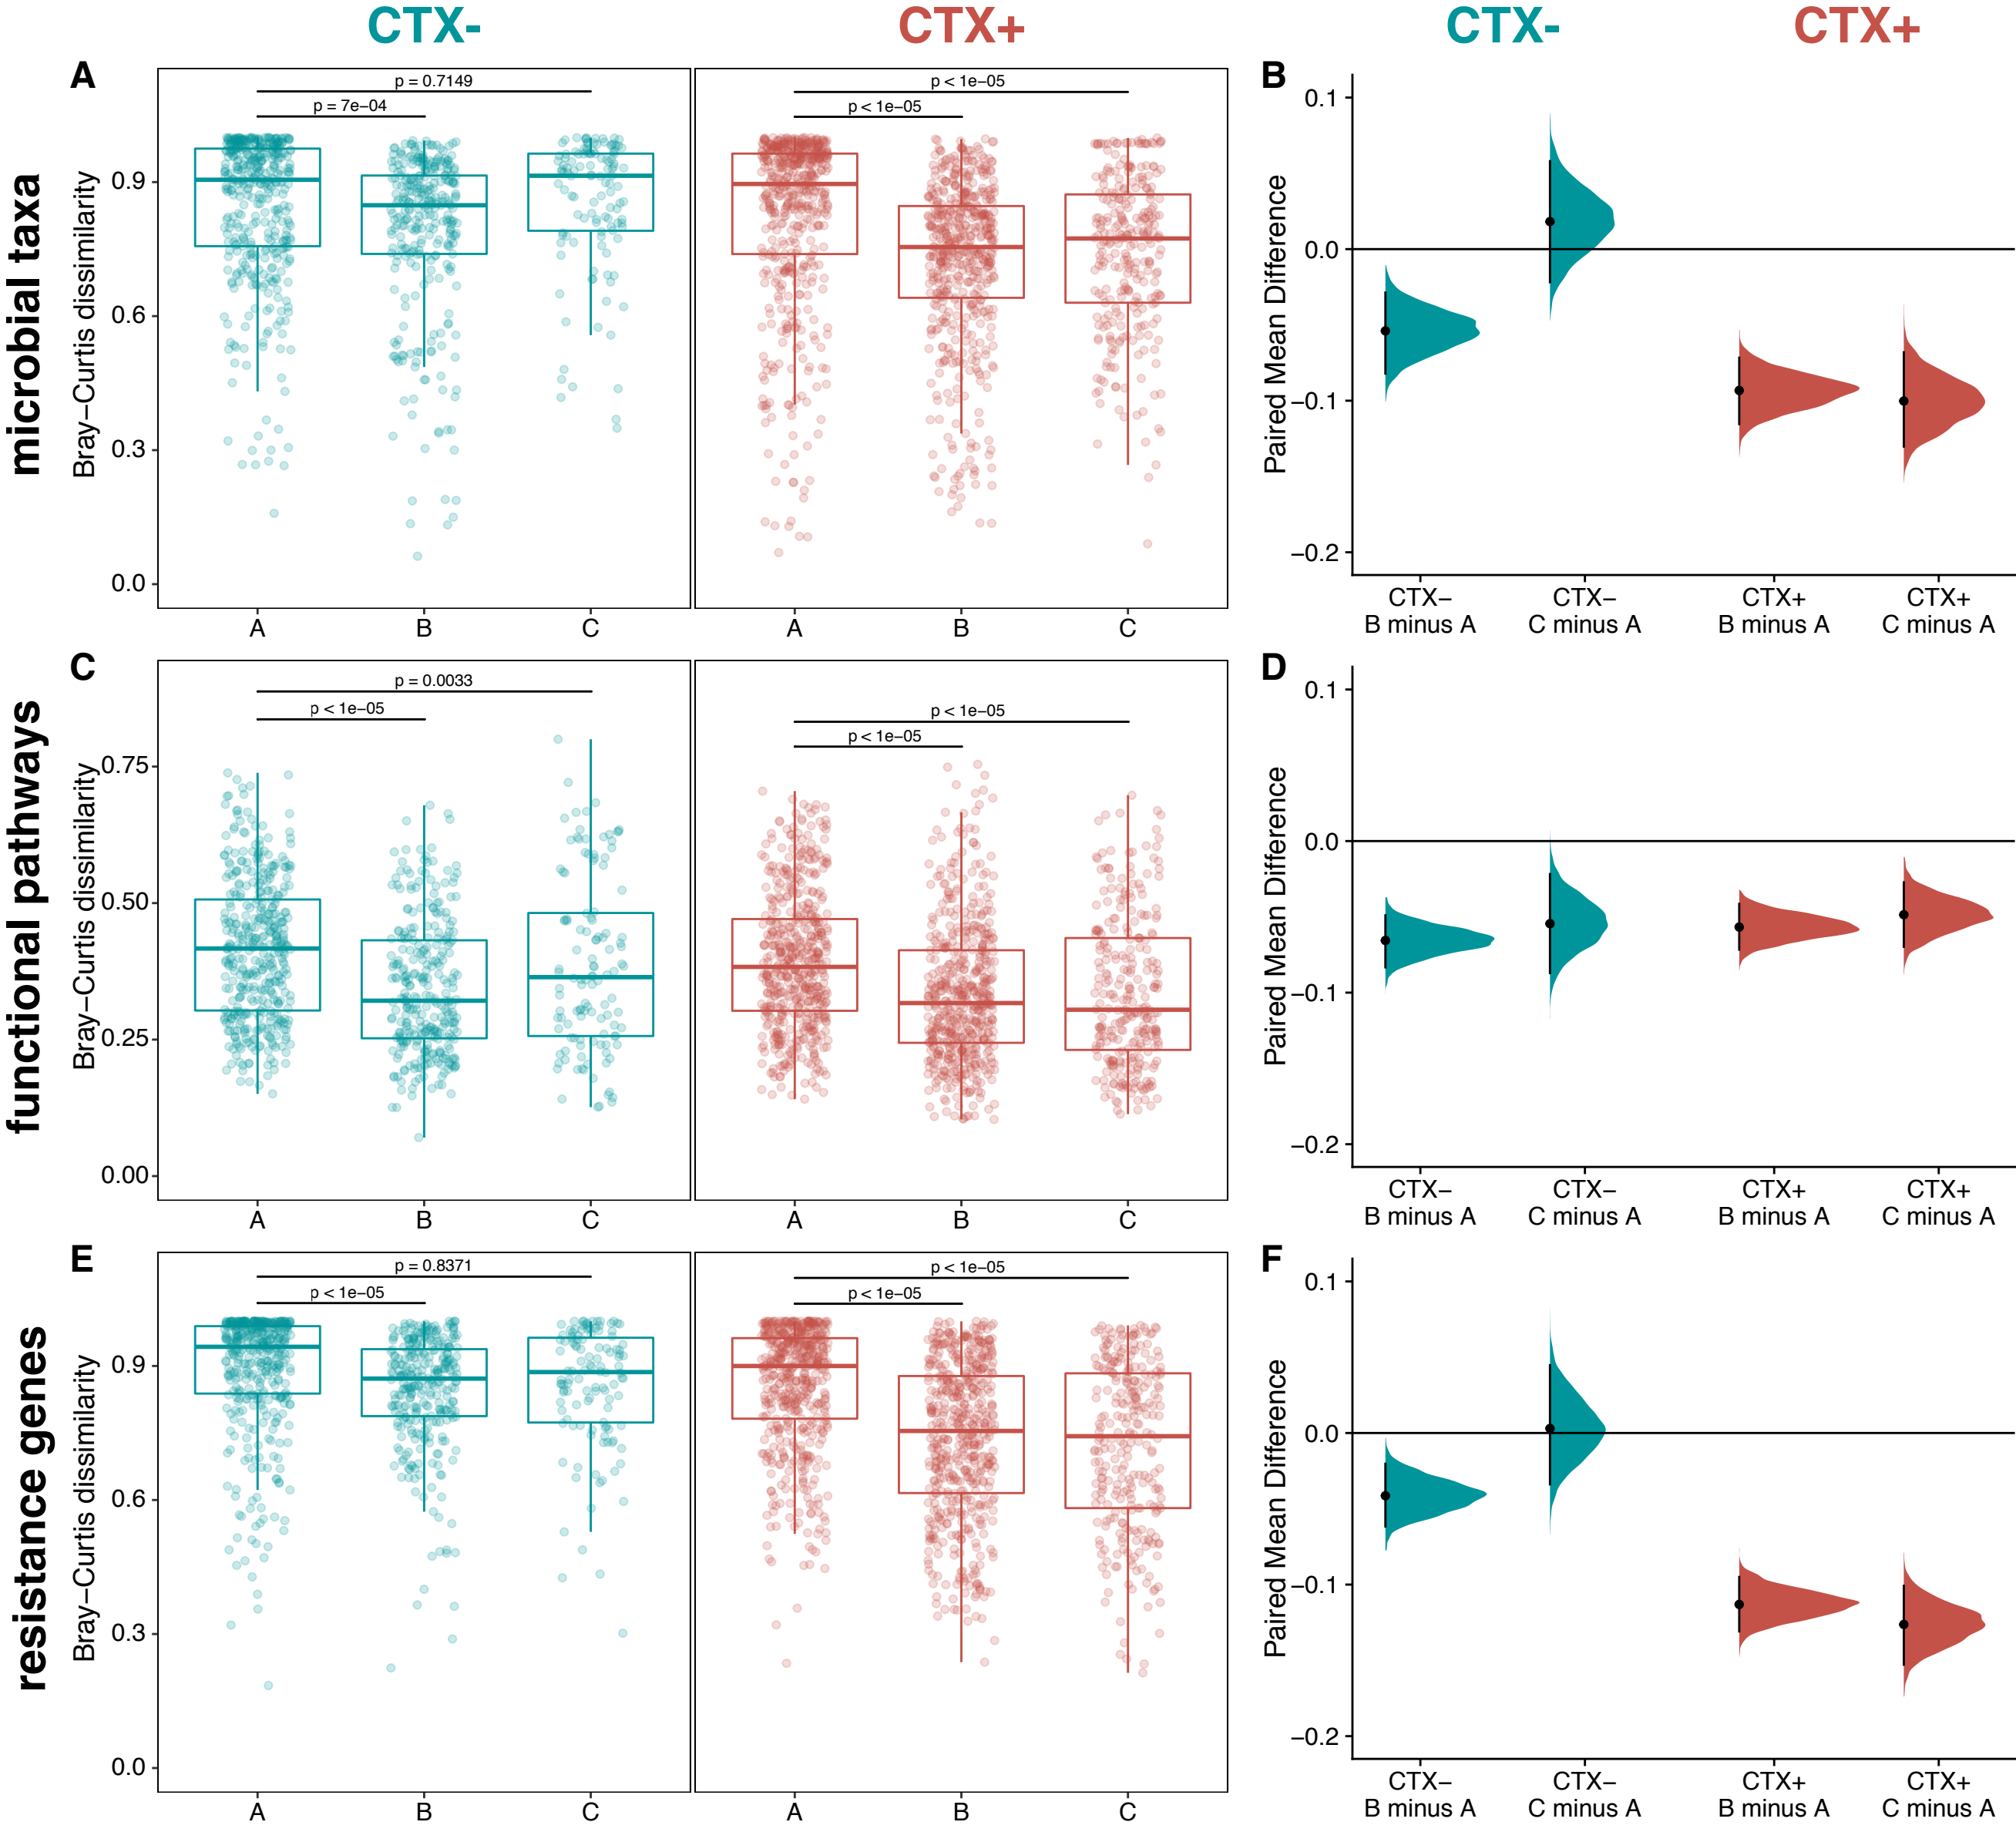

66 **Supplemental Figure 6: *dfr/sul* gene Shannon diversity is significantly higher for CTX-T**  
67 **infants compared to CTX-N infants.**

68 Points represent individual patient samples colored by treatment group (red for CTX-T infants and  
69 blue for CTX-N infants) and lines represent predictions of linear models for the two groups. The  
70 x-axis for each plot is the day of life for each infant calculated from their day of birth and y-axis  
71 is Shannon diversity. Models were made for **A.** microbial taxa, **B.** functional pathways, **C.**  
72 resistance genes, and **D.** trimethoprim- and sulphonamide-resistance (*dfr/sul*) genes. Formulas for  
73 each linear mixed-effects model are reported above the plots and these models were compared  
74 using likelihood-ratio tests to null models made without the cotrimoxazole treatment variable  
75 (CTX) included. The p-values for these comparisons of linear mixed-effects models are reported  
76 in the top left of each graph.

**microbial taxa****timepoint A****timepoint B****timepoint C****functional pathways****resistance genes**

77 **Supplemental Figure 7: Intragroup microbial taxonomic and resistance gene  $\beta$ -diversity for**  
78 **CTX-N infants is higher than CTX-T infant  $\beta$ -diversity and and intergroup  $\beta$ -diversity.**  
79 Points represent Bray-Curtis dissimilarity between two samples (higher dissimilarity means  
80 samples were more different). Boxplots show median values (dark middle line) and 1<sup>st</sup> and 3<sup>rd</sup>  
81 quartiles (lower and upper lines). The distribution for each set of points is shown to the right of  
82 the points. Dissimilarities are blue if both compared samples are from CTX-N infants (CTX\_neg),  
83 red if both samples are from CTX-T infants (CTX\_pos), and grey if one sample is from a CTX-N  
84 infant and the other is from a CTX-T infant (diff). Dissimilarities were calculated from microbial  
85 taxa community matrices for **A**, **B**, and **C**, from functional pathway matrices for **D**, **E**, and **F**, and  
86 for resistance gene matrices for **G**, **H**, and **I**.

87 **Supplemental Figure 8: Taxonomic, functional metabolic pathway, and resistance gene  $\beta$ -**  
88 **diversity decreases compared to baseline for CTX-T infants.**

89 Boxplots with points show the pairwise Bray-Curtis dissimilarities for samples within time and  
90 treatment group (CTX-T infants in red and CTX-N infants in blue) for **A.** microbial taxonomic  
91 profiles, **C.** functional metabolic pathways, and **E.** resistance gene profiles. Comparisons are  
92 made to the initial time of collection (time A) using paired Wilcoxon tests and p-values are  
93 reported above the boxplots. Paired samplings were bootstrapped to get the distributions shown  
94 in **B.** for microbial taxonomic profiles, **D.** for functional metabolic pathways, and **F.** for  
95 resistance gene profiles. The distributions show deviation of times B and C from the initial time  
96 A for CTX-N infants (blue, CTX-) and CTX-T infants (red, CTX+). Black points represent the  
97 mean difference of the bootstrapped sampling distribution from the starting value in time A and  
98 the black lines represent 95% confidence intervals.
