### **Supplementary Methods**

#### **Rotterdam RNA-Seq cohort includes sample size, RNA library preparation, sequencing, and data processing and data analysis**

Rotterdam Study RNA-Seq data was generated as part of the BIOS project and is described in detail elsewhere<sup>1</sup>. In short, Total RNA was globin cleared using Ambion GLOBINclear and sequenced to a minimum yield of 15M paired-end reads on an HiSeq 2000. Data was aligned to reference genome hg19 using STAR, followed by quantification of all GENCODE genes using custom scripts. We then extracted the counts of 56,515 transcripts for 807 participants of the Rotterdam Study (RS-I, II and III). Using edgeR, CPM values were generated for each sample, and transcripts with CPM<1 in more than 90% of samples were excluded, allowing 15,331 transcripts in further analysis.

For each coded phenotype, linear regression analysis was performed in R, correcting for age, gender, flowcell and the number of sequenced reads. A custom linear regression

script was used as the dataset was too large to be processed by edgeR or DEseq. The effect sizes and uncorrected p-values were reported for each of the candidate genes of the discovery analysis.

### **Rotterdam Study CAC data**

The Rotterdam Study is a population-based cohort study that started in 1990 (PMID: 26386597). All inhabitants aged 55 years and older, living in a suburb of Rotterdam were invited and 7983 agreed to participate (78%). This group is referred to as Rotterdam Study cohort I (RS-I). In 2000, a second study cohort was introduced (RS-II) comprising 3011 persons.

CAC was measured in the epicardial coronary arteries using an EBCT with a C-150 Imatron scanner (GE-Imatron, San Francisco, California) in the third visit of the original cohort (RS-I) and the first visit of the extended cohort (RS-II) (PMID: 20946998). Participants exercised adequate breath-holding before the scan. Thirty-eight images were obtained from the level of the root of the aorta through the heart with 100-ms scan time and 3-mm slice thickness. Images were acquired at 80% of the cardiac cycle, using electrocardiogram triggering, during a single breath-hold. Quantification of CAC was performed with Acculmage software (Acculmage Diagnostics Corporation), displaying all pixels with a density above 130 Hounsfield Units (HU). A calcification was defined as a minimum of 2 adjacent pixels with a density over 130 HU<sup>2</sup>.

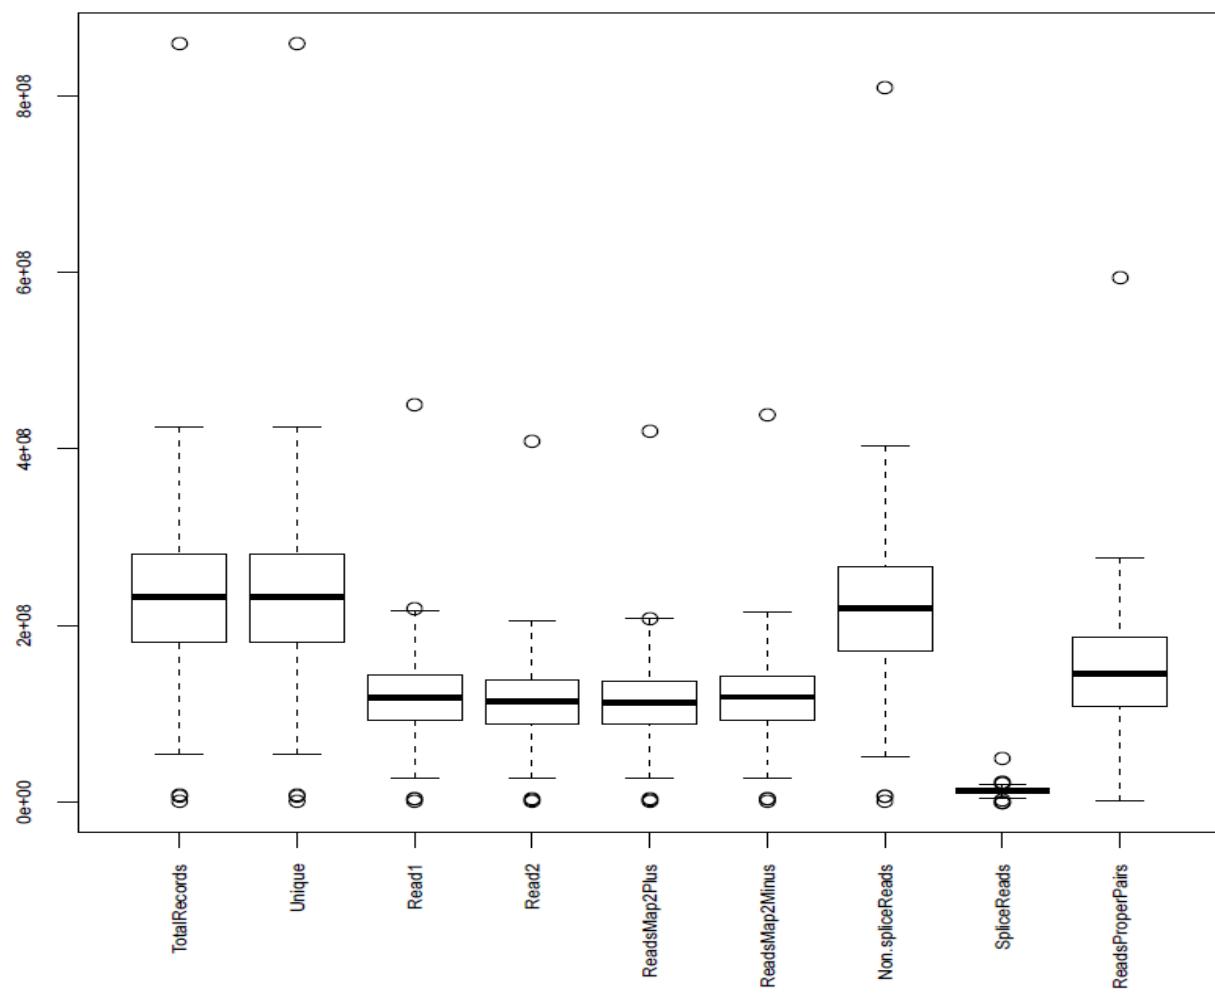

CAC was assessed by a 16-slice or 64-slice MDCT scanners (SOMATOM Sensation 16 or 64, Siemens, Forcheim, Germany) in the fourth visit of the original cohort (RS-I) and the second visit of the extended cohort (RS-II)<sup>3</sup>. The cardiac scan

reached from the apex of the heart to the tracheal bifurcation. Atherosclerotic calcification was identified based on a threshold of 130 HU, using dedicated software (Syngo Calcium Scoring, Siemens, Forcheim, Germany). Calcification was quantified with the Agatston score using dedicated software (syngo Calcium Scoring, Siemens, Forcheim, Germany). The total score per vascular bed was calculated by adding the scores of all lesions in that bed<sup>3</sup>.

#9 clinical covariates are DBP, TC, HDL, smoking, diabetes and treatments for hypertension, lipid, diabetes and aspirin, which are different across MI, high CAC and controls ( $P<0.05$ , see Table 1).

Model 1: adjusted for sex, batch, and two SVs (results were shown in Table 2)

Model 2: adjusted for additional 9 covariates (9 genes remained significant at FDR<0.1

**Supplemental Table 7. GSEA pathway analysis and leading-edge genes (FDR<0.25 including 215 gene sets are upregulated in phenotype MI, and 8 gene sets are upregulated in controls)**
