Table S1: Cell volume and formula data for $\epsilon\text{-Fe}_{2+x}\text{N}$ mined from the ICSD [28] and used to build the calibration and subsequent stoichiometry estimation shown in Figure S1. Note – quality data highlights with an asterisk data considered to be of highest quality by ICSD.

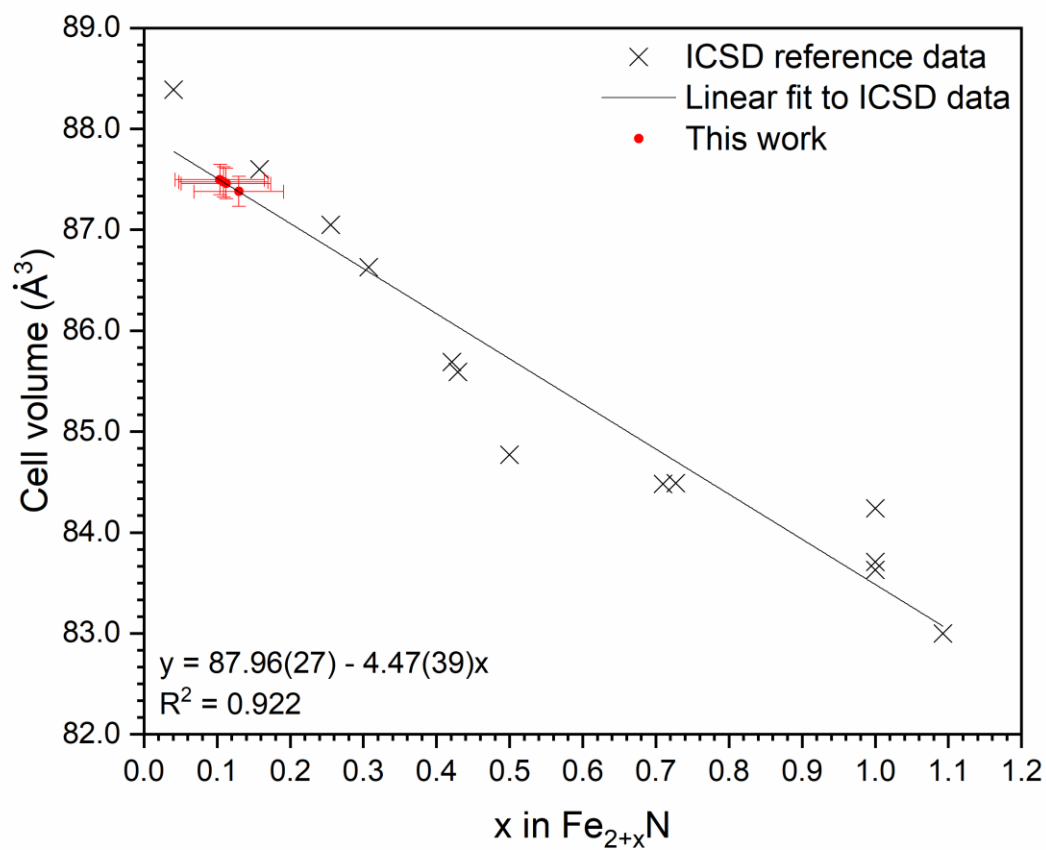

Figure S1: Dependence of unit cell volume on stoichiometry x in ϵ -Fe_{2+x}N assuming a linear dependence. Black crosses indicate data for $P6_322$ ϵ -Fe_{2+x}N data sourced from the ICSD (Table S1), normalised to the Fe_{2+x}N composition. The applied linear fit was then used to calculate the estimated x values for the data points in this work shown in red.

Figure S2: SEM images of raw and Fe_3O_4 powders reacted with NaNH_2 at $170\text{ }^\circ\text{C}$ for 24, 48 and 96 h. Top row L-R: untreated Fe_3O_4 , 24 h product. Bottom row L-R: 48 h product, 96 h product.

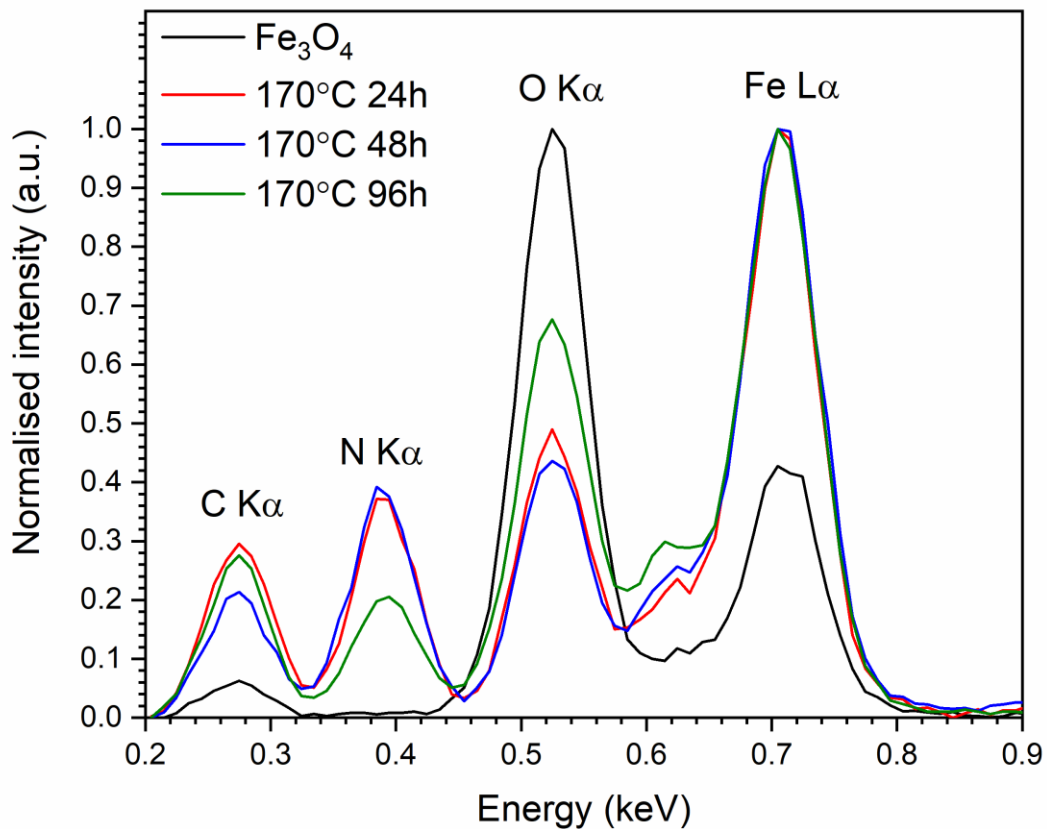

Figure S3: EDX spectra for starting Fe₃O₄ reagent (black) and products of amide reactions at 170 °C for 24 / 48 / 96 h (red/blue/green). Note the presence of N K α emission only in the reaction products. C K α emission is attributed to the adhesive tab used for securing the powder during SEM measurement.

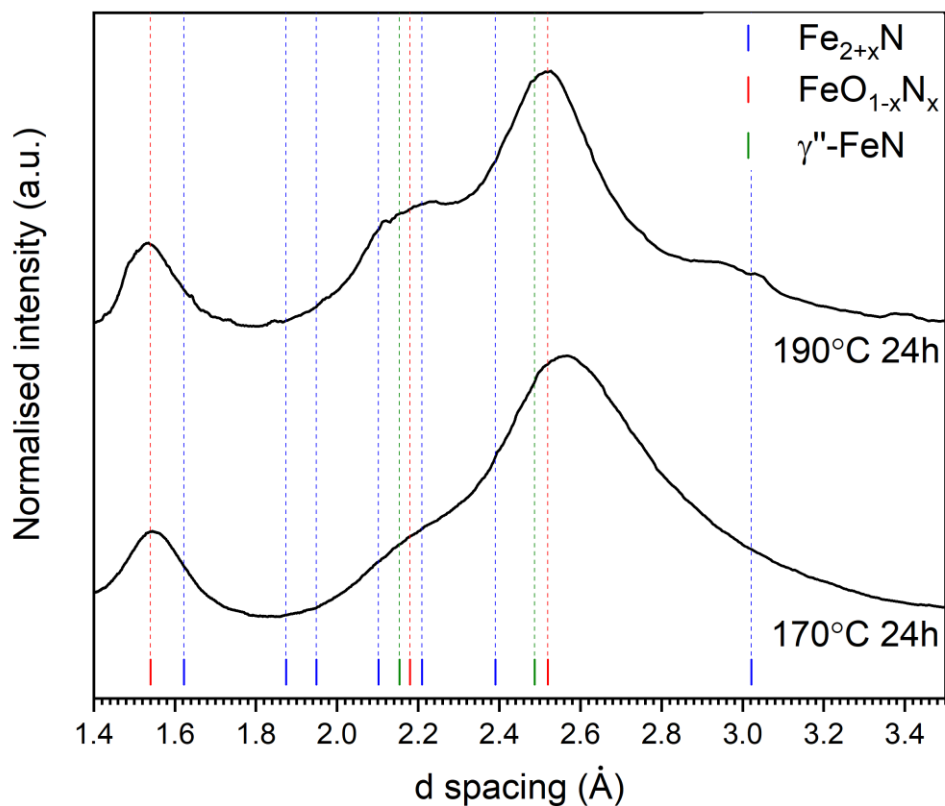

Figure S4: d spacing data integrated from electron diffraction linescans for (bottom) 170 °C / 24 h and (top) 190 °C / 24 h samples. Indexed are allowed reflections for $\epsilon\text{-Fe}_{2+x}\text{N}$ (blue), $\text{FeO}_{1-x}\text{N}_x$ (red) and $\gamma''\text{-FeN}$ (green) confirming the findings from recrystallisation data of the presence of the oxynitride and nitride phases.

Figure S5: Thermogravimetry (TG, black) curve and mass spectrometry (MS) signals of 190 °C / 24 h product (mass numbers 18 and 28 represent H₂O and N₂).
