

ON-LINE FIGURE. Several tracts showed sex effects (in *orange* color) in white matter development as reflected by differences ($P < .05$, corrected) in DTI parameter values (MD, mean diffusivity; AD, axial diffusivity) between sexes for the 8-year-old children: On the other hand, there were no sex effects in white matter development for the 2-week-old term infants. No tracts or voxels showed any difference ($P < .05$, corrected) in any DTI parameters between sexes for these infants.
