Part I

1) Synthesis of graphene oxide (GO)

GO was synthesized from natural graphite (325 mesh) via a modified Hummer's method. Briefly, 1 g graphite powder, 3 g KMnO_4 and 60 mL concentrated H_2SO_4 solution without mix was respectively introduced in a refrigerator ($-18\text{ }^\circ\text{C}$) for 30 min. Then the graphite powder, KMnO_4 and concentrated H_2SO_4 solution were successively introduced in a flask (250 mL). The mixture was stirred for 2 h and the temperature was controlled below $20\text{ }^\circ\text{C}$ in ice bath. After these steps, the mixture was moved to oil bath at $50\text{ }^\circ\text{C}$ and sequentially stirred for 6 hours. The result mixture was slowly poured into a 500 mL beaker with 120 mL of distilled water. The 30 % H_2O_2 solution was dropwise added into the mixture until no bubbling. Finally, the crude product was washed repeatedly with deionized water by centrifuge until the filtrate became neutral. The obtained brown-yellow graphene oxide was saved for use.

2) Synthesis of fluorinated GO (F-GO)

F-GO were synthesized through the one-step hydrothermal process using HF as the fluorination source. Typically, 1 mL HF (40 w.t.%) was added into 35 mL GO (1.0 mg mL^{-1}) aqueous dispersion and this mixture was ultrasonicated for 5 min. Then the dispersion was transferred to a 50 mL Teflon-lined autoclave and sealed. The hydrothermal process was carried out at $120\text{ }^\circ\text{C}$ for 24 h. After cooling to the room temperature, the prepared F-GO were taken out and immersed into the deionized water to remove the residual acid. The deionized water was changed once 12 h until neutral. The sample was finally vacuum freeze-dried for 48 h.

3) Synthesis of reduced graphene oxide aerogel (rGA)

In a typical fabrication process, 50 mg of GO and 50 mg of sodium dodecyl sulfate (SDS) were dispersed in 10 mL and 1 mL deionized water, respectively, and mixed evenly. Then 100 mg L-ascorbic acid (L-AA) were added into the mixed solution. The template foams were

formed after stirring the mixed solution at 2500 rpm for 10 minutes. Then the template foam was sealed and heated at 80 °C for 12 hours to get hydrogel. The hydrogel was frozen at 18 °C for 4 hours and then thawed at 25 °C. The hydrogel was washed several times with ethanol to remove unreacted substances. rGA could be obtained by drying the hydrogel at room temperature.

4) Synthesis of Cu NPs loaded rGA (Cu-rGA)

In a typical fabrication process, 16 mg of polyvinylpyrrolidone (PVP) and 80 mg of $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ were dissolved into 50 mL deionized water. Then, 5 mg of rGA was soaked in the above mixed solution at 25 °C for 24 hours, and was dried in vacuum drying oven. Finally, the sample was pyrolyzed at 500 °C for 2 h under the protection of Ar, and Cu-rGA aerogel can be obtained after cooling to room temperature.

5) The UPLC analytical method of PFOA

Separation of PFOA was performed using a ultra performance liquid chromatography (UPLC; Ultimate 3000, Dionex Inc., United States of America (USA)) consisting of a autosampler and a LC Pump. Aliquots of 10 μL of purified PFOA-methanol eluents were injected onto a guard column and an analytical column (50 \times 2.1 mm Waters BEH C18 column, 1.7 μm pore size, Waters, USA) by the autosampler, and a constant mobile phase of acetonitrile and perchloric acid aquatic solution (pH = 3) was delivered at a flow rate of 0.300 mL/min by the LC Pump. The eluent conditions were 50% acetonitrile and 50% perchloric acid aquatic solution keeping for 5 min at 192 nm. The column temperature were maintained at 50 °C. In addition, in order to avoid the contamination among different samples, the needle of autosampler was washed and flushed using 90% of methanol (V/V) after every injection.

6) Adsorption kinetic Models

Adsorption kinetics data were simulated by pseudo-first-order kinetics model, pseudo-second-order kinetics model, intra-particle diffusion model and Boyd model, and depicted by Eq. (2), (3), (4) and (5), respectively.

$$\text{Pseudo-first-order model: } q_t = q_e(1 - e^{-k_1 t}) \quad (1)$$

$$\text{Pseudo-second-order model: } q_t = \frac{t}{\frac{1}{k_2 q_e^2} + \frac{t}{q_e}} = \frac{t}{\frac{1}{v_0} + \frac{t}{q_e}} \quad (2)$$

$$\text{Intra-particle diffusion model: } q_t = K_i t^{1/2} + L \quad (3)$$

$$\text{Boyd model: } B_t = -0.4977 - \ln\left(1 - \frac{q_t}{q_e}\right) \quad (4)$$

where q_e (mg g⁻¹) and q_t (mg g⁻¹) are the amounts of contaminants adsorbed on the adsorbents at equilibrium and a given time t (min), respectively. k_1 (min⁻¹) and k_2 (g mg⁻¹ min⁻¹) are the adsorption rate constants of the pseudo-first-order model and the pseudo-second-order model, respectively. v_0 (μg min⁻¹ g⁻¹) is the initial adsorption rate; K_i (mg g⁻¹ min^{-1/2}) is the overall diffusion constant for the sorption, and L (mg g⁻¹) is the intercept of the vertical axis; B is $\pi^2 D_i r^{-2}$ (D_i is the effective diffusion coefficient of the adsorbate and r is the radius of adsorbent particles hypothesized to be spherical).

7) Adsorption isotherm Models

Adsorption data of PFOA onto tested adsorbents were analyzed by Langmuir and Freundlich models, where exhibited adsorption characteristics. Therefore, two isotherm models are expressed as following.

$$\text{Langmuir model: } q_e = \frac{q_m b C_e}{1 + b C_e} \quad (5)$$

$$\text{Freundlich model: } q_e = K_F C_e^{1/n} \quad (6)$$

where q_e (mg g⁻¹) is the solid-phase concentration, C_e (mg L⁻¹) is the solution concentration, q_m (mg g⁻¹) is the maximum adsorption capacity, b is Langmuir constant, K_F (mg^(1-1/n) L^{1/n} g⁻¹) and n are the Freundlich adsorption constants.

Table S4. RMSE and R² values of test models

| T (°C) | Langmuir | | Freundlich | | Model 1 | | Model 2 | | Model 3 | |
|--------|----------------|--------|----------------|--------|----------------|--------|----------------|--------|----------------|--------|
| | R ² | RMSE | R ² | RMSE | R ² | RMSE | R ² | RMSE | R ² | RMSE |
| 20 | 0.9987 | 0.3653 | 0.9727 | 1.7314 | 0.9924 | 0.3662 | 0.9972 | 0.3622 | 0.9992 | 0.3458 |
| 25 | 0.9981 | 0.3529 | 0.9705 | 1.6768 | 0.9957 | 0.3528 | 0.9966 | 0.3584 | 0.9989 | 0.3345 |
| 30 | 0.9976 | 0.4615 | 0.9603 | 1.7372 | 0.9964 | 0.4612 | 0.9969 | 0.4585 | 0.9984 | 0.4257 |
| 35 | 0.9964 | 0.5502 | 0.9646 | 1.7405 | 0.9961 | 0.5508 | 0.9959 | 0.5425 | 0.9981 | 0.5109 |
| 40 | 0.9977 | 0.4244 | 0.9701 | 1.5587 | 0.9973 | 0.4248 | 0.9986 | 0.4227 | 0.9987 | 0.4036 |

The R² coefficient determines the least sum of squares of the residuals between experimental and modelling data. The second coefficient is defined by the residual root mean square error (RMSE), which can estimate the standard fault of regression between the experimental data and the fit model.

The standard error estimated by RSME is given by:

$$\text{RMSE} = \sqrt{\frac{\text{RSS}}{m-p'}}$$

Where RSS represents the sum of residual squares, p' is an adjustable parameter and finally m' represents the number of points of the experimental isotherm. In other words, if the adsorption model is adequate and the estimated parameters are unbiased, then approximately 95 % of the estimated values should fall within $\pm 2\text{RMSE}$ of their true values.

Table S5. Parameters of model 3 for the adsorption of PFOA on Cu/F-rGA.

| T(°C) | <i>n</i> | N_M (mg g ⁻¹) | C_1 (mg L ⁻¹) | C_2 (mg L ⁻¹) | N_2 |
