#### eMethods.

### Description of Swedish registers used in this study

For this study, the data are from national Swedish registers. Each resident in Sweden is assigned a unique personal identification number, which is included in all registers and allows data linkage across the registers. The Medical Birth Register<sup>1</sup> includes maternal, obstetric and neonatal data for > 98% of all births in Sweden since 1973 including maternal diagnoses during pregnancy and child birth coded according to Swedish versions of the International Classification of Diseases (i.e. ICD-8 from 1969 to 1986 and ICD-9 from 1987 to 1996). The Multi-Generation Register<sup>2</sup> includes information on familial relationships for all individuals born since 1932, such that siblings, parents and offspring can be identified. The Total Population Register<sup>3</sup> includes dates of birth, death, and migration since 1915. The Cause of Death Register<sup>4</sup> is a virtually complete register of all deaths in Sweden since 1961. The National Patient Register<sup>5</sup> was established in 1964 and has covered all inpatient hospital admissions since 1987 and outpatient hospital visits to physicians since 2001. Diagnoses in the National Patient Register are coded according to Swedish versions of the International Classification of Diseases (i.e. ICD-9 from 1987 to 1996 and ICD-10 from 1997 onwards), and have been demonstrated to be of high validity with a reported positive predictive value for most diagnoses of 85-95%. Socioeconomic variables are registered in LISA (Longitudinal Integration Database for Health Insurance and Labour Market Studies), 6 which is managed by Statistics Sweden. Using these data sources, we identified 1,085,024 singletons born in Sweden between 1987 and 1996 with data on maternal hypertensive disorders of pregnancy (HDP) and who were followed up until December 31st, 2014. This cohort was used for examining associations of maternal HDP with offspring risk of autism spectrum disorders, attention-deficit/hyperactivity disorder and intellectual disability. For the sibling comparison analysis, we used a subset of the 1987-1996 birth cohort, comprising 716,521 individuals born to 324,713 mothers identified through linkage to the Multi-Generation Register.

The association of maternal HDP with overall cognitive performance in offspring was explored in a cohort including 295,448 male singletons born in Sweden between 1982 and 1992, with available data on cognitive function scores at the first military assessment, as identified through linkage to the Swedish Military Conscription Register. In Sweden, military conscription was mandatory for men at the age of 18 years, but from 2002/2003 the number of conscripts declined substantially due to reduced military needs, and conscription was officially suspended in 2010. Among this military conscription cohort, we identified 70,642 siblings born to 34,157 mothers based on linkage to the Multi-Generation Register. During the study period, different cognitive function tests were used as described in detail elsewhere. Priefly, between 1982 and 1994 a written test was used, and after 1994 a computer-based test. In both tests a global cognitive function score was obtained based on subtasks covering logical, spatial, verbal and technical abilities, and this score was standardised against the entire tested population to follow a Gaussian distribution with values between 1 and 9.

### Handling of missing covariate data

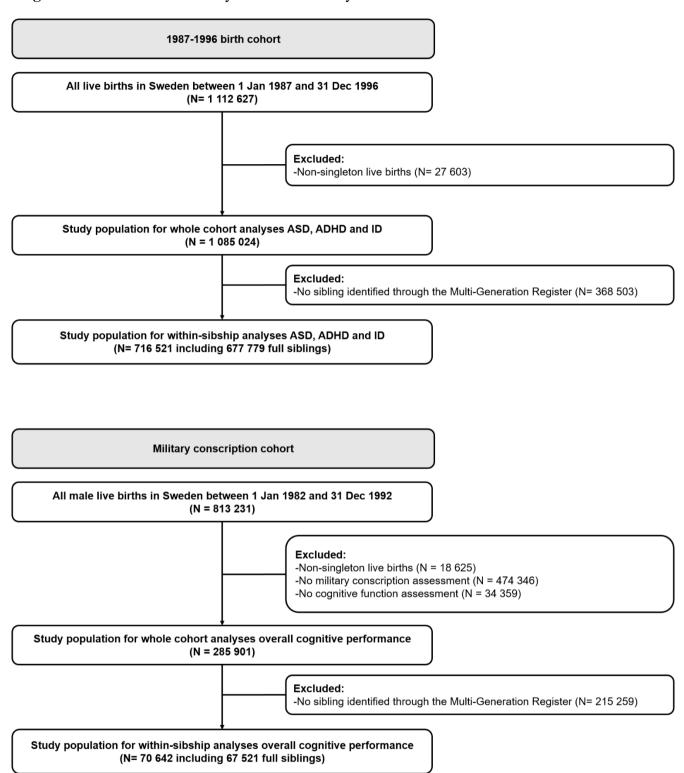

In total, 507,479 offspring (46.8%) in the 1987-1996 birth cohort and 131,861 offspring (46.1%) in the military conscription cohort had missing data on one or more covariates, which was mainly due to missing information on early pregnancy maternal BMI and height. This is because maternal weight and height were not routinely recorded in women who were pregnant before 1992. Missing covariate data were imputed under the 'missing at random assumption' using multivariate multiple imputation with chained equations, <sup>8</sup> and 5 imputed datasets were generated. The imputation model included the exposure (HDP), the outcome (for autism spectrum disorders, attention-deficit/hyperactivity disorder and intellectual disability the Nelson-Aalen estimator of the baseline cumulative hazard and event indicator for these outcomes), all covariates included in the multivariable adjusted model (i.e. birth year, offspring sex, maternal age, parity, height, body mass index, smoking, pregestational diabetes, parental education, occupation, and marital status). Main analyses were based on imputed data, but we also conducted sensitivity analyses with complete case data only.

eFigure. Flow Charts of the Study Cohorts for Analysis

Associations of HDP with autism spectrum disorders, attention-deficit/hyperactivity disorder and intellectual disability were studied in the 1987-1996 birth cohort. Associations of HDP with cognitive function in the normal range was studies in the military conscription cohort.

Abbreviations: ASD = autism spectrum disorders; ADHD = attention-deficit/hyperactivity disorder; ID = intellectual disability.

eTable 1. International Classification of Diseases Codes for Exposure, Outcomes and Covariates Included in Analyses

Variable	Source	Definition	ICD code
Exposure	Medical Birth Register	Hypertension disorders of pregnancy	ICD-9 (642), ICD-8 (401, 637)
Outcome	National Patient Register	Autism spectrum disorders	ICD-10 (F84), ICD-9 (299)
Outcome	National Patient Register	Attention-deficit hyperactivity disorder	ICD-10 (F90), ICD-9 (314)
Outcome	National Patient Register	Intellectual disability	ICD-10 (F70-79), ICD-9 (317-319)
Covariate	Medical Birth Register	Maternal pregestational diabetes	ICD-9 (250), ICD-8 (250)
Covariate	Medical Birth Register	Other conditions complicating pregnancy, childbirth or the puerperium (gestational diabetes, thyroid dysfunction, anaemia, drug dependency, mental disorders, congenital cardiovascular diseases, other cardiovascular diseases, bone and joint disorders of back pelvis and lower limbs)	ICD-9 (648) <sup>a</sup>

<sup>&</sup>lt;sup>a</sup> Information on other conditions complicating pregnancy, childbirth or the puerperium was only available for offspring with ICD-9 diagnostic code data, as equivalent codes do not exist in the ICD-8 chapter.

Abbreviations: ICD = international classification of diseases.

Hazard ratios for autism spectrum disorders, attention-deficit hyperactivity disorder and intellectual disability in the 1987-1996 birth cohort comparing offspring born to mothers with HDP with those born to mothers without HDP (= reference category) – analysis including cases based on two repeat diagnoses.

Model 1: adjusted for calendar year of birth only.

Model 2: adjusted for calendar year of birth, offspring sex, maternal age, parity, height, body mass index, smoking, pregestational diabetes, parental education, occupation and marital status. The within-sibship models include offspring with at least 1 sibling and compare siblings discordant for maternal HDP, including all covariates listed in whole cohort analyses except for maternal height and marital status (model 2), as these variables were among siblings within the same family.

N of within-sibship analyses refers to the number of offspring with siblings discordant on maternal HDP and each neurodevelopmental outcome.

Hazard ratios for autism spectrum disorders, attention-deficit hyperactivity disorder and intellectual disability in the 1987-1996 birth cohort and mean difference in cognitive function score in the military conscription cohort of offspring born between 1987 and 1996 comparing offspring born to mothers with HDP with those born to mothers without (= reference category).

Model 4: adjusted for calendar year of birth, offspring sex, maternal age, parity, height, body mass index, smoking, pregestational diabetes, parental education, occupation and marital status, other conditions complicating pregnancy, birth or the puerperium.

The within-sibship models include offspring with at least 1 sibling and compare siblings discordant for maternal HDP, including all covariates listed in whole cohort analyses except for maternal height and marital status, as these variables did not vary among siblings within the same family.

N of within-sibship analyses refer to the number of offspring with siblings discordant on maternal HDP and each neurodevelopmental outcome.

**eTable 9.** Associations Between Maternal Hypertensive Disorders of Pregnancy and Risk of Neurodevelopmental Disorders in Offspring – Analyses Stratified by Calendar Period of Birth

Hazard ratios for autism spectrum disorders, attention-deficit hyperactivity disorder and intellectual disability in the 1987-1996 birth cohort comparing offspring born to mothers with HDP with those born to mothers without (= reference category) – sensitivity analysis stratified by calendar period of birth.

Model 1: adjusted for calendar year of birth only.

Model 2: adjusted for calendar year of birth, offspring sex, maternal age, parity, height, body mass index, smoking, pregestational diabetes, parental education, occupation and marital status. The within-sibship models include offspring with at least 1 sibling and compare siblings discordant for maternal HDP, including all covariates listed in whole cohort analyses except for maternal height and marital status (model 2), as these variables did not vary among siblings within the same family.

P values refer to p values from interaction tests.

Abbreviations: HDP = hypertensive disorders of pregnancy; HR = hazard ratio; CI = confidence interval.
