## **eMethods 1. Protocol and Registration, Eligibility Criteria, Information Sources, Study Selection, Risk of Bias in Individual Studies, Data Extraction, Data Items, Statistical Analysis, and Evidence Synthesis**

We conducted a systematic review of the literature. Rapid reviews are used by health decision-makers (clinicians, patients, managers, and policy makers) who need timely access to health information to plan, develop and implement health care and policies.<sup>9-12</sup> We used methodology recommended by the World Health Organization, previously used by our group,<sup>13,14</sup> to answer our questions.

### **Protocol and Registration**

We reported our review according to the Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA) checklist.<sup>15</sup> The review protocol was submitted to the Open Science Framework Registry on April 21, 2020 (<https://osf.io/ux7wc>).

### **Eligibility Criteria**

#### *Participants*

We included studies of healthy and symptomatic participants.

#### *Interventions*

SMT includes spinal manipulation and spinal mobilization provided by any type of provider. Spinal manipulation includes techniques incorporating a high-velocity, low amplitude impulse or thrust (HVLA) applied at or near the end of a joint's passive range of motion.<sup>16</sup> Spinal mobilization includes techniques incorporating low-velocity and varying amplitude oscillatory movements within a joint's passive range of motion.<sup>16-18</sup> Spinal manipulation and mobilization involve manual, mechanically- or instrument-assisted procedures.

#### *Comparators*

We considered placebo, sham therapies, wait listing, usual care, no interventions, medication and other therapies.

#### *Outcomes*

We investigated clinical outcomes and changes in levels of immunological, endocrine and other physiological biomarkers. Clinical outcomes included incidence of infection or infectious disease, or changes in their disease-specific outcomes (e.g. number and severity of symptoms or faster recovery from illness). A biomarker is a "characteristic that is objectively measured and evaluated as an indicator of normal biological processes, pathogenic processes, or pharmacologic responses to a therapeutic intervention."<sup>19</sup> Biomarkers encompass a multitude of physiological indicators including molecules in the immune system such as cytokines, and chemokines, as well as endocrine biomarkers such as cortisol, testosterone, catecholamines and others.

#### *Study Designs*

Eligible study designs were randomized controlled trials (RCTs) and cohort studies. All other study designs were excluded.

### **Information Sources**

The search strategy was developed in consultation with a health sciences librarian, and a second librarian reviewed the strategy to ensure accuracy. We systematically searched five databases that index the manual therapy literature published by researchers from various health professions from inception to April 15, 2020: MEDLINE (U.S. National Library of Medicine, through Ovid Technologies Inc.), Cumulative Index to Nursing and Allied Health Literature (CINAHL, through EBSCOhost), Index to Chiropractic Literature (ICL, Chiropractic Library Collaboration), Cochrane Central Register of Controlled Trial and Embase (both through Ovid Technologies Inc). Search terms consisted of subject headings specific to each database (e.g. MeSH in MEDLINE) and free text words relevant to our objectives and study design (see Appendix 1). We restricted our search to papers published in English in peer-reviewed journals.

### **Study Selection**

A two-phase screening process was used to identify eligible studies. In phase one screening, we reviewed titles and abstracts and classified articles as possibly relevant or irrelevant. During phase two screening, the full text of possibly relevant articles was reviewed for final determination of eligibility. A trained reviewer (NC) conducted all of the

screenings. Prior to phase one screening, the quality of screening by NC was established by randomly selecting ten percent of all eligible articles, which were screened independently by a second experienced reviewer (SM). A 95% level of agreement was required between the two reviewers before moving to full screening. Once the 95% agreement was achieved, one reviewer (NC) completed phase one screening. For phase two screening, all potentially eligible articles were screened by rotating pairs of experienced reviewers (PC, CC, SM, JDC, SI, JTI).

### **Risk of Bias in Individual Studies**

The lead author (NC) critically appraised the internal validity of relevant articles using the Scottish Intercollegiate Guidelines Network (SIGN) criteria for RCTs and cohort studies.<sup>20</sup> A quality control step in the critical appraisal of studies was included, wherein the investigator assessing the risk of bias (NC) presented a summary of the critical appraisals to seven experienced reviewers (PC, SHJ, CC, SM, JDC, SI, JTI) who validated the outcome of the appraisals. Disagreements regarding the internal validity of papers were resolved through discussion. The lead author created risk of bias tables for all eligible studies, which was validated by the other reviewers (PC, SHJ, CC, SM, JDC, SI, JTI).

### **Data Extraction**

The lead author (NC) extracted data from high and acceptable quality (low risk of bias) studies and built evidence tables stratified by study objective and nature of the outcome. Data extraction was validated by the other reviewers (PC, SHJ, CC, SM, JDC, SI, JTI). We contacted the study authors when clarification or additional information was necessary to populate the evidence tables. Evidence tables summarized the pertinent information and were used to create summary statements describing the state of the evidence.

### **Data Items**

Information extracted from each study included study characteristics, (e.g. author, year and country of publication, study design, sample size, length of follow up), participant characteristics (e.g., age, and body region treated), intervention characteristics (e.g., description of interventions and comparison groups), and outcome data (e.g., incidence of infection or infectious disease, disease-specific outcomes, changes in the levels of immunological, endocrine and other physiological biomarkers).

### *Classification of Clinical Trial Phases*

We categorized RCTs into the different phases of clinical trials as described by Campbell et al.<sup>21</sup> The purpose of a phase 0 (exploratory) study is to gather preliminary data on whether the intervention behaves as expected in humans based on preclinical studies, and involves limited human exposure (10-15 healthy volunteers) to the intervention, with no therapeutic or diagnostic goals.<sup>21</sup> A phase 1 (safety) study aims to determine safety of the intervention and typically involves 20-80 healthy volunteers.<sup>21</sup> A phase 2 (biologic activity) study aims to establish proof of concept that the intervention has biologic activity, usually involving 100-300 patients with specific diseases.<sup>21</sup> A phase 3 (efficacy) study aims to confirm the efficacy and effectiveness of the intervention, monitor side effects, and frequently involves 300-3000 patients with specific diseases.<sup>21</sup> A phase 4 (post-marketing/confirmatory) study aims to provide surveillance and additional information on the intervention's risks, benefits and best use after the intervention is approved for human use, and involves several thousand patients treated with the intervention.<sup>21</sup>

### **Statistical Analysis**

We reported or computed (when data were available), the incidence and 95% confidence intervals (CI) of infection or infectious disease, and mean difference and 95% CI in change in the level of biomarkers. We reported or calculated the pre-post difference in means or mean differences between groups based on data derived from regression models. Incidence was measured by calculating the number of new cases of infection or infectious disease in a group divided by the total number of participants in the same group. Confidence intervals were calculated using incidence of infection or infectious disease in each group, total number of participants in each group, and  $\alpha = 0.05$ .

### **Evidence Synthesis**

We synthesized the evidence from high and acceptable quality studies according to the Synthesis without Meta-Analysis (SWiM) Guideline,<sup>22</sup> study objective, and type of biomarker. We restricted our synthesis to studies with high or acceptable quality because low/unacceptable quality studies are more likely to yield biased estimates of effect sizes.<sup>23-27</sup>

<sup>a</sup>Red: no effect of SMT; green: effect of SMT; yellow: results depend on processing of cells.

<sup>b</sup>Derived from regression models in Table 1, using a pre value of 3.0. Note that intercepts in the model are not significantly different, but the slope for SMT is significantly higher ( $p < .005$ ) than the slope for either sham or soft tissue.

<sup>c</sup>Derived from regression models in Table 2, using a pre value of 1.75. Note that intercepts in the model are not significantly different, but the slope for SMT is significantly higher ( $p < .005$ ) than the slope for either sham or soft tissue.

<sup>d</sup>SI conversion factors: To convert TNF- $\alpha$  from pg/mL to nM/L, multiply values by  $5.85 \times 10^{-5}$ . To convert IL-1 $\beta$  from pg/mL to nM/L, multiply values by  $5.85 \times 10^{-5}$ . To convert substance P from pg/mL to pmol/L, multiply values by 0.742.

<sup>e</sup>Unable to calculate mean difference (95% CI) due to lack of data reported.

<sup>f</sup>While a point estimate of the magnitude of the effect can be determined, a confidence interval cannot with the data as reported.

**eTable 2.** Evidence Table for Endocrine and Other Physiological Markers

1 <sup>st</sup> Author, Year	Study design, Participants, Setting, Number (n) enrolled	Interventions, Provider, Number (n) of subjects at baseline	Comparison, Provider, Number (n) of subjects at baseline	Follow-up	Outcome Measures	Results	Quality of Evidence	Conclusion (notes) <sup>a</sup>
Mackawan 2007 <sup>6</sup>	RCT; patients with chronic LBP (>12 wks), 20-60 yo, 61% female  Physical therapy department in Khon Kaen, Thailand  (n=67)	TTM Deep massage with prolonged pressure (10 min) on the muscles along with passive stretching  One session by physical therapist  (n=35)	Joint mobilization Grade 2 mobilization, 5 min/set, 2 sets/level at lumbar spinous process of L2–L5  One session by physical therapist  (n=32)	5 min post-tx  No loss to follow-up	Substance P <sup>b</sup>	Mean difference (95% CI) in change from pre- to post-tx (pg/mL): 1.2 (-21.6, 24.1)	Acceptable (+)	SMT is not associated with substance P levels
Puhl 2012 <sup>7</sup>	RCT; healthy adults, 20-45 yo, 47% female  Chiropractic teaching clinic in Toronto, Canada	SMT: HVLA thrust, either 1) combination type adjustment (hypothernar transverse push) for segments T1 to T3,	Sham: HVLA thrust, either combination or Carver-Bridge without cavitation	i. immediately post-tx ii. 15 min post-tx  Loss to follow-up: SMT: 5.3% Sham: 14.3%	Norepinephrine <sup>b</sup> Epinephrine <sup>b</sup>	<b>Immediately post-tx</b>  <b>SMT vs. Sham:</b> Mean difference in amount of change from baseline (nM):  Norepinephrine: -0.06 (-0.26, 0.38) <sup>c</sup> Epinephrine: 0.05 (-	Acceptable (+)	SMT is not associated with norepinephrine and epinephrine levels

	(n=56)	or 2) Carver-Bridge type adjustment (bilateral hypothenar push) for segments T4 to T6  One session by chiropractor in teaching clinic  (n=26)	One session by chiropractor in teaching clinic  (n=30)			0.39, 0.29 <sup>c</sup>  <b>15 min post-tx</b>  <b>SMT vs. Sham:</b> Mean difference in amount of change from baseline (nM):  Norepinephrine: 0.01 (-0.07, 0.05) <sup>c</sup> Epinephrine: 0.01 (-0.07, 0.05) <sup>c</sup>		
Sampath 2017 <sup>8</sup>	RCT; healthy men, 18-45 yo  Recruited through advertising  Physical therapy department in Dunedin, New Zealand  (n=24)	SMT HVLA thrust to T/S through the participant's upper extremity and thorax upon expiration  One session by physical therapist  (n=12)	Sham tx identical to SMT but therapist did not place a fixating hand against the thoracic spine, no thrust  One session by physical therapist  (n=12)	i. 5 min post-tx ii. 30 min post-tx iii. 6 hrs post-tx  No loss to follow-up	Salivary cortisol <sup>b</sup> Testosterone <sup>b</sup> T/C ratio <sup>b</sup> O <sub>2</sub> Hb <sup>b</sup> HRV <sup>b</sup>	<b>5 min post-tx</b>  <u>Mean difference (95% CI) in (pg/m)</u>  Cortisol: -0.4 (-0.6, -0.12) <sup>d</sup> Testosterone: 10.1 (-43.5, 63.8) T/C ratio: 0.04 (-0.05, 0.13) O <sub>2</sub> Hb: 0.89 (13.9, 15.6) HRV: -0.11 (-0.47, 0.25)  <b>30 min post-tx</b>  <u>Mean difference (95% CI) in (pg/m)</u>  Cortisol: -0.20 (-0.46, 0.05)	Acceptable (+)	SMT associated with changes in cortisol levels at 5 minutes only  (clinical meaning of effect is unknown)  SMT is not associated with levels of testosterone, T/C ratio, O <sub>2</sub> Hb, and HRV

					<p>Testosterone: -6.29 (-60, 47.5)  T/C ratio: 0.00 (-0.09, 0.09)  O<sub>2</sub>Hb: 15.2 (-30.5, 60.9)  HRV: 0.01 (-0.47, 0.25)</p> <p><b>6 hrs post-tx</b></p> <p><u>Mean difference (95% CI) in (pg/m)</u></p> <p>Cortisol: 0.23 (-0.06, 0.53)  Testosterone: -12.9 (-47.5, 21.8)  T/C ratio: -0.09 (-0.16, -0.04)</p> <p>O<sup>2</sup>Hb and HRV data not reported for 6 hrs post-tx</p>

Abbreviations: C/S cervical spine, HRV heart rate variability, HVLA high velocity low amplitude, LBP low back pain, min minutes, NO nitric oxide, O<sub>2</sub>Hb oxyhemoglobin, RCT randomized controlled trial, SD standard deviation, SMT spinal manipulative therapy, T/C ratio testosterone/cortisol ratio, T/S thoracic spine, TTM traditional Thai massage, Tx treatment, USA United States of America, w/o without, w/ with, wks weeks, yo years old

<sup>a</sup>Red: no effect of SMT; green: effect of SMT; yellow: results depend on processing of cells.

<sup>b</sup>SI conversion factors: To convert substance P from pg/mL to pmol/L, multiply values by 0.742. To convert norepinephrine from pg/mL to pmol/L, multiply values by 5.911. To convert epinephrine from pg/mL to pmol/L, multiply values by 5.459. To convert cortisol from µg/dL to nmol/L, multiply values by 27.588. To convert testosterone from ng/dL to nmol/L, multiply values by 0.0347.

<sup>c</sup>We report difference in mean change scores and 95% CI using the reported mean change scores and standard errors from Table 2 and 3. Note that in two instances in Table 2, the reported mean change scores cannot be reproduced taking differences in means. There is clearly an error in reporting, but we are unable to identify which values are in error.

<sup>d</sup>The reported results cannot be used because they are statistically incorrect. The reported p value was 0.005. There was likely a typo in the reporting of results; therefore, we imputed the 95% CI.
