

Supplementary Material

Table S1. Demographic data from healthy subjects (control group, CTRL)

Patient ID	Age (years)	Gender
C11	68	Female
C13	49	Female
C15	50	Male
C16	46	Female
C17	83	Female
C18	31	Female
C19	66	Female
C20	58	Male
C22	54	Female
C23	72	Male
C24	38	Female
C25	60	Female
C100	36	Male
C101	24	Female
C102	37	Male
C103	34	Female
C104	19	Male

Table S2. Demographic data and clinic-laboratory parameters from patients with polycythemia vera (PV).

Code	Mutation	Age	Gender	Treatment	Risk	VE	Fibrosis rate
P77	JAK2V617F ⁺	76	M	---	High	Yes	0

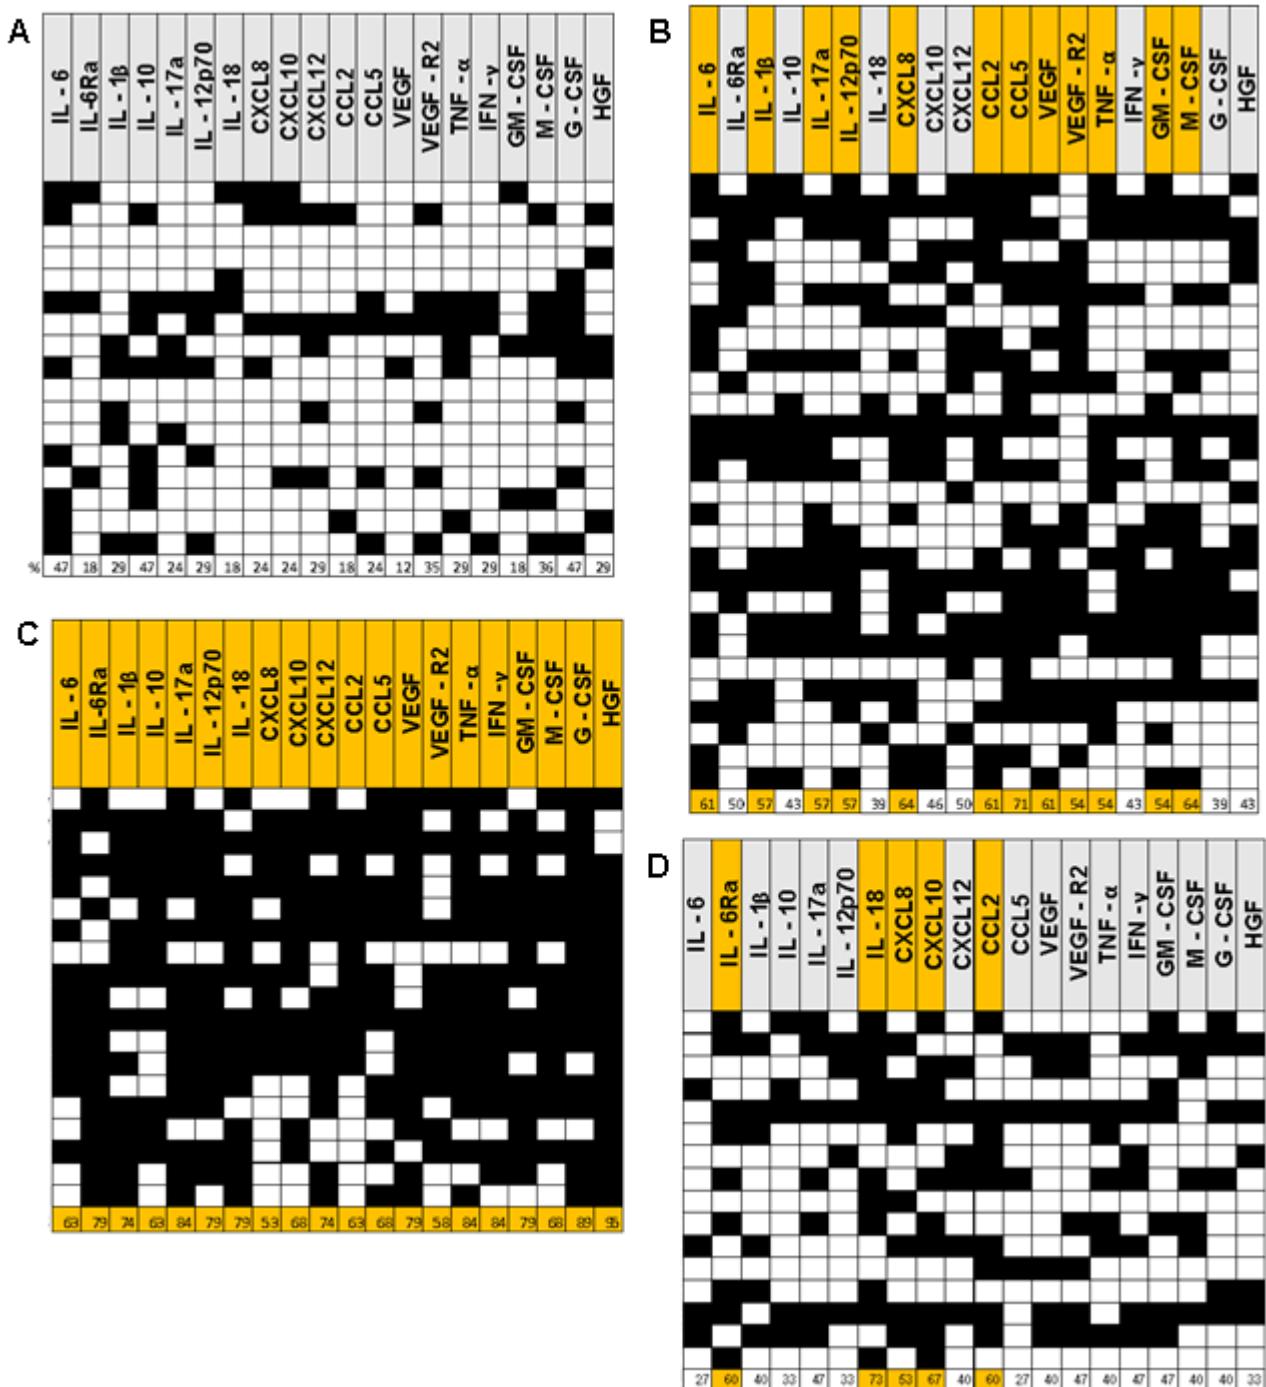

Figure S1. Bone marrow soluble mediator signatures. **(A)** Healthy subjects (CTRL, n=17). CTRL group showed low frequency (<50% of group individuals) of high soluble mediator producers for all analyzed mediators. Patients with **(B)** essential thrombocythemia (ET, n=28), **(C)** polycythemia vera (PV, n=19), and **(D)** primary myelofibrosis (PMF, n=16). Soluble mediator production was stratified as high and low. Black blocks indicate high producers and white blocks indicate low producers of each soluble mediator analyzed. Each column represents one analyte, and each row represents one subject. The number below each column corresponds to the frequency of high producers (%). The soluble mediator is highlighted when the frequency of high producers exceeded 50% of the group individuals, and the soluble mediator was considered relevant for the disease.

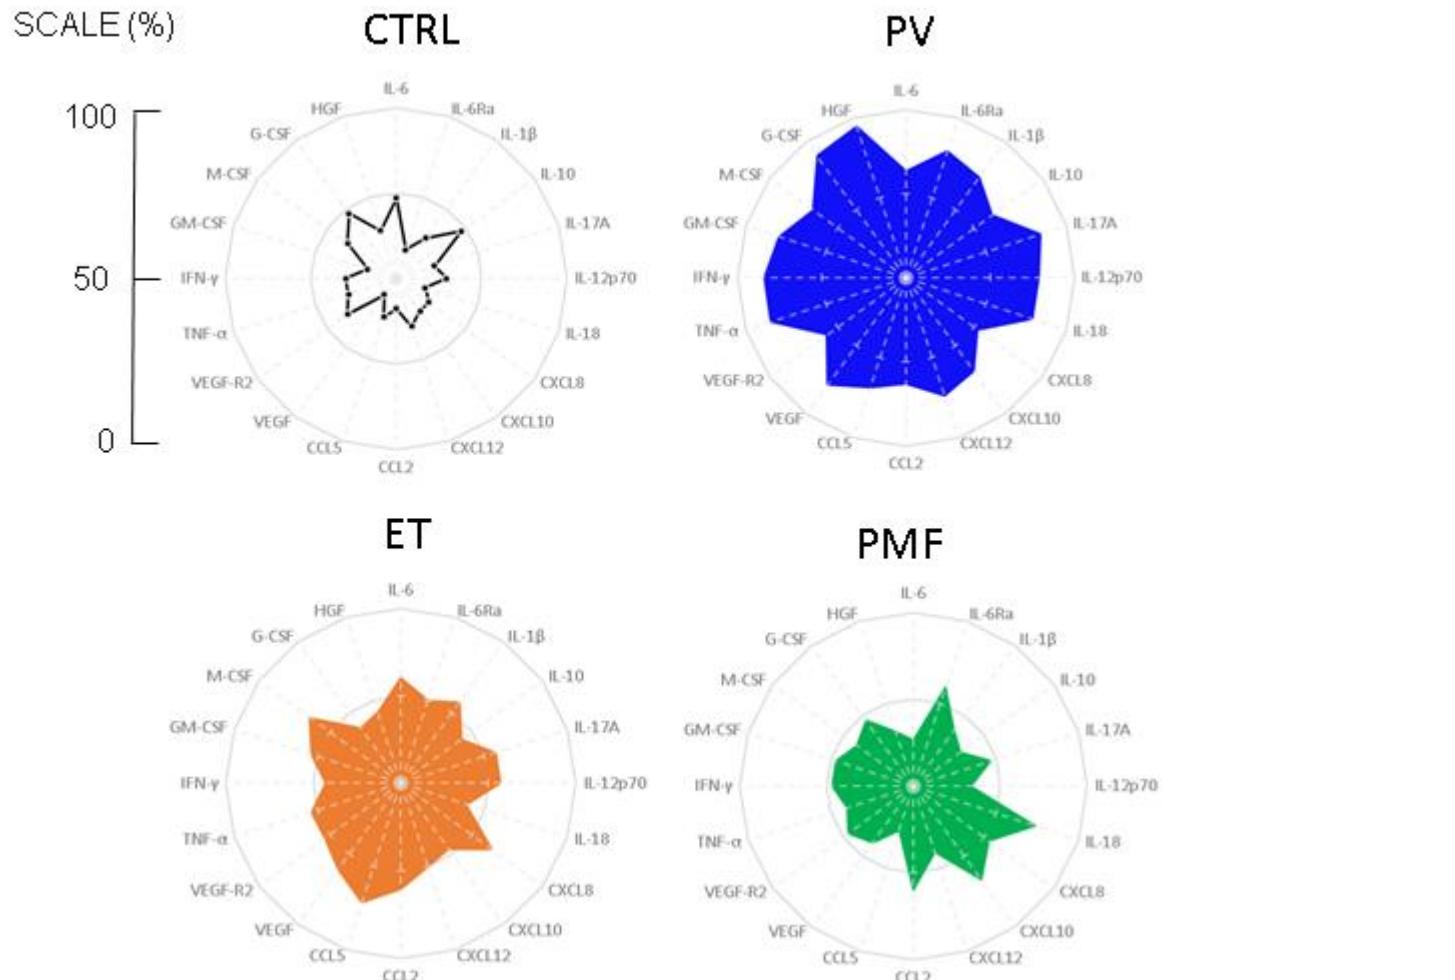

Figure S2. Spider charts of soluble mediator signatures from healthy subjects (CTRL, n=17) and patients with essential thrombocythemia (ET, n=28), polycythemia vera (PV, n=19), and primary myelofibrosis (PMF, n=16). Comparison of frequency of overall mediator production among the disease subtypes. The results are expressed in percentage.

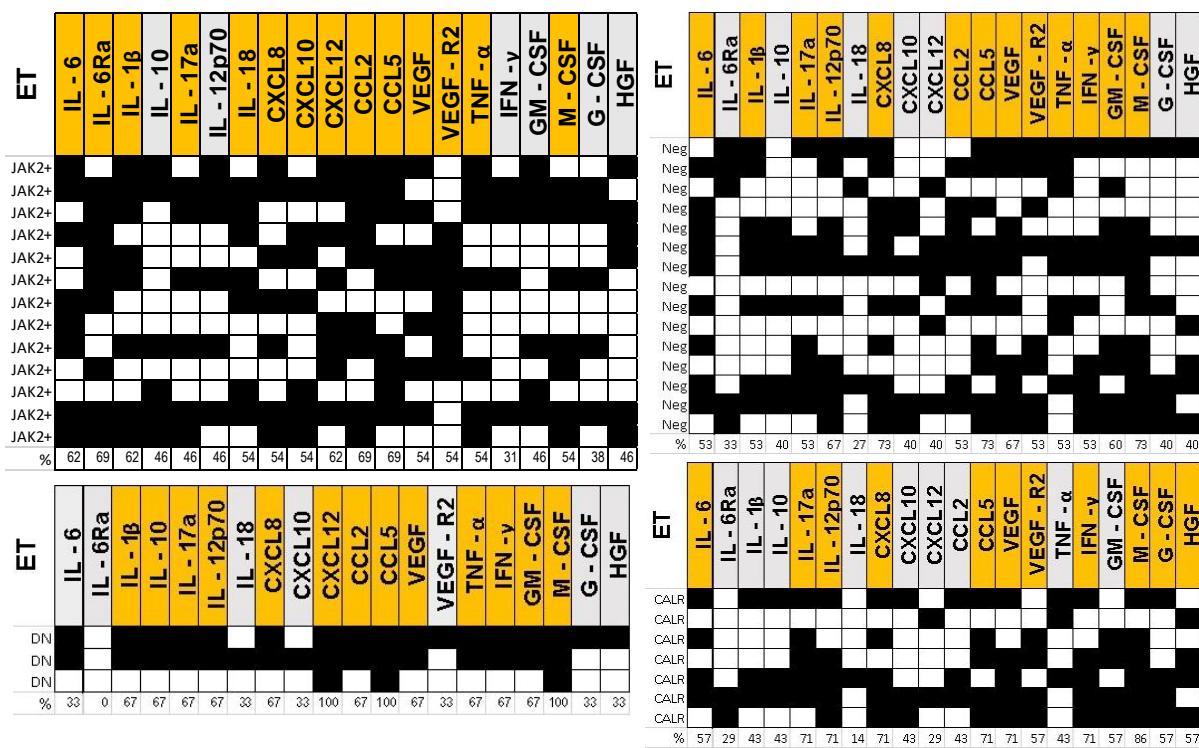

Figure S3. Association between driver mutation *status* and soluble mediator signature in patients with essential thrombocythemia (ET). JAK2V617⁺ (n=13; ET patients positive for JAK2V617F mutation), JAK2V617F⁻ (n=15; ET patients negative for JAK2V617F mutation), CALR⁺ (n=7; patients positive for calreticulin mutation), DN (n=3; double negative patients). Soluble mediator production was stratified as high and low. Black blocks indicate high producers and white blocks indicate low producers of each soluble mediator analyzed. Each column represents one analyte, and each row represents one individual. The number below each column corresponds to the frequency of high producers. Yellow boxes indicate that more than 50% of the individuals of the group were high producers of that soluble mediator.

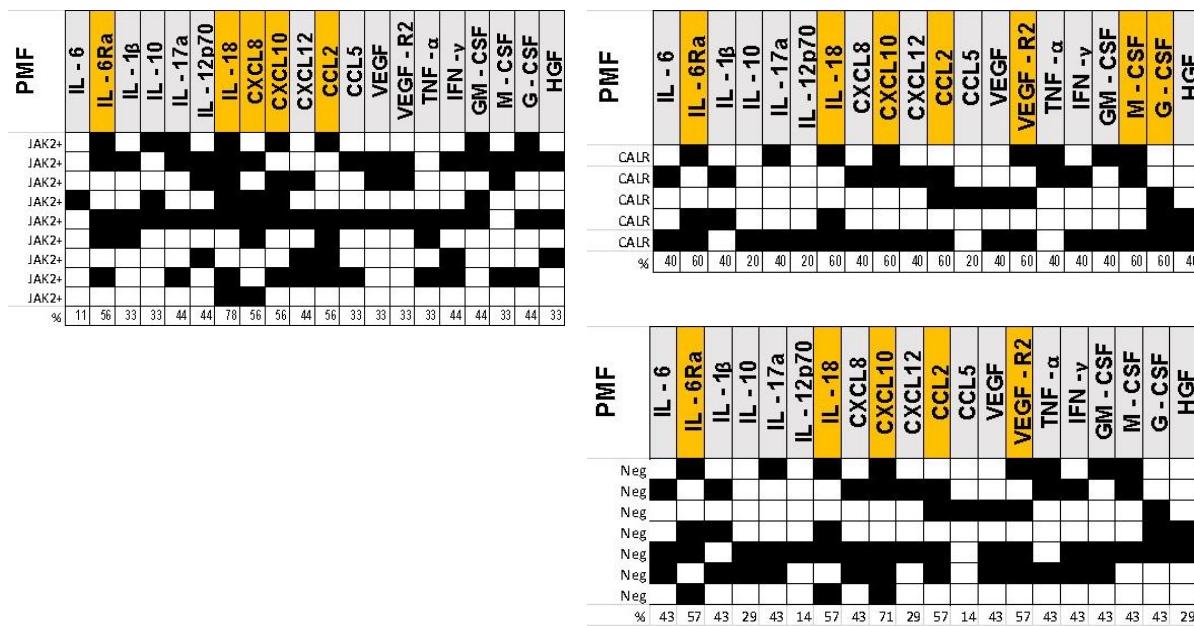

Figure S4. Association between driver mutation status and soluble mediator signature in patients with primary myelofibrosis (PMF). JAK2V617⁺ (n=9; PMF patients positive for JAK2V617F mutation), JAK2V617F⁻ (n=7; PMF patients negative for JAK2V617F mutation), CALR⁺ (n=5; PMF patients positive for calreticulin mutation). Soluble mediator production was stratified as high and low. Black blocks indicate high producers and white blocks indicate low producers of each soluble mediator analyzed. Each column represents one analyte, and each row represents one individual. The number below each column corresponds to the frequency of high producers. Yellow boxes indicate that more than 50% of the individuals of the group were high producers of that soluble mediator.
