Supplementary Figure 1. The unbalanced subnetworks identified by PaSSS analysis for 725 SKCM and THCA tumors. For every process α , the proteins were assembled into networks using functional interactions according to STRING database. **Note** that red proteins are upregulated, and blue proteins are downregulated given that the amplitude of the process is positive. In tumors where the amplitude is negative, the direction of change is opposite.

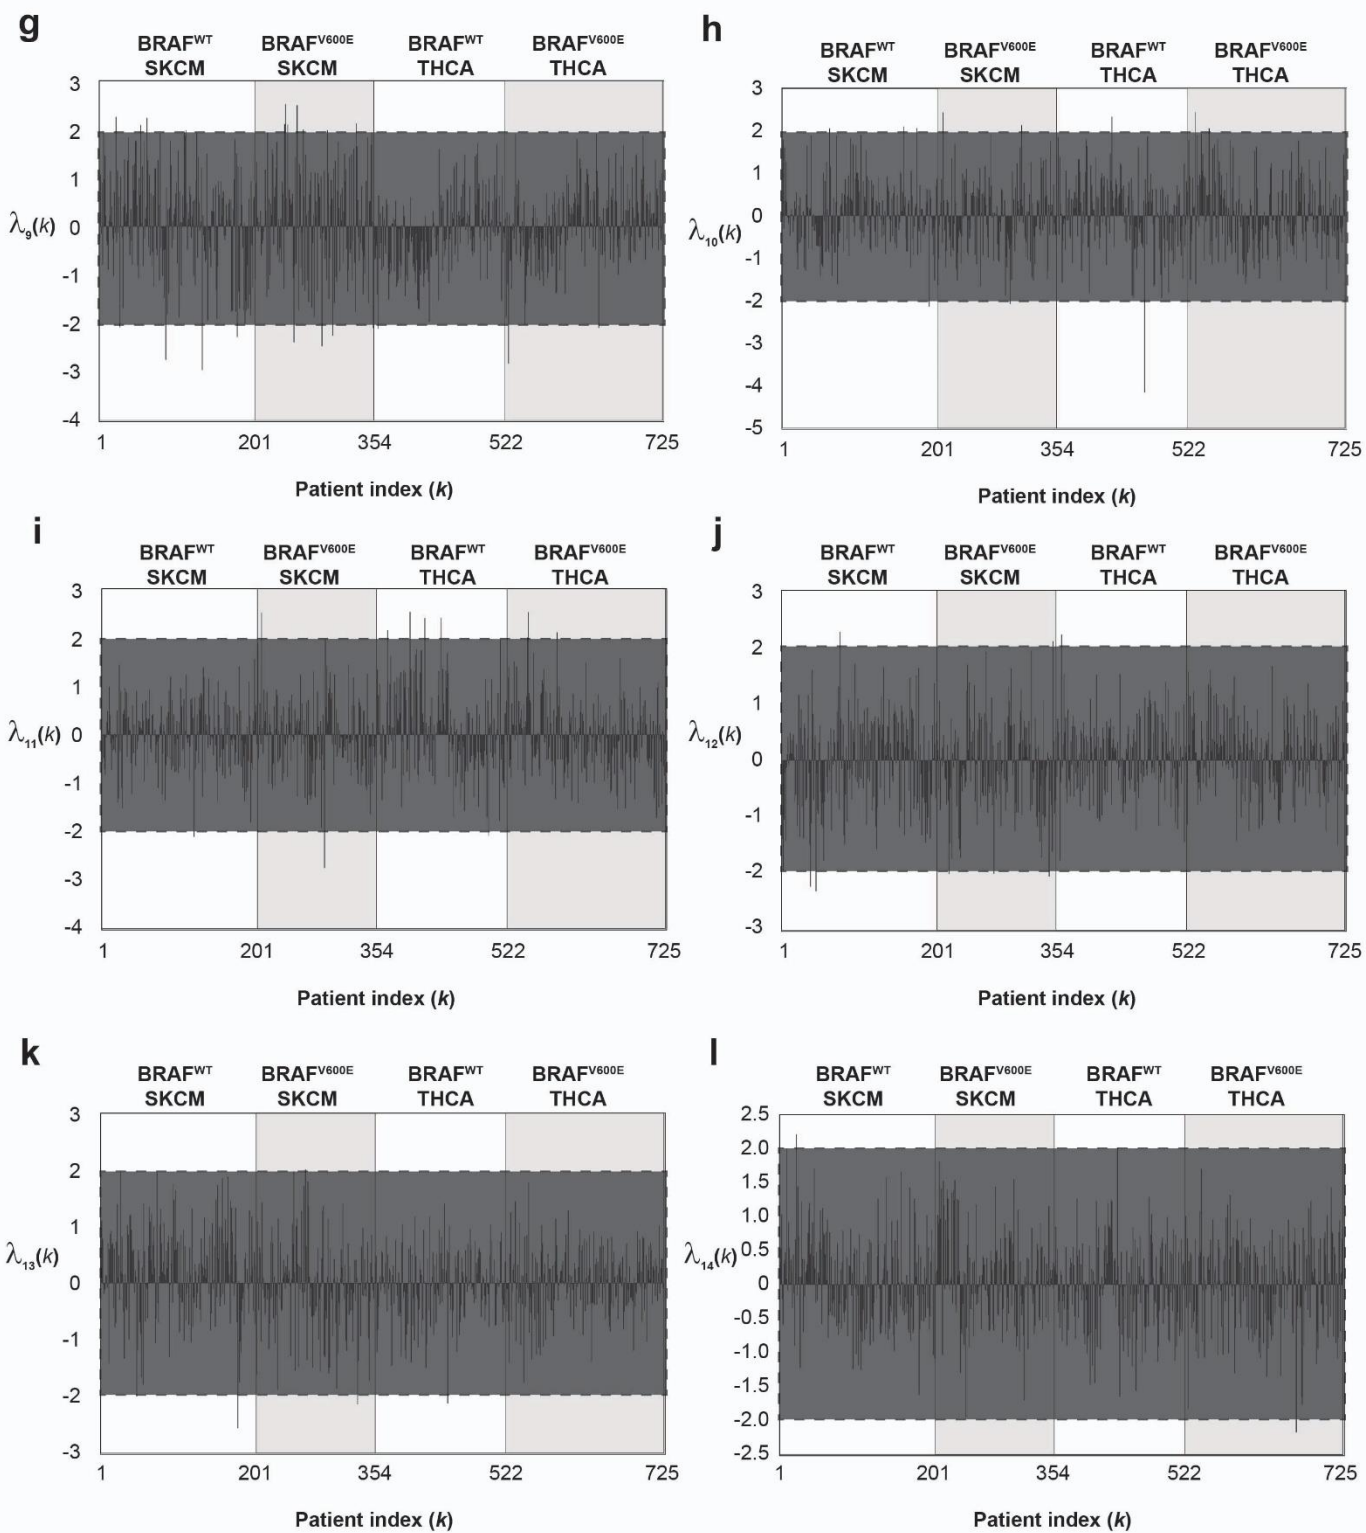

Supplementary Figure 2.

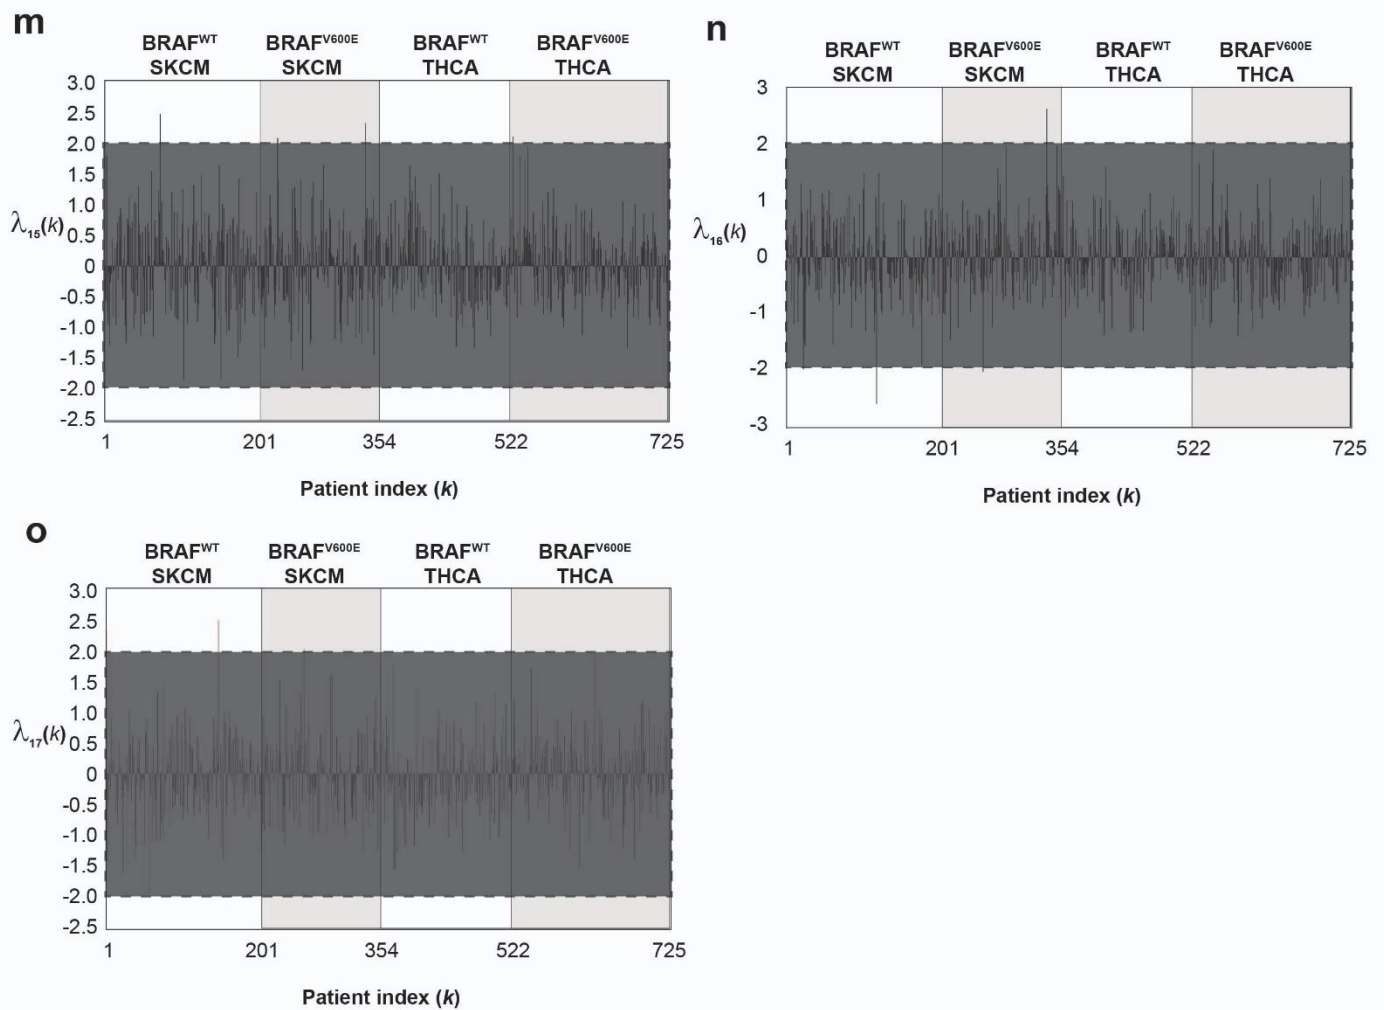

Supplementary Figure 2. 17 unbalanced processes suffice to describe the biological imbalance in 725 tumors. Presented are R^2 values for 14 random patients. The R^2 was calculated for every patient by plotting the natural logarithm of the experimental data ($\text{Ln}X_i$) vs. $\sum G_{i\alpha} \lambda_{\alpha}(k)$ for $\alpha = 0, 1, 2, \dots, 20$. As more constraints are added, we expect to get higher agreement between the experimental data and the theoretical calculation, reaching the highest level of correlation when the experimental data is fully reproduced by the theoretical fitting. The plot reaches a plateau after the 17th constraint. This indicates that for $\alpha = 18, 19, 20 \dots$ the data includes mainly noise.

Supplementary Figure 3.

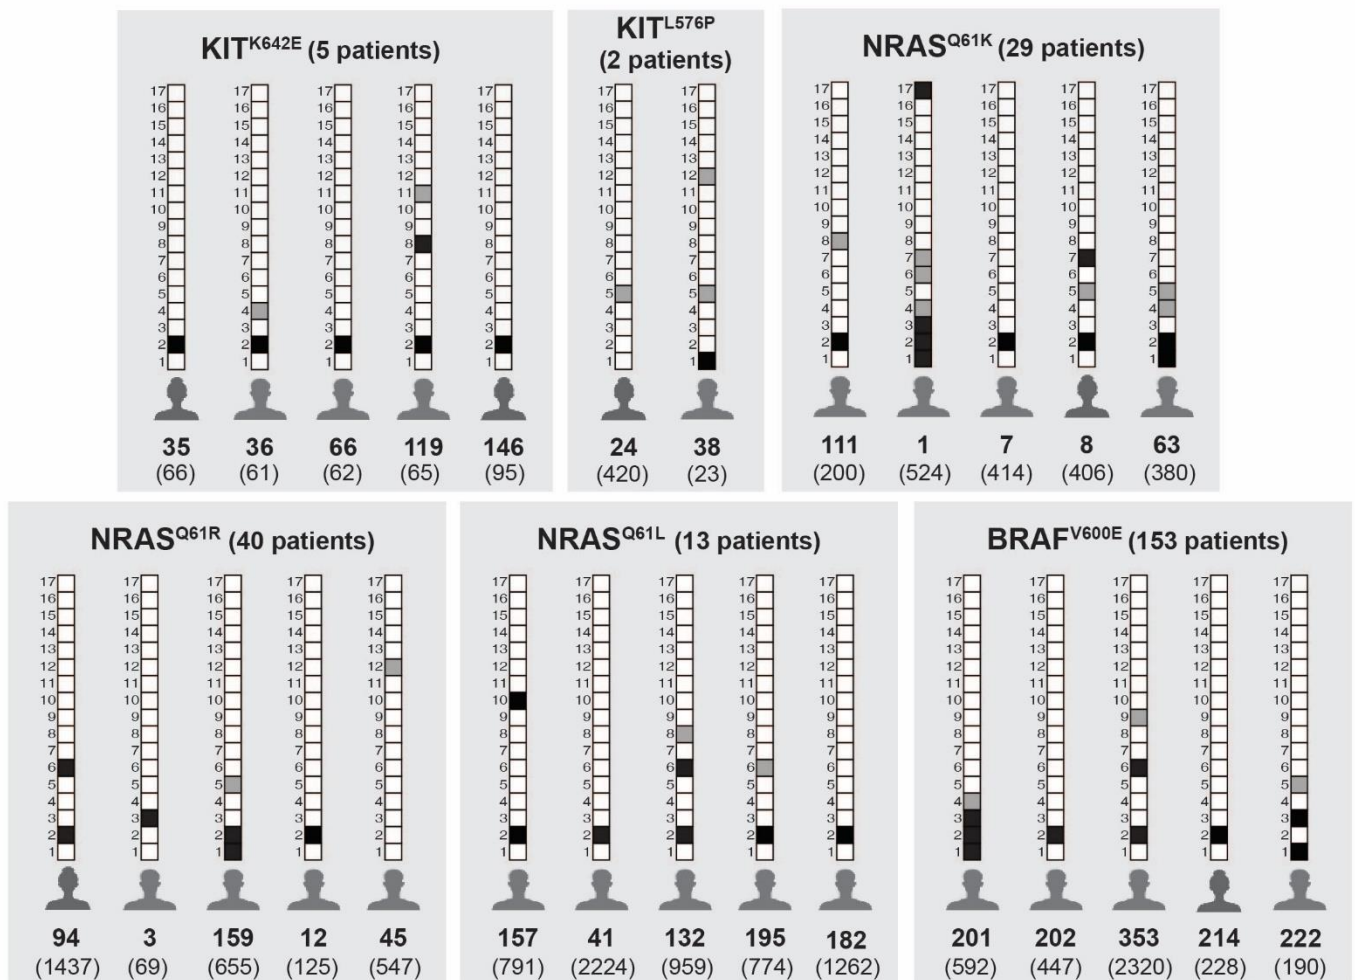

Supplementary Figure 3. Tumor-specific amplitudes ($\lambda_{\alpha}(k)$) of the 17 unbalanced processes. Not all unbalanced processes are active in all patients. Rather, each unbalanced process, α , is assigned an amplitude, $\lambda_{\alpha}(k)$, for the specific tumor, k (see also Supplementary Data 1). Every panel in the figure presents 725 values of $\lambda_{\alpha}(k)$ for a specific value of α . The gray boxes mark the threshold limits – only values greater than 2 or smaller than -2 were considered significant (see Methods for more details).

Supplementary Figure 4.

Supplementary Figure 4. SKCM patients harboring the same genomic mutations are characterized by various PaSSS-based barcodes. Patient-specific data regarding common mutations in melanoma was obtained from the GDC Data Portal. The full list can be found in Supplementary Data 6. For each mutation, the number of total patients harboring this mutation is stated. The mutations shown are mutually exclusive, namely a patient that harbors one of the mutations does not harbor any of the others [1]. Up to 5 patients were randomly selected for each mutation, and their PaSSS-based barcodes are shown, demonstrating that even though they carry the same mutation, their barcodes of unbalanced processes differ, and may thus demand distinct modes of treatment. The number in brackets (under patient index) denotes the total number of mutations, according to patient-specific data from cBioportal.org.

● Upregulated* due to process
● Downregulated* due to process
 * Given a positive amplitude; see legend

Supplementary Figure 5. The unbalanced subnetworks identified by PaSSS analysis for 219 cell lines. For every process α , the proteins were assembled into networks using functional interactions according to STRING database. **Note** that red proteins are upregulated, and blue proteins are downregulated given that the amplitude of the process is positive. In tumors where the amplitude is negative, the direction of change is opposite.

Supplementary Figure 7.

Supplementary Figure 7: Mice treated with SA-based drug combinations demonstrated no significant weight loss *in vivo*. A375 (a), G361 (b) or A2058 (c) were injected subcutaneously into mice, and once tumors reached 50 mm³, treatments were initiated. In all three cases, the PaSSS-based drug combinations or the monotherapy of trametinib or the combinations predicted to partially target the PaSSS did not cause any significant weight loss in the mice (less than 12% from the start of treatment) during the course of the treatment.

Supplementary Data Legends

Supplementary Data 1-9 are provided as excel files.

Each Supplementary Data file includes a legend located in the first tab of the dataset. The legend provides full description of the content.
