**eFigure 1. Federated data collection across participating sites.** Each site generated six data tables containing aggregate counts and statistics on their patient-level data: 1) demographic breakdowns, 2) clinical course accounts for daily admissions and discharges, 3) cumulative counts of total hospitalized patients, 4) diagnosis counts during hospitalization, 5) medication class counts during hospitalization, and 6) daily trajectories of lab tests. These aggregate descriptive files were provided to the 4CE consortium. This figure has been created with BioRender.com

**eFigure 2. Forest plots for laboratory values at admission.** Plots indicate mean values at admission with 95% confidence intervals based on Z-statistic at each site. The heterogeneous structure across different sites supported a random-effects meta-analysis for the statistical model. The aggregated mean values (Summary) and 95% confidence intervals in each forest plot were based on random-effects meta-analysis.

**eFigure 3. Plots of daily sample sizes for the temporal trend analyses over first 14 days of hospitalizations.**

**eMethods. Calculation of temporal trends for laboratory values**

To summarize the temporal trends of laboratory tests, we combined data from sites with at least three observations and analyzed temporal patterns by calculating mean laboratory values on each day of hospitalization, also using random-effects meta-analysis. Specifically, for a specific laboratory test and on each day of hospitalization, we conducted a random-effect meta-analysis using the site level mean and standard error (SE) as input to obtain an overall mean and SE estimate. We then plotted these estimates over the first 14 days of hospitalization.
