Web Appendix 1. Analysis plan

In our example the event of interest is death from prostate cancer, while the competing event is death from other causes.

Method 1

Sample two nested case-control studies, where:

1. Cases are all subjects who died from prostate cancer, $K = 1$, and incidence density sampling is used to select one control per case, matched on year and hospital of diagnosis (i.e. ProMort)
2. Cases are all subjects who died from other causes, $K = 2$, and incidence density sampling is used to select one control per case, matched on year and hospital of diagnosis.

Hence, there are two separate sets of controls for each endpoint.

Analysis steps:

1. Fit the flexible parametric proportional hazards model which is estimated on the log cumulative hazard scale where

$$\log[\Lambda_k(t|x_i, z_i)] = \log[\Lambda_{k,0}(t)] + \beta_k x_i + \gamma_k z_i$$

for each K , where x_i is a vector of covariates of interest and z_i is a vector of matching variables. The baseline log cumulative hazard function, $\ln[\Lambda_{k,0}(t)]$, is estimated using restricted cubic splines, so that

$$\log[\Lambda_k(t|x_i, z_i)] = s(\log(t)|\varepsilon_k, q_0) + \beta_k x_i + \gamma_k z_i$$

Where $s(\log(t)|\varepsilon_k, q_0)$ is a restricted cubic spline function basis of $\log(t)$ with a vector of knots q_0 and associated parameters ε_k .

$$\lambda_k(t|x_i, z_i) = \frac{d\log[\Lambda_k(t|x_i, z_i)]}{dt} = \frac{ds(\log(t)|\varepsilon_k, q_0)}{dt} \exp(\log[\Lambda_k(t|x_i, z_i)])$$

The parameters ε_k , β_k and γ_k can then be estimated by maximizing the weighted full likelihood:

$$\log[L(\varepsilon_k, \beta_k, \gamma_k)] = \sum_{i=1}^n (d_i \log[\lambda_k(t_i|x_i, z_i)] - \Lambda_k(t_i|x_i, z_i)) \omega_i$$

Where d_i is a binary event indicator, $d = 1$ if t_i is an observed time of the event k and $d = 0$ otherwise.

The weights are defined as

$$\omega_i = \frac{1}{p_i}$$

where p_i is a probability of being included in the nested case-control sample. For both the cases who died from prostate cancer and cases who died from other causes $p_i = 1$, while for controls we estimated p_i as

$$p_i = 1 - \prod_{T_i} \left(1 - \frac{m}{n_i - 1}\right)$$

T_i is the set of event times for both endpoints $K = 1, 2$ when subject i is a possible matched control and n_i is the risk set which satisfies the matching criteria at the time T_i .

2. Estimate the survival function:

$$S(t; x, z) = \prod_{t_j \leq t} [1 - (\lambda_1(\beta_1, \gamma_1) + \lambda_2(\beta_2, \gamma_2))]$$

3. Estimate the cumulative incidence function for endpoint of interest:

$$I_1(t; x, z) = \sum_{t_j \leq t} S(t_j; x, z) \lambda_1(\beta_1, \gamma_1)$$

Method 2

1. Sample a nested case-control study for the event of interest where cases are all subjects who died from prostate cancer, $K = 1$, and incidence density sampling is used to select one control per case, matched on year and hospital of diagnosis (i.e. ProMort)
2. Select all subjects who died from other causes, $K = 2$, and use controls selected for the endpoint 1 as controls for these cases.

Follow the same analysis steps as in Method 1.

1. Fit the flexible parametric proportional hazards models described for Method 1
The parameters $\varepsilon_k, \beta_k, \gamma_k$ can be estimated by maximizing the weighted full likelihood as in Method 1.
The weights ω_i and a probability of being included in the nested case-control sample p_i are still defined as in Method 1. However, T_i is now the set of event times only for

$K = 1$ when subject i is a possible matched control and n_i is the risk set which satisfies the matching criteria at the time T_i .

4. Estimate the survival function and the cumulative incidence functions described for Method 1.

Web Appendix 2. Stata codes

1. Estimating selection probability for controls

* Declare data as survival data (the time-scale is defined as time since the date of diagnosis, but the code can be applied to different time-scales).

* For ProMort and Method 2 failure event is death from prostate cancer, while for Method 2 failure event is death from prostate cancer and death from other causes

```
stset date_death, failure(status==1) origin(date_dg) exit(date_death) scale(365.25)
```

* Define matching strata (matching variables are year and hospital of diagnosis)

```
egen strata=group(diagyear hospital)
```

* Calculate the probability of being selected as a control within the matching stratum

```
gen p=.
```

```
sort strata _t
```

```
qui by strata: gen sum_status=sum(_d)
```

```
replace sum_status=. if _d!=1
```

```
gen num_control=1
```

* max_case – maximum number of cases in the matching stratum

```
foreach n of numlist 1/max_case {
```

```
    qui by strata: gen exit_t=_t if sum_status=='n'
```

```
    qui by strata: egen time=sum(exit_t)
```

```
    qui by strata: egen den=sum(float(_t)>=time & float(_t0)<=time)
```

```
    qui by strata: egen num=sum(float(_t)==exit_t & _d==1)
```

```
    replace p=1-min(1,num_control*num/(den-num)) if sum_status=='n'
```

```
    drop exit_t time den num
```

```
}
```

```
replace p=1 if p==.
```

```
gen k=1
```

* max_obs - maximum number of observations in the matching stratum with the largest sample size

```

foreach n of numlist 2/max_obs{
    foreach j of numlist 1(10)max_obs{
        qui by strata: replace k=k*p[_n-'j'] if _t0[_n]<=_t[_n-'j'] & _t[_n]>=_t[_n-'j'] & _n=='n' &
        _n>'j' & _d==0
        qui by strata: replace k=k*p[_n-(`j'+1)] if _t0[_n]<=_t[_n-(`j'+1)] & _t[_n]>=_t[_n-(`j'+1)]
        & _n=='n' & _n>(`j'+1) & _d==0
        qui by strata: replace k=k*p[_n-(`j'+2)] if _t0[_n]<=_t[_n-(`j'+2)] & _t[_n]>=_t[_n-(`j'+2)]
        & _n=='n' & _n>(`j'+2) & _d==0
        qui by strata: replace k=k*p[_n-(`j'+3)] if _t0[_n]<=_t[_n-(`j'+3)] & _t[_n]>=_t[_n-(`j'+3)]
        & _n=='n' & _n>(`j'+3) & _d==0
        qui by strata: replace k=k*p[_n-(`j'+4)] if _t0[_n]<=_t[_n-(`j'+4)] & _t[_n]>=_t[_n-(`j'+4)]
        & _n=='n' & _n>(`j'+4) & _d==0
        qui by strata: replace k=k*p[_n-(`j'+5)] if _t0[_n]<=_t[_n-(`j'+5)] & _t[_n]>=_t[_n-(`j'+5)]
        & _n=='n' & _n>(`j'+5) & _d==0
        qui by strata: replace k=k*p[_n-(`j'+6)] if _t0[_n]<=_t[_n-(`j'+6)] & _t[_n]>=_t[_n-(`j'+6)]
        & _n=='n' & _n>(`j'+6) & _d==0
        qui by strata: replace k=k*p[_n-(`j'+7)] if _t0[_n]<=_t[_n-(`j'+7)] & _t[_n]>=_t[_n-(`j'+7)]
        & _n=='n' & _n>(`j'+7) & _d==0
        qui by strata: replace k=k*p[_n-(`j'+8)] if _t0[_n]<=_t[_n-(`j'+8)] & _t[_n]>=_t[_n-(`j'+8)]
        & _n=='n' & _n>(`j'+8) & _d==0
        qui by strata: replace k=k*p[_n-(`j'+9)] if _t0[_n]<=_t[_n-(`j'+9)] & _t[_n]>=_t[_n-(`j'+9)]
        & _n=='n' & _n>(`j'+9) & _d==0
    }
}
gen p_final=1-k
replace p_final=1 if _d==1
gen ipw=1/p_final

```

2. Fitting a flexible parametric survival model

Variables included in the model:

- | | |
|--|----------------------------------|
| 1. Age at diagnosis (≤ 55 , $> 55-65$, $> 65-75$, > 75) | - age (coded as: 0, 1, 2, 3) |
| 2. PSA value at diagnosis (< 4 , 4-10, ≥ 10) | - psa (coded as: 0, 1, 2) |
| 3. Gleason score (< 7 , 7) | - gleason (coded as: 0, 1) |
| 4. Clinical tumor stage (T1a, T1b, T1c, T2) | - tstage (coded as: 0, 1, 2, 3) |
| 5. Year of diagnosis | - diagyear (coded as: 1998-2011) |
| 6. County of diagnosis | - county (coded as: 1-22) |

* Declare data as survival data

1. NPCR

```
stset date_death, fail(status==1) origin(date_dg) exit(date_death) scale(365.25)
```

2. ProMort

* casestrl – variable denoting case/control status (1 - case, 0 – control)

```
stset date_death [pw=ipw], fail(casestrl==1) origin(date_dg) exit(date_death) scale(365.25)
```

* Fit a flexible parametric proportional hazards model

```
stpm2 i.age i.psa gleason i.tstage i.diagyear i.county, scale(hazard) df(2) eform vce(robust)
```

3. Estimating cumulative incidence function

* Expand the data, two rows of data per individual, one per each cause of death
expand 2

* Generate an indicator variable for each cause of death and an overall indicator

```
bysort id_var: gen cause=_n  
gen cancer=(cause==1)  
gen other=(cause==2)  
gen event=(cause==status)
```

* Generate dummy variables for each category of factor variables included in the model

```
foreach var of varlist age psa gleason tstage diagyear county {  
    levelsof `var', local(levels)  
    foreach l of local levels {  
        gen `var'`l'ca=(`var'=='l' & cancer==1)  
        gen `var'`l'oth=(`var'=='l' & other==1)  
    }  
}
```

* Baseline categories:

- | | |
|---------------------------|---|
| 1. Age at diagnosis | - 55.1-65 (age1ca/age1oth), |
| 2. PSA value at diagnosis | - <4 (psa0ca/psa0oth), |
| 3. Gleason score | - ≤6 (gleason0ca/gleason0oth), |
| 4. Clinical tumor stage | - T1c (tstage2ca/tstage2oth), |
| 5. Year of diagnosis | - 2004 (diagyear2004ca/diagyear2004oth) |
| 6. County of diagnosis | - Västra Götaland (12) (county12ca/county12oth) |

qui ds age0ca-county22oth

Abbreviations: CIF_{NPCR}, Cumulative incidence functions estimated in the National Prostate Cancer Register of Sweden (NPCR); CIF_{ncc}, Cumulative incidence functions estimated from the 1,500 nested case-control studies sampled with replacement from NPCR; SD, Standard deviation; 25% and 75%, lower and upper 25th percentile of the distribution of the absolute bias across 1,500 subsamples; T, Clinical tumor stage; GS, Gleason score; PSA, Prostate Specific Antigen

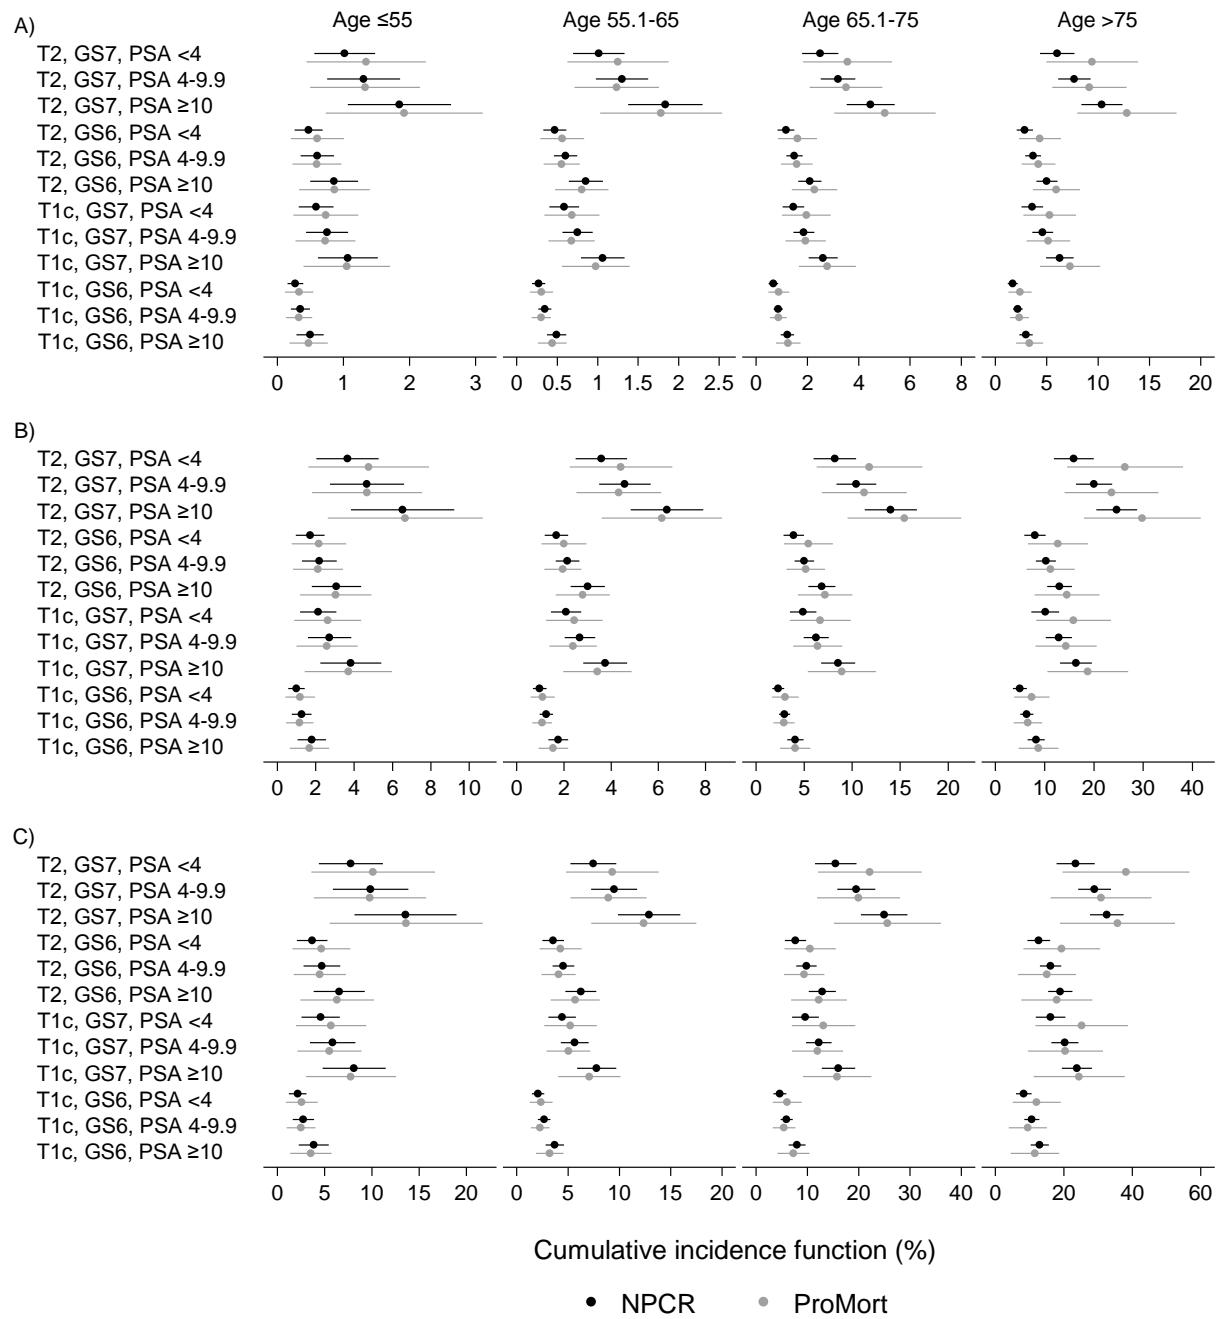

Web Figure 1. Logarithm of the cause-specific hazard ratios and 95% confidence intervals of the risk of dying from prostate cancer and other causes estimated in NPCR, Sweden, 1998-2011, and using Method 1 and Method 2. Reference categories (age 55.1-65, PSA <4, Gleason score ≤6, clinical tumor stage T1c) and estimates for the matching variables (year and county of diagnosis) are not shown in the figure.

Abbreviations: PSA, prostate-specific antigen; log(HR), Logarithm of the hazard ratio; NPCR, National Prostate Cancer Register of Sweden

Web Figure 2. Cumulative incidence function and 95% confidence intervals of dying from prostate cancer for men with low- and intermediate-risk prostate cancer in NPCR and in ProMort, Sweden, 1998-2011. CIFs were estimated for different combinations of risk factors at 5 (A), 10 (B) and 15 (C) years of follow-up. Year (2004) and county (Västra Götaland) of diagnosis were kept constant.

NPCR, National prostate cancer register of Sweden; T, Clinical tumor stage; GS, Gleason score; PSA, prostate-specific antigen

Web Figure 3. Cumulative incidence function and 95% confidence intervals of dying from prostate cancer for men with low- and intermediate-risk prostate cancer in NPCR, Sweden, 1998-2011, and using Method 1 and Method 2. CIFs were estimated for different combinations of risk factors at 5 (A), 10 (B) and 15 (C) years of follow-up. Year (2004) and county (Västra Götaland) of diagnosis were kept constant.

Abbreviations: T, Clinical tumor stage; GS, Gleason score; PSA, prostate-specific antigen, NPCR, National Prostate Cancer Register of Sweden
