### **16S rDNA MiSeq data processing**

Sequencing was performed at the Beijing Genome Institute (BGI) Shenzhen, China. The sequence data was de-multiplexed and quality-filtered by the following criteria, 1) reads with 20% of their original length of low quality (Q20) bases were removed; 2) reads contaminated by adapter, defined as 15 bases overlapped by reads and adapter sequence with maximal 3 bases mismatch allowed, were removed; 3) reads with ambiguous bases and its paired reads were removed; 4) reads containing any stretch of low complexity, defined as homopolymers of 10nt, were removed. Subsequently, the adaptor and primer sequences were trimmed from all reads using cutadapt 1.14 (Martin 2011) in Python 3.6.2.

### **DADA2 workflow**

The sequences were processed using the DADA2 pipeline (Callahan et al. 2017), following the official tutorial version 1.6 under the environment of R studio Version 1.1.383; R version 3.4.2

(2017-09-28); Bioconductor version 3.6 (2017-10-31); DADA2 version 1.6. Firstly the quality profiles of all the forward and reverse reads were examined and filtered by the function filterAndTrim using the following parameters, truncLen=c(250,230), maxN=0, maxEE=c(2,2), truncQ=2, rm.phix=TRUE. A parametric error model was then estimated from the amplicon dataset using the learnErrors function at the default settings until the error rates converged. The reads were dereplicated and have core samples inferred by the derepFastq and dada main function at the default settings. The forward and reverse reads were assembled using the mergePairs function, followed by an additional filtering of read size retaining only the merged reads between 401-450 bp. Chimeric sequences were removed using the removeBimeraDenovo function, which were the final output of this pipeline 1,753 ASVs from 86 samples.

### **Taxonomy Assignment**

The native implementation of the naive Bayesian classifier method (Wang et al. 2007) in the DADA2 package was used for taxonomy assignment at the default settings. A curated reference sequence database was used, which comprised the RDP trainset 16 (derived from RDP Release 11.5 that consisted of 3,356,809 aligned and annotated 16S rRNA sequences, updated on 2016-09-30), the eHOMD 16S rRNA RefSeq Version 15.1 (Chen et al. 2010, updated on 2017-11-16) and the full set of canine oral microbiome 16S rRNA gene sequences (Dewhirst et al. 2012, 416 full-length sequences). All these reference sequences were processed and formatted using the Mothur package (Schloss et al. 2009).

### **Phylogenetic analyses**

A Maximum likelihood (ML) tree containing all the aligned ASV sequences was constructed using Fasttree (Price, Dehal, & Arkin, 2010) for calculation of phylogenetic diversity and UniFrac distance.

### **Principal Response Curve**

The effect of microbiome transplantation was further evaluated with the Principal Response Curve (PRC) method using the default parameters (Van den Brink & Braak 1999). It focuses on the differences between the bacterial compositions in the test group compared to that of the control at the corresponding time. Data was logarithm transformed by taking log (count + 1). A clear effect was observed after Baseline in the test communities. This reveals the transfer of bacterial taxa from the donor microbiome into the test ones. For instance, there were boosts in abundances of ASV40 (Chlorobi G-1 sp.), ASV150 (*Neisseria* sp.), and ASV44 (*Bergeyella*

sp.) in the test group after OMT (Appendix-Figure 5 and 6). Meanwhile, some taxa that were absent in the donor healthy microbiome were reduced in the test group, such as ASV63 *Aquaspirillum* sp., ASV243 *Moraxella* sp. and ASV128 Absconditabacteria (SR1) G-2 sp.

## **Multivariate Statistical analyses**

### **1) Data normalization**

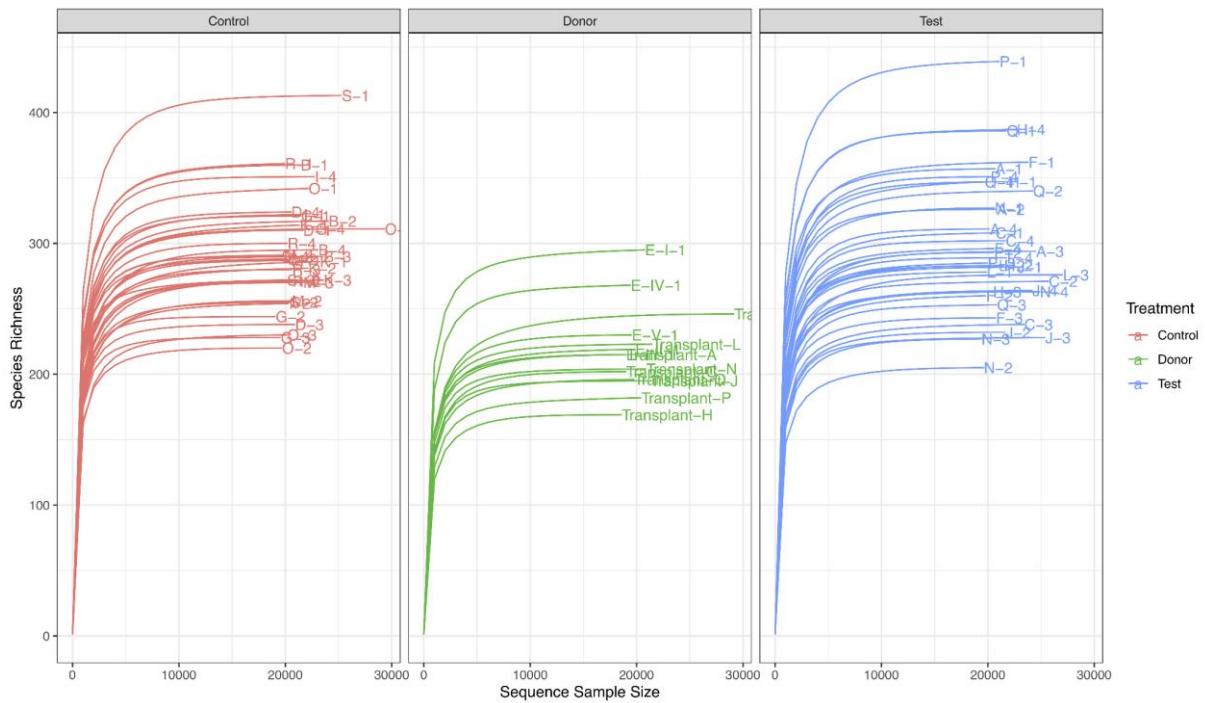

The 16S rRNA gene amplicon sequencing data contains high number of variables, relatively small sample sizes and many zeros entities, known as the large-p small-n problem, such that data normalization is needed for proper ecological and statistical interpretation as evaluated by Weiss and colleagues (2017). Different normalization methods were performed to fit the requirements for each analysis. Data was either normalized by the Sum of Count method, in which proportion in each sample was calculated and then scaling to the size of the smallest samples, or by random rarefying to the smallest sample size. Multivariate test statistics in this study were performed using the R package GenePiper (Tong & Chan 2020) unless elsewise specified.

### **2) Alpha-diversity analyses**

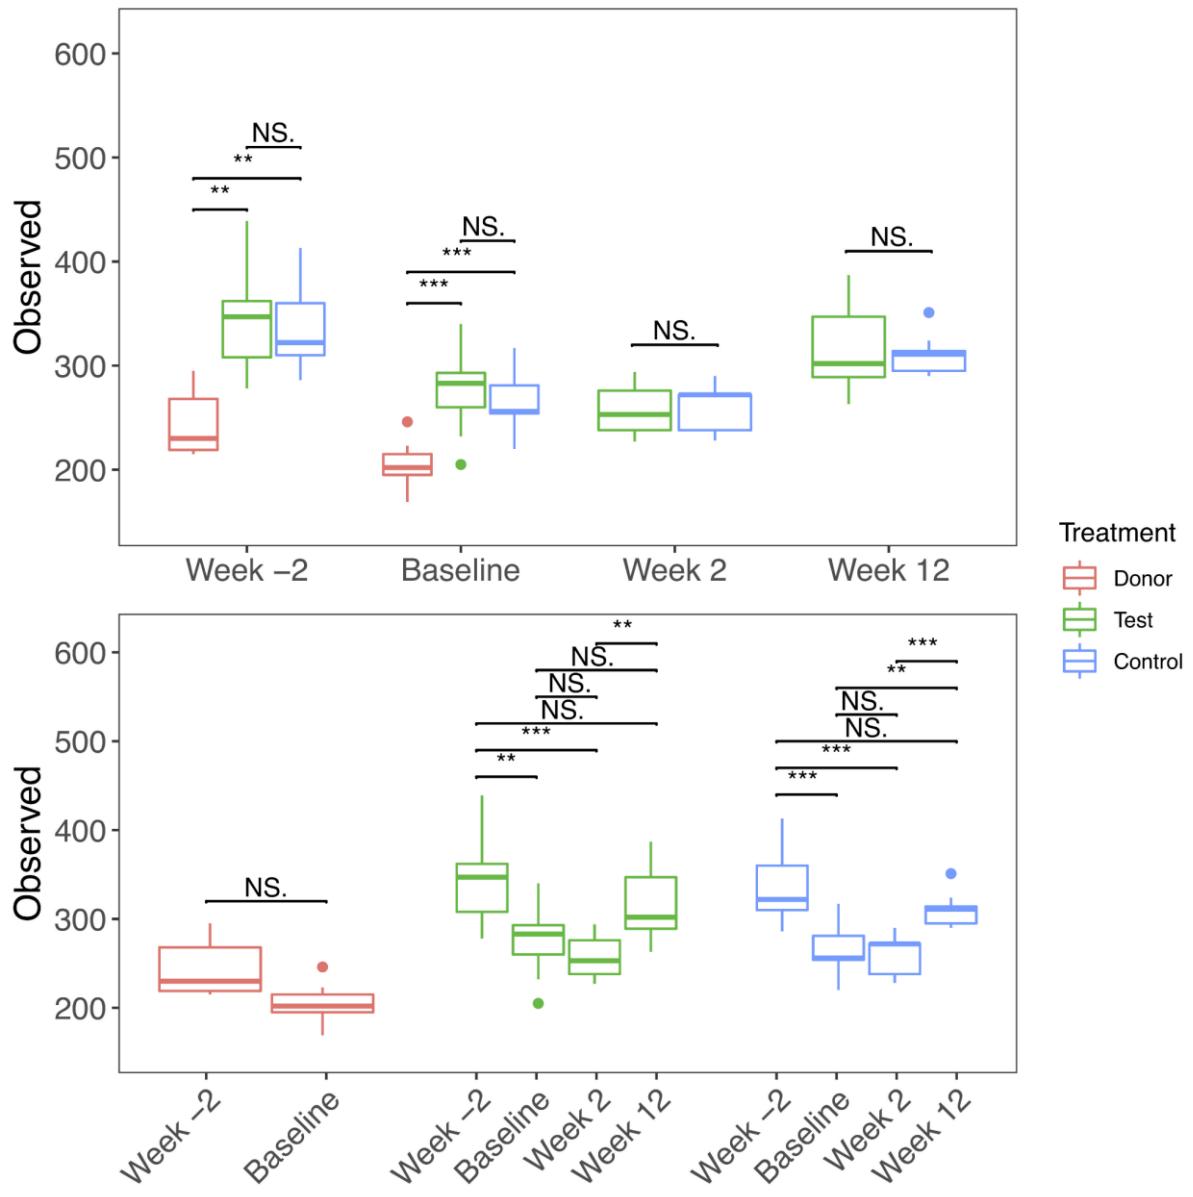

Alpha-diversity measures were calculated using the alpha-diversity module in the R package GenePiper. Shannon's entropy, Simpson diversity indices and their respective effective species numbers were calculated using the default parameters. Rarefaction curves were plotted using the diversity index curve module without normalization. When alpha-diversity measures were compared directly across samples, the dataset was normalized by random rarefying to achieve the same sampling depth. Statistical significance test and the visualization were done using the R package ggsignif.

### **3) Ordination**

Beta-diversities across samples were compared using several distance metrics including both the weighted and unweighted UniFrac, and the Bray-Curtis dissimilarities using GenePiper with normalization by the Sum of Count method. The distance matrices were visualized in Principal Coordinates Analysis (PCoA) ordinations. Permutational Multivariate Analysis of Variance (PERMANOVA) tests were performed to test if the clustering of samples was significant with p-value evaluated at 9999 random permutations.

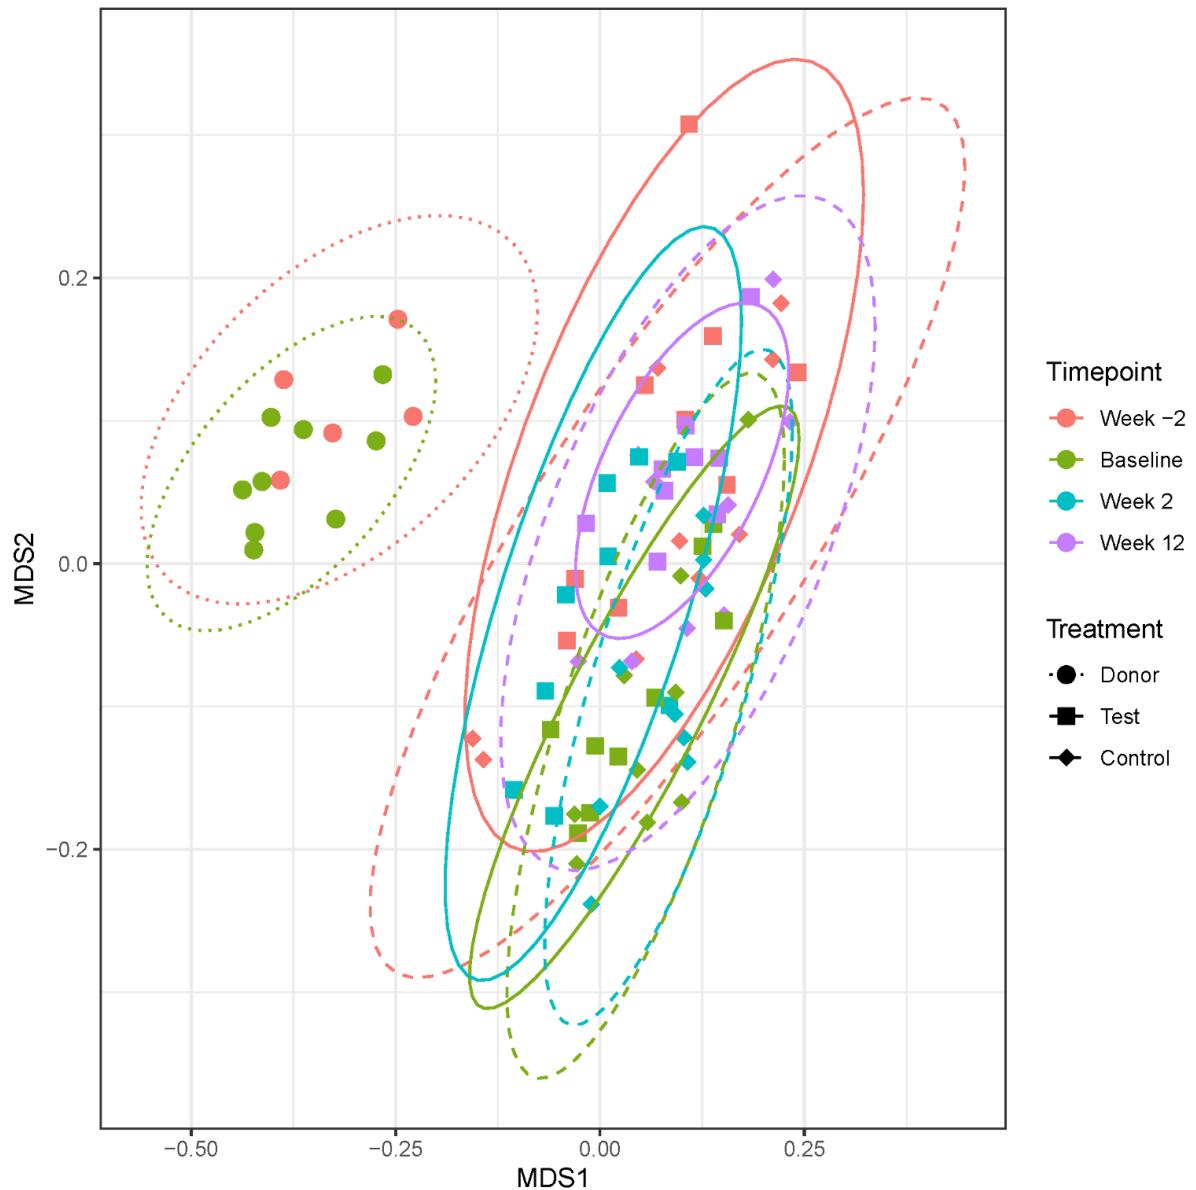

**Appendix-Figure 1** Rarefaction curves indicated sufficient sampling effort for the profiling of the oral microbiota in this study. Samples from the healthy oral microbiota donor had significantly lower species richness compared to the control and test group despite having equivalent sampling depth.

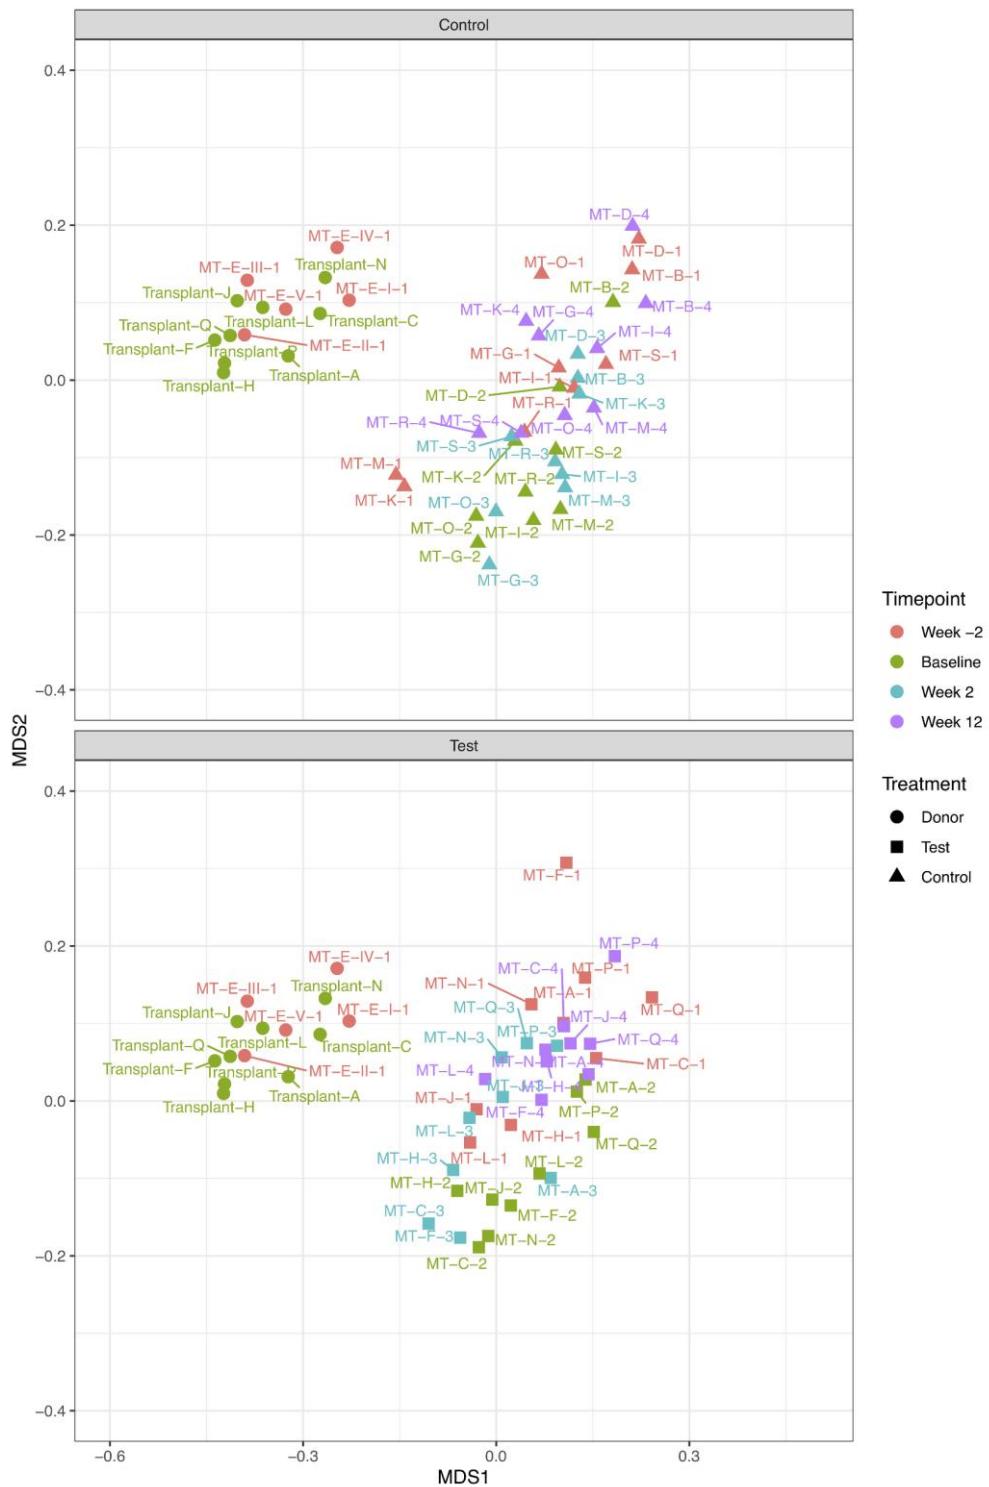

**Appendix-Figure 2** Comparison of the observed species richness of the oral microbiota of the Donor, Test and Control groups at the four experimental time-points.

The Observed species richness (Observed, y-axis; reported as the corresponding number of ASVs) in the respective sets of Donor (red coloured), Test (green coloured) and Control (blue coloured) subjects' oral microbiota samples were evaluated at the Week -2, Baseline, Week 2 and Week 12 time-points (indicated on the x-axis). The median, upper and lower quartile values, and  $\times 1.5$  interquartile ranges are indicated. The corresponding levels of species richness of the single healthy donor dog oral microbiota samples were evaluated at the Week -2 and Baseline time-points (red-coloured). Statistically significant differences were inferred by the Wilcoxon-signed rank Test at p-value cut-offs: \*\*\* indicates  $p \leq 0.001$ , \*\* indicates  $p \leq 0.01$ , \* indicates  $p \leq 0.05$ ; NS. indicates no significant difference. The two panels illustrate the results of different statistical comparisons between (upper panel) and within (lower panel) the respective sets of Test, Control and Donor subjects, at the various time-points. This plot complements the data shown in Figure 2.

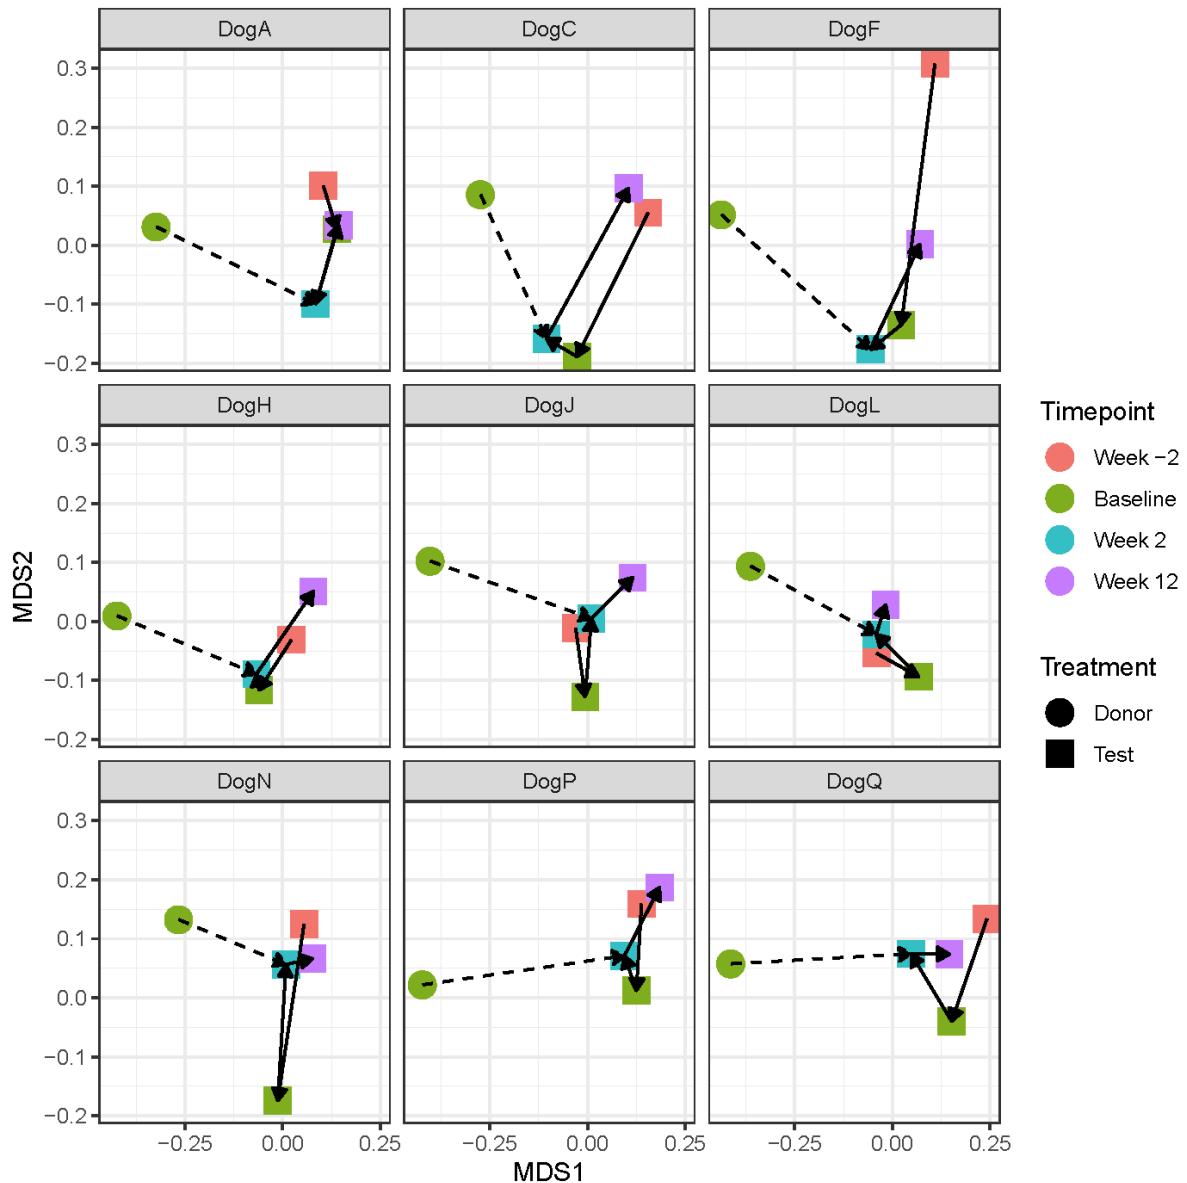

**Appendix-Figure 3 Principal Coordinates Analysis (PCoA) ordination of the oral microbiota of all samples analyzed in this study.**

The microbiota ASV abundance matrix was transformed to a pair-wise Bray-Curtis dissimilarity matrix, and the relationship among samples were visualized in this PCoA ordination plot. Each point represents an individual sample, and their relative distance in the ordination resembles the differences in their oral microbiota profiles. Periodontally-healthy Donor dog (filled circles); Test dogs (filled squares); Control Dogs (filled rhombuses). Week -2 time-point (red coloured), baseline time-point (green coloured), Week 2 time-point (blue coloured), Week 12 time-point (purple coloured), Ellipses were plotted at a confidence level of 0.95. Dashed ellipses enclose the Control group data-points, solid ellipses encircle the Test group data-points. The healthy oral microbiota donor samples were notably distinct from the control and test groups at all time-points analyzed.

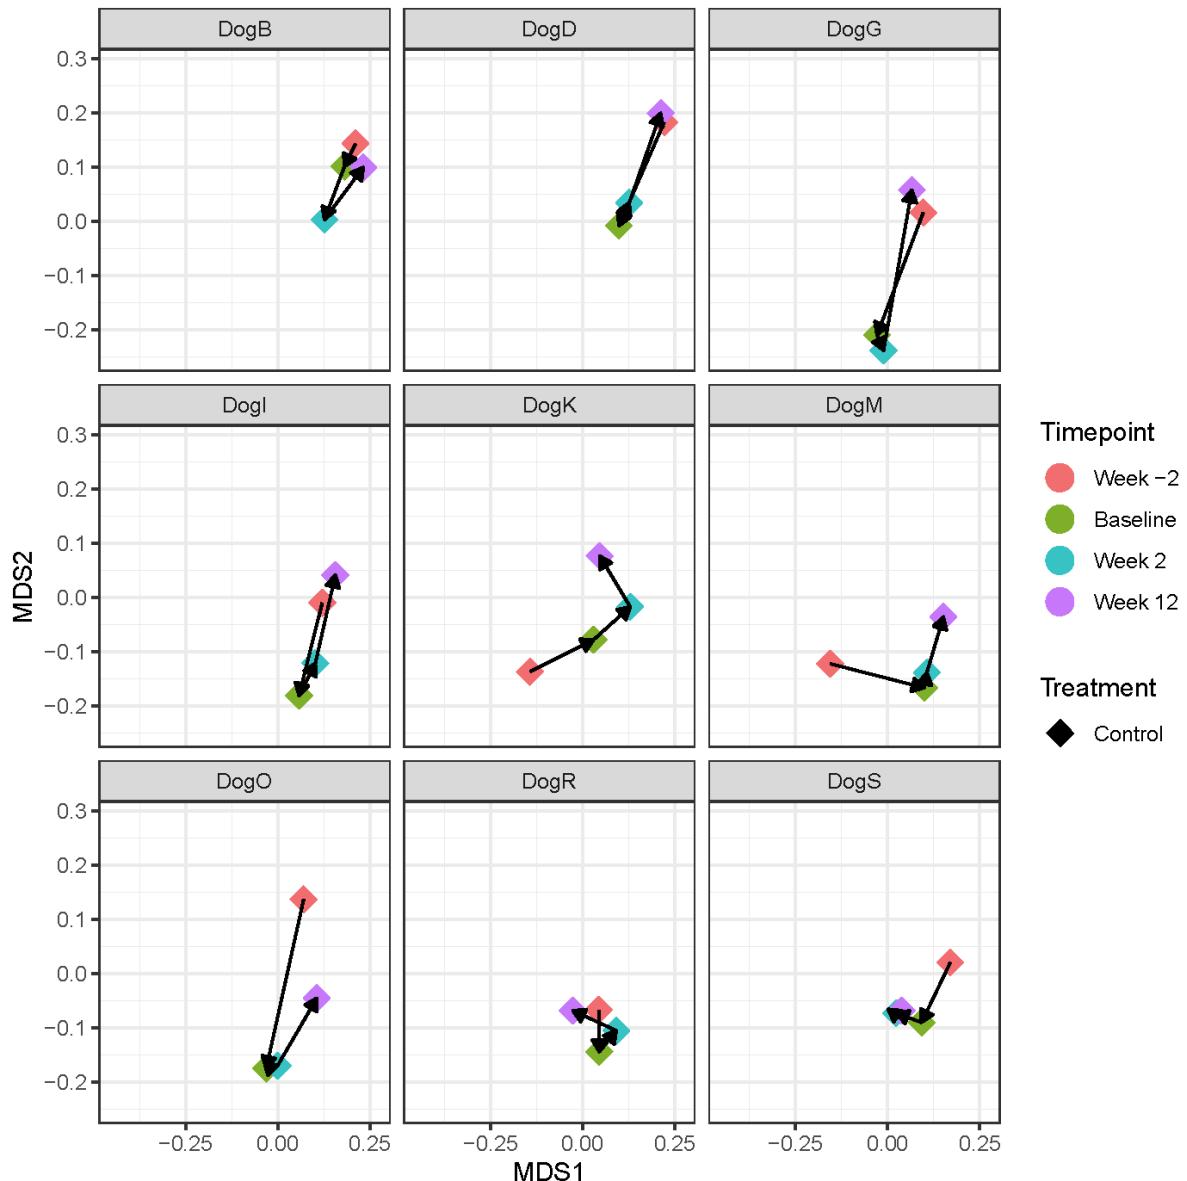

**Appendix-Figure 4 PCoA ordinations of the oral microbiota in the Donor, Control and Test groups with all data-points individually labelled**

The two PCoA plots above respectively show a subset of the data-points shown in Appendix-Figure 3 above. The upper panel includes all the Donor and Control subjects' data-points at each of the four time-points. The lower panel includes all the Donor and Test subjects' data-points at each time-point. The data-points are identified using the same codes used in Appendix-Tables 2 and 3. The symbol and colour scheme used is analogous to that used in Figure 3 and Appendix-Figure 3, without showing the ellipses to improve visual interpretation.

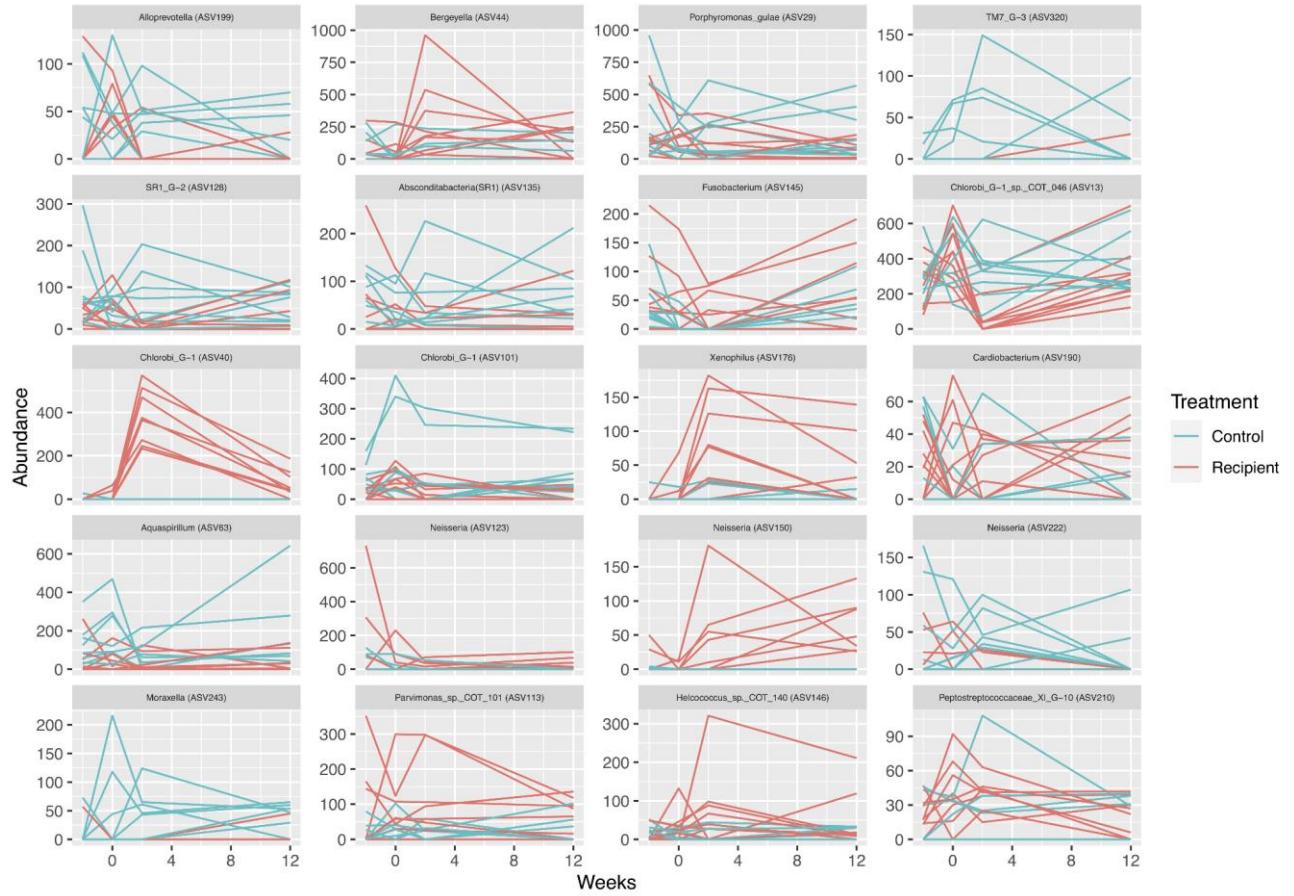

**Appendix Figure 5. PCoA plots of Test dogs' oral microbiota before and after OMT transplantation from donor.**

The nine respective panels show the PCoA plots of the ASV composition of the oral microbiota within each of the nine Test dogs (Dogs A, C, F, H, J, L, N, P, Q), as well as the corresponding oral microbiome transplant (OMT) they received from the healthy donor dog. MDS1 and MDS2 respectively refer to the two principal axes generated from PCoA analyses. The oral microbiome of the Test dogs was analyzed at four time-points: Week -2, 2 weeks before transplant (red filled squares); Baseline, immediately after oral prophylaxis (plaque removal), prior to receiving the OMT transplant; green squares); Week 2, 2 weeks after receiving OMT transplantation (blue squares); Week 12, 12 weeks after receiving OMT transplantation (purple squares). The respective OMT transplants (filled green circles) are linked to the Test dogs' microbiota at the week 2 time-point via a dashed line. The four respective time-points are linked by arrows, to indicate the 'trajectory' of the oral microbiome composition of the Test dogs during the experimental observation period. A common 'trend' in the respective trajectories may be observed in most of the respective Test dogs' oral microbiota compositions; with the composition of the oral microbiota at the Week 2 time-point generally being the most similar to that of the respective OMT.

**Appendix Figure 6. PCoA plots of Control dogs' oral microbiota across the four time-points**

The nine respective panels show the PCoA plots of the ASV composition of the oral microbiota within each of the nine Control dogs (Dogs B, D, G, I, K, M, O, R, S). MDS1 and MDS2 respectively refer to the two principal axes generated from PCoA analyses. The oral microbiome of the Control dogs was analyzed at four time-points: Week -2, 2 weeks prior to oral prophylaxis (plaque removal) (filled red rhombuses); Baseline, immediately after oral prophylaxis (green rhombuses); Week 2, 2 weeks after receiving oral prophylaxis (blue rhombuses); Week 12, 12 weeks after receiving oral prophylaxis (purple rhombuses). The four respective time-points are linked by arrows, to indicate the 'trajectory' of the oral microbiome composition of the Control dogs during the experimental observation period. The respective 'trends' in the PCoAs from the Control dogs should be compared and contrasted with those obtained from the Test dogs, shown in the Appendix-Figure 4.

### Appendix-Figure 7. Abundance plots of the top 20 PRC scoring species.

The relative abundance of the respective ASV is plotted on the y-axis. The four respective sampling time-points (in weeks) are plotted on the x-axis.

**Appendix-Table 1.** Differences in alpha diversity values (as evaluated by median Shannon entropy values) in the Donor, Test and Control subject groups, over the course of the trial, measured at four time-points (Week -2, Baseline, Week 2 and Week 12)

Subject Group	Time-point	25% Percentile	Median	75% Percentile
Donor	Wk -2	4.12	4.35	4.66
Donor	Baseline	3.98	4.16	4.23
Test	Wk -2	4.919	5.053	5.145
Test	Baseline	4.608	4.718	4.83
Test	Wk 2	4.419	4.637	4.708
Test	Wk 12	4.722	4.881	5.022
Control	Wk -2	4.755	4.959	5.056
Control	Baseline	4.622	4.632	4.774
Control	Wk 2	4.654	4.749	4.813
Control	Wk 12	4.759	4.875	4.948

**Appendix Table 2.** Summary of alpha diversity levels (evaluated by Shannon entropy values) in all microbiota samples collected from all subjects included in the study, at each of the four time-points.

**Appendix-Table 4.** PERMANOVA statistics testing for the differences between microbiome samples based on the Bray-Curtis dissimilarities measure. Pairwise comparison of samples grouped by time-point (week -2, baseline, week 2, week 12) and treatment category (Test Control, Donor) were assessed in PERMANOVA test (permutations = 9999). F.Model: PERMANOVA test statistics termed as pseudo F-ratio which is analogous to Fisher's F-ratio. R<sup>2</sup>: coefficient of determination, which refers to the proportion of sum of squares from the total. p.adjusted: p-value is adjusted for multiple comparisons by controlling for the false discovery rate using the Benjamini and Hochberg procedure. Only the pairs with p.adjusted <0.05 are listed in this table.

pairs		F.Model	R <sup>2</sup>	p.value	p.adjusted
