

# BMJ Open

BMJ Open is committed to open peer review. As part of this commitment we make the peer review history of every article we publish publicly available.

When an article is published we post the peer reviewers' comments and the authors' responses online. We also post the versions of the paper that were used during peer review. These are the versions that the peer review comments apply to.

The versions of the paper that follow are the versions that were submitted during the peer review process. They are not the versions of record or the final published versions. They should not be cited or distributed as the published version of this manuscript.

BMJ Open is an open access journal and the full, final, typeset and author-corrected version of record of the manuscript is available on our site with no access controls, subscription charges or pay-per-view fees (<http://bmjopen.bmj.com>).

If you have any questions on BMJ Open's open peer review process please email [info.bmjopen@bmj.com](mailto:info.bmjopen@bmj.com)

## Efficacy and safety of Remdesivir in COVID-19 caused by SARS-CoV-2: A systematic review and meta-analysis

Journal:	<i>BMJ Open</i>
Manuscript ID	bmjopen-2020-048416
Article Type:	Original research
Date Submitted by the Author:	24-Dec-2020
Complete List of Authors:	Singh, Surjit ; All India Institute of Medical Sciences, Department of Pharmacology Khera, Daisy; All India Institute of Medical Sciences, Department of Pediatrics Chugh, Ankita; All India Institute of Medical Sciences, Department of Dentistry Khera, Pushpinder; All India Institute of Medical Sciences, Department of Diagnostic and Interventional Radiology Chugh, Vinay; All India Institute of Medical Sciences, Department of Dentistry
Keywords:	COVID-19, Immunology < NATURAL SCIENCE DISCIPLINES, CLINICAL PHARMACOLOGY, Respiratory infections < THORACIC MEDICINE

SCHOLARONE™  
Manuscripts

I, the Submitting Author has the right to grant and does grant on behalf of all authors of the Work (as defined in the below author licence), an exclusive licence and/or a non-exclusive licence for contributions from authors who are: i) UK Crown employees; ii) where BMJ has agreed a CC-BY licence shall apply, and/or iii) in accordance with the terms applicable for US Federal Government officers or employees acting as part of their official duties; on a worldwide, perpetual, irrevocable, royalty-free basis to BMJ Publishing Group Ltd ("BMJ") its licensees and where the relevant Journal is co-owned by BMJ to the co-owners of the Journal, to publish the Work in this journal and any other BMJ products and to exploit all rights, as set out in our [licence](#).

The Submitting Author accepts and understands that any supply made under these terms is made by BMJ to the Submitting Author unless you are acting as an employee on behalf of your employer or a postgraduate student of an affiliated institution which is paying any applicable article publishing charge ("APC") for Open Access articles. Where the Submitting Author wishes to make the Work available on an Open Access basis (and intends to pay the relevant APC), the terms of reuse of such Open Access shall be governed by a Creative Commons licence – details of these licences and which [Creative Commons](#) licence will apply to this Work are set out in our licence referred to above.

Other than as permitted in any relevant BMJ Author's Self Archiving Policies, I confirm this Work has not been accepted for publication elsewhere, is not being considered for publication elsewhere and does not duplicate material already published. I confirm all authors consent to publication of this Work and authorise the granting of this licence.

3 **Title: Efficacy and safety of Remdesivir in COVID-19 caused by SARS-CoV-2: A**  
4 **systematic review and meta-analysis**  
5  
6  
7

8 **ABSTRACT**  
9

10  
11 **Objectives:** Remdesivir, an RNA polymerase inhibitor, evaluated for effectiveness in  
12 comparison to Standard therapy in adult COVID-19 patients.  
13  
14

15  
16 **Data sources:** Electronic search for eligible articles of Medline (via PubMed), The Cochrane  
17 Central Register of Controlled Trials, and clinicaltrials.gov was done.  
18  
19

20  
21 **Participants & study eligibility criteria:** Only RCTs aimed to evaluate the efficacy of  
22 Remdesivir in the treatment COVID-19 were considered eligible for this systematic review.  
23  
24

25  
26 **Interventions:** Remdesivir was compared with standard of care, which acts as control group  
27  
28

29  
30 **Primary and secondary outcomes:** Primary outcomes was mortality and secondary  
31 outcomes were time to clinical improvement and safety outcomes like serious adverse events,  
32 respiratory failure  
33  
34  
35

36  
37 **Study appraisal and synthesis methods:** Meta-analysis was performed by Cochrane review  
38 manager 5 (RevMan) version 5.3. Cochrane risk of bias 2.0 tool was used for methodological  
39 quality assessment. The GRADE pro GDT was applied for overall quality of evidence.  
40  
41  
42

43  
44 **Results:** 52 RCTs were screened and 4 studies were included in analysis, with total of 7324  
45 patients. No mortality benefit with use of remdesivir versus standard of care [OR=0.92  
46 (95%CI = 0.79 – 1.07), p=0.30, moderate quality evidence]. Significant clinical improvement  
47 [OR=1.52 (95%CI = 1.24 – 1.87), p<0.0001, low quality] and time to clinical improvement  
48 [HR=1.28 (95%CI = 1.12 – 1.46), p=0.0002, very low quality] with the use of remdesivir  
49 versus control group. Significant decrease was found in the risk of serious adverse  
50 events [RR=0.75 (95%CI = 0.62 – 0.90), p=0.0003, low quality], however no difference was  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 found in the risk of respiratory failure [RR=0.85 (95%CI = 0.41 – 1.77), p=0.67, very low  
4 quality evidence] with remdesivir.  
5  
6

7  
8 **Conclusions:** With the current evidence on efficacy and safety of remdesivir, authors do not  
9 recommend use of Remdesivir for treatment for COVID-19 patients caused by SARS-CoV-2,  
10 as it has shown no mortality benefit (moderate quality evidence) and cost-benefit analysis  
11 revealed limited use especially in developing countries.  
12  
13  
14  
15

16  
17  
18 **Systematic review registration:** PROSPERO registration number: CRD42020189517  
19

20  
21 **Keywords:** Remdesivir, COVID-19, SARS-CoV-2

- There is preliminary evidence of clinical benefit and approval of remdesivir as compassionate use by US FDA in COVID-19 patients.
- Our study showed No Mortality benefit with the use of Remdesivir in COVID-19 patients, with moderate quality evidence.
- Subgroup analysis showed No mortality benefit in patients with or without requirement of assisted ventilation.
- Benefit in time to clinical improvement but with “Very low” quality of evidence. Systematic review indicates no benefit with the use of remdesivir in COVID-19 patients.
- Overall evidence suggests no beneficial effect and thus recommend against the use of remdesivir, especially in lower to middle income countries.

## INTRODUCTION

A novel coronavirus disease (COVID-19), caused by infection with SARS-CoV-2, created a pandemic of mortality all over the world.[1, 2] The global pandemic of SARS-CoV-2 infections has affected more than 3.8 million people world-wide and has been the cause of 1.08 million deaths globally by the 10<sup>th</sup> of October 2020 as per COVID-19 statistics data. Twenty six million people have recovered and as the trend suggests most of them either stay asymptomatic and few of them develop pneumonia like symptoms that does not require oxygen support.[3] A very small percentage get critical to the limit of hypoxia, acute respiratory distress syndrome and multi- organ failure. Among these critical patients who are being put on mechanical ventilation, half of them die.

The search for an effective therapy or preventive modality has become the utmost need of the hour. There are few proposed and approved drugs with some antiviral action and they are under investigation simultaneously across the globe. But as yet no proven effective therapy for SARS -CoV-2 has been accepted widely. Amongst the few promising therapies available remdesivir, a viral RNA polymerase inhibitor has been recommended by US FDA as a drug for compassionate use for treatment of COVID-19 patients. Remdesivir, a nucleoside analogue prodrug, has shown inhibitory effects on SARS-CoV-2, both in vitro and in animal models. However even for the above mentioned studies, contrasting results have been reported in different nations like China and USA.[3] Varied study designs[4, 5], genetic reasons and different treatment regimens (5 or 10 days) have been attributed for this difference.

Only two randomized controlled clinical trials (RCT) have shown efficacy of remdesivir in COVID-19 patients. Many RCTs are undergoing to assess the benefit-risk ratio of remdesivir.

1  
2  
3 Current review was planned to assess the mortality and clinical benefit in addition to safety of  
4 remdesivir in the treatment of COVID-19 caused by SARS-CoV-2.  
5  
6

## 7 8 **METHODS**

### 9 10 **Protocol and registration**

11  
12  
13 The present systematic review was done as per the PRISMA (Preferred Reporting Items for  
14 Systematic Reviews and Meta-Analyses) statement. The protocol has been registered with  
15 PROSPERO (International Prospective Register of Systematic Reviews) database; protocol  
16 number as CRD42020189517.  
17  
18

### 19 20 **Criteria for study inclusion**

21  
22  
23 Only RCTs evaluating role of remdesivir compared to standard care in COVID-19 were  
24 included. Observational studies, review articles, case reports or case series were excluded.  
25  
26

### 27 28 **Search strategy and study selection**

29  
30  
31 Electronic literature search using Medline (via PubMed), The Cochrane Central Register of  
32 Controlled Trials and clinicaltrials.gov was conducted on 20<sup>th</sup> September 2020, to identify all  
33 the published relevant articles. Bibliographic search of published articles were also done  
34 manually to identify more studies. Language or publication status restriction was applied.  
35  
36 Search strategy using following medical subject headings (MeSH) was developed: ‘SARS-  
37 CoV-2’, ‘COVID-19’, ‘Remdesivir’, ‘COVID’, ‘novel coronavirus’. RCT restriction was  
38 applied.  
39  
40

41  
42  
43 The titles and abstracts retrieved by electronic searching were assessed by two independent  
44 researchers for potential eligibility and duplicates removed.  
45  
46

### 47 48 **Data extraction**

49  
50  
51 Study design, remdesivir doses and regimens, total subjects along with their characteristics,  
52 efficacy and safety outcomes were extracted on pre-structured form.  
53  
54  
55  
56  
57  
58  
59  
60

## Study outcomes

The primary outcome included in our review was mortality (defined as deaths in each group).

The secondary outcomes were clinical improvement and virological cure. In addition serious adverse events and other safety parameters were assessed.

## Quality assessment of studies

Two authors independently (DK and AC) assessed the methodological quality of included studies. Cochrane Collaboration risk of bias 2 tool (ROB-2) [6] was used. Overall assessment was recorded as high, low and some concerns. Robvis (visualization tool)[7] was used for synthesis of plots for risk of bias.[7]

For publication bias assessment, funnel plot asymmetry was not assessed as studies were less than five. However, Egger's regression test was applied.

## Data synthesis and summary measures

Dichotomous data were summarized as odd ratios (OR) and adjusted hazard ratios (HR) with 95% confidence intervals (CI) wherever applicable. Review Manager 5 (RevMan) Version 5.3. (Copenhagen: The Nordic Cochrane Centre, The Cochrane Collaboration, 2014) was used for all the analyses.[8] Heterogeneity was assessed using  $I^2$  [9, 10]. The results of both fixed and random effect model were assessed for interpretation [9, 11].

## Assessment of Quality of Evidence - GRADE Pro analysis

The overall quality of evidence for each of the outcomes was assessed using GRADE pro GDT (guideline development tool) software based on the principles of Grades of Recommendations, Assessment, Development and Evaluation (GRADE).[12] Optimal information size (OIS) was calculated to be 1213 patients in each group. Final overall

GRADE may be high, moderate, low or very low. The online version of GRADE pro GDT software was accessed from the site: <https://grade.pro.org/>. [12]

## **Patient and Public Involvement**

Patients or the public WERE NOT involved in the design, or conduct, or reporting, or dissemination plans of our research

## **RESULTS**

### **Study selection**

The study selection and exclusion process has been documented using the PRISMA flow diagram (Figure 1). Out of total 52 records screened, 4 RCTs[3, 13, 14] were included in analysis.

### **Study characteristics**

Study characteristics of RCTs of present systematic review are mentioned in Table 1.

### **Risk of bias (ROB) within the studies**

The overall risk of bias was assessed as “Low” as WHO solidarity trial[14] and Wang et al.[3] ROB was assessed as low. Study done by Beigel et al[13] and Spinner et al.[15] was regarded as having “High” ROB. Hence, ROB assessed for outcomes having data only from Beigel et al. and Spinner et al. in GRADE analysis was regarded as having serious issues. The ROB of RCTs was represented in Figure 2 and Supplementary Figure 1 (Weighted summary ROB).

### **Efficacy outcomes**

#### **Mortality**

Mortality data was included from 4 RCTs with 3818 and 3506 patients in Remdesivir and standard of care groups, respectively. Remdesivir has no mortality benefit as compared to control group [OR=0.92 (95%CI = 0.79 – 1.07), p=0.30; I<sup>2</sup>=0] (Figure 3a). Sub-group

1  
2  
3 analysis revealed no mortality benefit in low risk and high groups (Figure 3a, Supplementary  
4  
5 Figure 2)

### 6 7 8 **Clinical Improvement**

9  
10 Statistically significant increase in rates of clinical improvement in remdesivir versus controls  
11  
12 was found [OR=1.52 (95%CI = 1.24 – 1.87),  $p<0.0001$ ;  $I^2=0\%$ ] (Figure 3b). Results were  
13  
14 drawn from 3 RCTs with total of 1879 patients.

### 15 16 17 **Time to clinical improvement**

18  
19 Pooled analysis revealed that there was significant increase in the time to clinical  
20  
21 improvement in remdesivir group as compared to controls [HR=1.28 (95%CI = 1.12 – 1.46),  
22  
23  $p=0.0002$ ;  $I^2=0\%$ ](Figure 3c). Data extracted from 2 RCTs with total of 1292 patients.

### 24 25 26 **Safety outcomes**

#### 27 28 **Serious Adverse Events (AE)**

29  
30 Pooled analysis revealed significant increase in the risk of serious adverse events in control  
31  
32 group as compared to remdesivir [RR=0.75 (95%CI = 0.62 – 0.90),  $p=0.0003$ ;  $I^2=0\%$ ]  
33  
34 (Figure 4a). This data was extracted from 3 RCTs with a total of 1875 patients.

#### 35 36 37 **Respiratory Failure**

38  
39 No difference in the risk of respiratory failure between remdesivir and control groups was  
40  
41 found [RR=0.85 (95%CI = 0.41 – 1.77),  $p=0.67$ ;  $I^2=55\%$ ] (Figure 4b). Findings were derived  
42  
43 from 2 RCTs with a total of 1291 patients.

#### 44 45 46 **Publication bias**

47  
48 Though the funnel plot asymmetry was not assessed. The Egger's regression test applied on  
49  
50 four studies included in mortality rate assessment showed no publication bias ( $t = - 0.5947$ ,  $p$   
51  
52  $= 0.6123$ ).

#### 53 54 55 **GRADE analysis of the primary and secondary outcomes (Table 2)**

1  
2  
3 The GRADE analysis recommendation for mortality was ‘Moderate’ evidence quality.  
4  
5 Though there is low ROB, low heterogeneity and direct outcome but there are serious  
6  
7 concerns with imprecision. The quality of evidence for clinical improvement and time to  
8  
9 clinical improvement were graded as “Low” and “Very Low” respectively. The GRADE  
10  
11 recommendation for serious AE and respiratory failure were “Low” and “Very low” quality  
12  
13 of evidence respectively, as there was presence of high ROB and high imprecision. The  
14  
15 GRADE recommendation is shown in table 2.  
16  
17

19  
20  
21  
22

## 23 Discussion

24  
25  
26 With the existing recommendation of USFDA for compassionate use of Remdesivir in  
27  
28 COVID patients, it is being used worldwide. Current systematic review was planned for  
29  
30 recommendation drawn from RCTs evaluating the efficacy of remdesivir in COVID-19  
31  
32 patients.  
33  
34  
35

36  
37 In the current systematic review, ORs for mortality was unable to confer any mortality  
38  
39 benefit with the use of remdesivir. WHO solidarity trial[14] showed no mortality benefit with  
40  
41 the use of remdesivir. Though it was an open label study, it is less likely to have bias in  
42  
43 assessment of objective outcome like mortality. A total of 3451 patients were included in  
44  
45 remdesivir and standard of care groups. Subgroup analysis revealed no mortality benefit in  
46  
47 low risk (Figure 3a - no oxygen requirement, Supplementary Figure 2 – No invasive  
48  
49 ventilation) or high risk (Figure 3a - oxygen requirement or assisted ventilation,  
50  
51 Supplementary Figure 2 – Invasive ventilation) group of patients with remdesivir.  
52  
53  
54

55  
56 At the time of recruitment, more patients were on invasive mechanical ventilation or ECMO  
57  
58 in the placebo group. There were significantly more number of serious adverse events  
59  
60

1  
2  
3 reported in our review due to increase serious AE in Beigel et al study.[13] This is rare  
4  
5 occurrence that serious AE were significantly more in control group. The fact that more  
6  
7 severe patients were randomized into control group in the study by Beigel et al.[13] is the  
8  
9 major reason for this finding. Similarly, the serious AE which also included the clinical  
10  
11 events like renal failure and respiratory failure (5.2% in remdesivir and 8% in placebo arm)  
12  
13 were also observed more in placebo group. Despite this imbalance, remdesivir was unable to  
14  
15 show superiority in mortality rate.  
16  
17  
18  
19

20  
21 Sub-group analysis of Beigel et al.[13] study revealed that remdesivir resulted in significant  
22  
23 rate of clinical improvement in COVID-19 patients on oxygen therapy, while the patients not  
24  
25 on oxygen, or on high flow oxygen or non-invasive ventilation and receiving mechanical  
26  
27 ventilation or ECMO had similar clinical improvement as standard of care.  
28  
29

30  
31 Placebo used in Beigel et al.[13] study was sulfo-butyl-ether b-cyclodextrin-sodium  
32  
33 (SBECD), used to dissolve remdesivir. The maximum recommended daily dose is  
34  
35 approximately 250 mg/kg solvent used to dissolve remdesivir.[13] The amount of solvent  
36  
37 present in placebo was not quantified in protocol. Dose of solvent should be modified in  
38  
39 patients with eGFR fall of more than 50% from baseline and is contraindicated in patients  
40  
41 with eGFR less than 30ml/min. But such modification were not done in either arms. Hence  
42  
43 the effect of solvent on patients with impaired renal function can be detrimental and cannot  
44  
45 be ruled out.  
46  
47  
48  
49

50  
51 In the study by Beigel et al.[13], the median time of administration of drug from  
52  
53 randomization was nine days. Median recovery time from randomization was 11 days. In  
54  
55 addition, 302 patients in remdesivir group did not receive 10 days of treatment. Therefore, it  
56  
57 is difficult to infer that the remdesivir has resulted in recovery of patients, as average 2 days  
58  
59 of administration resulting in complete recovery of patients is impossible.  
60

1  
2  
3 The virological cure is the most important outcome which was neglected by the authors.  
4  
5 Wang et al reported no difference (percentage difference = -7.5 (95% CI = -19.2 to 4.2)) in  
6  
7 undetectable viral RNA load in remdesivir (75.6%) and placebo groups (83.1%). Patients  
8  
9 may become asymptomatic but not cured. It has been observed that asymptomatic patients  
10  
11 with RT-PCR positive test can have thromboembolic and chest CT changes. Study done by  
12  
13 Merkler et al observed that eight patients (26%) out of total 31 ischemic stroke patients  
14  
15 presented with ischemic stroke. They didn't have any COVID-19 symptoms on  
16  
17 presentation.[16]  
18  
19  
20  
21

22  
23 The SIMPLE trial[4] results published in New England Journal of Medicine does not include  
24  
25 a standard of care group. Similar to Beigel et al. virological cure was not reported.[4] Clinical  
26  
27 status at day 14 was similar in 5 day course of remdesivir as compared to 10 day course.  
28  
29 However, in comparison to standard care, 5 day group (OR 1.65 [95% CI 1.09-2.48];  
30  
31  $p=0.017$ ) showed significant improvement while 10 day group did not (OR 1.31 [95% CI  
32  
33 0.88-1.95];  $p=0.18$ ). Death reported on day 11 was similar in all three groups.[17]  
34  
35  
36  
37

38 In another study published by Grein et al.[5] on compassionate use of remdesivir did not have  
39  
40 a control arm. Hence, the conclusion that remdesivir is effective cannot be drawn as the  
41  
42 possibility of observing similar findings in control arm cannot be ruled out.  
43  
44  
45

46 Three systematic reviews and meta-analysis were published on remdesivir[18-20]. However,  
47  
48 none of the reviews have included WHO solidarity trials in review. Exclusion of such large  
49  
50 study (N=3451) decreases the power of systematic reviews. Our results are different from all  
51  
52 three systematic reviews as Wilt et al.[20] and Shrestha et al.[18] have concluded mortality  
53  
54 benefit with remdesivir while Elsayah et al.[19] concluded significant clinical improvement  
55  
56 with remdesivir as compared to standard care.  
57  
58  
59  
60

1  
2  
3 The cost of the drug is \$2340 per patient and with no mortality benefit. From a cost benefit  
4 perspective, it is our personal opinion that it should not be recommended for use, especially  
5  
6 in developing countries.[21]  
7  
8  
9

### 10 **Limitations and strengths**

11  
12  
13  
14 A major strength of our systematic review is that four RCTs were included in our analysis  
15 with total sample size of 7324 patients. Study done by Wang et al and WHO Solidarity trial  
16 has low ROB. Robust method of analysis using ROB-2 and GARDE analysis is another  
17 strength of the current systematic review.  
18  
19  
20  
21  
22  
23

### 24 **Quality of Evidence: (GRADE)**

25  
26  
27 The overall quality of systematic review is “Moderate”. Critical outcomes like mortality has  
28 moderate quality evidence. Clinical improvement was regarded as “Low”. Time to clinical  
29 improvement has “Very low” quality of evidence. Time to clinical improvement was used by  
30 regulatory agencies like US FDA for giving approval to remdesivir for treatment of severe  
31 COVID-19 patients. Hence, the quality of evidence for time to clinical improvement cannot  
32 be overlooked. This evidence suggests that further research is very likely to have an  
33 important impact on our confidence in the estimate of time to clinical improvement and likely  
34 to change the estimate. Moderate quality of evidence with regard to mortality showed that  
35 further RCTs are likely to have important impact and may change the no mortality benefit  
36 conclusion drawn from review.

48  
49

### 50 **Conclusion:**

51  
52  
53  
54 Evidence of our systematic review indicates no benefit in mortality rate with remdesivir, with  
55 moderate quality of evidence. Benefit does exist in terms of clinical improvement and time to  
56 clinical improvement, but the evidence is of low and very low quality. Significant decrease in  
57  
58  
59  
60

1  
2  
3 serious adverse events as compared to placebo, strengthens the evidence of more serious  
4 patients in placebo arm. No difference was shown in respiratory failure in the two groups  
5  
6 (very low quality evidence). All outcomes except mortality in our meta-analysis were  
7  
8 influenced by Beigel et al. and Spinner et al., which has high ROB. WHO solidarity trial and  
9  
10 Wang et al showed no mortality benefit, both having overall low ROB.  
11  
12  
13  
14

Table 1. Characteristics of clinical studies evaluating Remdesivir for treatment of COVID-19

Author, year (Study design)	Institution/ Country of study conduct	Study Interventions (N)/ Regimen	Study control (N)/ Regimen	Study population characteristics	Study outcomes
<b>Beigel et al 2020</b> (Randomized controlled trial)	Multicenter trial	Remdesivir (538); 200 mg on day 1 followed by 100 mg on days 2–10 in single daily infusions	Placebo (521)	Hospitalized adult COVID-19 patients with evidence of lower respiratory tract involvement.	<b>Time to recovery:</b> Patients in the remdesivir group had a shorter time to recovery than patients in the placebo group (median, 11 days, as compared with 15 days; rate ratio for recovery, 1.32; 95% confidence interval [CI], 1.12 to 1.55; P<0.001 <b>Mortality:</b> Kaplan Meier estimates of mortality by 14 days were 7.1% with remdesivir and 11.9% with placebo (hazard ratio for death, 0.70; 95% CI, 0.47 to 1.04)
<b>Spinner et al</b>	Multicenter trial	Remdesivir - 10-day (n = 197), Remdesivir - 5-day (n = 199)	Standard care (n = 200)	Confirmed severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) infection and moderate COVID-19 pneumonia (pulmonary infiltrates and room-air oxygen saturation >94%)	<b>Day 28</b> Mortality rate n(%) – Remdesivir 10 day = 3(2); Remdesivir 5 day = 2(1), Standard = 4(2) Clinical Improvement n(%) - Remdesivir 10 day =174(90), Remdesivir 5 day = 171(90), Standard = 166(83)
<b>Wang et al 2020</b> (Randomized controlled trial)	Department of Pulmonary and Critical Care Medicine, China-Japan Friendship Hospital,	Remdesivir (158); at least 1 dose after entering ICU; 200 mg on day 1 followed by 100 mg on days 2–10 in	Placebo (79)	Hospitalized adult COVID-19 patients with symptom onset to enrolment interval of $\leq 12$ days, oxygen saturation $\leq 94\%$ on room air or a ratio of arterial oxygen partial pressure to fractional	<b>Time to clinical improvement within 28 days after randomization:</b> Remdesivir use was not associated with a difference in time to clinical improvement (hazard ratio 1.23 [95% CI 0.87–1.75]). Although not statistically significant, patients receiving remdesivir had a numerically faster time to clinical improvement than those receiving placebo among patients with symptom duration of 10 days or less (hazard ratio 1.52 [0.95–2.43])

	Beijing, China	single daily infusions		inspired oxygen of 300 mm Hg or less, and radiologically confirmed pneumonia	<b>28-day mortality:</b> similar between the two groups (22 [14%] died in the remdesivir group vs 10 (13%) in the placebo group; difference 1·1% [95% CI -8·1 to 10·3]).
<b>WHO Solidarity Trial 2020</b> (Randomized controlled trial)	World Health Organization, Multicentric trial (405 hospitals in 30 countries)	Remdesivir (2743); Day 0, 200mg; days 1-9, 100mg	Placebo (2708)	Hospitalized with a diagnosis of COVID-19, age $\geq 18$ years, not known to have received any study drug, without anticipated transfer elsewhere within 72 hours	<b>Mortality rate:</b> Remdesivir RR=0.95 (0.81-1.11, p=0.50; 301/2743 active vs 303/2708 control). Hydroxychloroquine RR=1.19 (0.89-1.59, p=0.23; 104/947 vs 84/906), Lopinavir RR=1.00 (0.79-1.25, p=0.97; 148/1399 vs 146/1372) Interferon RR=1.16 (0.96-1.39, p=0.11; 243/2050 vs 216/2050)

Table 2: GRADE recommendation for primary and secondary outcomes of use of Remdesivir in COVID-19

Certainty assessment						№ of patients		Effect		Certainty Importance
№ of studies	Risk of bias	Inconsistency	Indirectness	Imprecision	Other considerations	Efficacy and Safety of Remdesivir	placebo	Relative (95% CI)	Absolute (95% CI)	
<b>Mortality at day 28</b>										
4 RCT	not serious <sup>a</sup>	not serious	not serious	serious <sup>b</sup>	none	387/3818 (10.1%)	394/3506 (11.2%)	<b>OR 0.92</b> (0.79 to 1.07)	<b>8 fewer per 1,000</b> (from 21 fewer to 7 more)	⊕⊕⊕○ MODERATE CRITICAL
<b>Clinical Improvement</b>										
3 RCT	serious <sup>c</sup>	not serious	not serious	serious <sup>d</sup>	none	782/1080 (72.4%)	484/799 (60.6%)	<b>OR 1.52</b> (1.24 to 1.87)	<b>94 more per 1,000</b> (from 50 more to 136 more)	⊕⊕○○ LOW IMPORTANT
<b>Time to clinical Improvement</b>										
2 RCT	serious <sup>e</sup>	not serious	serious <sup>f</sup>	serious <sup>d</sup>	none	-/0	-/0	<b>HR 1.28</b> (1.12 to 1.46)	<b>1 fewer per 1,000</b> (from 1 fewer to 1 fewer)	⊕○○○ VERY LOW IMPORTANT
<b>Serious Adverse events</b>										
3 RCT	serious <sup>c</sup>	not serious	not serious	serious <sup>d</sup>	none	161/1075 (15.0%)	179/800 (22.4%)	<b>RR 0.75</b> (0.62 to 0.90)	<b>56 fewer per 1,000</b> (from 85 fewer to 22 fewer)	⊕⊕○○ LOW IMPORTANT
<b>Respiratory Failure</b>

1  
2  
3 **CI:** Confidence interval; **OR:** Odds ratio; **HR:** Hazard Ratio; **RR:** Risk ratio; RCT – Randomized controlled trials  
4

5 *Explanations*

6 a. All studies have low ROB except Biegel et al. WHO solidarity trial contributes 77.9% weight to overall effect has low ROB. Hence overall  
7 low ROB.  
8

9 b. Overall information size of 1213 was achieved in either group. However, the overall effect estimate included one, hence downgraded for  
10 imprecision  
11

12 c. Biegel et al. and Spinner et al. have a high risk of bias (ROB) due to selective reporting of results. Hence, downgraded for ROB.  
13

14 d. Overall Information Size of 1213 was not achieved in either groups. Hence, downgraded for imprecision  
15

16 e. Biegel et al. has a high risk of bias (ROB) due to selective reporting of results. Hence, downgraded for ROB.  
17

18 f. Time to clinical improvement is not a direct estimate of the patient's oriented outcomes. Hence, downgraded for evidence  
19

20 g. As  $I^2 > 50\%$ , heterogeneity is significantly high. Hence, downgraded for Inconsistency  
21

22 h. Overall information size of 1213 was not achieved in either group and the overall effect estimate included one, hence downgraded for  
23 imprecision

# PRISMA 2009 Checklist

Section/topic	#	Checklist item	Reported on page #
<b>TITLE</b>			
Title	1	Identify the report as a systematic review, meta-analysis, or both.	1, 3
<b>ABSTRACT</b>			
Structured summary	2	Provide a structured summary including, as applicable: background; objectives; data sources; study eligibility criteria, participants, and interventions; study appraisal and synthesis methods; results; limitations; conclusions and implications of key findings; systematic review registration number.	3-4
<b>INTRODUCTION</b>			
Rationale	3	Describe the rationale for the review in the context of what is already known.	5
Objectives	4	Provide an explicit statement of questions being addressed with reference to participants, interventions, comparisons, outcomes, and study design (PICOS).	5
<b>METHODS</b>			
Protocol and registration	5	Indicate if a review protocol exists, if and where it can be accessed (e.g., Web address), and, if available, provide registration information including registration number.	6
Eligibility criteria	6	Specify study characteristics (e.g., PICOS, length of follow-up) and report characteristics (e.g., years considered, language, publication status) used as criteria for eligibility, giving rationale.	6
Information sources	7	Describe all information sources (e.g., databases with dates of coverage, contact with study authors to identify additional studies) in the search and date last searched.	6
Search	8	Present full electronic search strategy for at least one database, including any limits used, such that it could be repeated.	6
Study selection	9	State the process for selecting studies (i.e., screening, eligibility, included in systematic review, and, if applicable, included in the meta-analysis).	6
Data collection process	10	Describe method of data extraction from reports (e.g., piloted forms, independently, in duplicate) and any processes for obtaining and confirming data from investigators.	6
Data items	11	List and define all variables for which data were sought (e.g., PICOS, funding sources) and any assumptions and simplifications made.	6
Risk of bias in individual studies	12	Describe methods used for assessing risk of bias of individual studies (including specification of whether this was done at the study or outcome level), and how this information is to be used in any data synthesis.	7
Summary measures	13	State the principal summary measures (e.g., risk ratio, difference in means).	7
Synthesis of results	14	Describe the methods of handling data and combining results of studies, if done, including measures of consistency (e.g., I <sup>2</sup> ) for each meta-analysis.	7

# PRISMA 2009 Checklist

Page 1 of 2

Section/topic	#	Checklist item	Reported on page #
Risk of bias across studies	15	Specify any assessment of risk of bias that may affect the cumulative evidence (e.g., publication bias, selective reporting within studies).	7
Additional analyses	16	Describe methods of additional analyses (e.g., sensitivity or subgroup analyses, meta-regression), if done, indicating which were pre-specified.	7
<b>RESULTS</b>			
Study selection	17	Give numbers of studies screened, assessed for eligibility, and included in the review, with reasons for exclusions at each stage, ideally with a flow diagram.	8
Study characteristics	18	For each study, present characteristics for which data were extracted (e.g., study size, PICOS, follow-up period) and provide the citations.	8
Risk of bias within studies	19	Present data on risk of bias of each study and, if available, any outcome level assessment (see item 12).	8
Results of individual studies	20	For all outcomes considered (benefits or harms), present, for each study: (a) simple summary data for each intervention group (b) effect estimates and confidence intervals, ideally with a forest plot.	8
Synthesis of results	21	Present results of each meta-analysis done, including confidence intervals and measures of consistency.	8
Risk of bias across studies	22	Present results of any assessment of risk of bias across studies (see Item 15).	8
Additional analysis	23	Give results of additional analyses, if done (e.g., sensitivity or subgroup analyses, meta-regression [see Item 16]).	8-9
<b>DISCUSSION</b>			
Summary of evidence	24	Summarize the main findings including the strength of evidence for each main outcome; consider their relevance to key groups (e.g., healthcare providers, users, and policy makers).	12
Limitations	25	Discuss limitations at study and outcome level (e.g., risk of bias), and at review-level (e.g., incomplete retrieval of identified research, reporting bias).	12, 4
Conclusions	26	Provide a general interpretation of the results in the context of other evidence, and implications for future research.	13
<b>FUNDING</b>			
Funding	27	Describe sources of funding for the systematic review and other support (e.g., supply of data); role of funders for the systematic review.	None

4 **systematic review and meta-analysis**  
5  
6

7  
8 **ABSTRACT**  
9

10  
11 **Objectives:** Evaluation of remdesivir, an RNA polymerase inhibitor, for effectiveness in adults  
12 with COVID-19.  
13

14  
15 **Data sources:** Electronic search for eligible articles of PubMed, Cochrane Central and  
16 clinicaltrials.gov was performed on 20<sup>th</sup> September, 2020.  
17

18  
19 **Participants & study eligibility criteria:** Only RCTs evaluating efficacy of remdesivir in  
20 COVID-19 were included for meta-analysis.  
21

22  
23 **Interventions:** Remdesivir was compared with standard of care  
24

25  
26 **Primary and secondary outcomes:** Primary outcome was mortality and secondary outcomes  
27 were time to clinical improvement and safety outcomes like serious adverse events, respiratory  
28 failure.  
29

30  
31 **Study appraisal and synthesis methods:** Data synthesis was done with Cochrane review  
32 manager 5 (RevMan) version 5.3. Cochrane risk of bias 2.0 tool was used for methodological  
33 quality assessment. The GRADE pro GDT was applied for overall quality of evidence.  
34

35  
36 **Results:** 52 RCTs were screened and 4 studies were included in analysis, with total of 7324  
37 patients. No mortality benefit was observed with remdesivir versus control group[OR=0.92  
38 (95%CI = 0.79 – 1.07), p=0.30, moderate quality evidence]. Significantly higher rates of  
39 clinical improvement [OR=1.52 (95%CI = 1.24 – 1.87), p<0.0001, low quality] and faster time  
40 to clinical improvement [HR=1.28 (95%CI = 1.12 – 1.46), p=0.0002, very low quality] was  
41 observed with remdesivir versus control group. Significant decrease was found in the risk of  
42 serious adverse events[RR=0.75 (95%CI = 0.62 – 0.90), p=0.0003, low quality], however no

57  
58  
59  
60

1  
2  
3 difference was found in the risk of respiratory failure [RR=0.85 (95%CI = 0.41 – 1.77), p=0.67,  
4 very low quality evidence] with remdesivir.  
5  
6

7  
8 **Conclusions:** As per the evidence from current review, remdesivir has shown no mortality  
9 benefit (moderate quality evidence) in the treatment of COVID-19. From a cost benefit  
10 perspective, it is our personal opinion that it should not be recommended for use, especially in  
11 low and lower-middle income countries.

## INTRODUCTION

Coronavirus disease of 2019 (COVID-19), has created a pandemic all over the world [1, 2]. The global pandemic of SARS-CoV-2 infections has affected more than 141 million people world-wide and has been the cause of 3.026 million deaths globally by 18<sup>th</sup> of April 2021 as per COVID-19 statistics data. Around 120 million people have recovered and as the trend suggests most of them stay asymptomatic and few of them develop pneumonia like symptoms that does not require oxygen support [3]. A very small percentage get critical to the limit of hypoxia, acute respiratory distress syndrome and multi- organ failure. Among these critical patients who are being put on mechanical ventilation, half of them die.

The search for an effective therapy or preventive modality has become the utmost need of the hour. There are few proposed and approved drugs with some antiviral action and they are under investigation simultaneously across the globe. But as yet no proven effective therapy for SARS-CoV-2 has been accepted widely. Amongst the few promising therapies available remdesivir, a viral RNA polymerase inhibitor has been recommended by US FDA as a drug for compassionate use for treatment of COVID-19 patients. Remdesivir, a nucleoside analogue prodrug, has shown inhibitory effects on SARS-CoV-2, both in vitro and in animal models. However even for the above mentioned studies, contrasting results have been reported in different nations like China and USA [3]. Varied study designs [4, 5], genetic reasons and different treatment regimens (5 or 10 days) have been attributed for this difference.

Only two randomized controlled trials (RCT) have shown efficacy of remdesivir in COVID-19 patients. Many RCTs are undergoing to assess the benefit-risk ratio of remdesivir. Current review was planned to assess the mortality and clinical benefit in addition to safety of remdesivir in the treatment of COVID-19 caused by SARS-CoV-2.

## **METHODS**

### **Protocol and registration**

Review was done following the “PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses”) statement. “PROSPERO (International Prospective Register of Systematic Reviews) database” registration was done with study number as CRD42020189517.

### **Inclusion criteria**

Exclusively RCTs evaluating role of remdesivir compared to standard care in COVID-19 were included. Observational studies, review articles, case reports or case series were excluded.

### **Search and selection of studies**

Electronic literature search was performed in PubMed, Cochrane Central Register of Controlled Trials, in addition to clinicaltrials.gov on 20<sup>th</sup> September 2020, to identify the relevant published articles. Additional Search was done in November 2020 for results of completed trials. Bibliographic search of published articles were also done manually to identify more studies. Only English language studies published were included. Search was performed using medical headings like ‘SARS-CoV-2’, ‘COVID-19’, ‘Remdesivir’, ‘COVID’, ‘novel coronavirus’. RCT restriction was applied. PubMed search strategy is given in Supplementary file 1.

After removal of duplicate articles, two independent authors reviewed the studies for inclusion in review.

### **Data extraction**

Study design, remdesivir doses and regimens, total subjects along with their characteristics, efficacy and safety outcomes were extracted and filled on a pre-structured form.

## Study Objectives

The primary objective of review was assessment of mortality (defined as deaths in each group).

The secondary outcomes were clinical improvement and virological cure. In addition, serious adverse events and other safety parameters were assessed. Cost-benefit analysis was also performed for remdesivir.

## Quality assessment

Two authors independently (DK and AC) performed risk of bias (ROB) of RCTs using Cochrane Collaboration ROB-2 [6]. Overall assessment was recorded as high, low and some concerns. Synthesis of ROB plots was done using online software Robvis (visualization tool)[7].

For publication bias assessment, funnel plot asymmetry was not assessed as studies were less than five. However, Egger's regression test was applied.

## Data synthesis and summary measures

Mortality and other outcome data were presented as odd ratios (OR) or Hazard ratio (HR) with 95% confidence intervals (CI). Synthesis of data was done using "Review Manager 5 (RevMan) Version 5.3" (Copenhagen: The Nordic Cochrane Centre, The Cochrane Collaboration, 2014)[8]. The heterogeneity among RCTs included in review was judged with  $I^2$ [9, 10]. The results of both fixed and random effect model were assessed for interpretation [9, 11].

## Quality of Evidence - GRADE Pro GDT

GRADE pro GDT (guideline development tool) software (<https://gradepro.org/>) was applied for assessment of overall quality of evidence.[12] Optimal information size (OIS) or sample

1  
2  
3 size for either group was computed to be 1213 patients. Overall GRADE assessment was  
4  
5 classified as high, moderate, low or very low [12].  
6  
7

### 8 **Patient and Public Involvement**

9  
10  
11 Patients or the public WERE NOT involved in the design, or conduct, or reporting, or  
12  
13 dissemination plans of our research.  
14  
15

## 16 **RESULTS**

### 17 **Study PRISMA flow diagram**

18  
19  
20 The RCTs included in review are depicted in PRISMA flow chart (Figure 1). Out of total 52  
21  
22 records screened, 4 RCTs [3,13-15] were included in analysis. One study was excluded as it  
23  
24 was single arm study [4], one was in Spanish language and other two were non-COVID trial  
25  
26 [16] and historical control study [17].  
27  
28  
29

### 30 **Study characteristics**

31  
32 Study characteristics of RCTs of present systematic review are mentioned in Table 1.  
33  
34

### 35 **Risk of bias (ROB)**

36  
37  
38 The overall ROB was judged as “Low”, as ROB for WHO solidarity trial[14] and Wang et  
39  
40 al.[3] was assessed as low. Study done by Beigel et al.[13] and Spinner et al.[15] was regarded  
41  
42 as having “High” ROB. Hence, ROB assessed for outcomes having data only from Beigel et  
43  
44 al. and Spinner et al. in GRADE analysis was regarded as having serious issues. The ROB of  
45  
46 RCTs is represented in Figure 2 and Supplementary Figure 1.  
47  
48

### 49 **Efficacy outcomes**

#### 50 **Mortality**

51  
52  
53 Mortality data was included from 4 RCTs with 3818 and 3506 patients in remdesivir and  
54  
55 standard of care groups, respectively. Remdesivir was found to have no mortality benefit as  
56  
57 compared to control group [OR=0.92 (95%CI = 0.79 – 1.07), p=0.30; I<sup>2</sup>=0] (Figure 3a). Sub-  
58  
59  
60

1  
2  
3 group analysis revealed no mortality benefit in low risk and high risk groups (Figure 3a,  
4  
5 Supplementary Figure 2)

### 6 7 8 **Clinical Improvement**

9  
10 Statistically significant increase in rates of clinical improvement in remdesivir versus controls  
11  
12 was observed [OR=1.52 (95%CI = 1.24 – 1.87), p<0.0001; I<sup>2</sup>=0%] (Figure 3b). Results were  
13  
14 drawn from 3 RCTs with total of 1879 patients.

### 15 16 17 **Time to clinical improvement**

18  
19 Pooled analysis revealed that there was significantly faster time to clinical improvement in  
20  
21 remdesivir group as compared to controls [HR=1.28 (95%CI = 1.12 – 1.46), p=0.0002;  
22  
23 I<sup>2</sup>=0%](Figure 3c). Data extracted from 2 RCTs with total of 1292 patients.

### 24 25 26 **Safety outcomes**

#### 27 28 **Serious Adverse Events (AE)**

29  
30 Pooled analysis revealed significant decrease in the risk of serious adverse events in remdesivir  
31  
32 group as compared to control [RR=0.75 (95%CI = 0.62 – 0.90), p=0.0003; I<sup>2</sup>=0%] (Figure 4a).  
33  
34 This data was extracted from 3 RCTs with a total of 1875 patients.

#### 35 36 37 **Respiratory Failure**

38  
39 No difference in the risk of respiratory failure between remdesivir and control groups was  
40  
41 found [RR=0.85 (95%CI = 0.41 – 1.77), p=0.67; I<sup>2</sup>=55%] (Figure 4b). Findings were derived  
42  
43 from 2 RCTs with a total of 1291 patients.

#### 44 45 46 **Cost-benefit analysis**

47  
48 The cost of remdesivir is US \$ 2340 per patient. There is lack of mortality benefit as per our  
49  
50 review.

#### 51 52 53 **Publication bias**

59  
60

Though the funnel plot asymmetry was not assessed, the Egger's regression test applied on four studies included in mortality rate assessment showed no publication bias ( $t = -0.5947$ ,  $p = 0.6123$ ).

### **GRADE analysis of the primary and secondary outcomes (Table 2)**

The GRADE analysis recommendation for mortality was 'Moderate' evidence quality. Though there is low ROB, low heterogeneity and direct outcome but there are serious concerns with imprecision. The quality of evidence for clinical improvement and time to clinical improvement were graded as "Low" and "Very Low" respectively. The GRADE recommendation for serious AE and respiratory failure were "Low" and "Very low" quality of evidence respectively, as there was presence of high ROB and high imprecision. The GRADE recommendation is shown in table 2.

### **Discussion**

With the existing recommendation of USFDA for compassionate use of Remdesivir in COVID patients, it is being used worldwide. Current systematic review was planned for formulating recommendation from RCTs evaluating the efficacy of remdesivir in COVID-19 patients.

In the current systematic review, the OR for mortality failed to show any significant mortality benefit with the use of remdesivir. WHO solidarity trial[14] showed no mortality benefit with the use of remdesivir. Though it was an open label study, it is less likely to have bias in assessment of objective outcome like mortality. A total of 3451 patients were included in remdesivir and standard of care groups. Subgroup analysis revealed no mortality benefit in low risk (Figure 3a - no oxygen requirement, Supplementary Figure 2 – No invasive ventilation) or

1  
2  
3 high risk (Figure 3a - oxygen requirement or assisted ventilation, Supplementary Figure 2 –  
4 Invasive ventilation) group of patients with remdesivir.  
5  
6  
7

8  
9 At the time of recruitment, more patients were on invasive mechanical ventilation or ECMO in  
10 the placebo group. There were significantly more adverse events reported in the control group  
11 in our review. This was due to the high incidence of serious AE in Beigel et al study.[13] This  
12 is rare occurrence that serious AE were significantly more in control group. The fact that more  
13 severe patients were randomized into control group in the study by Beigel et al.[13] is the major  
14 reason for this finding. Similarly, the serious AE which also included the clinical events like  
15 renal failure and respiratory failure (5.2% in remdesivir and 8% in placebo arm) were also  
16 observed more in placebo group. Despite this imbalance, remdesivir was unable to show  
17 superiority in mortality rate.  
18  
19  
20  
21  
22  
23  
24  
25  
26  
27  
28  
29

30 Sub-group analysis of Beigel et al.[13] study revealed that remdesivir resulted in significant  
31 rate of clinical improvement in COVID-19 patients on oxygen therapy, while the patients not  
32 on oxygen, or on high flow oxygen or non-invasive ventilation and receiving mechanical  
33 ventilation or ECMO had similar clinical improvement as standard of care.  
34  
35  
36  
37  
38  
39

40 Placebo used in Beigel et al.[13] study was sulfo-butyl-ether b-cyclodextrin-sodium (SBECD),  
41 used to dissolve remdesivir. The maximum recommended daily dose is approximately 250  
42 mg/kg solvent used to dissolve remdesivir.[13] The amount of solvent present in placebo was  
43 not quantified in protocol. Dose of solvent should be modified in patients with eGFR fall of  
44 more than 50% from baseline and is contraindicated in patients with eGFR less than 30ml/min.  
45 But such modification were not done in either arms. Hence the effect of solvent on patients  
46 with impaired renal function can be detrimental and cannot be ruled out.  
47  
48  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 In the study by Beigel et al.[13], the median time of administration of drug from randomization  
4 was nine days. Median recovery time from randomization was 11 days. In addition, 302  
5 patients in remdesivir group did not receive 10 days of treatment. Therefore, it is difficult to  
6 infer that remdesivir resulted in recovery of patients, as an average of 2 days of administration  
7 of remdesivir resulting in complete recovery of patients seems implausible.  
8  
9

10  
11  
12  
13  
14  
15  
16 Virological cure is also an important outcome which was neglected by the authors. Wang et al.  
17 reported no difference (percentage difference = -7.5 (95% CI = -19.2 to 4.2)) in undetectable  
18 viral RNA load in remdesivir (75.6%) and placebo groups (83.1%). Patients may become  
19 asymptomatic but not cured. It has been observed that asymptomatic patients with RT-PCR  
20 positive test can have thromboembolic and chest CT changes. Study done by Merkler et al.  
21 observed that eight patients (26%) out of total 31 ischemic stroke patients were COVID-19  
22 positive on RT-PCR testing. They didn't have any COVID-19 symptoms on presentation [18].  
23 Silent hypoxemia is a disturbing feature in asymptomatic COVID patients and has been found  
24 to be associated with poor outcomes [19].

33  
34  
35

36  
37  
38 The SIMPLE trial [4] results published in New England Journal of Medicine does not include  
39 a standard of care group. Similar to Beigel et al. virological cure was not reported[4]. Clinical  
40 status at day 14 was similar in 5 day course of remdesivir as compared to 10 day course.  
41 However, in comparison to standard care, 5 day group (OR 1.65 [95% CI 1.09-2.48]; p=0.017)  
42 showed significant improvement while 10 day group did not (OR 1.31 [95% CI 0.88-1.95];  
43 p=0.18). Death reported on day 11 was similar in all three groups[20].  
44  
45  
46  
47  
48  
49  
50  
51

52  
53 In another study published by Grein et al.[5] in which compassionate use of remdesivir was  
54 done, did not have a control arm. Hence, the conclusion that remdesivir is effective cannot be  
55 drawn as the possibility of observing similar findings in control arm cannot be ruled out.  
56  
57  
58  
59  
60

1  
2  
3 Three systematic reviews and meta-analysis were published on remdesivir[21-23]. However,  
4 none of the reviews have included WHO solidarity trials in review. Exclusion of such large  
5 study (N=3451) decreases the power of systematic reviews. Our results are different from all  
6 three systematic reviews as Wilt et al.[23] and Shrestha et al.[21] have concluded mortality  
7 benefit with remdesivir while Elsayah et al.[22] concluded significant clinical improvement  
8 with remdesivir as compared to standard care. Meta-analysis performed by Solidarity trial  
9 group[14] has shown no mortality benefit (OR=0.91, 95% CI = 0.79-1.05), similar to our  
10 review. They did not perform meta-analysis with regard to other clinical endpoints and safety  
11 outcomes. Also, ROB-2 analysis of included RCTs and GRADE analysis was not applied.  
12

17  
18  
19  
20  
21  
22  
23  
24

25 The cost of the drug is \$2340 per patient but with no mortality benefit[24]. According to World  
26 Bank data, low and lower-middle income countries have Gross National Income (GNI) per  
27 capita less than or equal to \$ 1035 and between \$ 1036 to \$ 4045, respectively.[25] As per  
28 World Health Organization Global Health Expenditure database (2018), current health  
29 expenditure per capita in low and lower-middle income countries is less than \$36 and \$ 86,  
30 respectively.[26] Therefore, from a cost benefit perspective, we are of the opinion that their  
31 use should not be recommended, especially in low and lower-middle income countries. In case  
32 of limited use, strict evidence based guidelines should be followed for optimum health benefits.  
33  
34 The cost of the drug will put extra burden on government by increasing the health cost without  
35 any benefit. Injudicious use of remdesivir without mortality benefit may also lead to increased  
36 incidence of adverse events.

### 51 **Limitations and strengths**

52  
53

54 A major strength of our systematic review is that four RCTs were included in our analysis with  
55 total sample size of 7324 patients. Study done by Wang et al and WHO Solidarity trial has low  
56  
57  
58  
59  
60

1  
2  
3 ROB. Robust method of analysis using ROB-2 and GRADE analysis is another strength of the  
4  
5 current systematic review.  
6  
7

### 8 9 **Quality of Evidence: (GRADE)**

10  
11 The overall quality of systematic review is “Moderate”. Critical outcomes like mortality has  
12 moderate quality evidence. Clinical improvement was regarded as “Low”. Time to clinical  
13 improvement has “Very low” quality of evidence. Time to clinical improvement was used by  
14 regulatory agencies like US FDA for giving approval to remdesivir for treatment of severe  
15 COVID-19 patients. However, the quality of evidence for time to clinical improvement cannot  
16 be overlooked. This evidence suggests that further research is very likely to have an important  
17 impact on our confidence in the estimate of time to clinical improvement and likely to change  
18 the estimate. Moderate quality of evidence with regard to mortality showed that further RCTs  
19 are likely to have important impact and may change the no mortality benefit conclusion drawn  
20 from review.

30  
31  
32  
33

### 34 35 **Conclusion:**

36  
37 Evidence of our systematic review indicates no benefit in mortality rate with remdesivir, with  
38 moderate quality of evidence. Benefit does exist in terms of rates of clinical improvement and  
39 faster time to clinical improvement in favour of remdesivir, but the evidence is of low and very  
40 low quality, respectively. Significant decrease in serious adverse events as compared to  
41 placebo, strengthens the evidence of more serious patients in placebo arm. No difference was  
42 shown in respiratory failure in the two groups (very low quality evidence). All outcomes except  
43 mortality in our meta-analysis were influenced by Beigel et al. and Spinner et al., which has  
44 high ROB. WHO solidarity trial and Wang et al showed no mortality benefit, both having  
45 overall low ROB.

Table 1. Characteristics of clinical studies evaluating Remdesivir for treatment of COVID-19

Author, year (Study design)	Institution/ Country of study conduct	Study Interventions (N)/ Regimen	Study control (N)/ Regimen	Study population characteristics	Study outcomes
<b>Beigel et al 2020</b> (Randomized controlled trial)	Multicenter trial	Remdesivir (538); 200 mg on day 1 followed by 100 mg on days 2–10 in single daily infusions	Placebo (521)	Hospitalized adults COVID-19 patients with evidence of lower respiratory tract involvement.	<b>Time to recovery:</b> Patients in the remdesivir group had a shorter time to recovery than patients in the placebo group (median, 11 days, as compared with 15 days; rate ratio for recovery, 1.32; 95% confidence interval [CI], 1.12 to 1.55; P<0.001 <b>Mortality:</b> Kaplan Meier estimates of mortality by 14 days were 7.1% with remdesivir and 11.9% with placebo (hazard ratio for death, 0.70; 95% CI, 0.47 to 1.04)
<b>Spinner et al</b> (Randomized controlled trial)	Multicenter trial	Remdesivir - 10-day (n = 197), Remdesivir - 5-day (n = 199)	Standard care (n = 200)	Confirmed severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) infection and moderate COVID-19 pneumonia (pulmonary infiltrates and room-air oxygen saturation >94%)	<b>Day 28</b> Mortality rate n(%) – Remdesivir 10 day = 3(2); Remdesivir 5 day = 2(1), Standard = 4(2) Clinical Improvement n(%) - Remdesivir 10 day = 174(90), Remdesivir 5 day = 171(90), Standard = 166(83)
<b>Wang et al 2020</b> (Randomized controlled trial)	Department of Pulmonary and Critical Care Medicine, China-Japan Friendship Hospital,	Remdesivir (158); at least 1 dose after entering ICU; 200 mg on day 1 followed by 100 mg on days 2–10 in	Placebo (79)	Hospitalized adults COVID-19 patients with symptom onset to enrolment interval of $\leq 12$ days, oxygen saturation $\leq 94\%$ on room air or a ratio of arterial oxygen partial pressure to fractional inspired oxygen of 300	<b>Time to clinical improvement within 28 days after randomization:</b> Remdesivir use was not associated with a difference in time to clinical improvement (hazard ratio 1.23 [95% CI 0.87–1.75]). Although not statistically significant, patients receiving remdesivir had a numerically faster time to clinical improvement than those receiving placebo among patients with symptom duration of 10 days or less (hazard ratio 1.52 [0.95–2.43])

1  
2  
3 **CI:** Confidence interval; **OR:** Odds ratio; **HR:** Hazard Ratio; **RR:** Risk ratio; RCT – Randomized controlled trials  
4

5  
6 *Explanations*

7 a. All studies have low ROB except Biegel and Spinner et al. WHO solidarity trial contributing 77.9% weight to overall effect has low ROB.  
8 Hence overall low ROB.

9  
10 b. Overall information size of 1213 was achieved in either group. However, the overall effect estimate included one, hence downgraded for  
11 imprecision.

12  
13 c. Biegel et al. and Spinner et al. have a high risk of bias (ROB) due to selective reporting of results. Hence, downgraded for ROB.

14  
15 d. Overall Information Size of 1213 was not achieved in either groups. Hence, downgraded for imprecision.

16  
17 e. Biegel et al. has a high risk of bias (ROB) due to selective reporting of results. Hence, downgraded for ROB.

18  
19 f. Time to clinical improvement is not a direct estimate of the patient's oriented outcomes. Hence, downgraded for evidence.

20  
21 g. As  $I^2 > 50\%$ , heterogeneity is significantly high. Hence, downgraded for inconsistency

22  
23 h. Overall information size of 1213 was not achieved in either group and the overall effect estimate included one, hence downgraded for  
24 imprecision.

Section/topic	#	Checklist item	Reported on page #
<b>TITLE</b>			
Title	1	Identify the report as a systematic review, meta-analysis, or both.	1, 3
<b>ABSTRACT</b>			
Structured summary	2	Provide a structured summary including, as applicable: background; objectives; data sources; study eligibility criteria, participants, and interventions; study appraisal and synthesis methods; results; limitations; conclusions and implications of key findings; systematic review registration number.	3-4
<b>INTRODUCTION</b>			
Rationale	3	Describe the rationale for the review in the context of what is already known.	5
Objectives	4	Provide an explicit statement of questions being addressed with reference to participants, interventions, comparisons, outcomes, and study design (PICOS).	5
<b>METHODS</b>			
Protocol and registration	5	Indicate if a review protocol exists, if and where it can be accessed (e.g., Web address), and, if available, provide registration information including registration number.	6
Eligibility criteria	6	Specify study characteristics (e.g., PICOS, length of follow-up) and report characteristics (e.g., years considered, language, publication status) used as criteria for eligibility, giving rationale.	6
Information sources	7	Describe all information sources (e.g., databases with dates of coverage, contact with study authors to identify additional studies) in the search and date last searched.	6
Search	8	Present full electronic search strategy for at least one database, including any limits used, such that it could be repeated.	6
Study selection	9	State the process for selecting studies (i.e., screening, eligibility, included in systematic review, and, if applicable, included in the meta-analysis).	6
Data collection process	10	Describe method of data extraction from reports (e.g., piloted forms, independently, in duplicate) and any processes for obtaining and confirming data from investigators.	6
Data items	11	List and define all variables for which data were sought (e.g., PICOS, funding sources) and any assumptions and simplifications made.	6
Risk of bias in individual studies	12	Describe methods used for assessing risk of bias of individual studies (including specification of whether this was done at the study or outcome level), and how this information is to be used in any data synthesis.	7
Summary measures	13	State the principal summary measures (e.g., risk ratio, difference in means).	7
Synthesis of results	14	Describe the methods of handling data and combining results of studies, if done, including measures of consistency (e.g., I <sup>2</sup> ) for each meta-analysis.	7

# PRISMA 2009 Checklist

Page 1 of 2

Section/topic	#	Checklist item	Reported on page #
Risk of bias across studies	15	Specify any assessment of risk of bias that may affect the cumulative evidence (e.g., publication bias, selective reporting within studies).	7
Additional analyses	16	Describe methods of additional analyses (e.g., sensitivity or subgroup analyses, meta-regression), if done, indicating which were pre-specified.	7
<b>RESULTS</b>			
Study selection	17	Give numbers of studies screened, assessed for eligibility, and included in the review, with reasons for exclusions at each stage, ideally with a flow diagram.	8
Study characteristics	18	For each study, present characteristics for which data were extracted (e.g., study size, PICOS, follow-up period) and provide the citations.	8
Risk of bias within studies	19	Present data on risk of bias of each study and, if available, any outcome level assessment (see item 12).	8
Results of individual studies	20	For all outcomes considered (benefits or harms), present, for each study: (a) simple summary data for each intervention group (b) effect estimates and confidence intervals, ideally with a forest plot.	8
Synthesis of results	21	Present results of each meta-analysis done, including confidence intervals and measures of consistency.	8
Risk of bias across studies	22	Present results of any assessment of risk of bias across studies (see Item 15).	8
Additional analysis	23	Give results of additional analyses, if done (e.g., sensitivity or subgroup analyses, meta-regression [see Item 16]).	8-9
<b>DISCUSSION</b>			
Summary of evidence	24	Summarize the main findings including the strength of evidence for each main outcome; consider their relevance to key groups (e.g., healthcare providers, users, and policy makers).	12
Limitations	25	Discuss limitations at study and outcome level (e.g., risk of bias), and at review-level (e.g., incomplete retrieval of identified research, reporting bias).	12, 4
Conclusions	26	Provide a general interpretation of the results in the context of other evidence, and implications for future research.	13
<b>FUNDING</b>			
Funding	27	Describe sources of funding for the systematic review and other support (e.g., supply of data); role of funders for the systematic review.	None
