69 ● Section A: Supplemental Methods

70 A1: Catalyst characterization.

71 X-ray diffraction (XRD) patterns were collected via X-ray diffractometer (Rigaku D/max-
72 2400, $\lambda = 1.5406\text{\AA}$). Morphologies of the samples were obtained by a Field Emission Gun
73 Scanning Electron Microscopy (FESEM, Hitachi SU-8010) and a transmission electron
74 microscopy (TEM, Hitachi 7700) with an accelerating voltage of 100 kV. High resolution
75 transmission electron microscopy (HRTEM) images were captured via a JEM 2100F field
76 emission transmission electron microscope at an accelerating voltage of 200 kV. The element
77 composition and distribution were recorded by an energy dispersive (EDS) detector equipped
78 in JEM 2100F. XPS spectra were conducted in a PHI Quantera SXMTM system and the
79 binding energy was calibrated with the signal for adventitious carbon at 284.8 eV. FT-IR spectra
80 was recorded by Bruker V70 spectrometer. CHI-660D electrochemical system was used to
81 examine the electrochemical measurements. Electrochemical impedance spectroscopy (EIS)
82 were measured in a three-electrode quartz cells using 0.1 M Na₂SO₄ as electrolyte solution.
83 SCE served as reference electrode, platinum wire served as counter electrode, and sample film
84 electrodes on glassy-carbon electrode used as working electrode.

85 Temperature programmed desorption (TPD) was carried out on a Cat-Lab (BEL Japen,
86 Inc.) equipped with an online QIC-200 quadrupole mass (Inprocess Instruments, GAM 200) as
87 a detector. Firstly, 20 mg sample was added into the U-type quartz reactor and heated at 120°C
88 for 2 h in Ar atmosphere. When it cool to the room temperature, the sample was kept in a wet
89 gas flow (50°C, Ar, RH=70%) for 1 h. Then the TPD process was carried out with a heating
90 rate of 5°C/min.

91 A2: Catalyst evaluation.

92 The performance of catalyst for ozone decomposition was evaluated in a continuous fixed
93 bed reactor at 25°C. For each test, 100 mg catalyst was used and the gas flowrate into the reactor
94 was maintained at 900 mL/min. Ozone was generated by arc discharge in O₂ stream and the
95 inlet ozone concentration was kept at 50 ± 1 ppm by tuning the discharge voltage and the gas

96 flowrate through the ozonator (model 1000BT-12, Shanghai Enaly Mechanical and
97 Electrical Technology Company). Then, the generated ozone mixed adequately with clear air
98 in a mixing drum and then transported into the reactor. The inlet and outlet ozone concentration
99 was recorded (model 202, 2B Technologies) and the ozone conversion was calculated through
100 the following equation:

$$101 \quad \text{Ozone removal rate} = 100\% \times (C_{in} - C_{out})/C_{in}. \quad (1)$$

102 where C_{in} and C_{out} present inlet and outlet ozone concentration respectively.

103 **A3: DFT calculation methods**

104 All calculation were accomplished using density functional theory (DFT) with the
105 projected augmented wave (PAW) method, as implemented within the VASP code. The
106 Perdew-Burke-Ernzerhof (PBE) with Hubbard U corrections of generalized gradient
107 approximation (GGA + U) was utilized as the exchange-correlation functional. In this work,
108 we employ values of $U-J = 3.9$ eV, for the spherical part of the interaction, and $J = 1.0$ eV.¹ The
109 valence atomic configurations were Mn: $3p^63d^54s^2$, O: $2s^22p^4$, C: $2s^22p^3$, respectively. The
110 energy cutoff for a plane wave basis set was 400 eV, and a gamma centered Monkhorst-Pack
111 k-mesh of $2 \times 2 \times 1$ was used for heterojunction calculations. In geometry optimizations, the
112 self-consistent convergence accuracy was set at 1×10^{-6} eV/atom and the atomic Hellman-
113 Feynman forces are smaller than $0.02\text{eV}/\text{\AA}$. Furthermore, spin polarization, vdW correction
114 proposed by Grimme and Dipole correction along Z direction were considered in all
115 calculations.

116 The tetragonal MnO_2 with space group of $I4/M$ was selected as bulk MnO_2 , in which each
117 cell contained 36 atoms (12 Mn atoms and 24 O atoms). The lattice parameters of MnO_2 are
118 $a = 9.92\text{\AA}$, $b = 9.92\text{\AA}$, $c = 2.93\text{\AA}$, $\alpha = \beta = \gamma = 90^\circ$. For bulk graphene, the hexagonal graphene with
119 $P63/mmc$ space group was taken, each cell contained 10 atoms and the lattice parameters of
120 graphene are $a = b = 2.47\text{\AA}$, $c = 8.69\text{\AA}$, $\alpha = \beta = 90^\circ$, $\gamma = 120^\circ$. **Figure S1a, b** shows the initial crystal
121 structures of MnO_2 and graphene. Here, MnO_2 -one-OV/graphene and MnO_2 -ten-
122 OVs/graphene heterojunctions were modeled as the supercell slab, in which the geometry
123 structure contained parallel graphene (001) and MnO_2 (110) sheet. The (110) crystal plane of

124 MnO₂ was considered, because it has the lowest surface energy and is easy to dominate the
125 largest surface area comparing with other crystal planes.² A commensurability was taken
126 between graphene and MnO₂ sheet, where a 5×1 lateral periodicity of MnO₂ and 6×7 lateral
127 periodicity of graphene sheet were employed. A vacuum space of 15Å in the Z direction was
128 adopted to isolate slab as boundary condition. The side view of geometric structures of MnO₂-
129 one-OV/graphene and MnO₂-all-OVs/graphene heterojunctions were shown in **Figure S1c, d**.
130 The initial lattice parameters between the optimized MnO₂ and graphene sheet were presented
131 in **Table S1**. The lattice mismatch ratios of initial lattice parameters are 1.20% for a and 4.43%
132 for b, respectively.

● Section B: Supplemental Data

Figure S1. The structure parameters of synthesized 7.50% MnO₂@GR catalysts. (a-d) TEM images of 7.50% MnO₂@GR with varied hydrothermal time of 0 h, 4 h, 8 h, 12 h respectively. (e) XRD patterns of 7.50% MnO₂@GR with varied hydrothermal time.

Ultrathin graphene encapsulated α -MnO₂ nanofibers were prepared by a “complexation-reaction-growth” procedure.³ Amorphous MnO₂ firstly formed on the graphene, then MnO₆ octahedron units grew into α -MnO₂ and further transferred into α -MnO₂ nanofiber. At the same times, large-area graphene was further exfoliated and frizzled, finally displaying a core-shell structure. When the hydrothermal time kept at 12 h, the obtained sample displayed a pure α -MnO₂ (JCPDS No. 29-1020), in line with the variation of the morphology.

Figure S2. HRTEM images of 7.50% MnO₂@GR at different regions.

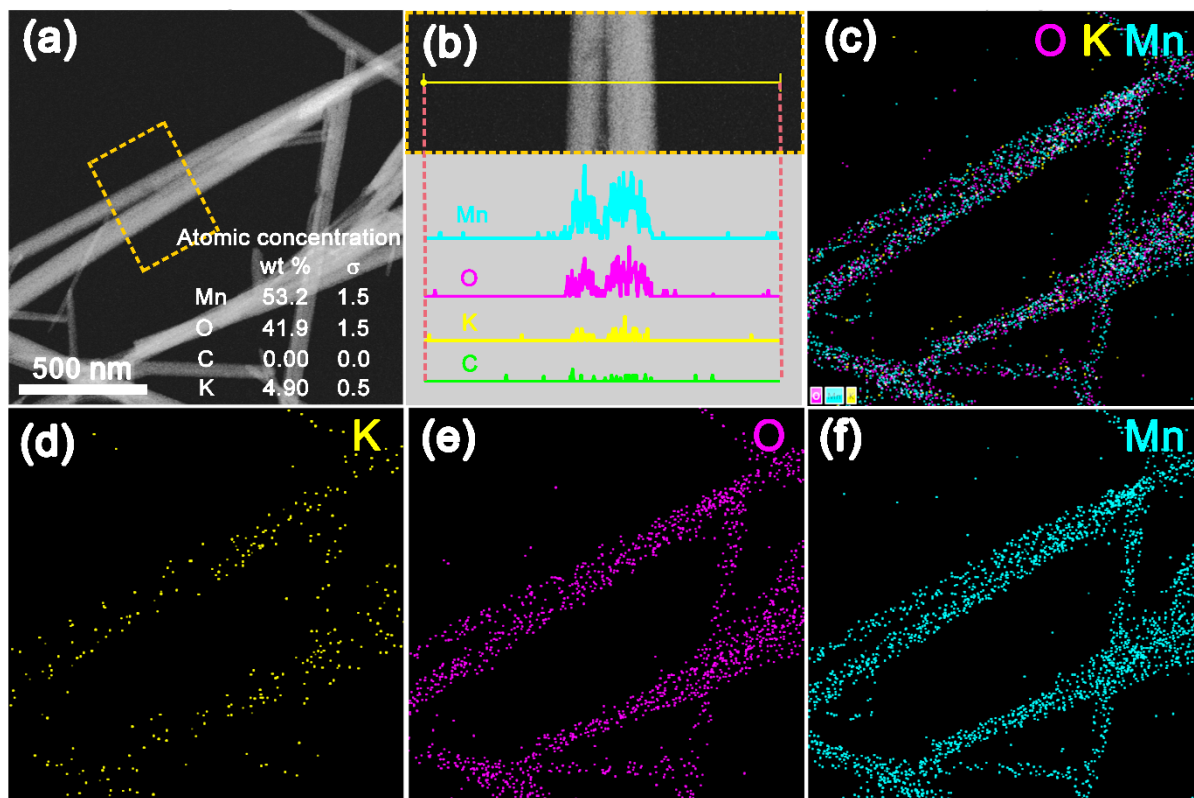

Figure S3. HAADF-STEM image (a) and corresponding EDX linear scanning (b) and maps scanning maps of α - MnO_2 for K (d), O (e), Mn (f) and combined image (c).

Figure S4. Optical micrographs of α -MnO₂ (a) and 7.50% MnO₂@GR (b) with 100 magnifications.

The optical micrographs shown that 7.50% MnO₂@GR presented an obvious high gloss, which often appeared in graphene. This indicated that 7.50% MnO₂@GR presented a uniform core-shell structure rather than local phenomenon. Therefore, the exposed surface in 7.50% MnO₂@GR almost was graphene shells.

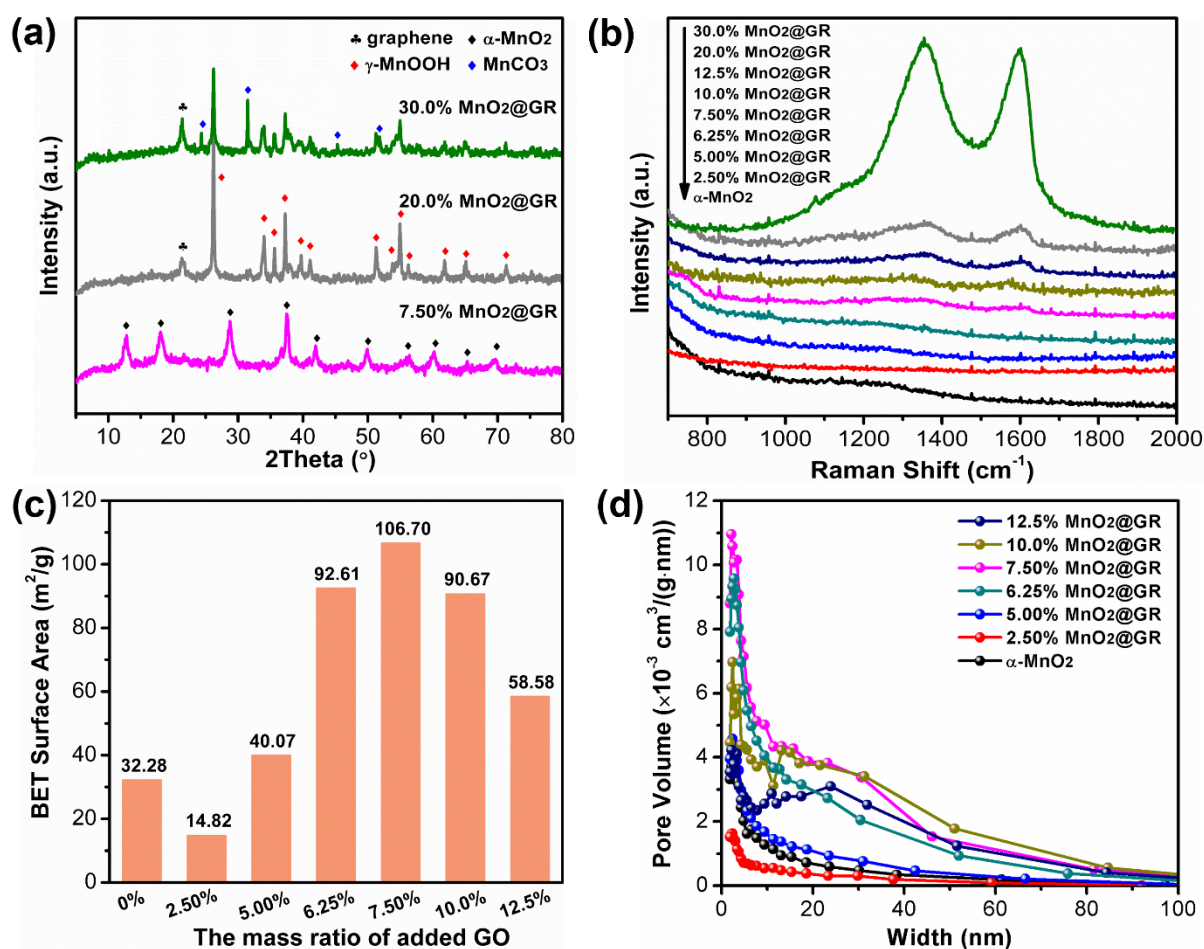

Figure S5. The structure parameters of synthesized MnO₂@GR catalysts. (a) XRD patterns of 7.50% MnO₂@GR, 20.0% MnO₂@GR, 30.0% MnO₂@GR. Raman shift (b), BET surface areas (c) and pore size distribution (d) of MnO₂@GR with different ratio of GR.

As shown in **figure S5a**, α-MnO₂ would transfer to α-MnOOH and MnCO₃, further confirming that the crystal structure of manganese oxide varied with the increase of the GO content, in agreement with the latest report.⁴ Besides, the diffraction peak of graphene was only found in the XRD patterns of 20.0% MnO₂@GR, 30.0% MnO₂@GR, indicating a low content of graphene in 7.50% MnO₂@GR. The Raman spectra (**figure S5b**) shown the peak intensity at 1347 cm⁻¹ and 1610 cm⁻¹ increased with the increase of the GO content, confirming the ultrathin graphene shells indeed existed on the surface of 7.50% MnO₂@GR. The BET surface areas of 7.50% MnO₂@GR also increased from 32.28 to 106.70 m²/g (**figure S5c**), comparing with MnO₂, offering abundant active sites for ozone decomposition. The pore size distribution (**figure S5d**) shown a large amount of micropore and mesoporous existed in 7.50% MnO₂@GR, corresponding to its hierarchical structure.

Figure S6. The morphology of synthesized MnO₂@GR catalysts. SEM images of α -MnO₂ nanowire (a), 2.50% MnO₂@GR (b), 5.00% MnO₂@GR (c), 6.25% MnO₂@GR (d), 7.50% MnO₂@GR (e), 10.0% MnO₂@GR (f), 12.5% MnO₂@GR (g), 20.0% MnO₂@GR (h) and 30.0% MnO₂@GR (i).

As shown in **figure S6**, the morphology varied with GO content, corresponding to the changes of the diffraction peak in XRD pattern. When GO content was lower than 7.5%, short nanorod was found, corresponding to α -MnO₂. When GO content reached at 7.5%, α -MnO₂ totally transferred to α -MnO₂ nanofiber. If GO content increased continuously, α -MnOOH and MnCO₃ appeared. As shown in **figure S6e**, 7.50% MnO₂@GR displayed a lamellar structure, similar to graphene network structure. Thus, it can be concluded that α -MnO₂ nanofiber growth on the graphene layer.

Figure S7. The morphology of synthesized MnO₂@GR catalysts. TEM images of EM i₂ nanowire (a), 2.50% MnO₂@GR (b), 5.00% MnO₂@GR (c), 6.25% MnO₂@GR (d), 7.50% MnO₂@GR (e), 10.0% MnO₂@GR (f), 12.5% MnO₂@GR (g), 20.0% MnO₂@GR (h) and 30.0% MnO₂@GR (i).

As shown in **figure S7**, the effect of GO content on the crystal structure and morphology was further confirmed by TEM images. Importantly, graphene layer was not found until GO content reached at 10.0%, confirming that added GO almost coated on the α -MnO₂ nanofiber. According to SEM and TEM images, it can be concluded that graphene layer was destroyed and coated on the surface of α -MnO₂ nanofiber under the process of crystal reconstruction, consequently displaying a core-shell structure.

Figure S8. O 1s spectra of fresh α -MnO₂ nanowire and 7.50% MnO₂@GR.

Figure S9. The catalytic performance and structural parameters of α -MnO₂, GO/MnO₂ and GO+MnO₂ catalysts. (a) Raman shift of GO, GR, GR-reaction (reaction for 20 h). (b) Ozone conversion on α -MnO₂, GO/MnO₂ and GO+MnO₂ (physical mixture).

1.0 g obtained α -MnO₂ nanowires physically mixed with 75 mg GO aerogel (dehydrated via a freeze-drying process) to prepare GO+MnO₂. In the Raman spectra, the peaks located at 1334 and 1597 cm^{-1} , which were assigned to the G band and D band of graphene respectively and were used to quantify the density of defects in sp^2 carbon atoms.⁵ **Figure S9a** shown the integrated intensity ratio of I_D/I_G increased from 1.22 to 1.44 after a hydrothermal reduction, indicating more nongraphitic impurities formed in GR. After treated in ozone for 20 h, the ratio of I_D/I_G decreased to 1.31, suggesting the nongraphitic impurities could react with ozone molecule.

Figure S10 SEM images of GR (a), α -MnO₂ (b), GO/MnO₂ (c) and 7.5% MnO₂@GR (d).

FESEM images in **figure S10** showed that GO/MnO₂ presented a regular composite structure, in which α -MnO₂ nanowires were located on the surface of the large-areas graphene.

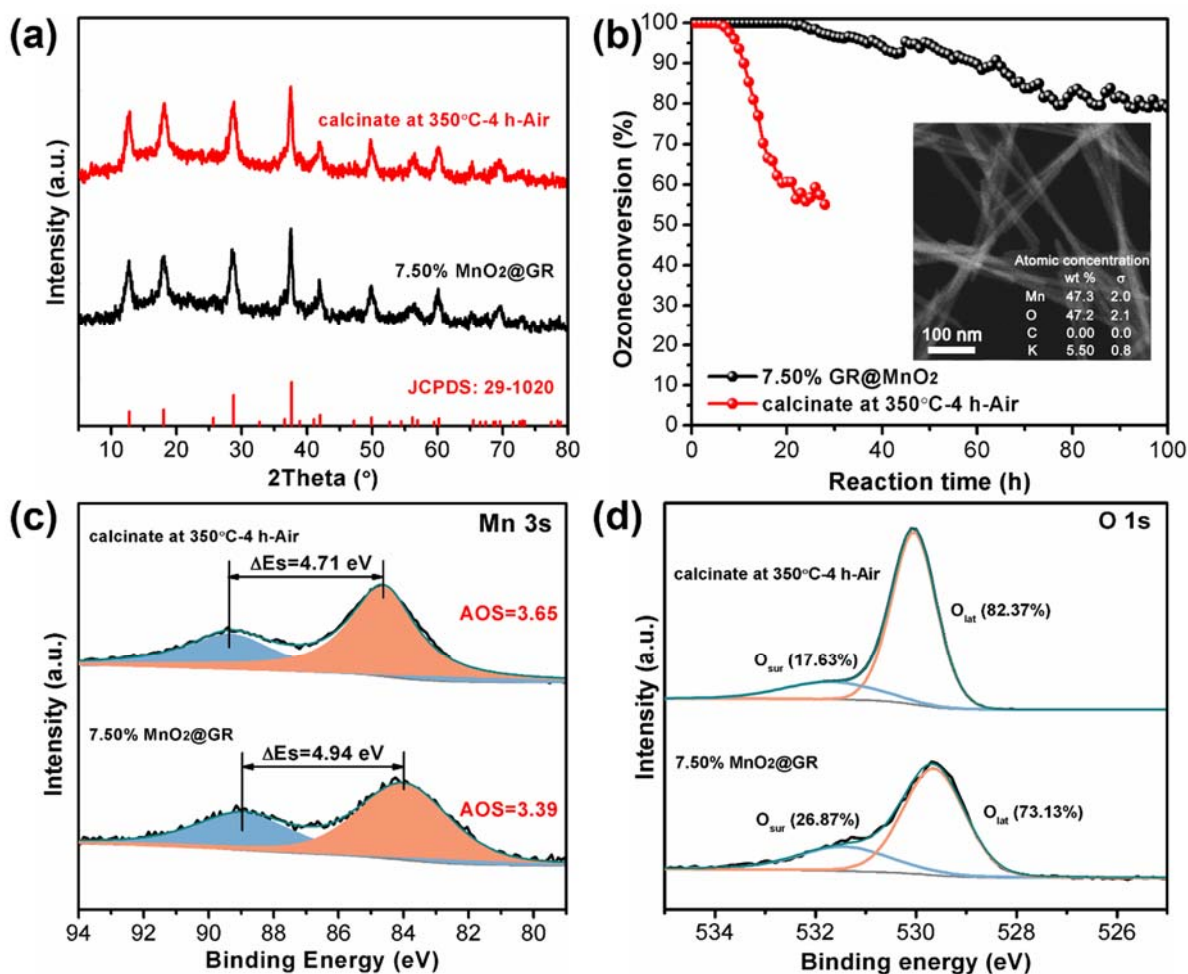

Figure S11. The effect of graphene layer on the ozone conversion of 7.50% MnO₂@GR calcinated at 350°C for 4 h under air atmosphere. (a) XRD patterns of 7.50% MnO₂@GR before and after calcination. (b) Ozone conversion of 7.50% MnO₂@GR before and after calcination and the element content for calcinated 7.50% MnO₂@GR obtained by EDS map scanning. Mn 3s (c) and O 1s (d) spectra of 7.50% MnO₂@GR before and after calcination. Experimental conditions: 0.1 g catalyst, 50 ppm O₃, flow rate = 900 mL/min, RH=20%, 25°C.

Figure S12. The performance of regenerated α -MnO₂ nanowires at different relative humidity.

As shown in **figure S12**, the regenerated α -MnO₂ nanowires exhibited an almost the same ozone conversion of fresh α -MnO₂ nanowires at 20% RH, indicating that the decline of the ozone conversion at 50% RH resulted from water adsorption rather than the accumulation of the intermediated oxygen species.

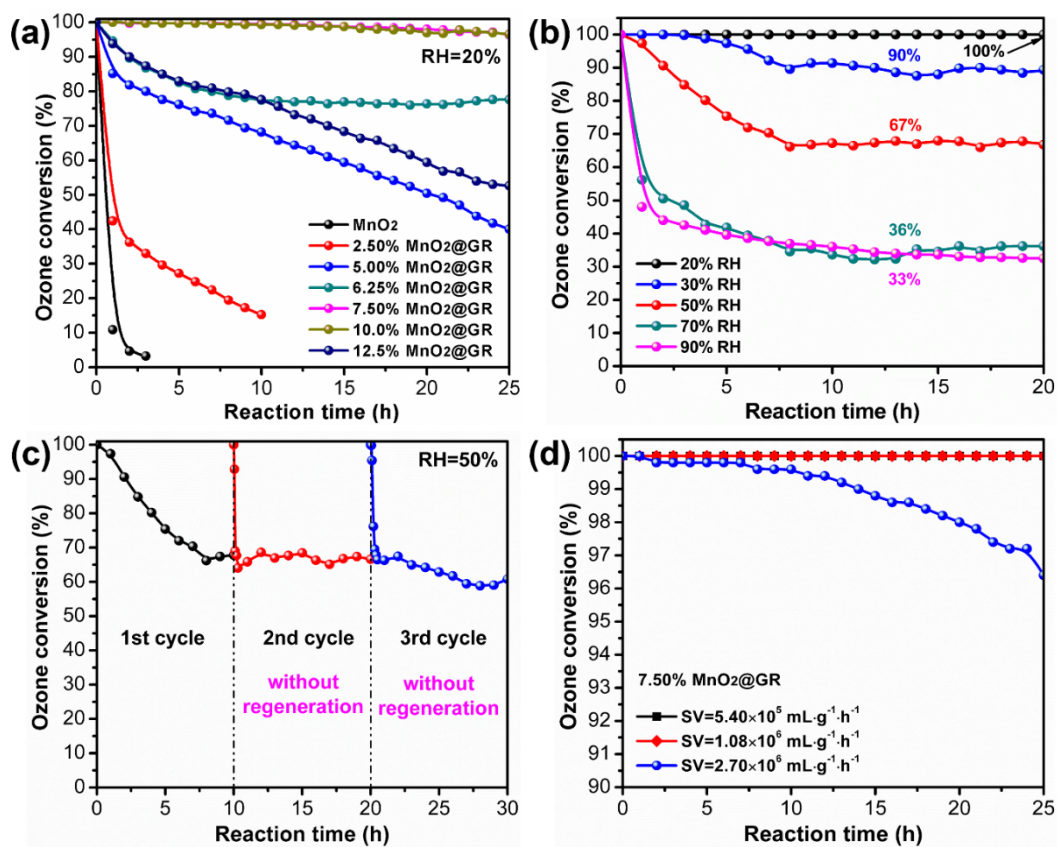

Figure S13. The regeneration ability of MnO₂@GR catalysts under different conditions. (a) Ozone conversion on MnO₂@GR with different content of GR (20 mg catalyst was used). (b) Ozone conversion on 7.50% MnO₂@GR at different relative humidity. (c) The cycle performance of 7.50% MnO₂@GR at 50% RH. (d) Ozone conversion on 7.50% MnO₂@GR at different space velocity. Experimental conditions: 0.1 g catalyst (except for (a) and (d)), 50 ppm O₃, flow rate = 900 mL/min, 25 °C.

Above results have indicated that the GO addition has a significant effect on the morphology and crystal structure of the catalyst. As displayed in **figure S13a**, 7.50% MnO₂@GR exhibited the highest ozone conversion among the samples with different GR content, suggesting that the unique core-shell structure is important for the ozone decomposition. In addition, we investigated the ozone conversion on 7.50% MnO₂@GR under different RH, as displayed in **figure S13b**. Because of the competitive adsorption, the conversion shown a sharp decrease and then remained stable in the wet gas flow. Although the stable conversion decreased with the increase of the RH, 7.50% MnO₂@GR remained 67% ozone conversion at 50% RH, significantly higher than the ratio (35%, **figure 4b in the main manuscript**) of α -MnO₂ nanowire. This suggested that the graphene indeed enhanced the ozone conversion efficiency under high humidity. As shown in **figure S13c**, the cycle performance of 7.50% MnO₂@GR

was evaluated at 50% RH to explain the effect of regeneration. **figure S13d** has shown the ozone conversion on 7.50% MnO₂@GR under different mass space velocity (WHSV). This indicated that the real catalytic performance of 7.50% MnO₂@GR can be reflected when the space velocity is below $1.80 \times 10^6 \text{ mL} \cdot \text{g}^{-1} \cdot \text{h}^{-1}$.

Figure S14. The XRD patterns of OMS-2-HH and MnO_x-HHB catalysts. XRD patterns of 7.50% MnO₂@GR, OMS-2-HH and MnO_x-HHB.

To compare the catalytic performance of 7.50% MnO₂@GR with the reported materials, OMS-2-HH⁶ and MnO_x-HHB⁷ were prepared. As shown in **figure S14**, OMS-2-HH displayed a pure α-MnO₂ (JCPDS No. 29-1020) and MnO_x-HHB has no obvious diffraction peak, in line with the reported results.

Figure S15. TEM images of OMS-2-HH (a) and MnO_x-HHB (b). HRTEM images of OMS-2-HH (c) and MnO_x-HHB (d).

Figure S15 shown the TEM and HRTEM images of OMS-2-HH and MnO_x-HHB, which are consisted with the the reported results. OMS-2-HH presented a rough surface, which induced abundant surface oxygen vacancy. MnO_x-HHB presented a low crystallinity and abundant crystal boundary formed, which resulted in a low AOS of Mn atoms (the reported AOS of Mn atoms was 3.43).

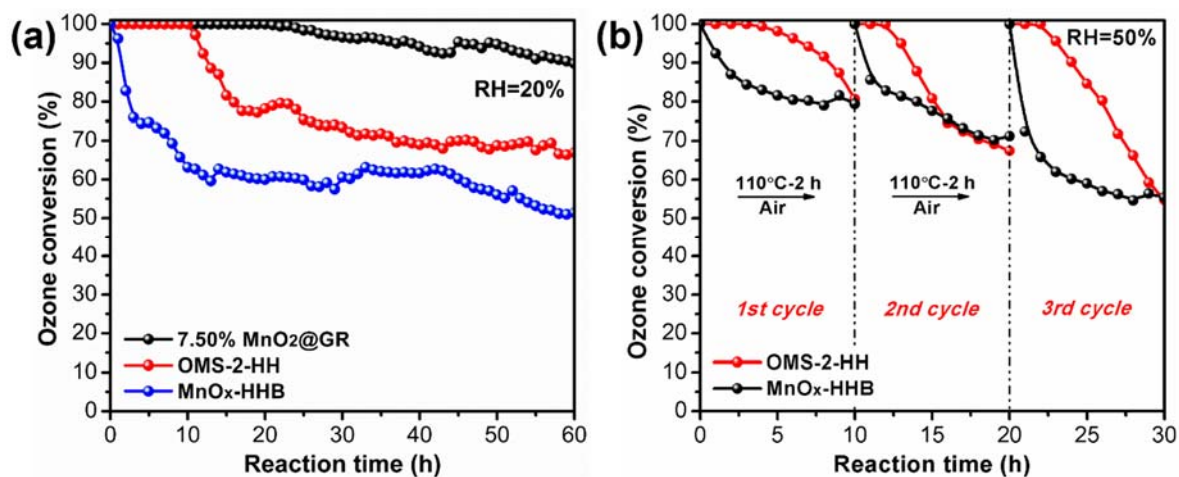

Figure S16. The comparison on the regeneration ability of MnO₂@GR and reported catalysts under different conditions. (a) Comparison of ozone conversion with 7.50% MnO₂@GR and other reported catalysts. (b) Ozone conversion on OMS-2-HH and MnO_x-HH at 50% RH and their regeneration performance (Regenerate condition: 110°C, air atmosphere).

Figure S17. SEM images of 7.50% MnO₂@GR coated stainless steel mesh.

As shown in **figure S17**, 7.50% MnO₂@GR was built into a lamellar structure and uniformly coated on the wire mesh (10 × 15 cm), using graphene layer as the framework.

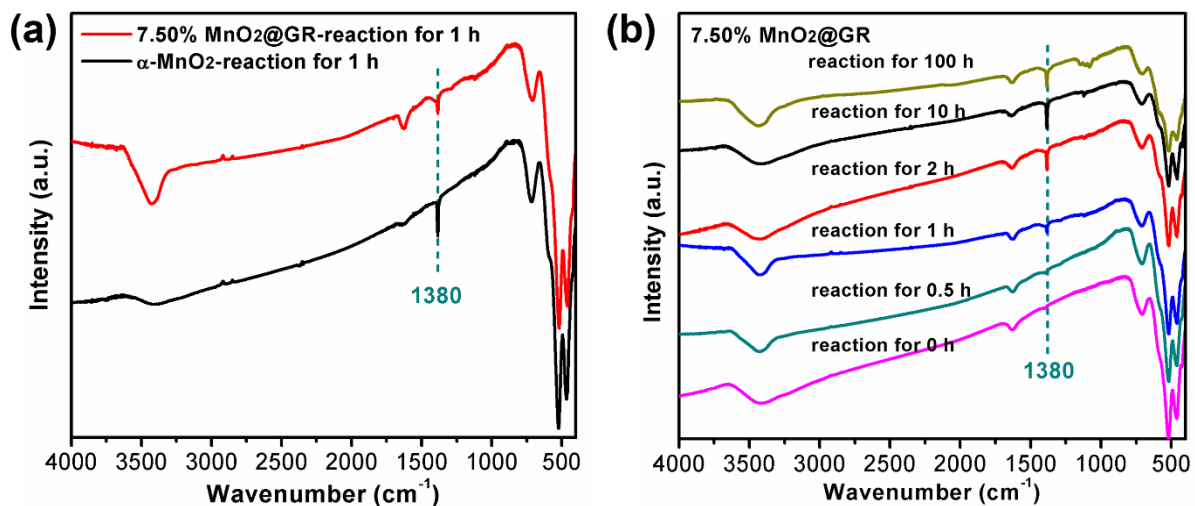

Figure S18. The accumulation of intermediated oxygen species. (a) FT-IR spectra of α -MnO₂ and 7.50% MnO₂@GR treated with O₃ for 1 h. (b) FT-IR spectra of 7.50% MnO₂@GR treated with O₃ for different time.

Figure S18a showed the accumulation of the intermediated oxygen species on the 7.50% MnO₂@GR was lower than the α -MnO₂ nanowire. **Figure S18** showed the accumulation of the intermediated oxygen species on the 7.50% MnO₂@GR was remained stable after 2 h.

Figure S19. The AOS of Mn, surface adsorbed oxygen content in O 1s and C=O content in C1s after 7.50% MnO₂@GR treated with ozone for different time.

As shown in **Figure S19**, the AOS of Mn and surface adsorbed oxygen content have same variation tendency. The variation of C=O content was slightly slow, which confirmed that the nongraphitic impurities in graphene shells would be oxidized to C=O groups and COOH groups. These results suggested the oxidation state of Mn was closely related to the surface oxygen species in 7.50% MnO₂@GR.

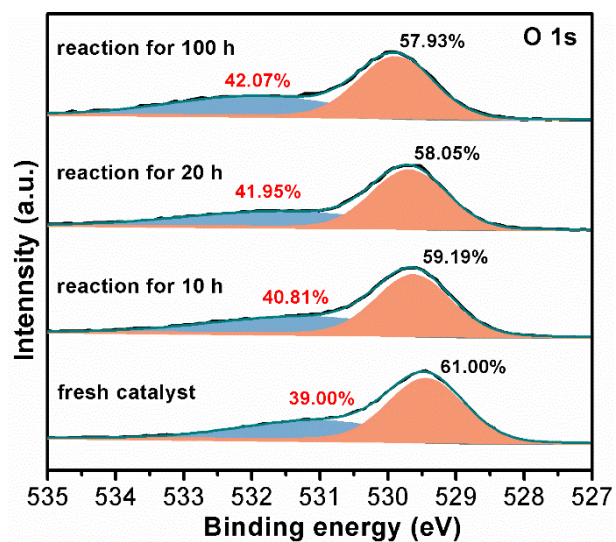

Figure S20. Analysis of the surface bonding environment via XPS. O 1s spectra of 7.50% MnO₂@GR treated with ozone for different time.

Figure S21. Dissociative chemisorption of an ozone molecule from the physisorbed state is shown with the transition state.⁸

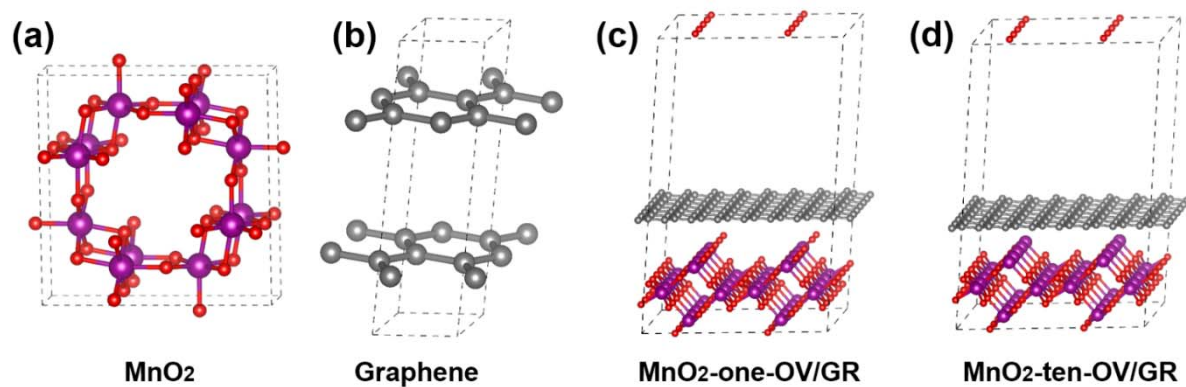

Figure S22. The initial crystal structures of MnO₂ (a) and graphene. (b) The models of MnO₂-one-OV/GR and MnO₂-ten-OV/GR heterojunctions.

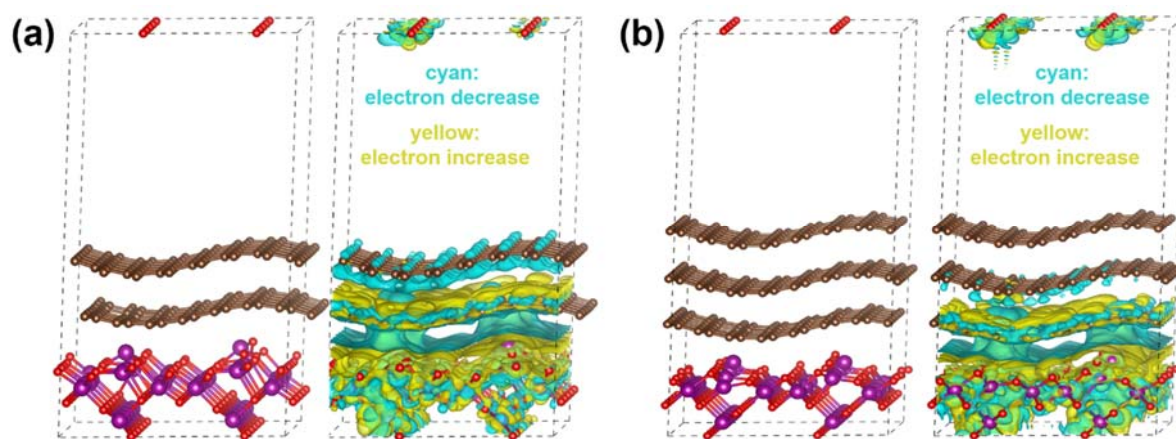

Figure S23. The optimized structure of MnO₂-ten-OV@GR with different graphene layers and their charge density differences. (The yellow and cyan regions refer to increased and decreased charge distributions, respectively. The isosurface value of the colour region is 0.0001e-Å⁻³. The purple, red and gray ball in the models corresponds to the Mn, oxygen and carbon atoms, respectively.)

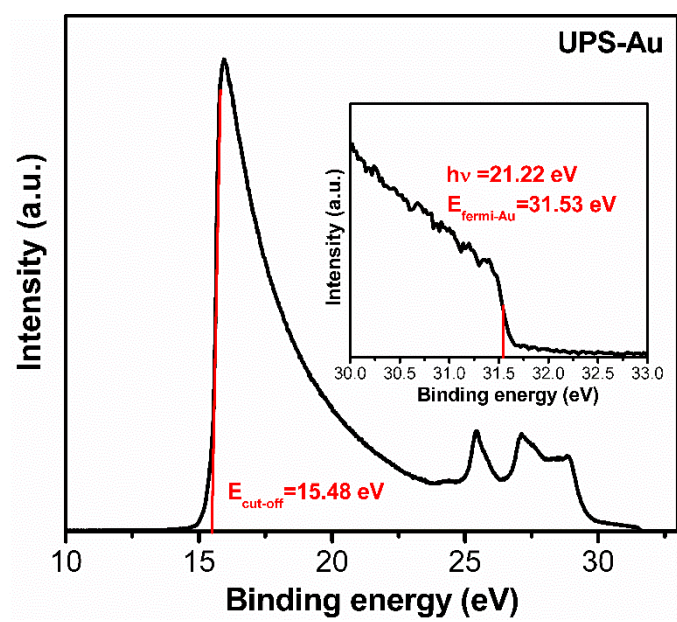

Figure S24. Ultraviolet Photoelectron Spectroscopy of Au.

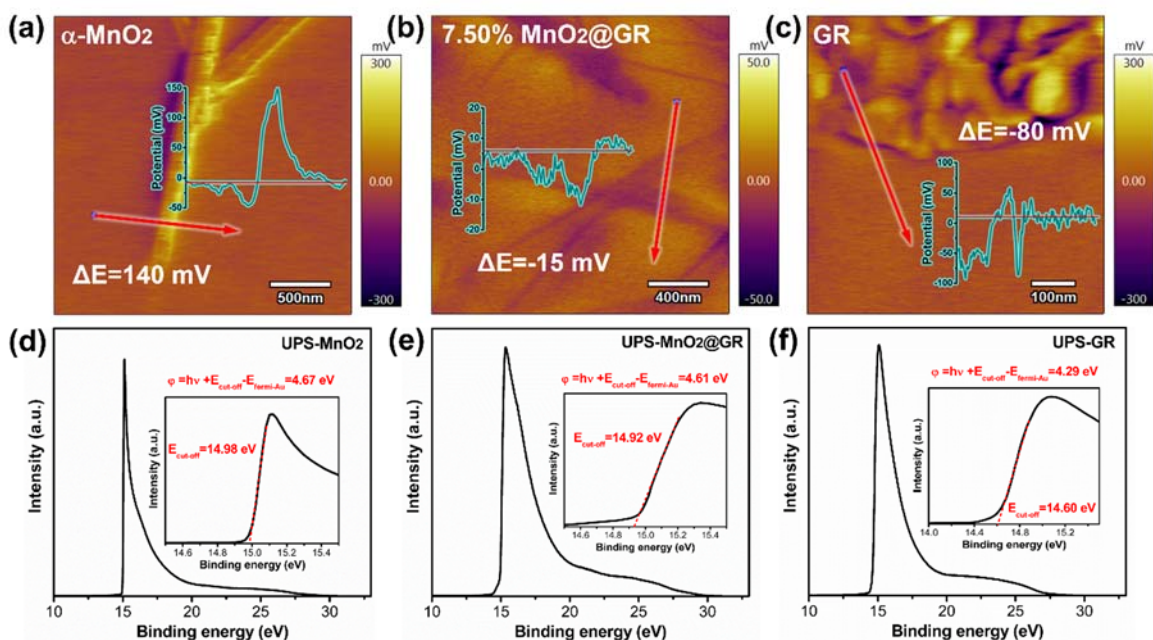

Figure S25. The unique surface electronic structure in MnO₂@GR. Surface potential of α -MnO₂ (a), 7.50% MnO₂@GR (b) and GR (c). UPS spectra of α -MnO₂ (d), 7.50% MnO₂@GR (e) and GR (f).

To explore the reason why the accumulation of peroxide species is inhibited, the surface electronic structure is investigated. Firstly, the average electronic potential on the catalyst surface is measured by Atomic Force Microscope with a Kelvin Probe. As shown in **figure S25a-c**, the surface potential of α -MnO₂ nanowire is higher (140 mV) than that of the mica sheet, while that of GR is lower (80 mV) than that of the mica sheet. For 7.50% MnO₂@GR, the surface potential is lower (15 mV) than that of the mica sheet, between the value of α -MnO₂ nanowire and 7.50% MnO₂@GR. These results indicate that the average work function is varied as followed: α -MnO₂ > 7.50% MnO₂@GR > GR. As a result, the difference on work function drives the electrons transfer from the graphene shells to inner α -MnO₂ nanofiber in the core-shell structure of MnO₂@GR. Besides, the average work function (4.67 eV for α -MnO₂, 4.61 eV for 7.50% MnO₂@GR, and 4.29 eV for GR) calculated from the UPS spectra (**figure S24**) further confirms that the graphene shell indeed modifies the surface electronic structure as shown in **figure S25d-e**.

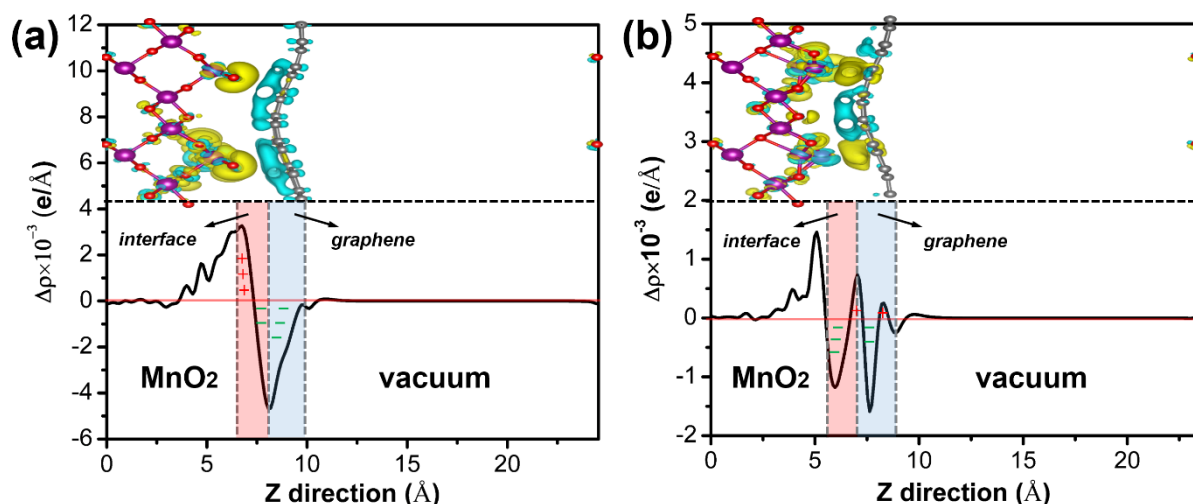

Figure S26. The front view of the charge density differences (above) in MnO₂-one-OV@GR (a) and MnO₂-ten-OV@GR (b). The isosurface value of the color region is $0.01\text{e}\cdot\text{\AA}^{-3}$. Planar-averaged electron density difference (below) in MnO₂-one-OV@GR (a) and MnO₂-ten-OV@GR (b) along the Z direction, where the positive values refers to the increased electron and the negative values refers to the decreased charge distribution.

As shown in **figure S26a**, the electron density increased on the surface of MnO₂ and decreased on graphene shell, suggesting the electron transfer from MnO₂ to graphene in MnO₂-one-OV@GR. However, for MnO₂-ten-OV@GR (**figure S26b**), the electron density difference is different and varied with the position, which further confirmed the electron transfer direction depends on the exposed atoms on the surface of MnO₂.

Figure S27. The model of graphene unit (left) and ozone molecule (right).

As shown in **figure S27**, the carbon-carbon bond was 1.42\AA in graphene and the covalent radius of carbon atom was 0.77\AA . Thus, the biggest pore size of benzene ring was 1.30\AA considering the covalent radius. For ozone molecule, the oxygen-oxygen bond was 1.28\AA and its angle was $116^{\circ}49'$. The covalent radius of oxygen atom was 0.66\AA . Thus, the smallest size was 1.99\AA . Thus, ozone molecule can't enter the confined space between graphene layer and manganese oxide by the hole of benzene ring. Although some small molecule can enter the confined space under graphene through open channels at island edges, the process was very slow.⁹ However, ozone catalytic decomposition on $7.50\% \text{ MnO}_2@\text{GR}$ was quick and high-throughput. Therefore, the surface of Mn in the confined space between graphene layer and manganese oxide was not the main active site for ozone decomposition.

Table S1. Comparison of ozone catalytic decomposition performance between MnO₂@GR and other reported materials.

Catalyst	Inlet ozone concentration [ppm]	Reaction temperature [°C]	Relative humidity [%]	Space velocity [L/g·h]	Ozone conversion [%]	References
MnO₂@GR	50	25	20	540	100 (20 h) / 80 (100 h)	This work

α , β , γ -MnO ₂	14		dry	660	-MnO ₂ > - MnO ₂ > -MnO ₂	20
MnCO ₃	14	25	dry	460	85 (22 h)	21

To define the advantages of MnO₂@GR in ozone conversion, the performance of latest reported catalyst was listed in **Table S1**. Among these materials, OMS-2-HH and MnO_x-HHB displayed best performance for ozone decomposition.

Table S2 Lattice parameters of MnO₂ layer, graphene layer, MnO₂-one-OV/GR and MnO₂-ten-OV/GR heterojunctions.

Model	a (Å)	b (Å)
MnO₂	14.618	16.526
graphene	14.793	17.258
MnO₂-one-OV/GR	14.705	16.893
MnO₂-ten-OV/GR	14.705	16.893
