

Supplementary Methods

Primary bone marrow stromal cells (BMSC) were obtained from 10-12 weeks old mice, following previously described procedures ^(31,38). Briefly, the bone marrow from an entire bone (femur) was flushed with PBS, resuspended in culture media, filtered through 70- μ filter, and plated in a 15-mm plate. Cells were incubated in growth medium for 2 weeks until 70-80% confluence, then plated in 10mm plates and exposed to insulin 20 μ g/mL for different times.

Supplementary Figure Legends

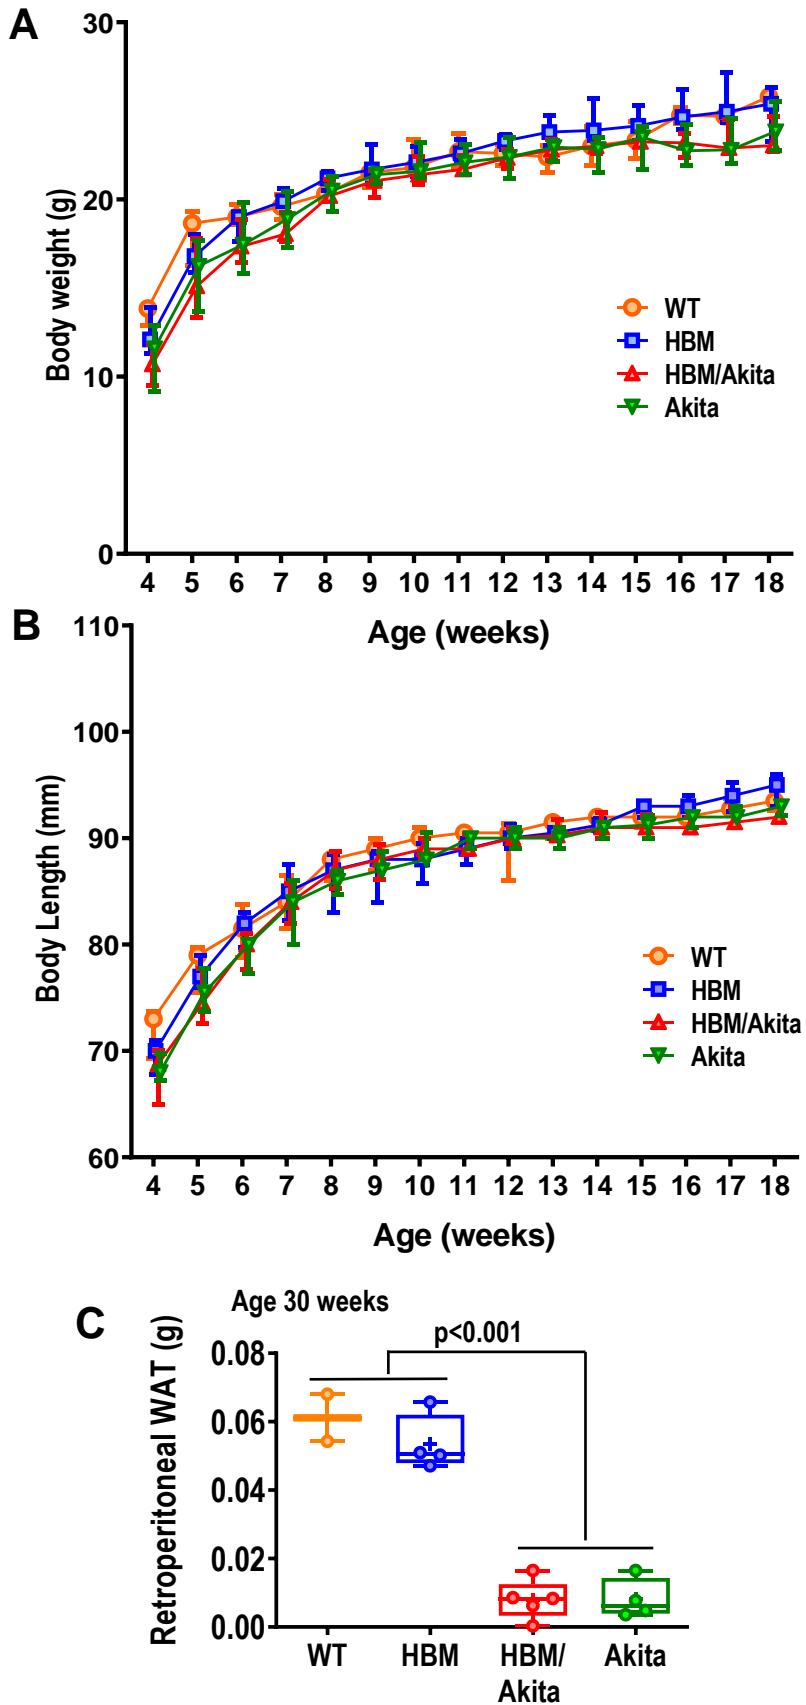

Supplemental Figure 1. Post-natal Growth and WAT Mass. (A) Body weight, and (B) length at different ages in the different mutants. N=11-16 at 4 weeks and 4-6 at 18 weeks. $P>0.05$ by 2-way ANOVA for genotype effect in both measures. (C) Retroperitoneal white adipose tissue (WAT) mass determined post-mortem at 30 weeks of age. Brackets represent adjusted p-values (Tukey's multiple comparison test) after one-way ANOVA, comparing all groups on one side with all groups on the other side.

Supplemental Figure 2. Bone Microarchitecture in Vivo. (A) Trabecular thickness, (B) trabecular spacing, (C) cortical bone area, (D) cortical medullary area, (E) trabecular tissue mineral density, and (D) cortical tissue mineral density assessed by in vivo μ CT in the 4 genotype groups at 6 and 20 weeks of age. Brackets represent adjusted p-values (Tukey's multiple comparison test) after two-way ANOVA. Brackets on multiple groups (C-F) indicate pairwise comparison of each genotype group at 6 and 20 weeks. Pairwise comparisons with $p>0.10$ are not indicated.

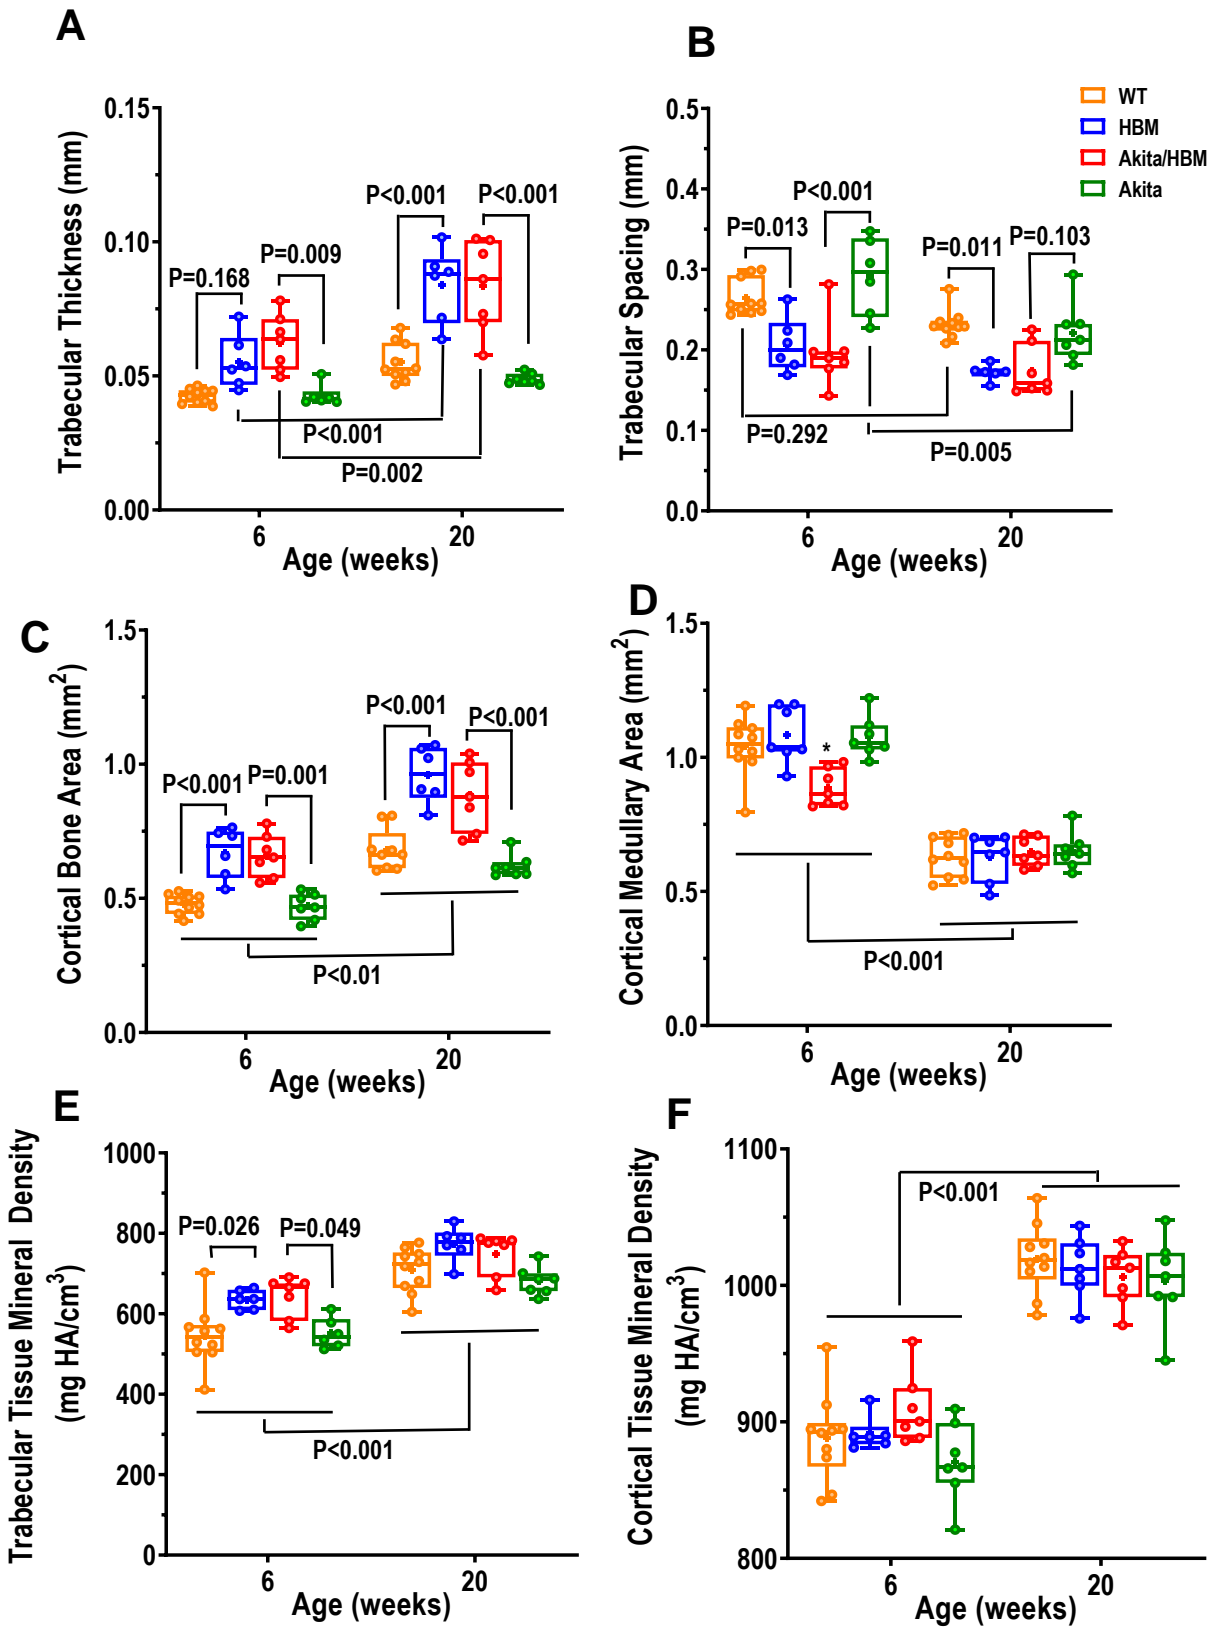

Supplemental Figure 3. Bone Microarchitecture Post-Mortem. (A) Volumetric trabecular bone volume/total volume (BV/TV), (B) trabecular bone mineral density, (C) cortical thickness, and (D) cortical bone area in the 4 genotype groups at 30 weeks of age measured by μ CT. Brackets represent adjusted p-values (Tukey's multiple comparison test) after one-way ANOVA..

Supplemental Figure 4. Intraperitoneal Glucose Tolerance Test and Serum Osteocalcin. (A) Blood glucose before and after an intraperitoneal glucose load (1.5 mg/kg) at age 10-12 weeks (n=7-10). *p=0.0192 for WT vs. *Lrp5*^{A214V/A214V}; two-way ANOVA and Bonferroni post-hoc test. (B) Serum Gla13 (carboxylated) osteocalcin in ***-week-old mice. F=1.257, p=0.312 (ANOVA).

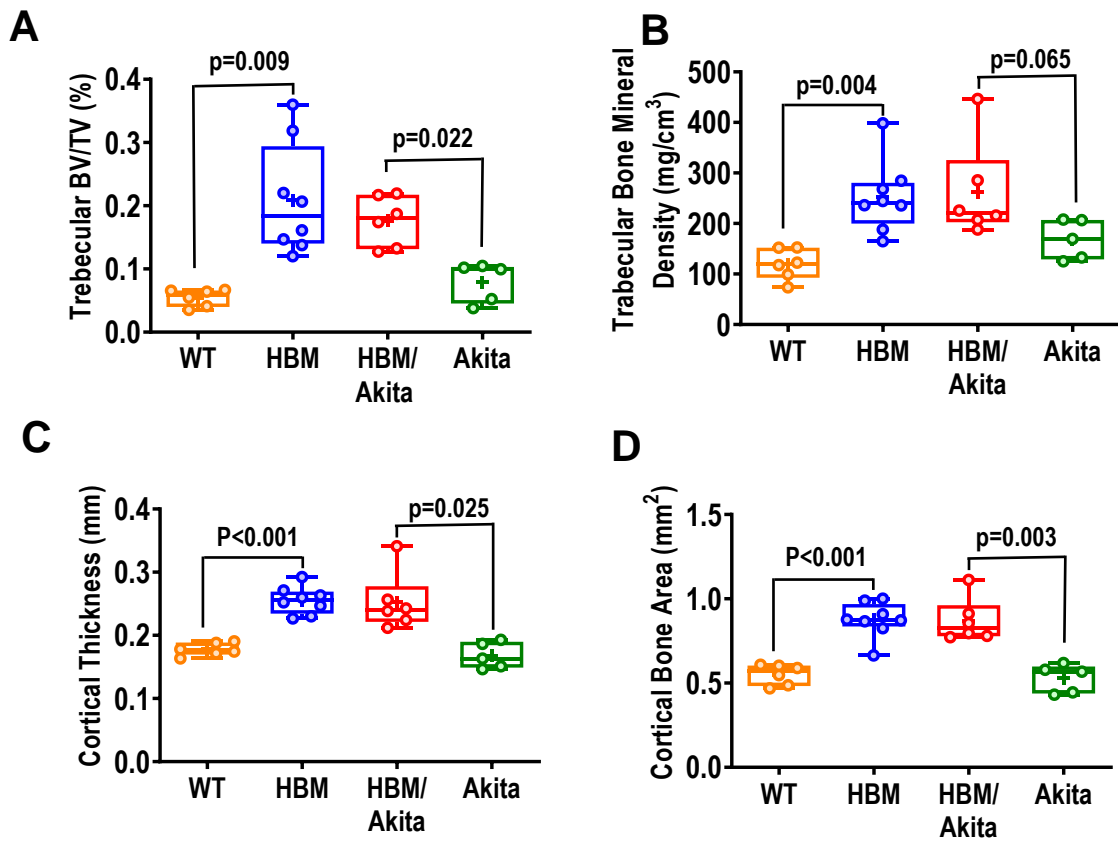

Supplemental Figure 5. Insulin Signaling. (A, B) Two replicates of immunoblots of whole cell lysates from external ear-derived adipocyte cultures before and after 5 or 30 minutes of exposure to 1 μ g/ml of insulin. Quantitative band densitometry is shown in Fig. 8. (C) Immunoblot of bone marrow stromal cell lysates before and after 5 or 30 minutes of exposure to 20 μ g/ml of insulin.
