CANCER-SPECIFIC PROTEOME

The defined proteome specified for group of patients with ovarian cancer or patients with breast cancer

Comparative symmetry analysis showed that the mutual proteome size (between all studied groups) was $n = 147$ protein identifications. The common proteome size of two cancer-specific groups was $n = 50$ protein identifications, whereas the group-specific proteomes were $n = 74$ and $n = 25$ protein identifications amongst patients with ovarian and breast cancer, correspondingly. Proteins, attributed for the pathology groups and featured by a statistically significant between-groups quantitative difference, are given below in **Supplementary Table S1**.

Supplementary Table S1: Plasma-based differentially expressed proteins (DEP) selected upon results of semi-quantitative and symmetry analysis at statistical significance cut-off level of $p < 0.05$.

We focused in on three known types of PTMs to identify them amongst patients under consideration (**Figure S1**). The discovered PTMs were ranged and plotted against each study group to reveal their input. It has been found, that ubiquitination is the least prevalent type of PTM in cancer phenotypes, but can be readily extracted from healthy donors. At the same time, phosphorylation was found to be most frequent type of PTM in ovarian cancer patients with the local input of 55%.

Supplementary Figure S1: Distribution of identified PTMs types within studied groups. The defined PTMs of interest are distributed unequally among different cancer groups and the control group. Particularly, ubiquitination of the most prevalent type of PTM among healthy donors in contrast to cancer phenotype patients, where this PTM made only 32% and 7% in ovarian and breast cancer, correspondingly. Likewise, acetylation is more general PTM for cancer phenotype and constitutes only 8% on the control group of healthy donors. Altogether, it may partially conform the known phenomenon of actively ongoing chromatin remodeling and significantly suppressed apoptosis processes in tumor cells.

Supplementary Figure S2: Fragmentation spectra of the selected peptides obtained after targeted MS2 analysis. Top panel (A) shows fragmentation of intact(unmodified) peptide KVPQVSTPTLVEVSR (ALBU) detected as an ion with m/z $m/z=820.4719^{2+}$ (mass error is -0.73 ppm) at 14.12 minutes (see Figure 2 in the Main text); middle panel (B) demonstrates the fragmentation spectrum of its modified counterpart acetylated at lysine, and detected as an ion with $m/z=841.4774^{2+}$ (mass error is -0.83 ppm) at 14.46 minutes (see Figure 2 in the Main test). Bottom panel (C) shows the fragmentation spectrum of the modified peptide with amino acid sequence MDAKMYLGYEYVTAIR derived from TRFE and found in both ovarian and breast cancer groups of study. The peptide is acetylated at lysine and was detected as an ion with $m/z=983.4725$ (mass error is -0.91 pm) at 34.47 minutes.

MOLECULAR GEOMETRY FEATURES OF THE MODIFIED ALBUMIN (ALBU)

There were five different PTMs identified specifically in serum samples of patients with breast cancer or ovarian cancer only and were not detected amongst patients of the control group. Each of selected PTMs were further categorized by the spatial geometry feature assisted by the molecular dynamic experiments.

The following characteristics were calculated along the molecular dynamic itemizing:

- LocPTM –type and localization of the modified amino acid residue in the chain-A;
- rA, rB – is a root mean square deviations (RMSD) for helices;
- d – mean value of inter-planar distance;
- r – minimal distance;
- α – angle between helices axis;
- θ – torsion angle;
- S – area of intercept between helices;
- P – polygonal perimeter between helices;
- sd, sr, sa, s θ , sS, sP – root mean square deviation of the above-mentioned parameters;
- stat – qualification pattern of the original (initial) structure;
- nmd – qualification of the unmodified (intact) structure;
- mod – qualification of the modified structure;

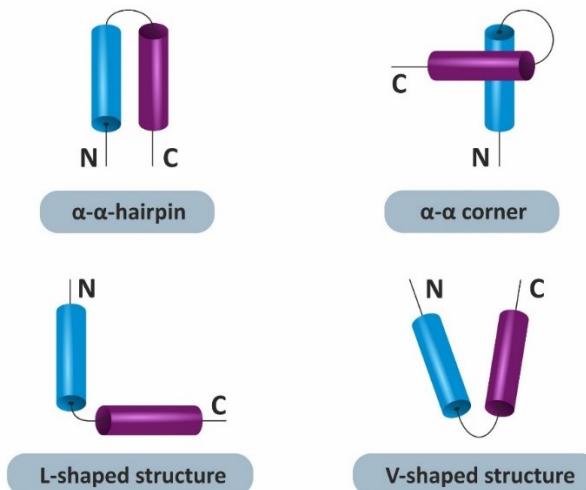

Supplementary Table S2: Molecular dynamics simulation results of the geometry calculations for modified albumin

RULES OF PROTEIN SPATIAL ORGANIZATION

General rules of proteins structure organization Depending in the length, size of connections and angles, up to four typical closely packed conformations of the consequent alpha-helices can be distinguished and itemized.

Feature	$\alpha\text{-}\alpha$ corner	$\alpha\text{-}\alpha$ hairpin	L-shaped structure	V-shaped structure
Folding of alpha helices	orthogonal	antiparallel	dense laterally beveled	dense laterally beveled
Projection and axes of helices	intersect	not intersect	not intersect	not intersect
Inter-planar (d) and minimal (r) distances	$d=r$	d varied in a wide range	–	–
Distance between turns	9-11 Å	–	–	–
Angle between helices (ϕ)	70-110°	0-30°	90°	50°
Length of linker	4-5 amino acid residues	varies	varies	varies

Supplementary Figure S3: Types and rules for qualification of secondary structures comprised of two distinct α -helices and unstructured
