## 1. Experimental Section

**General procedure.** All experiments and manipulations were carried out under a dry argon atmosphere using either standard Schlenk or glovebox techniques. Toluene, benzene, and *n*-hexane were dried using an MBraun solvent drying system (SPS), degassed, and stored over 4Å molecular sieve. Deuterated solvents ( $C_6D_6$ , toluene-d<sub>8</sub>) were dried by refluxing over NaK alloy, distilled prior to use, and stored over 4Å molecular sieve. Commercial reagents were purchased from Aldrich, Acros, or Alfa-Aesar Chemical Co. and used as received. LGa(Cl)PLGa **1** ( $L = HC[C(Me)N(Ar)]_2$ , Ar = 2,6-*i*Pr<sub>2</sub>-C<sub>6</sub>H<sub>3</sub>), was prepared by literature method.<sup>[1]</sup> NMR spectra ( $\delta$  in ppm) were recorded using a Bruker Avance DPX 300 (<sup>1</sup>H 300 MHz, <sup>13</sup>C{<sup>1</sup>H} 75 MHz, <sup>31</sup>P{<sup>1</sup>H} 121 MHz), a Bruker Avance II 500 (<sup>1</sup>H 500 MHz, <sup>13</sup>C{<sup>1</sup>H} 126 MHz, <sup>31</sup>P{<sup>1</sup>H} 202 MHz), or a Bruker Avance III HD 600 (<sup>1</sup>H 600 MHz, <sup>13</sup>C{<sup>1</sup>H} 151 MHz, <sup>31</sup>P{<sup>1</sup>H} 243 MHz) spectrometer and were referenced to internal  $C_6D_5H$  (<sup>1</sup>H  $\delta$  = 7.16; <sup>13</sup>C  $\delta$  = 128.06) or  $C_7D_7H$  (<sup>1</sup>H  $\delta$  = 2.08, 6.97, 7.01, 7.09; <sup>13</sup>C  $\delta$  = 137.48, 128.87, 127.96, 125.13, 20.43), the <sup>31</sup>P NMR spectra are referenced to internal  $C_6D_5H$  (<sup>1</sup>H  $\delta$  = 7.16) or  $C_7D_7H$  (<sup>1</sup>H  $\delta$  = 2.08, 6.97, 7.01, 7.09) using chi-values ( $\chi$ ).<sup>[2]</sup> Elemental analyses were performed at the *Elementaranalyse Labor* of the University of Duisburg-Essen. IR spectra were recorded by a Bruker ALPHA-T FT-IR spectrometer equipped with a single-reflection ATR sampling module.

**Synthesis of 2:** *N,N'*-diisopropylcarbodiimide (45 mg, 0.29 mmol) was added to a toluene solution (10 mL) of **1** (300 mg, 0.29 mmol). After shaking the reaction mixture at ambient temperature for one minute, all volatiles were removed under vacuum to yield a colorless crystalline solid. Yield: 99% (330 mg). M.p. 91 °C (dec.). Single crystals suitable for X-ray diffraction were grown by cooling a toluene solution of **2** at -30 °C for 12 h. Anal. calcd. **Reaction of 2 with CO<sub>2</sub>:** A toluene solution (5 mL) of **2** (150 mg, 0.13 mmol) in a *J*-Young Schlenk flask was degassed using the freeze pump-thaw method. CO<sub>2</sub> (1 bar) gas was added, and the solution was stirred at ambient temperature for 1 h. All volatiles were then removed in *vacuo* to yield a colorless crystalline powder. The  $^{31}\text{P}\{\text{H}\}$  NMR spectrum at 25 °C shows two sharp singlets, which were assigned to the mono and double<sup>[1]</sup> CO<sub>2</sub> addition products. Unfortunately, due to the similar solubility of these two products, we failed to isolate a pure sample of the mono CO<sub>2</sub> addition product. The crude  $^1\text{H}$  and  $^{31}\text{P}\{\text{H}\}$  NMR spectra of the mixture are provided to confirm the bulk material's constitutions match (Figures S29-S30).

**Reaction of 3 with CO<sub>2</sub>:** Compound **3** also led to the mono and double<sup>[1]</sup> CO<sub>2</sub> addition products at room temperature, when exposed to CO<sub>2</sub> gas (1 bar) in toluene similar to compound **2**. Again, we failed to isolate a sample of the pure mono CO<sub>2</sub> addition product due to the similar solubility of these two products. The  $^1\text{H}$  and  $^{31}\text{P}\{\text{H}\}$  NMR spectra of this mixture are provided to confirm the bulk material's constitutions match (Figures S30-S31).

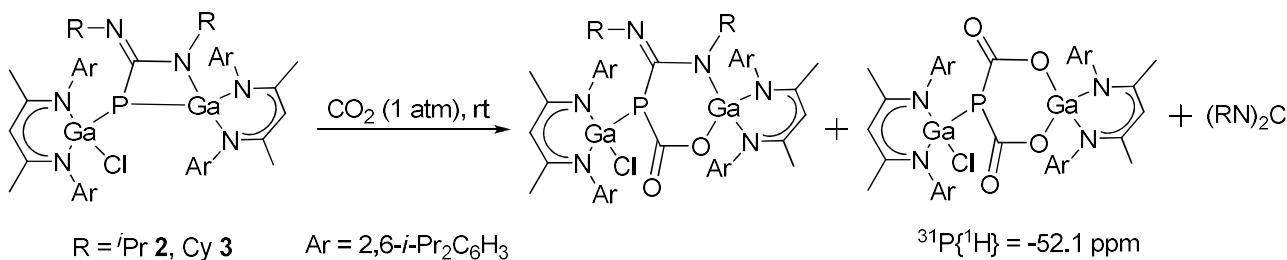

**Synthesis of 7:** A toluene solution (5 mL) of **4** (150 g, 0.13 mmol) in a *J*-Young Schlenk flask was degassed using the freeze pump-thaw method. CO<sub>2</sub> (1 bar) gas was added and the solution was stirred at room temperature for 1 h. All volatiles were then removed in *vacuo* to yield a colorless crystalline powder of **7**. ### 3. X-Ray Crystallographic Analysis

The crystals were mounted on nylon loops in inert oil. Data for **2** were collected on a Bruker AXS D8 Kappa diffractometer with APEX2 detector (mono-chromated  $\text{MoK}\alpha$  radiation,  $\lambda = 0.71073 \text{ \AA}$ ) and for **6**, **8**, and **9** were collected on a Bruker AXS D8 Venture diffractometer with Photon II detector (mono-chromated  $\text{CuK}\alpha$  radiation,  $\lambda = 1.54178 \text{ \AA}$ , micro-focus source) at 100(2) K. The structures were solved by Direct Methods (SHELXS-97)<sup>[3]</sup> and refined anisotropically by full-matrix least-squares on  $F^2$  (SHELXL-2014).<sup>[4-6]</sup> Absorption corrections were performed semi-empirically from equivalent reflections on basis of multi-scans (Bruker AXS APEX2). Hydrogen atoms were refined using a riding model or rigid methyl groups. **2** was refined as a 2-component inversion twin. The toluene molecule is disordered over two alternate sites. The bond lengths and angles of its phenyl ring were constrained to be equal (SADI) and its anisotropic displacement parameters were restrained with RIGU. In **6** an *i*-Pr group in residue 2 is disordered over two positions. All its corresponding bond lengths and angles were restrained to be equal (SADI). In both residues the phosphorous atom is disordered over two positions. In addition, in the residual density near C11 of residue 1 the CNCO unit of an alternate orientation of the CyNCO ligand can be identified, however, finding and refining the whole moiety failed due to the low residual density. The small displacement ellipsoid of N5 suggests that in the elusive second orientation CyNCO and Cl swap places. N5 would then be over-layered with a Cl atom leading to more electron density in the place. A refinement of a partially occupied Cl here failed due to the low occupancy. Considering the unresolved disorder, quantitative results should be carefully assessed. The crystal of **8** was a non-merohedral twin of strongly overlapping components which was identified but not integrated separately. Consequently, only the connectivity should be taken for granted. Quantitative results should not be discussed since the obtained intensity data is strongly distorted by the ignored twin components as indicated by the high  $R_{\text{int}}$ . A more suitable specimen was not available. In addition, the structure contains a highly disordered toluene molecule. The final refinement was done with a solvent free dataset from a PLATON/SQUEEZE run.<sup>[7]</sup> The molecule was included in the sum formula for completeness. A toluene molecule in **9** is disordered over three alternate positions. The occupancies were constrained to the values of the free variables in the last refinement cycles to avoid correlations and ensure a convergence of the refinement. All bond lengths and angles of the solvents' phenyl rings were restrained to be equal (SADI) and RIGU restraints were applied to the anisotropic displacement parameters.

#### 4. Computational Details

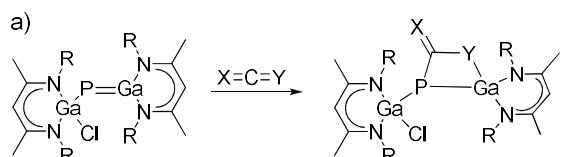

All calculations were performed by using the program package Gaussian 16<sup>[8]</sup>. The geometrical parameters of all stationary points were optimized by means of the density functional B3LYP<sup>[9]</sup> together with the dispersion correction with Becke-Johnson damping<sup>[10]</sup> (D3BJ). For the determination of the energetics of the reaction, the basis set def2-TZVP was applied. In order to calculate the reaction mechanism, the 6-31G\* basis was used. For all structures C1 symmetry was applied. Frequency calculations were carried out at each of the stationary points to verify the nature of the stationary point. It turned out that all products have no imaginary frequency, whereas the two transition states have exactly one. Furthermore, single point calculations were performed on the B3LYP-D3BJ/6-31G\*-optimized structures by means of B3LYP-D3BJ/def2-TZVP.

#### *Influence of the Dipp groups on the reaction behavior*

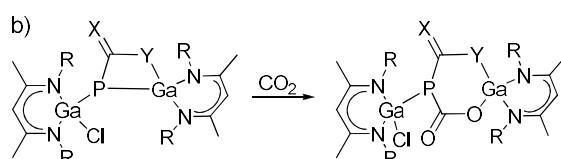

In order to determine the influence of the sterically demanding Dipp groups on the observed reaction behavior, the [2+2] cycloaddition of the reference system (RS) **RS1**, in which the Dipp groups in **1** are replaced by small methyl substituents, to the corresponding heterocycles **RS2–RS5** were studied (Scheme S2). In a second step, the energetic parameters of the cycloaddition reaction of the four-membered metallaheterocycles **2**, **4**, **10**, **12** and **RS2–RS5** with CO<sub>2</sub> to the six-membered metallaheterocycles **7**, **13–15** and **RS6–RS9** were calculated (Scheme S2). A comparison between the data for the gallaphosphenes **1** and **RS1** reveals, that only in the case of the carbodiimides a strong deviation from one another is found. For the addition of DMC to **1** and **RS1**, almost the same values are found, while this is not the case for the cycloaddition of the larger carbodiimide DIC. The reaction of DIC with **RS1** is energetically more favorable than that of DMC with **RS1**; in the case of **1**, the order is reversed. This demonstrates the influence of the Dipp groups of the β-diketminate ligands: the large isopropyl groups lead to steric repulsive interactions making the formation of **2** (R = Dipp) approx. 4 kcal/mol less favorable than that of **RS5** (R = Me).

The calculated Gibbs free energies (ΔG) for the addition to the reference system **RS1** show the same trend as the calculated energies (ΔE): CO<sub>2</sub> addition is by far the most unfavorable, then EtNCO and DMC additions follow, and the addition of DIC exhibits the energetically most favored value. A different order is found for gallaphosphene **1**. Here, the addition of DIC is even less favorable than that of EtNCO. This means that starting from **1** the formation of **2** is less favorable than the formation of **4** due to entropic reasons. Presumably, the free

rotation of the large groups in **2** is severely restricted and the entropy loss during the cycloaddition is correspondingly high.
