eMethods.

Definitions of Severe, Critical, and Fatal COVID-19

Severe COVID-19 was defined per the World Health Organization (WHO) classification as a severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2)-infected person with “oxygen saturation of <90% on room air, and/or respiratory rate of >30 breaths/minute in adults and children >5 years old (or ≥ 60 breaths/minute in children <2 months old or ≥ 50 breaths/minute in children 2-11 months old or ≥ 40 breaths/minute in children 1–5 years old), and/or signs of severe respiratory distress (accessory muscle use and inability to complete full sentences, and, in children, very severe chest wall indrawing, grunting, central cyanosis, or presence of any other general danger signs)”.¹ Detailed WHO criteria for classifying SARS-CoV-2 infection severity can be found in the WHO technical report.¹

Critical COVID-19 was defined per WHO classification as a SARS-CoV-2-infected person with “acute respiratory distress syndrome, sepsis, septic shock, or other conditions that would normally require the provision of life sustaining therapies such as mechanical ventilation (invasive or non-invasive) or vasopressor therapy”.¹ Detailed WHO criteria for classifying SARS-CoV-2 infection criticality can be found in the WHO technical report.¹

COVID-19 death was defined per WHO classification as “a death resulting from a clinically compatible illness, in a probable or confirmed COVID-19 case, unless there is a clear alternative cause of death that cannot be related to COVID-19 disease (e.g. trauma). There should be no period of complete recovery from COVID-19 between illness and death. A death due to COVID-19 may not be attributed to another disease (e.g. cancer) and should be counted independently of preexisting conditions that are suspected of triggering a severe course of COVID-19”. Detailed WHO criteria for classifying COVID-19 death can be found in the WHO technical report.²

Laboratory methods

Nasopharyngeal and/or oropharyngeal swabs were collected for PCR testing and placed in Universal Transport Medium (UTM). Aliquots of UTM were: extracted on a QIAasymphony platform (QIAGEN, USA) and tested with real-time reverse-transcription PCR (RT-qPCR) using TaqPath™ COVID-19 Combo Kits (Thermo Fisher Scientific, USA) on an ABI 7500 FAST (Thermo Fisher, USA); tested directly on the Cepheid GeneXpert system using the Xpert Xpress SARS-CoV-2 (Cepheid, USA); or loaded directly into a Roche cobas® 6800 system and assayed with a cobas® SARS-CoV-2 Test (Roche, Switzerland). The first assay targets the viral S, N, and ORF1ab gene regions. The second targets the viral N and E-gene regions, and the third targets the ORF1ab and E-gene regions.

All PCR testing was conducted at the Hamad Medical Corporation Central Laboratory or Sidra Medicine Laboratory, following standardized protocols.

Classification of infections by variant type

Surveillance for SARS-CoV-2 variants in Qatar is based on viral genome sequencing and multiplex, real-time reverse-transcription PCR (RT-qPCR) variant screening³ of random positive clinical samples,⁴⁻⁸ and complemented by deep sequencing of wastewater samples.^{6,9} The latter is used to compare the distribution of variants in wastewater with that in clinical samples collected from SARS-CoV-2 patients.

Between March 23, 2021 and September 7, 2021, RT-qPCR genotyping identified 6005 (35.5%) Beta (B.1.351)-like cases, 3658 (21.6%) Alpha (B.1.1.7)-like cases, 7218 (42.6%) “other” variant cases, and 51 (0.3%) B.1.375-like or B.1.258-like cases in 16 932 randomly collected

SARS-CoV-2-positive specimens.^{6,8} Since RT-qPCR genotyping started on March 23, 2021, the proportion of all diagnosed infections in Qatar that have been RT-qPCR genotyped was 12.0%.

The accuracy of the RT-qPCR genotyping was verified against either Sanger sequencing of the receptor-binding domain (RBD) of SARS-CoV-2 surface glycoprotein (S) gene, or by viral whole-genome sequencing on a Nanopore GridION sequencing device. From 236 random samples (27 Alpha-like, 186 Beta-like, and 23 “other” variants), PCR genotyping results for Alpha-like, Beta-like, and ‘other’ variants were in 88.8% (23 out of 27), 99.5% (185 out of 186), and 100% (23 out of 23) agreement with the SARS-CoV-2 lineages assigned by sequencing.

Within the “other” variant category, Sanger sequencing and/or Illumina sequencing of the RBD of SARS-CoV-2 spike gene on 728 random samples confirmed that 701 (96.3%) were Delta cases and 17 (2.3%) were other variant cases, with 10 (1.4%) samples failing lineage assignment.^{6,8} Accordingly, a Delta case was proxied as any “other” case identified through the RT-qPCR based variant screening.

All the variant RT-qPCR screening was conducted at the Sidra Medicine Laboratory following standardized protocols.

eTable 1. Demographic characteristics of cohorts that received the BNT162b2 and mRNA-1273 vaccines.

Abbreviations: IQR, interquartile range; SMD, standardized mean difference.

^aSMD is the difference in the mean of a covariate between groups divided by the pooled standard deviation. An SMD less than 0.1 indicates adequate matching.

^bSMD reported here is for the mean difference between groups divided by the pooled standard deviation.

^cNationalities were chosen to represent the most numerous groups in the population of Qatar.

⁴Individuals with a prior PCR-confirmed infection in Qatar comprised 133 other nationalities in the full cohort of individuals who received the BNT162b2 vaccine and 114 other nationalities in the full cohort of individuals who received the mRNA-1273 vaccine. Meanwhile, individuals with no prior PCR-confirmed infection in Qatar comprised 184 other nationalities in the full cohort of individuals who received the BNT162b2 vaccine and 163 other nationalities in the full cohort of individuals who received the mRNA-1273 vaccine.
