1 Computational details

Following the computational work of Ref. 1, we have studied four different oxidation states of the six-porphyrin nanoring: neutral, +4, +6, and +12. The molecules have been studied considering not only the isolated belt structure (c-P6, c-P6⁴⁺, c-P6⁶⁺, and c-P6¹²⁺) but also taking into account the encapsulated template and the two phenyl substituents in each porphyrin (c-P6·T6, c-P6·T6⁴⁺, c-P6·T6⁶⁺, and c-P6·T6¹²⁺).

Geometry optimizations and frequency calculations have been performed with the Gaussian16 software package² using B3LYP,³⁻⁶ CAM-B3LYP,⁷ LC- ω HPBE ($\omega=0.1$ and $\omega=0.2$),⁸ and M06-2X⁹ density functional approximations (DFAs) including Grimme's D3 dispersion correction (for the first two DFAs)¹⁰ and in combination with the 6-31G* basis set.¹¹ The initial structures have been obtained from a previous work.¹ The geometry minima of all the oxidation states of c-P6 and the transition state of c-P6⁶⁺ have been confirmed by analyzing the harmonic frequencies and the stability of the single-determinant wavefunction with respect to relaxing various constraints (spin and orbital symmetry, real orbitals) was confirmed. For c-P6⁴⁺ and c-P6⁶⁺, single-point coupled-cluster calculations were performed with ORCA software package¹² using DLPNO-CCSD(T)¹³ with resolution of identity¹⁴ in combination with the Def-SVP/C basis set¹⁵ and the corresponding auxiliary basis set in order to obtain accurate reference calculations to assess the accuracy of DFAs. Additional optimization and magnetic calculations have been performed with 6-31+G* and 6-311+G* basis sets. The results, which are collected in Tables S15 and S16, show that the conclusions drawn for these systems do not change with the basis set size.

The calculation of the electronic aromaticity indices (AV1245,¹⁶ AV_{min},¹⁷ BOA,¹⁸ and FLU^{19,20}) and the delocalization indices (DIs)^{21,22} employs the quantum theory of atoms in molecules (QTAIM)²³ atomic partition performed by the AIMall software.²⁴ The atomic overlap matrices resulting from this partition and the wavefunction files are the input of the in-house ESI-3D code,^{19,25,26} which provides AV1245,¹⁶ AV_{min},¹⁷ BLA,¹⁸ BOA,¹⁸ DIs,^{22,26} FLU,^{19,20} the harmonic oscillator model of aromaticity (HOMA),²⁷ and MCI²⁸ values. The numerical integrations of the atoms in the QTAIM²³ as well as the corresponding oxidation states have errors below 0.004 and 0.03 electrons for c-P6 (in all its oxidation states) and c-P6·T6 (in all its oxidation states), respectively. The ESI-3D code is available upon request (ematito@gmail.com).^{19,25,26} Anisotropy of the induced current density (ACID)²⁹ and nuclear-independent chemical shift (NICS)³⁰⁻³⁴ calculations were conducted using the CSGT and GIAO methods, respectively, using Gaussian software packages (Gaussian09³⁵ and Gaussian16²). NICS grids were calculated with 1 Å resolution (plots 20 Å x 20 Å grid) and the plots were generated with a Python script. The version 2.0.0 of the AICD program²⁹ was used to generate ACID results and they were visualized using POV-Ray.³⁶

We also dissected AV1245 values and assigned a delocalization value to each atom in the corresponding pathway by splitting the MCI(1,2,4,5) of each five-atom fragment among the atoms in the fragment.¹⁶ These profiles are called 1245-index distribution plots and help detect the fragments responsible for the loss of aromaticity.

The effective oxidation state (EOS) analysis^{37,38} was performed with APOST-3D. The software provided in Ref. 39 was used to assess the similarity of two molecular geometries through the calculation of the root mean square deviation (RMSD) of the atomic distances.

NMR calculations were also performed using GIAO method in Gaussian16 software package² with B3LYP,^{3,4} CAM-B3LYP,⁷ and M06-2X⁹ functionals including Grimme's D3 dispersion correction¹⁰ and in combination with the 6-31G* basis set.¹¹ Solvent effects of dichloromethane were taken into account using the Polarizable Continuum Model (PCM).⁴⁰

2 Geometry assessment

In order to quantify the structural differences among the several optimized geometries, the root mean square deviation (RMSD) of two molecules has been calculated. The RMSD of two structures was calculated using the software provided in Ref. 39. This program calculates the RMSD between two Cartesian geometries in either .xyz or .pdb format and uses the Kabsch algorithm (1976)⁴¹ or Quaternion algorithm⁴² if rotation is needed before the calculation of RMSD. All the RMSD values included in this work compare two structures ignoring all the hydrogen atoms.

From the data in Table S1, we conclude that the structures found by Anderson *et al.* at the B3LYP/6-31G* level of theory were not absolute minima of the corresponding potential energies for c-P6, c-P6⁴⁺, c-P6⁶⁺, and c-P6¹²⁺. However, their geometries are very similar to the ones we have found in this work at the same level of theory.

Table S1 Energy comparison and the RMSD of the minimum geometries calculated by Anderson *et al.*¹ and this work at the B3LYP/6-31G* level of theory. Energy units are atomic units (au) while RMSD are in Ångstroms (Å).

The third last columns correspond to the RMSD values obtained from these geometries. All the calculations employed the 6-31G* basis set. Energy units are atomic units (au) while RMSD are in Ångstroms (Å).

The results of Table S2 demonstrate that the B3LYP energy minima found for c-P6 and c-P6¹²⁺ structures are well reproduced by the CAM-B3LYP and M06-2X methods. However, the geometries of the B3LYP energy minima of c-P6⁴⁺ and c-P6⁶⁺ are significantly different from those found at the M06-2X and CAM-B3LYP levels of theory. Since the latter functional approximations do not suffer from large electron delocalization errors, one is prompted to conclude that B3LYP overestimates the symmetry of c-P6⁶⁺ (and, hence, its aromaticity, see below), whereas it overestimates the asymmetry of c-P6⁴⁺ (RMSD=0.661) resulting in a spurious enhancement of the antiaromatic features of this molecule (see below). Similar results have been recently reported by our group^{18,43-46} and others.⁴⁷⁻⁵⁰

We have also characterized the structure of c-P6⁶⁺ using the LC- ω HPBE^{8,51} method with $\omega=0.1$ and $\omega=0.2$ in combination with the 6-31G* basis set. Using LC- ω HPBE with $\omega=0.1$, the optimized structure lies in between the B3LYP and CAM-B3LYP ones, as confirmed by the fact that the RMSD values between the LC- ω HPBE($\omega=0.1$) geometry and these two geometries are quite similar (0.160 and 0.142, for B3LYP and CAM-B3LYP, respectively). On the contrary, LC- ω HPBE with $\omega=0.2$ provides a geometry closer to the CAM-B3LYP one (RMSD=0.095). This further demonstrates the importance of including a large percentage (typically above 50%) of HF exchange in the functional in order to correctly characterize conjugated molecules (avoiding the delocalization error⁵²).

3 ^1H -NMR calculations

We have calculated the ^1H -NMR spectra for all species, including the template structure and the phenyl substituents. The most important protons for the study of aromaticity are highlighted in the following figure.

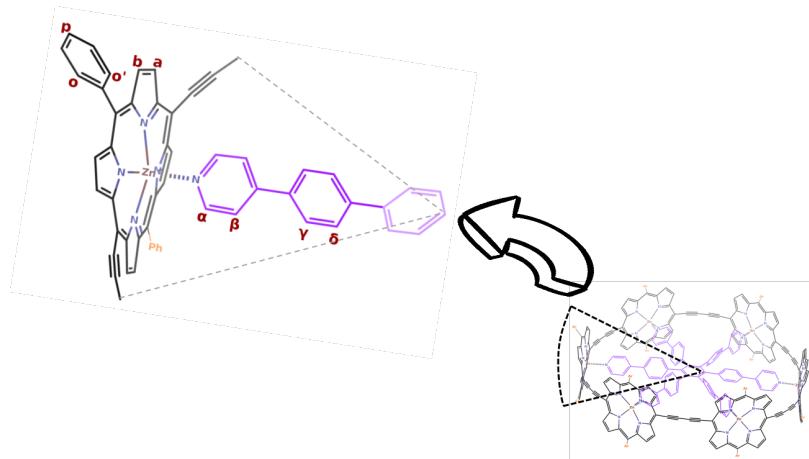

Figure S1 Nanoring's structure where the most important protons of the ^1H -NMR spectra are highlighted (see also Table S3).

In Table S3, we have summarized the shielding of the most relevant protons for the study of aromaticity and compared them with the experimental values from the literature.¹

Table S3 ^1H -NMR values (in ppm) calculated using CAM-B3LYP, M06-2X, and B3LYP methods in combination with 6-31G* basis set and using CH_2Cl_2 as a solvent (PCM model).⁴⁰ We have compared with the experimental data from the literature.¹ Maximum error (MAX), root mean square error (RMSE), and mean absolute error (MAE) of each method are also given.

All the errors presented in Table S3 (MAX, MAE, and RMSE) clearly indicate that the functional that better reproduces the experimental data is CAM-B3LYP. While errors are of similar magnitude for c-P6·T6, they are much larger for c-P6·T6⁶⁺, indicating that B3LYP geometry is quite different from the experimental one.

To assess to which extent we can rely on the ^1H -NMR data to analyze the aromaticity of these systems, we have constructed a structure that has no current, therefore, is not aromatic. To construct it, we have taken the optimized structure of each species and replaced all the bridging butadiyne linkers by capping hydrogen atoms. Then, we made a single-point calculation to obtain the chemical shieldings of the disconnected structure (see Figure S2). In the following table, the chemical shielding of the protons that are used to analyze of the aromatic character are presented for both disconnected and connected structures of the nanoring's species. In addition, the ^1H -NMR chemical shift of α and β protons of the free template are presented in Table S5.

Comparing the ^1H -NMR data of all the species' connected and disconnected structures, we can appreciate that the values are pretty similar. Even in some cases, the disconnected structure presents a slightly higher value. Therefore, these results show that, although the porphyrins are not connected, a ring current is present. For this reason, we can say that this is another piece of evidence that proves that none of the species studied is aromatic.

4 Aromaticity

4.1 Porphyrinoid reference systems

In order to assess the aromaticity of the molecules presented in the manuscript, we have collected in Table S6 the aromaticity indices for the different pathways of a simple aromatic porphyrin molecule, porphin (**18H**). All the values presented in this section regarding **18H** were calculated at the CAM-B3LYP/6-31G(d,p) level of theory.⁴³ A molecular graph of porphin, with delocalization indices values included, can be found in Figure S3. If the pathway goes either through C-N bonds of the pyrrole or the imine groups, this fragment is labeled as "i" (inner), otherwise "o" (outer) is used. As a result, all the pathways are characterized by four letters, the first of which corresponds to pyrrole group at the top-left corner of Figure S3. The "oioi" pathway corresponds to the annulene pathway.

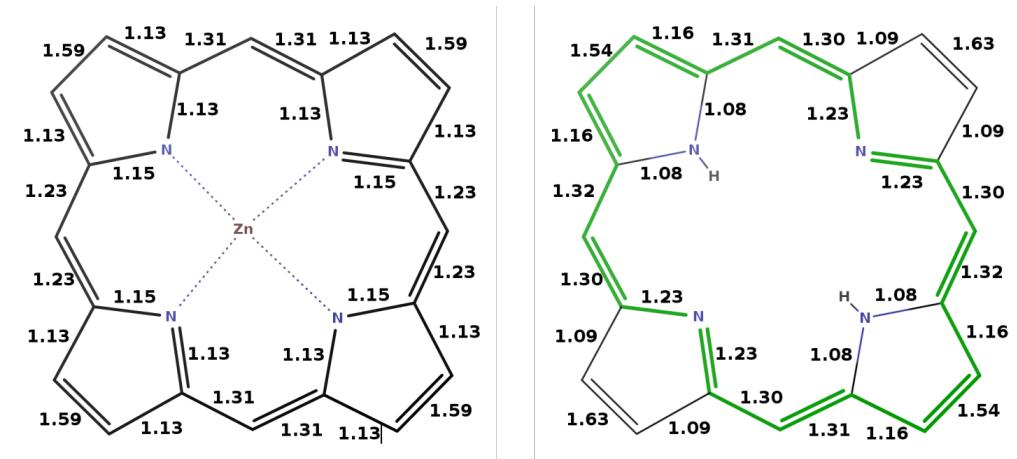

Figure S3 Delocalization indices of (left) c-P6 porphyrins and (right) porphin. In green, we have highlighted the annulene pathway (the most aromatic one) of **18H**.⁴³ Calculations employed the CAM-B3LYP functional in combination with 6-31G* and 6-311G** basis set, respectively.

Table S6 Aromaticity indices for the different pathways of porphin (**18H**). Geometries and some results extracted from Ref. 43. The number in parentheses indicates the number of pathways that are equivalent by symmetry.

In order to compare 1245-index distribution graphs of the nanoring structure with different oxidation states, we have included the 1245-index distribution plots of the 26 π -electron porphyrin in Hückel conformation (**26H**) and the 32 π -electron porphyrin in Möbius conformation (**32M**) as examples of aromatic expanded porphyrins (see Figure S4). For a detailed analysis of the aromaticity of **26H** and **32M** see Ref 43.

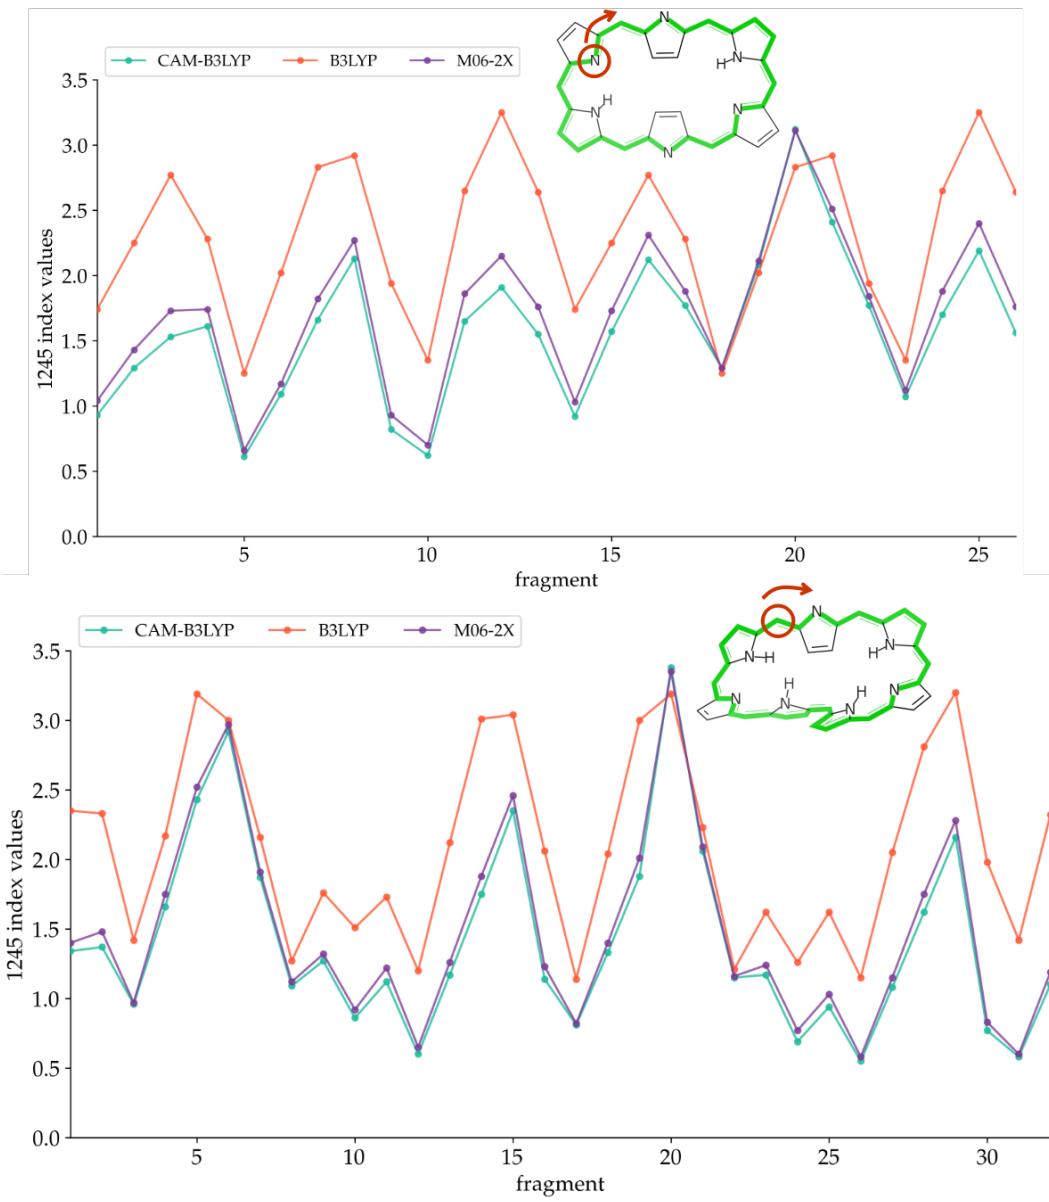

Figure S4 1245-index distribution along the most aromatic path, the annulene path, of (top) **26H** and (bottom) **32M** for the three DFAs exposed in combination with the 6-311G(d,p) basis set.⁵⁴ We have highlighted the first atom of the starting fragment of the 1245-index distribution with an orange circle and used an arrow to indicate the direction of the x-axis.

4.2 Local Aromaticity indices values

In the following tables, the values of the aromaticity indices corresponding to the porphyrins of the four oxidation states of the nanoring structure are summarized. In all cases, the six porphyrins are either symmetrically equivalent or give quantitatively similar values. The only exception is c-P6⁴⁺ for which the values of one porphyrin (P₁) are presented, and the reader is referred to Figure S9 for the values of all the porphyrins. In all cases, all the possible pathways of the porphyrin were analyzed, and three different DFAs with a variable amount of HF exchange (B3LYP, CAM-B3LYP, and M06-2X) were used.

Table S7 Aromaticity indices values for the different pathways of the porphyrins in c-P6, c-P6⁴⁺, c-P6⁶⁺, and c-P6¹²⁺ nanoring. The number in parentheses indicates the number of pathways that are equivalent by symmetry. c-P6⁴⁺ is asymmetric, therefore, the values differ slightly from porphyrin to porphyrin. Here values of the first porphyrin (P₁) are presented, see Table S9 for a full study of the other porphyrins.

Table S9 Aromaticity indices values of the three asymmetric porphyrins of c-P6⁴⁺. We can group the six porphyrins of the structure into three groups of two porphyrins each, according to symmetry. The members of the same group exhibit very similar aromaticity values. Labels P₁, P₂, and P₃ match with the representation exposed in Figure 6 of the manuscript. These porphyrins host inside Zn₃₃, Zn₄₈, and Zn₉₆, respectively, where the numeration of the Zn atoms follows the enumeration of the Cartesian coordinates given in a separate file of this Supporting Information.

4.3 Global Aromaticity indices values

In this section, we have gathered different tables with aromaticity indices and images related to the global aromaticity of the nanoring structure. In Tables S10 and S11, the MCI values of the linkers bridging the porphyrins are analyzed, while in Tables S12 and S13, the aromatic pathways consisting of large conjugated chains along the whole belt structure of the nanoring are given. Afterward, we present the 1245-index distribution plots, ACID plots, and NICS values.

Table S10 MCI ($\times 1000$) values for the six carbon atoms that form the linker bridging two porphyrins for c-P6, c-P6⁴⁺, c-P6⁶⁺, and c-P6¹²⁺ calculated at the B3LYP, CAM-B3LYP, and M06-2X/6-31G* levels of theory.

4.3.2 ACID plots

ACID calculations were performed using the CSGT method with B3LYP and CAM-B3LYP density functional approximations in combination with the 6-31G* basis set, including Grimme's dispersion (no solvent model was employed). In Figures S13 and S14, we present two perspectives of the ACID plots for the four oxidation states of the nanoring at the B3LYP/6-31G* computational level. The former picture can be used to assess the local aromaticity of the porphyrin, whereas the latter is useful in analyzing the global aromaticity of nanoring. Similar pictures of the CAM-B3LYP geometries can be found in the manuscript.

4.3.3 NICS

NICS values calculated with CAM-B3LYP and B3LYP density functional approximations in combination with the 6-31G* basis set. NICS(0,0) refers to the NICS value computed at the center of the nanoring (blue circle), whereas NICS(20,20) corresponds to the NICS value calculated at point (20,20) (orange circle) of a frame centered at the center of the nanoring with x- and y-axis pointing towards one linker and the center of a porphyrin, respectively (see Figure S15). Therefore, (20,20) corresponds to a point outside the nanoring at a fairly large distance. The distance unit is Ångströms (Å).

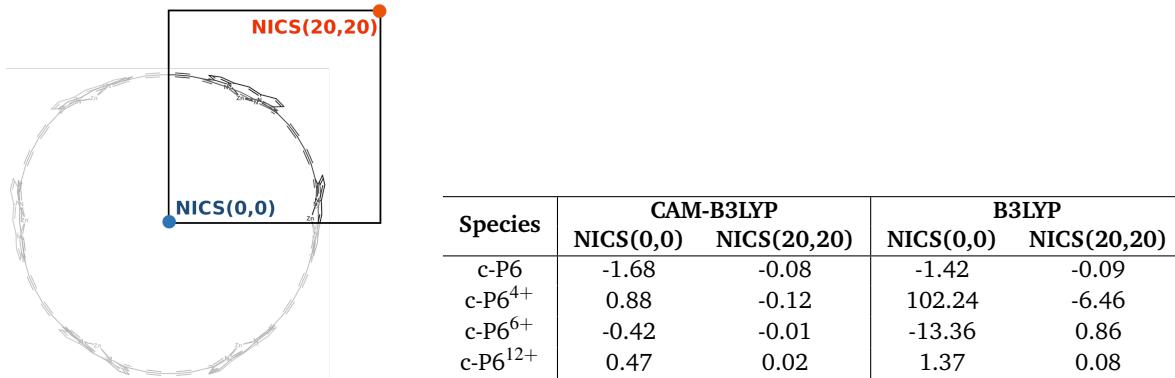

Figure S15 & Table S14 NICS(0,0) and NICS(20,20) values.

We have checked the dependency of the NICS with the basis set and included these results in Tables S15 and S16. Since there is a good agreement between the experimental and computational data for c-P6 and c-P6¹²⁺ (regardless of the density functional approximation employed in the calculation), we have only included the results for c-P6⁴⁺ and c-P6⁶⁺. In particular, we have performed optimization and NMR calculations using various combinations of 6-31G*, 6-31+G*, and 6-311+G* basis sets. As we can see in Tables S15, the results barely change with the basis set size for c-P6⁶⁺ and only small changes occur in the case of c-P6⁴⁺ (see Table S16). All in all, the conclusions drawn in the manuscript are not affected by the use of the 6-31G* basis set.

5 Aromaticity indices

In the present section, the aromaticity indices used in the manuscript will be briefly reviewed. Henceforth, we will use the short-hand notation $\mathbf{1} \equiv (\vec{r}_1, \sigma_1)$ to denote the coordinates of an electron and $d\mathbf{1} \equiv d\vec{r}_1, d\sigma_1$ for the electron positions and their derivatives. To provide a general expression, we will consider a molecule including at least one ring structure consisting of n atoms, represented by the string $\mathcal{A} = \{A_1, A_2, \dots, A_n\}$ and whose elements are ordered according to the connectivity of the atoms in the ring.

First of all, we will define the delocalization index (DI)^{21,22,26} using the exchange-correlation density (XCD)⁵⁵ between points belonging to two different atoms A_1 and A_2 ,

$$\delta(A_1, A_2) = 2 \int_{A_1} \int_{A_2} d\mathbf{1} d\mathbf{2} \rho_{xc}(\mathbf{1}, \mathbf{2}) = -2 \text{cov}(N_{A_1}, N_{A_2}), \quad (1)$$

where N_{A_1} and N_{A_2} are the atomic populations of atoms A_1 and A_2 . The delocalization index is related to the covariance of these populations and, for this reason, the DI is a measure of the number of electrons fluctuating between these atoms concurrently. On the other hand, the localization index (LI) is defined as

$$\lambda(\mathcal{A}) = \int_A \int_A d\mathbf{1} d\mathbf{2} \rho_{xc}(\mathbf{1}, \mathbf{2}), \quad (2)$$

where we integrate the two points of the XCD over the same atom A_1 .

Secondly, we define the geometric aromaticity indices: the so-called harmonic oscillator model of aromaticity (HOMA)⁵⁶ and the bond-length alternation (BLA). Kruszewski and Krygowski defined the former, and they used bond-length references, R_{opt} , to compare with the actual bond length of the ring structure:

$$HOMA(\mathcal{A}) = 1 - \frac{1}{n} \sum_i^n \alpha_i (r_{opt} - r_{A_i, A_{i+1}})^2, \quad (3)$$

where $r_{A,B}$ is the distance between atoms A and B , and α_i is an empirical constant fixed to give values close to one for aromatic species and small or negative values for non-aromatic and antiaromatic species. The geometrical data of reference (R_{opt}) is such that the compression energy of the double bond and the expansion energy of the single bond are minimal in accordance with the harmonic potential model. The bond-length alternation indicator compares the bond-length among the consecutive bonds along the perimeter of the ring,

$$BLA(\mathcal{A}) = \frac{1}{2n} \sum_{i=1}^n |r_{A_i, A_{i+1}} - r_{A_{i+1}, A_{i+2}}|, \quad (4)$$

where $n_1 = \lfloor (n+1)/2 \rfloor$ and $n_2 = \lfloor n/2 \rfloor$, $\lfloor x \rfloor$ being floor function of x , which returns the largest integer less than or equal to x .

We now consider the electronic aromaticity indices. The bond-order alternation (BOA) is one of the most popular aromatic indicators, and it corresponds to the electronic structure analogous to BLA. BOA uses bond orders or electron-sharing indices²⁶ rather than the bond length,

$$BOA(\mathcal{A}) = \frac{1}{2n} \sum_{i=1}^n |\delta(A_i, A_{i+1}) - \delta(A_{i+1}, A_{i+2})|. \quad (5)$$

Aromaticity indicators based on bond orders, such as BLA or FLU (see below), do not have a strong dependency on the computational method used.⁵⁷

Just as we had the electronic counterpart of BLA, we have the counterpart of HOMA, the aromatic fluctuation index (FLU), which goes beyond the bond length information employed in HOMA.^{19,20} The FLU index also employs references to measure the electron delocalization:

$$FLU(\mathcal{A}) = \frac{1}{n} \sum_{i=1}^n \left[\left(\frac{\delta(A_i)}{\delta(A_{i-1})} \right)^\alpha \left(\frac{\delta(A_i, A_{i-1}) - \delta_{ref}(A_i, A_{i-1})}{\delta_{ref}(A_i, A_{i-1})} \right) \right]^2 \quad (6)$$

where α is a simple function to ensure the first term in Eq. 6 is always greater or equal to 1,

$$\alpha \begin{cases} 1 & \delta(A_{i-1}) \leq \delta(A_i) \\ -1 & \delta(A_i) < \delta(A_{i-1}) \end{cases} \quad (7)$$

and $\delta_{ref}(A, B)$ is the DI of an aromatic molecule of reference. For C-C bonds, benzene is used as a reference while the C-N value is taken from pyridine.¹⁹ When the molecule is aromatic, the FLU index will be close to zero, whereas for non-aromatic or antiaromatic species it will be greater than zero.

Giambiagi employed one of the most reliable electronic multicenter indices as an aromaticity index. This many-center electron delocalization index (I_{ring}) measures the delocalization along the ring:⁵⁸

$$I_{ring}(\mathcal{A}) = \sum_{i_1 i_2 \dots i_n}^{occ} S_{i_1 i_2}(A_1) S_{i_2 i_3}(A_2) \dots S_{i_n i_1}(A_n) \quad (8)$$

and if one takes into account all the permutations of the atoms in the ring, thus including delocalization patterns across the ring, we obtain the expression of the multicenter index (MCI):²⁸

$$MCI(\mathcal{A}) = \frac{1}{2n} \sum_{\mathcal{P}(\mathcal{A})} I_{ring}(\mathcal{A}) = \frac{1}{2n} \sum_{\mathcal{P}(\mathcal{A})} \sum_{i_1 i_2 \dots i_n}^{occ} S_{i_1 i_2}(A_1) S_{i_2 i_3}(A_2) \dots S_{i_n i_1}(A_n) \quad (9)$$

where $\mathcal{P}(\mathcal{A})$ stands for the $n!$ permutations of the elements in the string \mathcal{A} . Like I_{ring} , MCI gives large numbers for aromatic species and the authors claim negative values for antiaromatic molecules.⁵⁹ However, these two electronic indices are not suitable for large (anti)aromatic molecules because they scale exponentially with the number of atoms in the ring and present large numerical errors derived from the numerical integration of the atomic overlap matrices.

In order to solve the drawbacks of I_{ring} and MCI, one of us defined the AV1245 index¹⁶ as the average value of the four-atom MCI index between relative positions 1-2 and 4-5 constructed from every five consecutive atoms along the perimeter of the ring. Lately, it has been seen that the average value could hinder some important values and that the minimal value of the index, AV_{min} ,^{17,43} could be more useful. The AV_{min} value corresponds to the least delocalized fragment of the ring. Aromatic molecules present large values of AV_{min} while non-aromatic molecules exhibit low values. Antiaromatic molecules are more difficult to identify because they usually present intermediate values of AV_{min} . To identify the antiaromatic molecules, we could help ourselves using BOA values (if the species are smaller) or the 1245-index distributions plots (from which the average value, AV1245, is obtained) along the ring (see e.g., Figure S12).

Finally, we have the magnetic aromaticity indices. When an (anti)aromatic species is exposed to an external field, this field induces a π -electron ring current that can be measured to characterize the molecule either as an aromatic or antiaromatic molecule. Aromatic molecules will show diatropic ring currents. On the contrary, the antiaromatic species will present paratropic ring currents. The most important and popular magnetic index of aromaticity is the nucleus independent chemical shift (NICS) due to Paul Schleyer and co-workers.³⁰ NICS is defined as the negative value of the absolute shielding computed at a certain point of the space. It is usually calculated at the center of the ring, NICS(0). However, it could also be calculated in other important points (see e.g., Table S14), or one could calculate a NICS scan along some region of the space to obtain a NICS grid plot (see manuscript).⁶⁰ Negative values are a signature of aromaticity, whereas positive values indicate antiaromaticity. Another well-known magnetic index is the Anisotropy of the Induced Current Density (ACID)²⁹. Using the ACID software,²⁹ one can visualize ACID scalar field isosurfaces and the current density vectors (see e.g. Figure S14).

Electronic Supplementary Information

Complete optimized geometries (in Å) of the studied six-porphyrin nanoring in four different oxidation states using B3LYP, CAM-B3LYP, and M06-2X density functional approximations in combination with 6-31G* basis set and Grimme's D3 dispersion correction. First the naked belt geometries (c-P6) for all the species are given and then the structure including the phenyl substituents and the encapsulated template (c-P6·T6) are provided.
