Supporting TABLE S2. Risk of NAFLD in Patients With Type 2 Diabetes Using TZDs Compared With SUs stratified by cumulative dose.

Exposure to glucose-lowering agents	Risk of NAFLD				
	No. of Events (n = 634)	PYs	IR/ 1,000 PYs	Age/Sex aHR (95% CI)	aHR (95% CI)*
Current use of glucose-lowering agents					
SUs	616	172,309	3.6	Reference	Reference
TZDs	18	14,732	1.2	0.32 (0.20-0.51)	0.32 (0.20-0.51)
By cumulative dose (pioglitazone equivalents)					
<5.4 g	7	3,713	1.9	0.47 (0.22-0.99)	0.44 (0.21-0.93)
5.4-21.8 g	<6	5,759	0.9	0.23 (0.09-0.55)	0.23 (0.09-0.55)
≥21.9 g	6	5,260	1.1	0.31 (0.14-0.70)	0.32 (0.14-0.71)

*Statistically adjusted for age, sex, BMI, HbA1c, and use of systemic glucocorticoids and all other exposure categories in this table. Note: Table shows stratification of TZD users by cumulative dose, other exposure groups included in this analysis were DPP-4 inhibitors, other glucose-lowering agents, concurrent use of SUs and TZDs and past use of any glucose-lowering agents; data shown in Table 2. All groups were mutually exclusive.

*The number of TZD users is different than the number of TZD users in Table 1 of the manuscript. This is due to a difference in selection of the patients between the analyses. For the propensity score analysis we started follow-up at the first TZD or SU prescription, whereas in the main analysis we started follow-up at the first glucose-lowering drug prescription.

**Within 1 year prior to index date.

Abbreviations: IQR, interquartile range; SD, standardized difference.

Supporting TABLE S4. Risk of NAFLD in Patients With Type 2 Diabetes Using TZDs Compared With SUs in a Propensity Score–Matched Analysis

Exposure to glucose-lowering agents*	Risk of NAFLD			
	Patients	No. of Events (n = 57)	IR/ 1,000 PYs	aHR (95% CI)
SUs	5,728	45	5.4	Reference
TZDs	5,728	12	1.5	0.27 (0.14-0.52)

*Current use of the glucose-lowering agent at start of follow-up.

Supporting TABLE S5. Incidence Rate of HCC in Patients With Type 2 Diabetes Using TZDs and SUs

	Latency Period of 6 Months			Latency Period of 24 Months		
	No. of Events (n = 213)	PYs	IR/ 1,000 PYs	No. of Events (n = 142)	PYs	IR/ 1,000 PYs
Exposure to glucose-lowering agents						
Current use of glucose-lowering agents						
SUs	55	176,845	0.3	42	176,828	0.2
TZDs	<6	15,016	0.3	<6	15,014	0.3
DPP-4 inhibitors	13	46,960	0.3	12	46,958	0.3
Other glucose-lowering agents	96	470,394	0.2	57	470,338	0.1
Current combined use						
TZDs and SUs	<6	9,826	0.2	<6	9,826	0.2
Past use						
Past use of glucose-lowering agents	42	371,335	0.1	25	371,326	0.1

Note: All groups in this table were mutually exclusive. Current use (1-90 days) or past use (>90 days) were defined by the time since the most recent prescription.

*The number of GLP-1 receptor agonist users is different than the number of GLP-1 receptor agonist users in Table 1 of the manuscript. This is due to a difference in selection of the patients between the analyses. For the propensity score analysis we started follow-up at the first GLP-1 receptor agonist or insulin prescription, whereas in the main analysis we started follow-up at the first glucose-lowering drug prescription.

**Within 1 year prior to index date.

Supporting TABLE S7. Risk of NAFLD in Patients With Type 2 Diabetes Using Insulins Compared With GLP-1 Receptor Agonists in a Propensity Score–Matched analysis

	Risk of NAFLD			
	Patients	No. of Events (n = 65)	IR/ 1,000 PYs	aHR (95% CI)
Exposure to glucose-lowering agents*				
Insulins	4,944	31	6.4	Reference
GLP-1 receptor agonists	4,944	34	5.4	1.08 (0.66-1.77)

*Current use of the glucose-lowering agent at start of follow-up.

Supporting TABLE S8. Risk of NAFLD in Patients With Type 2 Diabetes Using GLP-1 Receptor Agonists Compared With SUs

Exposure to glucose-lowering agents	Risk of NAFLD				
	No. of Events (n = 2,526)	PYs	IR/ 1,000 PYs	Age/Sex aHR (95% CI)	aHR (95% CI)*
Current use of glucose-lowering agents

Past use						
Past use of glucose-lowering agents	42	371,335	0.1	25	371,326	0.1

Note: All groups in this table were mutually exclusive. Current use (1-90 days) or past use (>90 days) were defined by the time since the most recent prescription.

Supporting Information

Propensity score–matched sensitivity analyses

Study population

Comparing use of sulfonylureas with use of thiazolidinediones

In the first sensitivity analysis, we used propensity score matching to control for confounding in the analysis comparing use of thiazolidinediones (TZDs) with use of sulfonylureas (SUs). For the propensity score analyses we included all patients who were new users of SUs or TZDs during the study period. The date of the first prescription (of an SU or TZD) determined the index date. Patients who were prescribed both an SU and a TZD at the index date were excluded. Patients with a history of polycystic ovarian syndrome (PCOS), nonalcoholic fatty liver disease (NAFLD), or hepatocellular carcinoma (HCC) were excluded as well.

Comparing use of glucagon-like peptide-1 receptor agonists with use of insulin

We also performed a propensity score–matched sensitivity analysis comparing use of glucagon-like peptide-1 (GLP-1) receptor agonists with use of insulin. In this analysis we included all patients who were new users of GLP-1 receptor agonists or insulin during the study period. The date of the first prescription (of a GLP-1 receptor agonist or insulin) determined the index date. Patients who were prescribed both a GLP-1 receptor agonist and an insulin at the index date were excluded. Patients with a history of PCOS, NAFLD, or HCC were excluded as well.

Follow-up

Comparing use of SUs with use of TZDs

Patients were followed from their index date until the date of the event of interest, end of data collection, death, switch to the comparator drug, or treatment discontinuation, whichever came first. The expected end date was calculated for each prescription based on the prescribed quantity and written dosage instructions. Treatment discontinuation was defined as no refill after the last prescription or within 30 days after the expected end date of the last prescription.

Comparing use of GLP-1 receptor agonists with use of insulin

Patients were followed from their index date until the date of the event of interest, end of data collection, death, switch to the comparator drug, or treatment discontinuation, whichever came first. The total amount of defined daily dosages (DDD) was calculated for each prescription based on the prescribed number of pens and the amount of DDDs per pen.⁽¹⁾ The expected end date of a prescription was calculated as the date of the prescription plus the number of prescribed DDDs, assuming that patients used 1 DDD per day. Treatment discontinuation was defined as no refill after the last prescription or within 30 days after the expected end date of the last prescription.

Baseline covariates

For both propensity score analyses

Based on the literature, we selected covariates related to NAFLD and the exposure of interest. We determined the presence of the following covariates at index date: age, sex, smoking status, body mass index (BMI), and alcohol use. A history of the following covariates was also determined at index date: cardiovascular disease, chronic kidney disease, heart failure, chronic liver disease, hypertension, neuropathy, retinopathy, microalbuminuria, and macroalbuminuria, as well as use of the following drugs in the 6 months before the index date: amiodarone, methotrexate, systemic glucocorticoids, and valproate. Furthermore, we

determined the following most recently recorded laboratory values in the year prior to the index date: hemoglobin A1c (HbA1c), total cholesterol (TC), low-density lipoprotein cholesterol (LDL-C), high-density lipoprotein cholesterol (HDL-C), fasting plasma glucose (FPG), systolic blood pressure (SBD), and diastolic blood pressure (DBD). If two or more laboratory measurements were recorded on the same date, the average value was used in the analysis. An indicator variable was used to account for missing data.

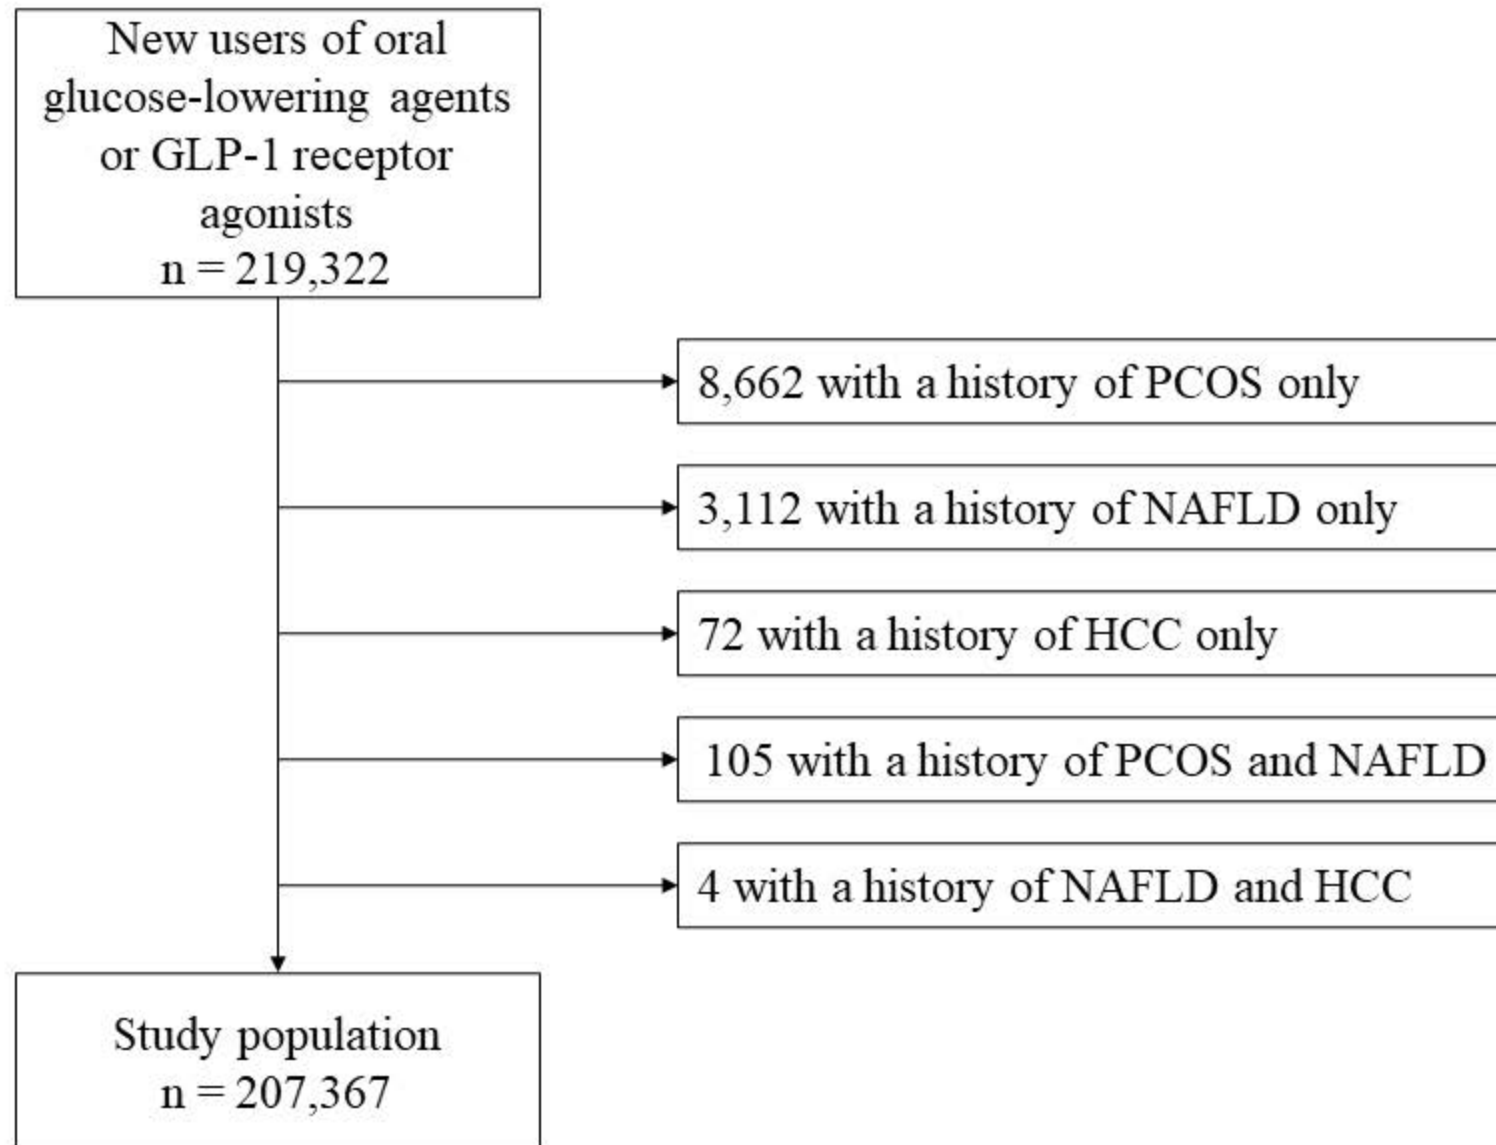

Statistical analysis

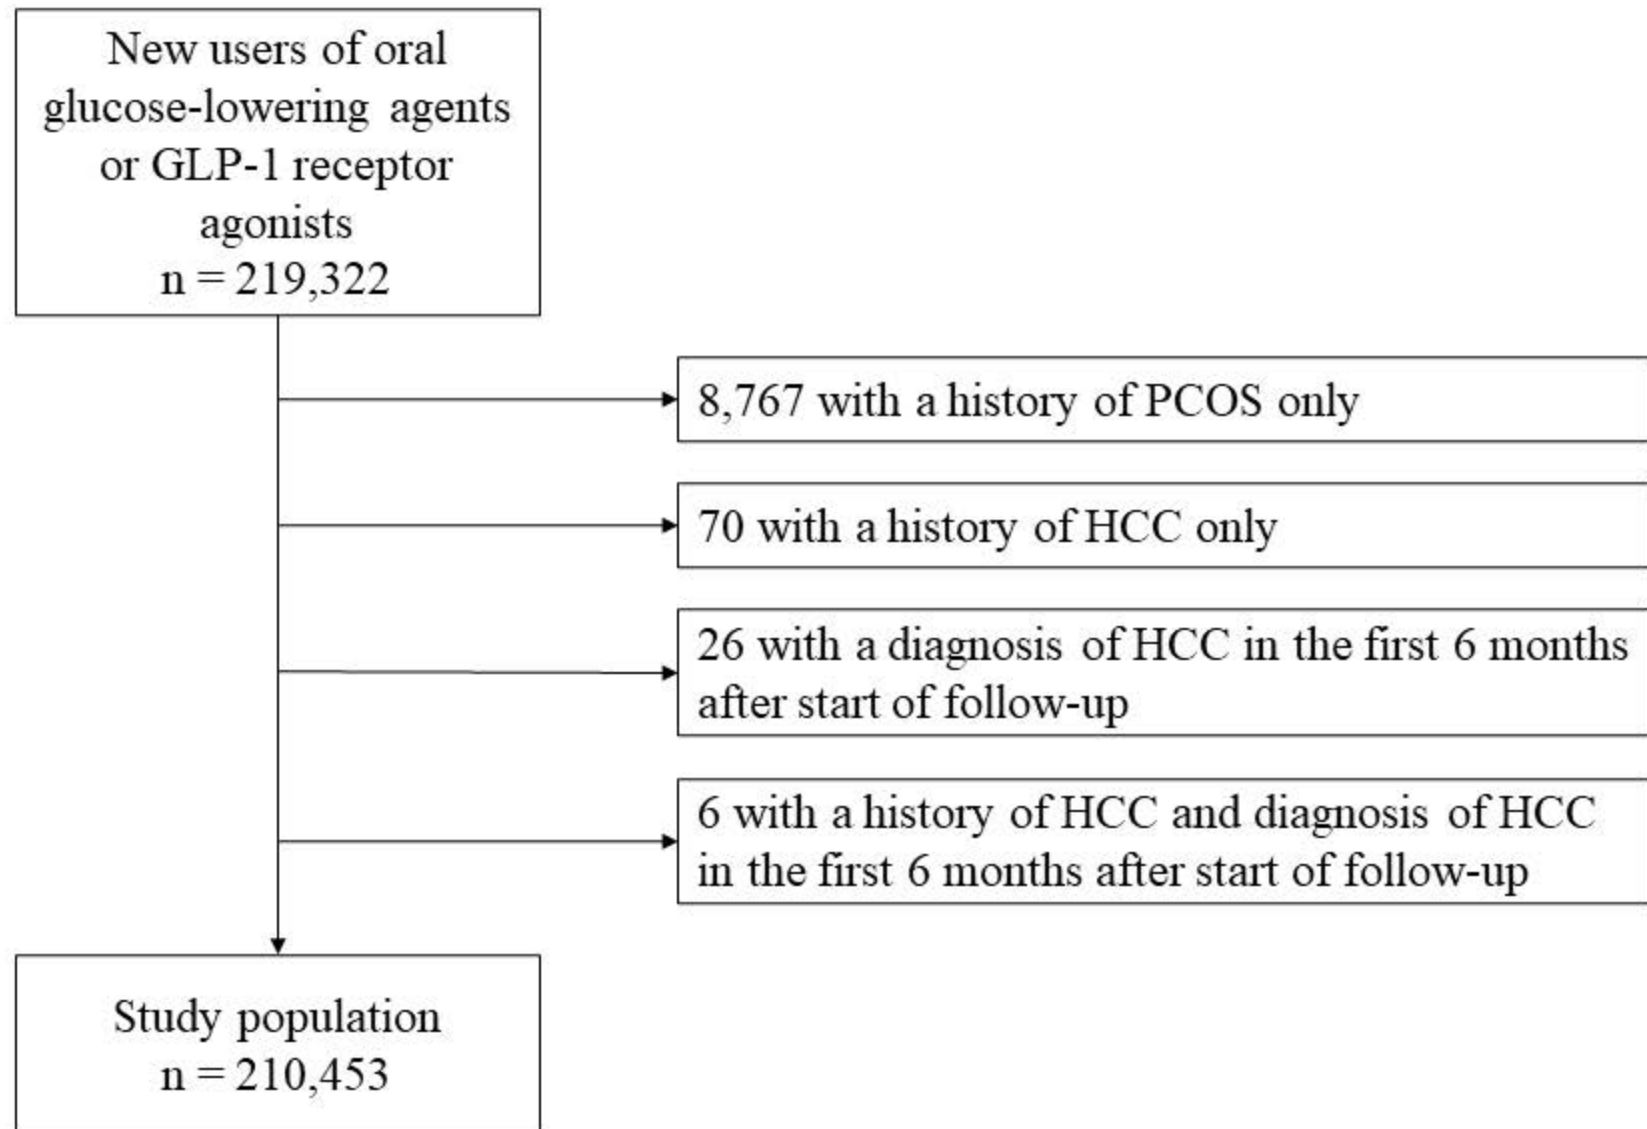

For both propensity score analyses

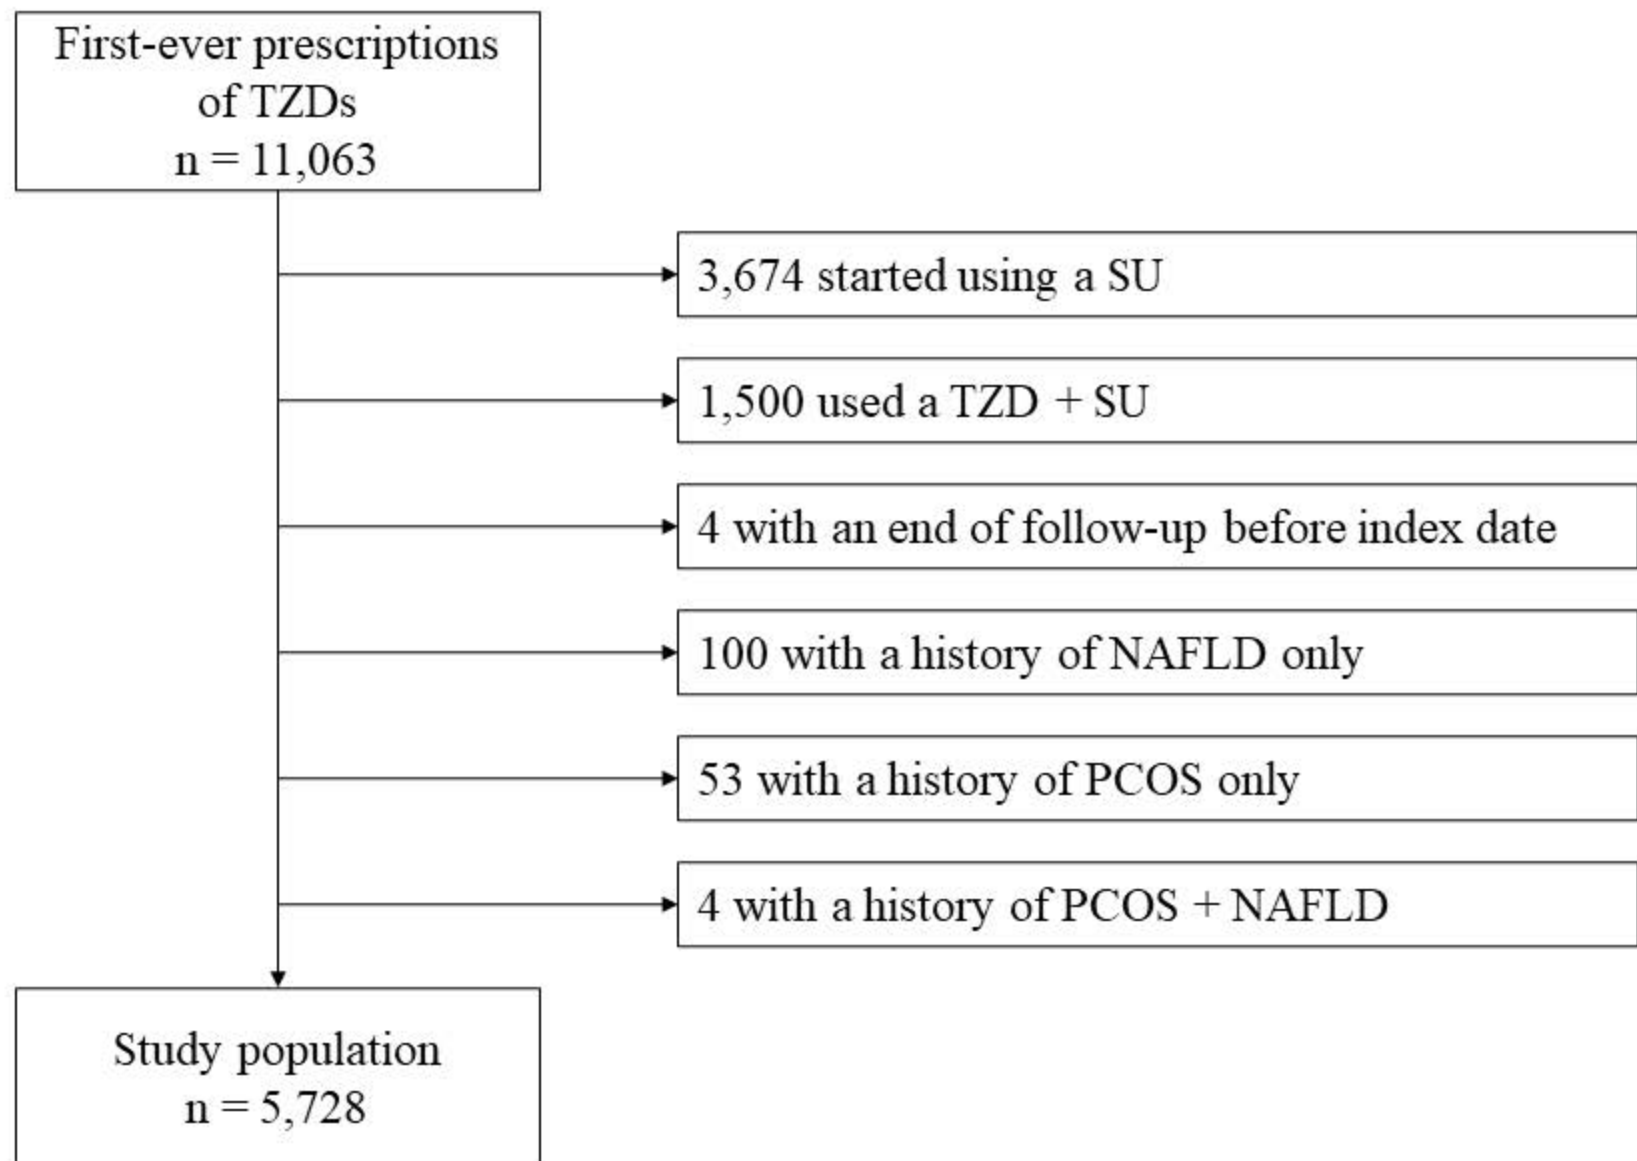

Multivariable logistic regression, including all baseline covariates mentioned in the previous section, was used to estimate the probability of receiving a TZD versus an SU or a GLP-1 receptor agonist versus an insulin, respectively. A histogram of the estimated probabilities per exposure was created to check for the overlap in the estimated probabilities (Supporting Fig. S5). This was done both before and after matching. Patients initiating TZDs or GLP-1 receptor agonists were matched (without replacement) to one patient initiating SUs or insulins, respectively, on their estimated propensity score using nearest neighbor matching with a matching caliper of 0.02 on the propensity score scale.^(2, 3) Standardized differences were calculated to check the balance after matching. After matching, Cox proportional hazards models were used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for NAFLD associated with use of TZDs compared with use of SUs and use of GLP-1 receptor agonists compared with use of insulins. A Kaplan-Meier curve was used to visualize the time to NAFLD for both exposure groups.
