Supplementary Results

Main Analyses (Primary Outcomes)

Major or Disabling stroke

Pooled analysis suggested that the overall risk of having a major or disabling stroke was numerically decreased by 15% for TAVI compared to SAVR by 30 days following surgery (RR 0.85, 95% CI 0.56 to 1.29, P=0.45, I² 28%; 7 studies, n=7,712 patients ¹⁻⁷), by 20% at one year (RR 0.80, 95% CI 0.53 to 1.20, P=0.28, I² 52%; 6 studies, n=7,642 patients ¹⁻⁴⁶⁷) and by 21% at two years (RR 0.79, 95% CI 0.60 to 1.04, P=0.09, I² 9%; 4 studies, n=4,665 patients ¹³⁶⁷); however, these differences were not statistically significant (Supplementary Figure S1).

Pooled analysis reported no evidence of a difference in the risk of major or disabling stroke at five years for TAVI compared to SAVR (RR 1.05, 95% CI 0.82 to 1.34, P=0.71, I² 0%; 2 studies, n=2,782 patients ³ (Supplementary Figure S1). Heterogeneity was moderate at 30 days, moderate for high-risk studies at one year and moderate for intermediate-risk studies at two years.

By study risk group (defined by the criteria reported in Supplementary Table S3, which were not exclusively based on STS-PROM scores), the confidence intervals overlapped between each group at all timepoints, suggesting no significant difference in the risk of major or disabling stroke between study risk groups. Generally, the trend appeared to be towards a lower risk of major or disabling stroke in the low-risk studies, which increased for intermediate-risk, high-risk and all-risk studies (Supplementary Figure S1).

Main Analyses (Secondary Outcomes)

Myocardial Infarction

A single study reported that the risk of MI at periprocedural time points was numerically increased by 38% for TAVI compared to SAVR (RR 1.38, 95% CI 0.23 to 8.20, P=0.73, I² N/A; 1 study, n=750 patients ⁷); however, this was not statistically significant (Supplementary Figure S2). The risk of MI was numerically decreased by 16% for TAVI compared to SAVR at 30 days (RR 0.84, 95% CI 0.55 to 1.28, P=0.41, I² 0%; 9 studies, n=8,877 patients ¹⁻⁹); however, this was not statistically significant (Supplementary Figure S2).

There was no evidence of a difference in the risk of MI for TAVI vs. SAVR at one year (RR 0.92, 95% CI 0.68 to 1.25, P=0.58, I² 0%; 9 studies, n=8,901 patients ¹⁻⁹), at two years (RR 0.91, 95% CI 0.68 to 1.23, P=0.54, I² 0%; 6 studies, n=6,453 patients ²⁻⁴ 6-8) or at five years following surgery (RR 1.08, 95% CI 0.73 to 1.61, P=0.70, I² 28%; 4 studies, n=3,761 patients ^{2 3 7 8}); however, these were not statistically significant changes (Supplementary Figure S2).

Heterogeneity was moderate at 30 days and one year for intermediate-risk studies; moderate for high-risk studies at two years; and low at five years.

Based on study risk group (defined by the criteria reported in Supplementary Table S3, which were not exclusively based on STS-PROM scores), the confidence intervals overlapped between each group at all timepoints, suggesting no significant difference in the risk of MI between study risk groups (Supplementary Figure S1).

Major Bleeding

The risk of major bleeding was significantly decreased by 59% for TAVI compared to SAVR at periprocedural or in-hospital timepoints (RR 0.41, 95% CI 0.28 to 0.60, P<0.00001, I² 39%; 2 studies, n=1,026 patients ^{7 8}), by 63% at 30 days (RR 0.37, 95% CI 0.21 to 0.64, P=0.0004, I² 94%; 8 studies, n=8,446 patients ^{1-7 9}), by 62% at one year (RR 0.38, 95% CI 0.31 to 0.48, P<0.00001, I² 64%; 6 studies, n=6,744 patients ^{1-4 7 9}), by 54% at two years (RR 0.46, 95% CI 0.34 to 0.64, P<0.00001, I² 83%; 3 studies, n=3,481 patients ^{2 3 7}) and by 20% at five years (RR 0.80, 95% CI 0.69 to 0.93, P=0.005, I² 0%; 2 studies, n=1,449 patients ^{2 7}) (Supplementary Figure S3). Heterogeneity was moderate at periprocedural or in-hospital and one year timepoints, and high at 30 days and two years, possibly due to the different definitions of major bleeding in the two intermediate-risk studies (PARTNER 2A: life-threatening or disabling bleeding; SURTAVI: life-threatening or major bleeding). Although there was no evidence of heterogeneity at five years, it should be noted that these studies only used the definition 'major bleeding' in comparison with studies that reported data at the earlier time points, which predominantly used the definition 'life-threatening or disabling bleeding'. This was assessed further in sensitivity analysis (see 'Sensitivity Analyses' section; Supplementary Figure S4).

Based on study risk group (defined by the criteria reported in Supplementary Table S3, which were not exclusively based on STS-PROM scores), the confidence intervals overlapped between each group at all timepoints, suggesting no significant difference in major bleeding between study risk groups (Supplementary Figure S3).

Major Vascular Complications

The risk of major vascular complications was significantly increased by 383% for TAVI compared to SAVR at periprocedural or in-hospital time points (RR 3.83, 95% CI 1.69 to 8.67, P=0.001, I^2 0%; 2 studies, n=1,026 patients I^{7} 8), by 242% at 30 days (RR 2.42, 95% CI 1.55 to 3.80, P=0.0007, I^{2} 72%; 7 studies, n=8,376 patients I^{14} 679), by 205% at one year (RR 2.05, 95% CI 1.38 to 3.04, P=0.002, I^{2} 56%; 6 studies, n=6,744 patients I^{14} 79), by 239% at two years (RR 2.39, 95% CI 1.36 to 4.18, P=0.002, I^{2} 66%; 3 studies,

n=3,480 patients $^{2\ 3\ 7}$) and by 314% at five years (RR 3.14, 95% CI: 1.95 to 5.07, P<0.00001, I² 0%; 2 studies, n=1,449 patients $^{2\ 7}$) (Supplementary Figure S5).

Based on study risk group (defined by the criteria reported in Table S3, which were not exclusively based on STS-PROM scores), the confidence intervals overlapped between each group at all timepoints, suggesting no significant difference in major vascular complications between study risk groups (Supplementary Figure S5).

Permanent Pacemaker Implantation (PPM)

A single study reported that the risk of permanent pacemaker (PPM) implantation was significantly increased by 719% for TAVI compared to SAVR at periprocedural timepoints (RR 7.19, 95% CI 3.11 to 16.62, P<0.00001, I² N/A; 1 study, n=750 patients ⁷) (Supplementary Figure S6). Similarly, the risk of PPM implantation was significantly increased by 247% for TAVI compared to SAVR at 30 days (RR 2.47, 95% CI 1.55 to 3.93, P=0.0001, I² 87%; 7 studies, n=7,767 patients ^{1.46.8}), by 223% at one year (RR 2.23, 95% CI 1.44 to 3.46, P=0.0004, I² 89%; 7 studies, n=7,767 patients ^{1.46.8}), by 211% at two years (RR 2.11, 95% CI 1.31 to 3.42, P=0.002, I² 90%; 6 studies, n=6,367 patients ^{2.46.8}) and by 190% at five years (RR 1.90, 95% CI 1.14 to 3.16, P=0.01, I² 86%; 4 studies, n=3,761 patients ^{2.378}) (Supplementary Figure S6). However, all analyses had high levels of heterogeneity. While this heterogeneity could not be explained by the different study risk levels, it may be explained through differences in the definition of permanent pacemaker implantation, which in some cases did not specify whether pre-existing pacemakers at baseline were included or excluded in the analysis. Since these definitions were not consistently reported, sensitivity analyses were not possible.

Based on study risk group (defined by the criteria reported in Supplementary Table S3, which were not exclusively based on STS-PROM scores), the confidence intervals overlapped for low-risk, intermediaterisk and high-risk study risk groups at all timepoints; however, the confidence intervals for all-risk patients did not overlap with these other study risk groups at several timepoints, suggesting a significantly greater decrease in the risk of new PPM for SAVR compared to TAVI in all-risk patients (Supplementary Figure S6).

Acute Kidney Injury

The risk of acute kidney injury (AKI) was significantly decreased by 70% for TAVI compared to SAVR at periprocedural or in-hospital timepoints (RR 0.30, 95% CI 0.10 to 0.93, P=0.04, I^2 39%; 2 studies, n=1,026 patients $^{7\,8}$), by 60% at 30 days (RR 0.40, 95% CI 0.30 to 0.53, P<0.00001, I^2 0%; 6 studies, n=7,441 patients $^{1-4\,6\,7}$), by 42% at one year (RR 0.58, 95% CI 0.34 to 1.00, P=0.05, I^2 67%; 4 studies, n=4,831 patients $^{1-3\,7}$) and by 48% at two years (RR 0.52, 95% CI 0.33 to 0.80, P=0.003, I^2 51%; 2 studies, n=2,782

patients ^{3 7}) (Supplementary Figure S7). Moderate heterogeneity was observed for the periprocedural, one-year and two-year analyses; no heterogeneity was observed at 30 days. One possible contributing factor to the observed heterogeneity was the different definitions of AKI used within the studies. Some studies included Stage 3 disease alone (PARTNER 1A), whilst other studies included Stage 2 to 3 (EVOLUT) or Stage 1 to 3 (PARTNER 2A) disease.

Based on study risk group (defined by the criteria reported in Supplementary Table S3, which were not exclusively based on STS-PROM scores), the confidence intervals overlapped between each group at all timepoints, suggesting no significant difference in the risk of AKI between study risk groups (Supplementary Figure S7).

New-Onset or Worsening Atrial Fibrillation

The risk of new-onset or worsening atrial fibrillation (NOW-AF) was significantly reduced by 77% for TAVI compared to SAVR at periprocedural or in-hospital timepoints (RR 0.23, 95% CI 0.06 to 0.91, P=0.04, I² 95%; 2 studies, n=1,536 patients ^{4 7}), by 71% at 30 days (RR 0.29, 95% CI 0.23 to 0.38, P<0.00001, I² 80%; 7 studies, n=7,767 patients ^{1-4 6-8}), by 64% at one year (RR 0.36, 95% CI 0.28 to 0.47, P<0.00001, I² 85%; 7 studies, n=7,767 patients ^{1-4 6-8}), by 64% at two years (RR 0.36, 95% CI 0.25 to 0.52, P<0.00001, I² 86%; 4 studies, n=4,008 patients ^{3 4 7 8}) and by 55% at five years (RR 0.45, 95% CI 0.36 to 0.56, P<0.00001, I² 37%; 2 studies, n=2,312 patients ^{3 8}) (Supplementary Figure S8). Heterogeneity was high at periprocedural/in-hospital, 30 day, one year and two year timepoints, and moderate at five years.

Based on study risk group (defined by the criteria reported in Supplementary Table S3, which were not exclusively based on STS-PROM scores), the confidence intervals overlapped for intermediate-risk and high-risk groups at all timepoints; however, the confidence intervals for low-risk patients did not overlap with those in these two study risk groups at several timepoints, suggesting a significantly greater decrease in the risk of new-onset or worsening atrial fibrillation for TAVI compared to SAVR in low-risk patients (Supplementary Figure S8).

Endocarditis

The risk of endocarditis was numerically reduced by 21% for TAVI compared to SAVR at 30 days (RR 0.79, 95% CI 0.21 to 3.04, P=0.74, I² 0%; 6 studies, n=6,310 patients ^{1-4 8 9}); however, this was not a statistically significant difference (Supplementary Figure S9).

There was no evidence of a difference in the risk of endocarditis for TAVI compared to SAVR at one year (RR 1.02, 95% CI 0.55 to 1.89, P=0.96, I² 0%; 7 studies, n=7,088 patients ^{1-4 8 9}) or at two years (RR 0.99, 95% CI 0.43 to 2.24, P=0.97, I² 25%; 4 studies; n=4,431 patients ²⁻⁴) (Supplementary Figure S9).

At five years, the risk of endocarditis was numerically increased by 134% for TAVI compared to SAVR (RR 1.34, 95% CI 0.87 to 2.05, P=0.18, I² 0%; 4 studies, n=3,761 patients ^{2 3 7 8}); however, this was not a statistically significant difference. Low or no heterogeneity was evident in any of these analyses (Supplementary Figure S9).

At six years, a single study reported no evidence of a difference in the risk of endocarditis in all-risk patients (RR 0.97, 95% CI 0.38 to 2.51, P=0.95, I² N/A; 1 study, n=274 ⁸).

Based on study risk group (defined by the criteria reported in Supplementary Table S3, which were not exclusively based on STS-PROM scores), the confidence intervals overlapped between each group at all timepoints, suggesting no significant difference in the risk of endocarditis between study risk groups (Supplementary Figure S9).

Reintervention or Reoperation

A single study reported that the risk of reintervention or reoperation was numerically increased by 459% for TAVI compared to SAVR at periprocedural timepoints (RR 4.59, 95% CI 0.22 to 95.32, P=0.32, I² N/A 1 study, n=750 patients ⁷); however, this was not a statistically significant difference and there was a large amount of uncertainty in the result (Supplementary Figure S10). The risk of reintervention or reoperation was numerically increased by 154% for TAVI compared to SAVR at 30 days (RR 1.54, 95% CI 0.50 to 4.77, P=0.46, I² 40%; 6 studies, n=7,828 patients ¹³⁴⁶⁷⁹) and by 195% at one year (RR 1.95, 95% CI 0.92 to 4.13, P=0.08, I² 50%; 6 studies, n=7,856 patients ¹³⁴⁶⁷⁹); however, very few events were identified by any study (especially at 30 days), this result was not statistically significant, and there was a large amount of uncertainty in the result (Supplementary Figure S10). There was moderate heterogeneity at 30 days. The risk of reintervention or reoperation was significantly increased by 278% for TAVI compared to SAVR at two years (RR 2.78, 95% CI 1.35 to 5.71, P=0.005, I² 29%; 4 studies, n=5,478 patients ³⁴⁶⁷) and by 367% at five years (RR 3.67, 95% CI 1.76 to 7.63, P=0.0005, I² 0%; 3 studies, n=3,062 patients ³⁷⁸) (Supplementary Figure S10). There was low heterogeneity across these analyses.

Based on study risk group (defined by the criteria reported in Supplementary Table S3, which were not exclusively based on STS-PROM scores), the confidence intervals overlapped between each group at all timepoints, suggesting no significant difference in the risk of reintervention or reoperation between study risk groups (Supplementary Figure S10). Generally, there was a trend towards a lower risk of reintervention or reoperation for TAVI compared to SAVR in low-risk studies (EVOLUT, PARTNER 3), but a trend towards a higher risk of reintervention or reoperation for TAVI compared to SAVR in intermediate-, high-and all-risk studies.

Rehospitalisation

The risk of rehospitalisation across all levels of surgical risk was numerically reduced by 12% for TAVI compared to SAVR at 30 days (RR 0.88, 95% CI 0.70 to 1.10, P=0.27, I² 0%; 6 studies, n=7,645 patients ^{1-4 6 7}); however, this did not reach statistical significance (Supplementary Figure S11). There was no evidence of a difference in the risk of rehospitalisation for TAVI compared to SAVR at one year following surgery (RR 0.95, 95% CI 0.76 to 1.20, P=0.69, I² 65%; 6 studies, n=7,645 patients ^{1-4 6 7}) (Supplementary Figure S11). The risk of rehospitalisation was numerically increased by 14% for TAVI compared to SAVR at two years (RR 1.14, 95% CI 0.94 to 1.38, P=0.19, I² 59%; 5 studies, n=6,177 patients ^{2-4 6 7}); however, this was not a statistically significant difference (Supplementary Figure S11). The risk of rehospitalisation was significantly increased by 35% for TAVI compared to SAVR at five years (RR 1.35, 95% CI 1.20 to 1.51, P<0.00001, I² 0%; 3 studies, n=3,481 patients ^{2 3 7}) (Supplementary Figure S11). Heterogeneity was low at 30 days, two years and five years, and moderate at one year.

One study also reported continuous data for the number of hospital days from the index surgical procedure or randomisation into the control arm up to one-year post procedure or randomisation. This study reported that the total number of days spent in hospital after the index procedure was numerically reduced for TAVI compared to SAVR (17.42 days (19.05 SD) vs. 20.14 days (20.14 SD); 1 study, n=699 patients ²); however, no statistical comparisons were provided.

Based on study risk group (defined by the criteria reported in Supplementary Table S3, which were not exclusively based on STS-PROM scores), the confidence intervals overlapped for intermediate-risk and high-risk patients at 1 year; however, the confidence intervals for low-risk patients at this timepoint did not overlap with those in other study risk groups at several timepoints, suggesting a significantly greater decrease in the risk of rehospitalisation for TAVI compared to SAVR in low-risk patients (Supplementary Figure S11).

Length of Hospital Stay

Length of Stay in ICU

Four studies reported on the length of stay in the intensive care unit (ICU) ²⁻⁴ ⁹. All studies reported that patients spent fewer days in the ICU after TAVI treatment (2-3 days) than after SAVR treatment (3-5 days); the mean difference ranged from -1 to -2 days (based on n=4,549 patients) (Supplementary Table S4).

Length of Stay in Hospital

Four studies reported sufficient information (mean and SD values) to enable meta-analysis to be performed to analyse length of hospital stay.⁵⁻⁸ Pooled analysis suggested that the total length of hospital stay after the index procedure was significantly shorter following TAVI compared to SAVR (mean difference [MD]

3.08 days, 95% CI -4.86 to -1.29 days, P=0.0007, I² 84%; 4 studies, n=2,758 patients ⁵⁻⁸) (Supplementary Figure S12). Overall, seven out of the eight studies that presented data for length of hospital stay reported a reduction in the length of hospital stay for TAVI compared to SAVR (Supplementary Table S5) ^{1-4 6-9}. The difference in stay generally ranged from -3.0 to -4.0 days for TAVI compared to SAVR (Supplementary Table S5). One of eight studies reported a non-significant increase of 1.2 days in the length of hospital stay for TAVI compared to SAVR (Supplementary Table S5).⁵

Valve Durability

Two studies reported on rates of structural valve deterioration for TAVI compared to SAVR.^{2 8} At five years, the rate of structural valve deterioration (not further defined) was reported to be zero in both TAVI and SAVR patients in the PARTNER 1A trial (Supplementary Table S9).² At six years, the rate of structural valve deterioration was reported to be significantly lower in the TAVI arm (4.8%) compared to the SAVR arm (24%) in the NOTION study (Supplementary Table S9) (79% reduced risk; RR 0.21, 95% CI 0.10 to 0.46, P<0.0001; 1 study, n=274 patients ⁸). This was based on a definition of structural valve deterioration as moderate/severe hemodynamic structural valve deterioration (mean gradient ≥20 mm Hg, increase in mean gradient ≥10 mm Hg from three months post-procedure, or > mild intraprosthetic aortic regurgitation either new or worsening from three months post-procedure. However, three other definitions of valve dysfunction were reported by the NOTION study, with no statistically significant differences between TAVI vs. SAVR arms (Supplementary Table S9).

A single study (US CoreValve) reported on rates of valve frame fracture for the TAVI arm alone.⁷ No cases of valve frame fracture were reported in 21 TAVI patients who had undergone surgical valve explantation or autopsy after death. Transcatheter valves had been implanted for a median duration of 17 days (range: 0 to 503 days).

Recovery Time

No studies were identified that reported on recovery time.

Pain

No studies were identified that reported on pain.

Subgroup Analyses

For the major or disabling stroke outcome, subgroup results generally suggested that patients at low or intermediate risk (based exclusively on STS-PROM scores alone) had a higher risk of a major or disabling stroke after TAVI compared to patients at high risk by one year following surgery (Supplementary Table S6); and that patients who had TAVI through the transferoral route had a significantly or numerically

lower risk of a major or disabling stroke than patients who had TAVI through a non-TF route from periprocedural timepoints through to 5 years following surgery (Supplementary Table S7).

For the myocardial infarction outcome, subgroup results generally suggested that patients at low or intermediate risk (based exclusively on STS-PROM scores alone) had a higher risk of MI after TAVI compared to patients at high risk by one year following surgery (Supplementary Table S6); and that patients who had TAVI through the transferoral route had a significantly or numerically lower risk of MI than patients who had TAVI through a non-TF route from 30 days to 2 years following surgery (Supplementary Table S7).

For the major bleeding outcome, subgroup results generally suggested that patients at low or intermediate risk (based exclusively on STS-PROM scores alone) had a higher risk of major bleeding after TAVI compared to patients at high risk by one year following surgery (Supplementary Table S6); and that patients who had TAVI through the transfemoral route had a significantly or numerically lower risk of major bleeding than patients who had TAVI through a non-TF route from periprocedural timepoints through to 2 years following surgery (Supplementary Table S7).

For the major vascular complications outcome, subgroup results generally suggested that patients at low or intermediate risk (based exclusively on STS-PROM scores alone) had a significantly higher risk of major vascular complications after TAVI compared to patients at high risk by one year following surgery (Supplementary Table S6); and that patients who had TAVI through the transfemoral route had a numerically higher risk of major vascular complications than patients who had TAVI through a non-TF route from periprocedural timepoints through to 2 years following surgery (Supplementary Table S7).

For the PPM implantation outcome, subgroup results generally suggested that patients at low or intermediate risk (based exclusively on STS-PROM scores alone) had a significantly higher risk of PPM implantation after TAVI compared to patients at high risk by one year following surgery (Supplementary Table S6); that patients who had TAVI through the transferoral route had no difference in the risk of PPM implantation compared to patients who had TAVI through a non-TF route from 1 to 2 years following surgery (Supplementary Table S7); and that patients receiving a self-expanding valve were at higher risk of PPM implantation compared to patients receiving a balloon expandable valve from 30 days to 5 years following surgery (Supplementary Table S8).

For the acute kidney injury outcome, subgroup results generally suggested that patients at low or intermediate risk (based exclusively on STS-PROM scores alone) had a numerically lower risk of AKI after TAVI compared to patients at high risk by one year following surgery (Supplementary Table S6); and that patients who had TAVI through the transferoral route had a numerically or significantly lower risk of AKI

than patients who had TAVI through a non-TF route at periprocedural timepoints and at 30 days or 2 years following surgery (Supplementary Table S7).

For the new-onset or worsening atrial fibrillation outcome, subgroup results generally suggested that patients at low or intermediate risk (based exclusively on STS-PROM scores alone) had a numerically lower risk of NOW-AF after TAVI compared to patients at high risk by one year following surgery (Supplementary Table S6); and that patients who had TAVI through the transferoral route had a numerically or significantly lower risk of NOW-AF than patients who had TAVI through a non-TF route from 30 days to 2 years following surgery (Supplementary Table S7).

For the endocarditis outcome, subgroup results generally suggested that patients at low or intermediate risk (based exclusively on STS-PROM scores alone) had a numerically lower risk of endocarditis after TAVI compared to patients at high risk by one year following surgery (Supplementary Table S6); and that patients who had TAVI through the transfermoral route had no difference in the risk of endocarditis than patients who had TAVI through a non-TF route up to 1 year following surgery (Supplementary Table S7).

For the reintervention or reoperation outcome, subgroup results generally suggested that patients at low or intermediate risk (based exclusively on STS-PROM scores alone) had a numerically higher risk of reintervention or reoperation after TAVI compared to patients at high risk by one year following surgery (Supplementary Table S6); and that patients who had TAVI through the transfemoral route had a numerically lower risk of reintervention or reoperation from periprocedural timepoints through to 2 years, and a numerically higher risk at 5 years compared to patients who had TAVI through a non-TF route up to 1 year following surgery (Supplementary Table S7).

For the rehospitalisation outcome, subgroup results generally suggested that patients at low or intermediate risk (based exclusively on STS-PROM scores alone) had a numerically lower risk of rehospitalisation after TAVI compared to patients at high risk by one year following surgery (Supplementary Table S6); and that patients who had TAVI through the transfemoral route had a numerically lower risk of rehospitalisation compared to patients who had TAVI through a non-TF route from 30 days to 5 years (Supplementary Table S7).

Sensitivity Analyses

For the major bleeding outcome, a sensitivity analysis focusing on the four studies that reported exclusively on major bleeding defined as "life-threatening or disabling bleeding" at one year reduced the overall level of heterogeneity but it still remained high (Supplementary Figure S6).

SUPPLEMENTARY TABLE S1: INCLUSION AND EXCLUSION CRITERIA

Study ID	Risk Level	Inclusion criteria	Exclusion criteria	
High Risk				
PARTNER 1A ²	High	Patients with severe aortic stenosis (aortic-valve area of less than 0.8cm² plus either a mean valve gradient of at least 40 mm Hg or a peak velocity of at least 4.0m per second), and cardiac symptoms (New York Heart Association class II function or worse). Included patients were considered candidates for conventional surgical aortic-valve repair with a high risk for operative complications or death on the basis of coexisting conditions that were associated with a risk of death of at least 15% by 30 days after the procedure, as defined by surgeons at each study centre (based on a guideline score of at least 10% on the risk model developed by the Society of Thoracic Surgeons).	Bicuspid or non-calcified valve, coronary artery disease requiring revascularisation, a left ventricular ejection fraction of less than 20%, an aortic annulus diameter of less than 18mm or more than 25mm, severe (4+) mitral or aortic regurgitation, a recent neurological event, and severe renal insufficiency.	
US CoreValve ⁷	High	Patients with senile degenerative severe aortic stenosis (defined as an initial aortic valve area of ≤0.8 cm² or an aortic valve area index ≤0.5cm²/m² AND either mean aortic-valve gradient > 40mm Hg or a peak aortic-jet velocity >4.0m/s); symptomatic as defined by NYHA class II or higher; considered to be at increased risk for undergoing surgical aortic-valve replacement (defined as whether two cardiac surgeons and one interventional cardiologist estimated that the risk of death within 30 days after surgery was ≥15% and predicted operative mortality or serious irreversible morbidity risk <50% within 30 days after surgery)	Evidence of acute MI ≤30 days before treatment; any percutaneous coronary or peripheral interventional procedure performed within 30 days prior to the index procedure with bare metal stents and 6 months with drug eluting stents; blood dyscrasias as defined by leukopenia (WBC <1000 mm3), thrombocytopenia (platelet count <50,000 cells/mm3), history of bleeding diathesis or coagulopathy or hypercoagulable states; untreated clinically significant coronary artery disease requiring revascularization; cardiogenic shock manifested by low cardiac output, vasopressor dependence or mechanical haemodynamic support; need for emergency surgery for any reason; severe ventricular dysfunction with LVEF <20% as measured by resting echocardiogram; recent (within 6 months) cerebrovascular accident or transient ischaemic attack; end stage renal disease requiring chronic dialysis or creatinine clearance <20 cc/min; GI bleeding within the past 3 months; known hypersensitivity to medications including aspirin, heparin, nitinol, ticlopidine/clopidogrel or contrast media; ongoing sepsis, including active endocarditis; refusal of blood transfusion; life expectancy <12 months due to associated non-cardiac comorbidities; severe dementia; symptomatic carotid or vertebral

		• •	transcatheter ablation for atrial fibrillation; leukopenia (WBC
			<3000 cell/ml), acute anaemia (HgB <9 g/dl), thrombocytopenia
			(Plt <50,000 cell/ml); hypertrophic cardiomyopathy with or
			without obsctruction; severe ventricular dysfunction with LVEF
			<20%; echocardiographic evidence of intracardiac mass,
			thrombus or vegetation; active upper GI bleeding within 3
			months prior to procedure; contraindication or hypersensitivity
			to all anticoagulation regimens; native aortic annulus size <
			18mm or > 27 mm as measured by echocardiogram; clinical or
			neuroimaging confirmed stroke or transient ischemic attack
			within 6 months of procedure, renal insufficiency (creatinine
			>3.0 mg/dl) and/or renal replacement therapy at the time of
			screening; estimated life expectancy of <24 months due to
			carcinomas, chronic liver disease, chronic renal disease or
			chronic end stage pulmonary disease; expectation that patient

Study ID	Risk Level	Inclusion criteria Exclusion criteria	
Low Risk			
EVOLUT ¹	Low	Severe aortic-valve stenosis with suitable anatomy for TAVI or surgery and no more than a predicted 3% risk of death by 30 days with surgery, as assessed by members of the local heart team. For symptomatic patients, aortic stenosis was defined as an aortic-valve area ≤ 1.0 cm² (or area index of ≤0.6 cm²/m²) or a mean gradient of 40 mm Hg or more or maximal aortic-valve velocity of 4.0 m or more per second as assessed by transthoracic echocardiography performed with the patient at rest. For asymptomatic patients, aortic stenosis was defined as: i. valve area of ≤1.0 cm² (or aortic valve area index of ≤0.6 cm²/m²) AND maximal aortic velocity ≥5.0 m/sec or mean gradient ≥60 mmHg by transthoracic echocardiography at rest; OR ii. Aortic valve area of ≤1.0 cm² (or aortic valve area index of ≤0.6 cm²/m²) AND a mean gradient ≥40 mmHg or maximal aortic valve velocity ≥4.0 m/sec by transthoracic echocardiography at rest AND an exercise tolerance test that demonstrates a limited exercise capacity, abnormal blood pressure response or arrhythmia; OR iii. Aortic valve area of ≤1.0 cm² (or aortic valve area index of ≤0.6 cm²/m²) AND mean gradient ≥40 mmHg or maximal aortic valve velocity ≥4.0 m/sec by transthoracic echocardiography at rest AND a left ventricular ejection fraction <50%.	Patients with bicuspid aortic valves; candidates for mechanical valves; severe mitral/tricuspid regurgitation or moderate/severe mitral stenosis amenable to surgical replacement or repair; pre-existing prosthetic heart valve in any position; hypertrophic obstructive cardiomyopathy with left ventricular outflow gradient; prohibitive left ventricular outflow tract calcification; sinus of Valsalva diameter unsuitable for placement of the self-expanding bioprosthesis; aortic annulus diameter <18 or >30 mm; significant aortopathy requiring ascending aortic replacement; blood dyscrasias (defined as leukopenia (WBC <1000mm3), thrombocytopenia (platelet count <50,000 cells/mm3), history of bleeding diathesis or coagulopathy of hypercoagulable states); ongoing sepsis (including active endocarditis); percutaneous coronary or peripheral interventional procedure with a bare metal stent within 30 days prior to randomisation; drug eluting stent implanted within 180 days prior to randomisation; multivessel coronary artery disease with a synergy between percutaneous coronary intervention with SYNTAX score >22 and/or unprotected left main coronary artery; symptomatic carotid or vertebral artery disease or successful treatment of carotid stenosis within 10 weeks of heart team assessment; cardiogenic shock manifested by low cardiac output, vasopressor dependence or mechanical haemodynamic support; recent cerebrovascular accident or transient ischaemic attack; gastrointestinal bleeding that would preclude anticoagulation; severe dementia; estimated life expectancy <24 months; evidence of an acute myocardial infarction ≤30 days before the trial procedure due to unstable coronary artery disease
PARTNER 3 ⁴	Low	Severe, calcific aortic stenosis (defined as AVA ≤1.0cm² or AVA index ≤0.6 cm²/m² and jet velocity ≥4.0m/s or mean gradient ≥40mmHg AND NYHA functional class ≥2 or exercise tolerance test that demonstrates a limited exercise capacity, abnormal blood pressure response or arrhythmia OR asymptomatic with LVEF <50%); heart team agrees the patient has a risk of operative mortality and has an STS <4.	Native aortic annulus size unsuitable for sizes 20, 23, 26 or 29mm THV based on 3-D imaging analysis; ilio-femoral vessel characteristics that would preclude safe placement of the introducer sheath; evidence of an acute myocardial infarction ≤ 1 month (30 days) before randomisation; congenital unicuspid, bicuspid or non-calcified aortic valve; severe aortic regurgitation (>3+); severe mitral regurgitation (>3+) or moderate (or more than moderate) stenosis; pre-existing mechanical or bioprosthetic valve in any position; complex coronary artery disease (unprotected left main coronary artery, syntax score >32 in

Study ID	Risk Level	Inclusion criteria	Exclusion criteria

			pacemaker; atrial fibrillation or flutter; and vascular, renal, and bleeding complications after 1 and 12 months. Clinical improvement was assessed according to NYHA functional classification. Echocardiographic outcomes included aortic valve effective orifice area, mean pressure gradient, and degree of total aortic valve regurgitation (graded as none/trace, mild, moderate, and severe) at 3 and 12 months. All outcomes were defined according to VARC-2 definitions.
STACCATO ⁵	"Operable"	Composite of all-cause mortality, major stroke or renal failure requiring dialysis at 30 days	All-cause death, cardiac death, stroke, myocardial infarction, NYHA functional class, SF-36 composite physical and mental functional scores, echocardiographic parameters (aortic valve area, peak aortic valve gradient, aortic valve leakage, LVEF), duration of hospital stay, operation for bleeding; permanent pacemaker treatment; valve performance.

Abbreviations: 6MWT = 6 minute walk test; AR = aortic regurgitation; cm = centimetres; DAOH = days alive and out of hospital; DVI = Doppler velocity index; EOA = effective orifice area; HF = heart failure; ICU = intensive care unit; KCCQ = Kansas City cardiomyopathy questionnaire; LVEF = left ventricular ejection fraction; MACCE = major adverse cardiac and cerebrovascular events; MAE = major adverse events; MI = myocardial infarction; mm = millimetre; NYHA = New York heart association; SAVR = surgical aortic valve replacement; SF-36 = short-form survey 36; TAVI = transcatheter aortic valve implantation; TIA = transient ischaemic attack; VARC = Valve Academic Research Consortium; y = years.

^aDefined as a score of ≥2 on the modified Rankin scale (which ranges from 0 (no symptoms) to 6 (death)) at 90 days after the index clinical event.

^bDefined as a score of ≥2 on the modified Rankin scale at 90 days AND an increase in at least one modified Rankin scale category from the individual's prestroke baseline.

SUPPLEMENTARY TABLE S3: STUDY DEFINITIONS OF DISEASE AND LEVEL OF SURGICAL RISK

Study ID	Disease	Definition of Disease	Level of Surgical Risk	Definition of Surgical Risk
High Risk				
PARTNER 1A ²	Symptomatic senile degenerative severe aortic stenosis and cardiac symptoms	Aortic valve area <0.8 cm² (or AVA index <0.5cm²/m²) plus either a mean valve gradient of ≥40 mmHg or a peak velocity of ≥4.0 m/s AND NYHA class II or greater	High	Risk of death ≥15% by 30 days following surgery and/or STS ≥ 10%
US CoreValve ⁷ Intermediate Risk	Senile degenerative symptomatic severe aortic stenosis and heart failure symptoms	Initial aortic valve area ≤0.8cm² (or AVA index ≤ 0.5 cm²/m²) by resting echocardiogram or simultaneous pressure recordings at cardiac catheterisation AND mean gradient >40 mmHg or jet velocity >4.0 m/s by either resting or dobutamine stress echocardiogram, or simultaneous pressure recordings at cardiac catheterisation (either resting or dobutamine stress) AND NYHA class II or greater	High	Risk of operative mortality ≥15% by 30 days following surgery; risk of serious irreversible morbidity <50% by 30 days following surgery
PARTNER 2A ³	Senile degenerative severe aortic stenosis	Initial aortic valve area <0.8 cm ² or indexed effective orifice area <0.5cm ² /m ² plus a mean gradient >40 mmHg or jet velocity >4.0 m/s AND NYHA class II or greater	Intermediate	STS ≥4.0% (or <4% if determined as intermediate risk by the heart team)
SURTAVI ⁶	Severe symptomatic severe aortic stenosis	Initial aortic valve area of ≤1.0 cm² (or AVA index <0.6cm²/m²) AND mean gradient > 40mmHg or peak velocity >4m/s by resting echocardiogram or simultaneous pressure recordings at cardiac catheterisation [or with dobutamine stress, if subject has a LVEF <55%] or velocity	Intermediate	Risk of operative mortality ≥3 to <15% by 30 days following surgery; plus consideration of overall clinical status and co- morbidities not measured by the STS score

ratio < 0.25 AND NYHA class II or greater
