Contents of Supplementary Information

## Materials and Methods

**Animals.** Banded houndshark (*Triakis scyllium*) individuals were obtained as described in a previous paper (17). Zebrafish (*Danio rerio*) were obtained from the Zebrafish National BioResource Project, Laboratory for Developmental Gene Regulation, RIKEN Brain Science Institute (Wako, Saitama, Japan). Goldfish (*Carassius auratus*), Mexican tetra (*Astyanax mexicanus*), West African lungfish (*Protopterus annectens*) and tiger salamander (*Ambystoma tigrinum)* were all obtained from Meitosuien Co. Ltd. (Nagakute, Aichi, Japan). All animals were handled according to the Guidelines for the Management of Laboratory Animals in Fujita Health University.

**DNA and RNA.** The isolation of the genomic DNA of banded houndshark was described in a previous paper (17). For banded houndshark, total RNA was isolated from kidney, spleen, liver and blood using ISOGEN (Nippon Gene, Tokyo, Japan) or TRIzol (Invitrogen, Thermo Fisher Scientific, Waltham, MA, USA). For the other animal species, total RNA was isolated from various tissues (gills of goldfish and Mexican tetra; anterior half of zebrafish; kidney of West African lungfish; internal organs of tiger salamander) using TRIzol. Total RNA was used for RACE and RT-PCR experiments.

**Genomic and cDNA libraries.** The construction of a genomic library of banded houndshark (individual N0) was described previously (23). In the present study, an additional genomic library was constructed by partial digestion of banded houndshark (individual N0) red blood cell DNA with *Sau*3AI. The construction of a cDNA library of banded houndshark (individual N2) was described previously (17). The primers used to amplify and prepare various probes to screen the libraries are listed in Table S2.

**RACE reactions.** RACE reactions were conducted to obtain sequence information for 5'- and 3'-UTRs of relevant genes using SMART RACE cDNA Amplification Kit (Clontech, Takara Bio USA, Mountain View, CA, USA), SMARTer RACE cDNA Amplification Kit (Clontech) and GeneRacer Kit (Invitrogen). RACE-PCR was conducted to obtain entire coding regions of relevant genes using Advantage 2 Polymerase (Clontech, Takara Bio USA, Mountain View, CA, USA) with SMART RACE cDNA Amplification Kit, Advantage 2 Polymerase or Ex Taq DNA polymerase (Takara Bio Inc., Shiga, Japan) with SMARTer RACE cDNA Amplification Kit, and Ex Taq DNA polymerase with GeneRacer Kit.

**PCR.** The primer sequences used in PCR and RT-PCR are listed in Table S2. To obtain the coding sequences of banded houndshark *WA_DS5*, *WB_DS1* and *WB_DS3* genes, total kidney RNA (individual N1) was reverse-transcribed into cDNA using ReverTra Ace (TOYOBO, Osaka, Japan). In case of banded houndshark *WA_DS10*, Prime Script II High Fidelity RT-PCR kit (Takara) was used to reverse-transcribe RNA into cDNA. The coding sequences were amplified from cDNA using specific primers designed at 5' and 3' UTRs. PCR reactions were conducted using Ex Taq HS DNA polymerase (Takara) with 35 cycles and PCR products were cloned into pGEM-T Easy vector (Promega, Madison, WI, USA). In case of *WA_DS10*, PCR reactions were conducted using Prime STAR GXL DNA polymerase (Takara) with 32 cycles and PCR products were cloned into Bluescript vectors (Stratagene, Agilent Technologies, CA, USA) as described previously (23).

The genomic sequences of banded houndshark *WA_DS5* and *WA_DS10* genes were amplified from genomic DNA (individual N1) using specific primers designed at 5' and 3' UTRs. A partial genomic sequence containing the β2 domain exon of banded houndshark *WB_DS1* gene (individual N0) was reported previously (23; M85291) whereas part of the upstream intron region was additionally determined in the present study (LC200978). The CP/TM/CY region sequence of the banded houndshark *WB_DS1* gene was amplified from genomic DNA (individual N1) using specific primers derived from β2 domain and 3' UTR regions, and was determined in the present study (LC009542). The genomic sequence of 10.9 kb, which contains the first four exons of the banded houndshark *WB_DS3* gene, was determined using a λ phage clone isolated from a genomic library of banded houndshark individual N0. The genomic sequence of 4.5 kb, which contains the last three exons of the banded houndshark *WB_DS3* gene, was amplified from genomic DNA of banded houndshark individual N0 using specific primers derived from intron 4 and 3' UTR regions.

PCR conditions for amplification of genomic *WA_DS5*, *WA_DS10* and *WB_DS3* were as follows: denaturation at 94°C for 2 min, 5 cycles of denaturation at 98°C for 10 sec, annealing and elongation at 74°C for 10 min, 5 cycles of denaturation at 98°C for 10 sec, annealing and elongation at 72°C for 10 min, 5 cycles of denaturation at 98°C for 10 sec, annealing and elongation at 70°C for 10 min, 40 cycles of denaturation at 98°C for 10 sec, annealing and elongation at 68°C for 10 min and final elongation at 68°C for 7 min with KOD Fx Neo DNA polymerase (TOYOBO). PCR conditions for amplification of genomic *WB_DS1* were as follows: denaturation at 94°C for 2 min, 5 cycles of denaturation at 98°C for 10 sec, annealing and elongation at 74°C for 20 min, 5 cycles of denaturation at 98°C for 10 sec, annealing and elongation at 72°C for 20 min, 5 cycles of denaturation at 98°C for 10 sec, annealing and elongation at 70°C for 20 min, 40 cycles of denaturation at 98°C for 10 sec, annealing and elongation at 68°C for 20 min and final elongation at 68°C for 7 min with KOD Fx Neo DNA polymerase (TOYOBO). The PCR products were cloned into pCR-XL-TOPO vector (Invitrogen) or used as templates for direct sequencing.

For the isolation of the teleost fish and lungfish W-category genes, SuperScript III reverse transcriptase kit (Invitrogen) with random hexamer primers was used to construct cDNA. RT-PCR was conducted using Ex Taq DNA polymerase (Takara) with 40 or less PCR cycles. For isolation of tiger salamander W-category genes, RACE reactions were conducted using GeneRacer Kit and the entire coding sequences were amplified using Prime STAR HS DNA polymerase (Takara) with 35 cycles. PCR products were cloned into Bluescript vectors as described previously (23).

For linkage analyses of the banded houndshark *WB_DS10* gene using *Hha*I digestion, PCR conditions for amplification using DS10-2 and DS10-8 primers were as follows: denaturation of genomic DNA at 94 °C for 1 min, 40 cycles of denaturation at 94 °C for 30 sec, annealing at 60 °C for 30 sec and elongation at 72 °C for 4 min, and final elongation at 72 °C for 5 min with LA-Taq HS DNA polymerase (Takara). For linkage analyses using DS10-6 and DS10-14 primers, PCR conditions were the same as above except for using 35 cycles. For linkage analyses of the banded houndshark *$\beta_2$-m* gene, PCR conditions for amplification using $\beta_2$-m-F11 and $\beta_2$-m-R10 primers were as follows: denaturation of genomic DNA at 98 °C for 10 sec, 50 cycles of denaturation at 98 °C for 10 sec, annealing at 61 °C for 15 sec and elongation at 72 °C for 5 min, and final elongation at 72 °C for 10 min with Prime STAR DNA polymerase (Takara).

Expression of the banded houndshark *WA* and *WB* genes was studied using RT-PCR using RNA from spleen, kidney, liver and blood (individual N1) and two gene-specific primers, using Prime Script II High Fidelity RT-PCR Kit (Takara). RT-PCR conditions were as follows: denaturation at 98 °C for 1 min, 27, 32, 37 or 42 cycles of denaturation at 98 °C for 10 sec, annealing at 60 °C for 15 sec and elongation at 68 °C for 3 min, and final elongation at 68 °C for 5 min with Prime STAR GXL DNA polymerase (Takara). As a control gene, banded houndshark β-actin gene (39) was used under the following RT-PCR conditions: denaturation at 98 °C for 1 min, 16, 19, 22 or 27 cycles of denaturation at 98 °C for 10 sec, annealing at 60 °C for 15 sec and elongation at 68 °C for 3 min, and final elongation at 68 °C for 3 min with Prime STAR GXL (Takara Bio Inc., Shiga, Japan). In some experiments, RT-PCR conditions were slightly different (protocol No. 2) and as follows: denaturation at 98 °C for 30 sec, 35 cycles of denaturation at 98 °C for 10 sec, annealing and elongation at 60 °C for 3 min, and final elongation at 72 °C for 3 min with Ex Taq HS DNA polymerase (Takara).

Variations in the cDNA sequences of zebrafish WA and WB genes were studied with RT-PCR using RNA from anterior halves of adult zebrafish of various strains: AB, India (IND), TL and WIK. PCR reactions were conducted using Ex Taq DNA polymerase (Takara) with 40 or less PCR cycles.

**Sequencing.** Sequencing reactions were performed with BigDye Terminator v3.1 Sequencing Standard kit (Applied Biosystems), and nucleotide sequences were determined using 3100Avant/3130xl Genetic Analyzer (Applied Biosystems Life Technologies, Foster City, CA, USA). The DNA sequence of one genomic phage clone of *WB_DS3* was also determined using the above sequencing method. For the sequence determination of PCR products, various techniques including independent PCR reactions, analyses of multiple independent clones, PCR with different sets of primers and direct sequencing reactions were used to eliminate possible PCR and sequencing errors.

In the initial phase of our study, radio-labeled methods were used for sequencing PCR-amplified genomic DNA fragments and clones from genomic libraries and from cDNA libraries.

**Southern blot analyses.** Southern blot analyses for the linkage analyses of banded houndshark *WA_DS5*, *WB_DS1* and *WB_DS3* (Figs. S9 and S10) were performed essentially as described previously (17). Briefly, 5 μg of DNA digested with a restriction enzyme was electrophoresed through an agarose gel (0.8 %) and blotted onto a nylon membrane. The restriction enzymes used for the experiments for the analyses of *WA_DS5*, *WB_DS1* and *WB_DS3* were *Bam*HI, *Stu*I and *Bam*HI, respectively. After hybridization with the specific radio-labeled probes, membranes were finally washed with 0.1 x SSC/0.05 % SDS at 42° C for 30 min and autoradiographs were obtained. Southern blot analyses for banded houndshark individual N1 (Fig. S3 and *SI Appendix*) were performed with the DIG system using the PCR DIG Probe Synthesis Kit and the DIG Luminescent Detection Kit (Roche Applied Science).

**Linkage analyses.** As described above, the linkage analyses of the banded houndshark *WA_DS5*, *WB_DS1* and *WB_DS3* genes (Figs. S9 *A*, *C* and *D*, respectively) were performed using gene-specific probes (Table S2) for Southern blot hybridization. Restricted by the limited amount of genomic DNA available, PCR-based methods was used for linkage analysis of banded houndshark *WA_DS10* (Fig. S9*B*) with PCR conditions described above. DNA fragments amplified with the primers DS10-2 and DS10-8 (for primer sequences, see Table S2) were digested with the restriction enzyme *Hha*I to look for haplotype differences within the seventeen littermate banded houndshark individuals (Fig. S9*B* left). Amplification of *WA_DS10* gene with another set of primers, DS10-6 and DS10-14, was also conducted (Fig. S9*B* right). For linkage analyses of the banded houndshark $\beta_2$*-m* gene, PCR-based amplification was also performed using primers $\beta_2$-m-F11 and $\beta_2$-m-R10. Obtained DNA fragments were digested with *Mbo*II restriction enzyme (Fig. S15*A*; *SI Appendix* section 8).

**Database searches.** Database searches with annotation keywords and similarity searches were conducted using programs such as BLASTN, BLASTP and TBLASTN at NCBI (National Center for Biotechnology Information) (40) or Ensembl (41) Web sites. Specifically for sequence information of little skates and salamanders, SkateBase (42) and SalSite (43) were also used, respectively.

**Analyses of DNA and amino acid sequences.** The nucleotide sequences that were determined by experiments and sequences retrieved from databases were handled and analyzed with Genetyx software ver. 12 (Genetyx Co. Ltd. Tokyo). For prediction of protein-coding regions in genomic sequences, comparisons with matching cDNA sequences were performed and GENSCAN (44) and FGENESH (45) programs were also used. For prediction of signal peptides, SignalP 4.1 Server (46) was used. For prediction of secondary structures of protein sequences, JPred4 (47) was used.

**Alignments of amino acid sequences.** Alignments of amino acid sequences were performed with MUSCLE program (48) and also with Genetyx software. Alignments were adjusted based on the previously reported studies (22, 23, 25, 49) and on structural comparisons using the UCSF Chimera package (50). For alignment of the membrane-distal domains of W-category molecules, the positions of conserved and variable residues of the teleost fish W-category molecules were used to compare with other MHC molecules.

**Phylogenetic tree analyses.** Phylogenetic tree analyses of the MHC Ig-like C1-set domains were conducted with Maximum Likelihood, a tree-searching method, in MEGA6 (51). The best combination of evolutionary model and rates was selected from 56 different amino acid substitution models or from 24 nucleotide substitution models using the log likelihood, and models with the lowest BIC (Bayesian Information Criterion) were considered to describe the substitution pattern the best in MEGA6. For the amino acid sequence analyses, the WAG+G+I model (see below for the abbreviations) was selected and for the DNA sequence analyses, the GTR+G+I model was selected using MEGA6. Abbreviations are as follows: WAG, Whelan And Goldman model (52); +G, a discrete Gamma distribution used to model evolutionary rate differences among sites with

5 rate categories; +I, assuming that a certain fraction of sites are evolutionarily invariable; GTR, General Time Reversible model (53). For the analyses shown in Fig. S19, Neighbor Joining (54), which is an algorithmic method, was conducted in MEGA6. With this method, the JTT (Jones-Taylor-Thornton) matrix model (55) or the p-distance model (53) were used.

Partial deletion was used in the analyses and the tree is drawn to scale, with branch lengths measured in the number of substitutions per site. Reliability of a tree was estimated using Bootstrap method (56) with 1000 bootstrap replications. Percentage of replicate trees in the bootstrap test are indicated next to the nodes (Values of 50 or greater are shown).

For the outgroups in the phylogenetic analyses, Ig-like C1-set domains of three molecules were used: Ig M $C_H4$ domain (previously used in ref. 28), TCR β chain constant domain (previously used in ref. 10) and tapasin Ig-like domain (e. g., 57) of human and house mouse. The alignments of the outgroup sequences with MHC domains (Dataset S2) were based on previous amino acid sequence comparisons (e. g., 57) and on structural comparisons with the reported structures of mouse IgM (PDB ID: 4JVW), human TCR β chain (PDB ID: 1OGA), and human tapasin (PDB ID: 3F8U) using the Chimera program. The regions between the β-strand-forming sequence blocks which show high sequence-length variation were not included for the comparison and the relevant regions were described in *SI Appendix*.

In Fig. 7, phylogenetic tree analyses are shown with amino acid sequences of Ig-like domains of selected W-category and MHC class I and class II molecules using Maximum Likelihood. In Supplementary Information, additional phylogenetic tree analyses of Ig-like domains are shown as follows: analyses with DNA sequences of selected W-category and MHC class I and class II molecules using Maximum Likelihood (Fig. S16); analyses with amino acid sequences of selected W-category and MHC class I and class II molecules using JTT (Fig. S17*A*) or p-distance (Fig. S17*B*) of Neighbor Joining; analyses of the additional W-category and MHC class I and class II molecules including nonclassical MHC class I and class II molecules using Maximum Likelihood (Fig. S18).

**Structural comparisons.** Comparative structural molecular analyses were conducted using Cn3D (58) and UCSF Chimera package (50). Figures 4 and S5-S7 were prepared with Cn3D.

**Recombinant protein studies.** *Cell lines:* CHO (Chinese hamster ovary)-K1 cells were obtained from RIKEN BRC (BioResource Research Center) through the National Bio-Resource Project of the MEXT (the Ministry of Education, Culture, Sports, Science and Technology) of Japan, and grown in Ham's F-12 medium (Wako) containing 10% fetal bovine serum (FBS) in 5% $CO_2$ at 37℃.

*Vector construction and transfection:* Signal peptides encoded by *WA* and *WB* genes were predicted using the SignalP 4.1 Server (46). DNA encoding a mature protein of tiger salamander (TS) WA_01 (residues 21-250) was cloned into the pFLAG-CMV-3 Expression Vector (Sigma). DNA encoding a mature protein of TS WB_01 (residues 20-273) or Mexican tetra (MT) WB_01 (residues 23-272) was cloned into the pCAG-Hyg PA tag-N Vector (Wako). The pFLAG-CMV-3 Expression Vector and pCAG-Hyg PA tag-N Vector without insert sequences were used as negative controls (designated pFLAG and pPA, respectively). The following combinations were used for co-transfection experiments: N-terminal FLAG tagged WA (TS FLAG-WA) and N-terminal PA tagged WB (TS PA-WB or MT PA-WB); TS FLAG-WA and pPA; pFLAG and TS PA-WB or MT PA-WB; and pFLAG and pPA vectors. CHO-K1 cells were transfected using Lipofectamine 2000 (Invitrogen) according to the manufacturer's instruction. After 24 h, cells were harvested for flow cytometry and protein extraction.

*Protein extraction:* The co-transfected cells, a portion of which were analyzed for flow cytometry described below, were lysed using ice-cold lysis buffer containing 50 mM Tris-HCl (pH 7.5), 150 mM NaCl, 5 mM EDTA, 1% NP-40, 10 mM iodoacetamide. After placement on ice for 30 min, mixture was centrifugated at 20,000 x *g* for 20 min at 4℃. The supernatants were used as cell lysates for Western blotting to investigate the expression of recombinant proteins.

*Endoglycosydase H and Glycopeptidase F treatments:* Lysates from co-transfected cells were prepared as described above. Based on the manufacturer's instructions, the cell lysates prepared under protein denaturing conditions were treated with Endoglycosydase H (Endo H, NEB) or Glycopeptidase F (GPF, Takara Bio).

*Western blotting:* Equal amounts of total proteins of cell lysates were separated using SDS-PAGE (12% Tris-glycine gel), and transferred to polyvinylidene difluoride membranes. The membranes were incubated with 5% skim milk in PBST (0.05% Tween 20 in PBS) for 1 h. The PBST-washed membranes were incubated with mouse anti DYKDDDDK tag monoclonal antibody or rat anti PA tag monoclonal antibody for 1 h, washed with PBST and then incubated with anti-mouse IgG, HRP-linked whole Ab sheep (GE Healthcare) or goat anti-rat IgG(H+L)-HRP conjugate (SouthernBiotech) for 1 h. The HRP-conjugated antibodies were visualized using Pierce ECL Plus Western Blotting Substrate (Thermo Scientific) on ImageQuant LAS 4000mini (GE Healthcare). The MagicMark XP Western Protein Standard (Invitrogen) was used as protein size marker. After HRP-inactivation with 15% $H_2O_2$ for 1 h, the membranes were incubated with mouse anti β-actin monoclonal antibody (MBL) for 1 h prior to incubation with anti-mouse IgG, HRP-linked whole Ab sheep (GE Healthcare) for 1 h. Visualization of β-actin was performed as described above.

*Flow cytometry:* Cells were incubated with primary antibody in FCM buffer (2% FBS and 0.1% sodium azide in PBS) for 1 h on ice. Then cells were washed with FCM buffer and incubated with secondary antibody in FCM buffer for 1 h on ice. The washed cells were suspended in PBS containing propidium iodide for staining of dead cells which were excluded from the analyses. The cells were analyzed using Gallios (Beckman Coulter) with Kaluza v1.3 software (Beckman Coulter). The FLAG tag was detected with mouse anti DYKDDDDK tag monoclonal antibody (Wako) and mouse $IgG_{2b}$ (SouthernBiotech) was used as isotype control. The PA tag was detected with rat anti PA tag monoclonal antibody (Wako) and rat $IgG_{2a}$ (SouthernBiotech) was used as isotype control. The mouse and rat IgG were detected using secondary antibodies Goat $F(ab')_2$ Anti-Mouse IgG(H+L) PE-conjugated (Beckman Coulter) and Goat $F(ab')_2$ Anti-Rat IgG(H+L) FITC-conjugated (SouthernBiotech), respectively.

**Analysis of the conservation profile of a W-category subgroup.** The amino acid sequences of the membrane-distal domains of the teleost fish W-category molecules (Figs. S1 and S2) were compared and, to understand the conservation profile, Wu-Kabat variability values were calculated as described (59; Table S4). Wu-Kabat variability (V) is defined as the number of different amino acids at a given position (Nd) divided by the frequency of the most common amino acid at that position (Nc/N; Nc, the number of the most common amino acid at that position; N, the number of sequences studied at that position) (59).

## Appendix

### 1. Overview of W-category genes

### 1-1 Various animal groups possess W-category genes

W-category genes were identified in various jawed vertebrates. Table S1 shows the current identification of W-category genes. The animal groups shown to possess W-category genes include cartilaginous fish (sharks and skates), ray-finned fish (the teleost fish group), lobe-finned fish (coelacanth and lungfish) and tetrapods (salamanders). Thus, the ancestral W-category genes should have existed in the common ancestor of cartilaginous fish and ray-finned fish/lobe-finned fish/tetrapods, estimated to have diverged from each other around 457 million years ago (MYA) (posterior mean and 95 % credible interval of 443-464 MYA according to ref. 60). Therefore, W-category genes should be very ancient members of the MHC gene family.

Although W-category genes can be found in various animal groups, their distribution appears to be somewhat restricted within each group. Some examples are as follows. Cartilaginous fish (class Chondrichthyes) include two Subclasses, Holocephali (e.g., elephant shark) and Elasmobranchii (modern sharks and rays), estimated to have diverged around 421 MYA (410-447 MYA) (60). So far, W-category genes have been identified in Elasmobranchii. Among ray-finned fish, W-category genes have thus far been identified in the teleost fish group which include, for example, herring and zebrafish. The ancestors of ray-finned fish and lobe-finned fish/tetrapods are estimated to have diverged from each other around 419 MYA (416-422 MYA) (60). In lobe-finned fish, W-category genes have been identified in coelacanth and lungfish. The ancestors of lungfish and tetrapods are estimated to have diverged from each other around 392 MYA (375-408 MYA) (60). Among tetrapods, W-category genes have thus far been identified in salamanders. Restricted identification within a certain group may be related to genuine differences in gene inactivation but in some cases possibly also to incompleteness of sequence information or to sequence diversification beyond recognition.

### 1-2 Nomenclature of W-category genes

#### 1-2-1 General description

Like conventional MHC class II molecules, a W-category molecule is expected to be composed of an α chain and a β chain. In the present study, we name W-category α chain WA, and W-category β chain WB. The assignments of the sequences as an α chain-type or as a β chain-type are supported by their possession of amino acid residues specific for the respective chain and also by phylogenetic analyses (Fig. 2*A* and *B*; Datasets S1-S3; Fig. 7; Figs. S16-S18).

Except for W-category genes of cartilaginous fishes, some teleost fishes (described below) and lobe-finned fishes, simple “WA” and “WB” names for W-category genes are used, because information regarding the relationship among W-category genes is still limited and information about the gene locations is also limited. Numbers were added to the gene names like WA _01 to specify each sequence even when only a single member for the relevant gene has been found. In case of cartilaginous fish, multiple loci were found in some cases and locus identifications remain to be studied. In those cases, additional symbols like “n1”, “n2” and so on, were temporarily used to discriminate related sequences of which at least some are expected to be from different loci.

#### 1-2-2 Nomenclature of cartilaginous fish W-category genes

In cartilaginous fish, currently six W-category genes have been identified; three *WA* genes and three *WB* genes. *WA_DS5*, *WA_DS10*, *WB_DS1* and *WB_DS3* were found in banded houndshark, and *WA_Nds3L* and *WB_Nds5L* were recently found in various other sharks. The somewhat complicated nomenclature for these shark W-category genes has historical reasons as explained below.

*About banded houndshark WA_DS5, WA_DS10, WB_DS1 and WB_DS3*

All *WA* and *WB* genes of banded houndshark were found to be linked in the genome (Fig. S9), but relative positions of individual genes of this shark species remain unknown. In the early phase of the present study (including the part described in ref. 23), fragments of MHC-like genes were found from the banded

houndshark genomic DNA or cDNA, and were named sequentially as *DS1*, *DS2*, *DS3* and so on. After some of them were recognized to belong to W-category genes and could be classified into *WA* or *WB*, they were renamed and their original tentative names were incorporated into the new names as *WB_DS1*, *WB_DS3*, *WA_DS5* and *WA_DS10*. That is the reason why these genes have a somewhat peculiar numerical nomenclature.

Probable numbers of gene loci of banded houndshark W-category genes are as follows (indicated in parentheses): *WA_DS5* (three), *WA_DS10* (one), *WB_DS1* (two) and *WB_DS3* (one). While simple names can be used for *WA_DS10* and *WB_DS3*, a more refined nomenclature is necessary for *WA_DS5* and *WB_DS1* as described below.

A banded houndshark presumably possesses three loci for *WA_DS5* based on isolated cDNAs and Southern blot analyses (Figs. S1A, S3, S9A). Four kinds of cDNA sequences for *WA_DS5* from a single individual banded houndshark N1 were identified. These four sequences were named as *WA_DS5_n1_01*, *WA_DS5_n2_01*, *WA_DS5_n3_01* and *WA_DS5_n4_01* (Fig. S1A). At present, relationships among these *WA_DS5* sequences are only partially clarified.

For *WB_DS1*, there presumably exist two loci in a banded houndshark based on the genomic sequencing and Southern blot analyses (Figs. S2A, S3, S9C and *SI Appendix*). However, complete expressed sequences could be identified from only one of these loci. This gene locus was named *WB_DS1_n1* and the other one was named *WB_DS1_n2*. A cDNA sequence of *WB_DS1_n2* could only be identified in an unusual cDNA form in which parts of *WA_DS10* and *WB_DS1_n2* are combined together (LC218721, Table S3).

*About W-category genes of other cartilaginous fishes*

Similar to banded houndshark, other cartilaginous fishes also possess *WA_DS5-like*, *WA_DS10-like*, *WB_DS1-like* and *WB_DS3-like* sequences. Names with "*-like*" are used for those sequences with respective homology in the present study. In some cases, "L" instead of "-like" is used to save space.

The recent whole genome shotgun sequencing of great white shark revealed two additional W-category genes, namely, *WA_Nds3L* and *WB_Nds5L* and showed that three *WA* genes and three *WB* genes are located closely to each other forming three pairs of *WA*/*WB* genes (Fig. S11A). These pairs are: *WA_Nds3L*/*WB_DS3L*, *WA_DS10L*/*WB_DS1L* and *WA_DS5L*/*WB_Nds5L*. In the names of *WA_Nds3L* and *WB_Nds5L* , "N" represents "next to", and "L" represents "-like". The genes homologous to *WA_Nds3L* or *WB_Nds5L* could be identified in other cartilaginous fish species as shown in Table S1.

1-2-3 Nomenclature of teleost fish W-category genes

In many teleost fishes (61) possessing W-category genes, only a single pair of intact *WA* and *WB* genes appears to exist. Exceptions are members of a group of Cyprinidae, including common carp and Chinese cavefish, which have two pairs of *WA/WB* genes in the genome (Fig. S11) and which are believed to have experienced a relatively recent additional whole genome duplication approximately 8.2 MYA (62). Therefore, the names *WA_A1* and *WB_B1* are used for one pair and *WA_A2* and *WB_B2* for the other. For the zebrafish W-category genes identified in the NCBI genomic sequence database, we use the names *WA_13A* and *WB_13B* referring to their location on zebrafish chromosome 13. This allows distinction from the zebrafish W-category sequences that were amplified from cDNA and were named zebrafish *WA_01* to *05* and zebrafish *WB_01* to *05* (Fig. S19).

1-2-4 Nomenclature of lobe-finned fish W-category genes

As two distinct groups of *WA* genes were identified in lungfish based on similarity in the Ig-like domains, temporarily *WA_1* and *WA_2* were used for those genes. For *WB* genes, two kinds of *WB* genes were also identified in lungfish, and the names *WB_1* and *WB_2* were used for those genes. The *WB_2* genes could be further classified into two groups, and the names *WB_2_1* and *WB_2_2* were used for those genes. Numerical supplements were used to specify the sequences.

1-2-5 Nomenclature of salamander W-category genes

For the W-category genes of salamanders, simply *WA* and *WB* names were used, and numerical supplements were added like *WA_01* and *WB_01* to specify the sequences.

## 2. Identification of W-category genes

Various W-category genes were identified through our own experiments and also through database searches using various datasets. Below, accession numbers for sequences are provided where relevant. Accession numbers refer to those jointly used by GenBank at NCBI, DNA DataBank of Japan (DDBJ) and European Nucleotide Archive (ENA) unless mentioned otherwise.

### 2-1 Cartilaginous fish - modern sharks and skates

Extant Elasmobranchii (Neoselachii) contain two subgroups, Selachii (modern sharks) and Batoidea (rays, skates and sawfish). The divergence time of these two groups is estimated to be around 281 MYA (251-318 MYA) (60).

Three pairs of *WA*/*WB* genes were found in sharks. Two *WA* genes (*WA_DS5* and *WA_DS10*) and two *WB* genes (*WB_DS1* and *WB_DS3*) were isolated from banded houndshark. DNA fragments of *WA_DS5*, *WB_DS1* and *WB_DS3* were originally amplified together in a single PCR reaction, and *WA_DS10* was later discovered in a different way as described below. The homologs of these genes in other cartilaginous fishes were identified through searches of cartilaginous fish sequence databases.

*WA_Nds3L* and *WB_Nds5L* genes were identified in the whole genome shotgun sequence data of great white shark and then also found in other sequence data of cartilaginous fish.

Below, the identification of W-category genes of cartilaginous fish are described per species.

#### 2-1-1 Banded houndshark (*Triakis scyllium*)

Two *WA* genes (*WA_DS5* and *WA_DS10*) and two *WB* genes (*WB_DS1* and *WB_DS3*) were initially discovered experimantally in banded houndshark. Banded houndshark may have genes similar to *WA_Nds3L* and *WB_Nds5L*, but those have not been identified yet.

##### 2-1-1-1 Banded houndshark *WA_DS5*

A short DNA fragment in the banded houndshark *WA_DS5* Ig-like domain exon was found among the mixture of products (*Ban*I/*Pst*I restriction enzyme-resistant fractions) of the same PCR reaction products from which banded houndshark *WB_DS1* (previously called DI) was found (23). Using this DNA fragment as a probe, the genomic library of banded houndshark was screened and positive clones were isolated, and then the genomic sequence of the Ig-like domain exon of banded houndshark *WA_DS5* was determined. As positive clones could not be obtained in the screening of a banded houndshark cDNA library, the "rapid amplification of cDNA ends (RACE)" method was conducted using WA_DS5-specific primers, and then 5'- and 3'-untranslated region (UTR) sequences were obtained. Using 5'- and 3'-UTR primers, four different cDNA sequences (*WA_DS5_n1_01*, *n2_01*, *n3_01*, and *n4_01*) could be amplified from a single individual of the banded houndshark N1 (similarities of these four sequences is described in section 5). The genomic exon/intron organization of banded houndshark *WA_DS5_n3* was determined as described in the Materials and Methods and shown in Figs. 5 and S8.

##### 2-1-1-2 Banded houndshark *WA_DS10*

As stated above, *WA_DS10* was discovered separately from the other banded houndshark W-category genes, and here some details on its discovery are described.

The banded houndshark *WA_DS10* was found in one cDNA sequence (named F02_14, LC218721, Table S3) among the products of the 5'-RACE reactions for *WB_DS1* gene. This cDNA looked like a read-through fusion product and contained an - until then - unknown Ig-like domain exon which was combined with the Ig-like domain exon of *WB_DS1_n2* (a possible pseudogene, see the section of *WB_DS1*) with an apparently normal splicing junction. Then RACE reactions were conducted using primers specific to this novel Ig-like domain exon sequence. After 5'- and 3'-regions of the cDNA were obtained, the complete coding sequence was obtained. It turned out that this new gene had a domain structure of MHC class II and could be classified as a W-category α chain gene. This gene was named the banded houndshark *WA_DS10*. Two kinds of *WA_DS10* cDNA sequences were identified from the single individual banded houndshark N1 (Table S3). At

amino acid position 40 in Fig. 3, one (*WA_DS10_01*) has an "AAC" codon for an asparagine, the other (*WA_DS10_02*) has "AAT". Otherwise they possess the same open reading frame sequences. The genomic exon/intron organization of banded houndshark *WA_DS10* was determined as described in the Materials and Methods and shown in Fig. S8.

2-1-1-3 Banded houndshark *WB_DS1*

In 1992 we published the DNA sequence of the exon encoding the Ig-like domain of, now named, *WB_DS1* (M85291) (23). However, at the time, we had not yet a concept of W-category genes. Later, one incomplete cDNA sequence of *WB_DS1_n1* was isolated by us from a kidney cDNA library of banded houndshark individual N2 and was registered (AY227971). In the present study, two loci for banded houndshark *WB_DS1*, namely, *WB_DS1_n1* and *WB_DS1_n2* were identified. From *WB_DS1_n1* locus, the complete coding regions of two highly similar presumed allelic sequences, *WB_DS1_n1_01* and *WB_DS1_n1_02* were obtained (Fig. S2) using RT-PCR method based on information obtained from RACE studies. Shorter cDNA forms of both sequences lacking the penultimate CP/TM/CY exon were identified in our experiments and these presumably are alternatively spliced sequences. On the other hand, the β2 domain exon of *WB_DS1_n2* was only found as part of an unusual cDNA (described above in the section for *WA_DS10*) and other *WB_DS1_n2* exons were not detected. The β2 domain exons were compared between *WB_DS1_n1* and *WB_DS1_n2* genes and high similarity between these genes was found in the β2 domain exons and surrounding regions. In the β2 domain exons, there are only three nucleotide differences between *WB_DS1_n1* and *WB_DS1_n2* (e.g. M85291 vs. LC200979, Table S3) and thus the probe consisting of the central portion of the β2 domain exon should be able to detect both genes (Figs. S3, S9 and S10). The genomic region of *WB_DS1_n1* containing a partial β2 domain exon and CP/TM/CY exons was determined using PCR method and the genomic DNA of banded houndshark individual N1 (LC009542). The upstream region of *WB_DS1_n1* β2 domain exon was partially investigated using genomic phage library clones of banded houndshark individual N0 (LC200978). These two genomic sequences were preliminarily combined in Fig. S8. Identification of genomic regions containing the leader and β1 domain exons of *WB_DS1_n1* gene of banded houndshark has not been successful thus far and remains to be investigated.

2-1-1-4 Banded houndshark *WB_DS3*

A short DNA fragment within the banded houndshark *WB_DS3* Ig-like domain was found among the mixture of products (*Ban*I/*Pst*I restriction enzyme-resistant fractions) of the same PCR reaction products from which banded houndshark *WB_DS1* (previously called DI) was found (23), just like the case of banded houndshark *WA_DS5*. Using this DNA fragment as a probe, the genomic library of banded houndshark was screened and positive phage clones were isolated, and then the genomic sequence of banded houndshark *WB_DS3* was determined as described in the Materials and Methods. *WB_DS3* cDNA clones could be isolated from the kidney cDNA library of banded houndshark individual N2, and the sequence of one cDNA clone (*WB_DS3_01*) was determined. A complete coding sequence of banded houndshark *WB_DS3* was amplified with two UTR primers and only a single *WB_DS3* sequence (*WB_DS3_02*) was obtained in banded houndshark individual N1. There are only two amino acid differences between the two obtained *WB_DS3* sequences (Fig. S2). Based on these cDNA sequences, exons in the genomic sequence of *WB_DS3* could be assigned. The genomic exon/intron organization is presented in Fig. 5 and Fig. S8.

2-1-2 Blue shark (*Prionace glauca*)

2-1-2-1 Blue shark *WA_DS5-like*

Blue shark *WA_DS5-like* partial sequences were found through tblastn searches with banded houndshark WA_DS5_n1_01 sequence using SRX1823831 (white muscle tissue) of *Prionace glauca* SRA (Sequence Read Archive, NCBI). Representative sequences are as follows: SRR3632063.60991435.2, SRR3632063.65504350.1, and SRR3632063.57575183.1. Blue shark *WA_DS5-like* partial sequences were also found using SRX3298485 (male immature kidney) of *Prionace glauca* SRA. Representative sequences are as follows: SRR6188468.25604256.2, SRR6188468.25604256.1, and SRR6188468.12728785.1.

2-1-2-2 Blue shark *WA_DS10-like*
Blue shark *WA_DS10-like* sequence was found in GFYY01081745.1 (corresponding to the amino acid residues 15-143 of banded houndshark WA_DS10_01) and GFYY01081744.1 (139-243) through tblastn searches with banded houndshark WA_DS10_01 sequence using transcriptome shotgun assembly (TSA) databases of cartilaginous fishes. For Fig. S1, a hypothetical combined sequence was used, which is composed of GFYY01081745.1 for the partial α1 domain and GFYY01081744.1 for the α2 domain and CP/TM/CY region as blue shark WA_DS10_like sequence.

2-1-2-3 Blue shark *WA_Nds3L*
Blue shark *WA_Nds3L* sequence was found in GFYY01021401.1 through tblastn searches with great white shark WA_Nds3L sequence using TSA databases of cartilaginous fishes.

2-1-2-4 Blue shark *WB_DS1-like*
Blue shark *WB_DS1-like* sequence was found in GFYY01012278.1 (corresponding to the amino acid residues 1-282 of banded houndshark WB_DS1_01) through tblastn searches with banded houndshark WB_DS1_01 sequence using TSA databases of cartilaginous fishes.

2-1-2-5 Blue shark *WB_DS3-like*
Blue shark *WB_DS3-like* sequence was found in GFYY01033062.1 (corresponding to the amino acid residues 1-137 of banded houndshark WB_DS3_01) through tlastn searches with banded houndshark WB_DS3_01 sequence using TSA databases of cartilaginous fishes.

2-1-2-6 Blue shark *WB_Nds5L*
Blue shark *WB_Nds5L* sequence was found in GFYY01040305.1 (corresponding to the amino acid residues 12-83 of great white shark WB_Nds5L) through tblastn searches with great white shark WB_Nds5L sequence using TSA databases of cartilaginous fishes.

2-1-3 Cloudy catshark (*Scyliorhinus torazame*)
Two pairs of W-category genes, *WA_DS5-like*/*WB_Nds5L* and *WA_DS10-like*/*WB_DS1-like*, were found in a 159 K contig, and *WA_DS5-like*/*WB_Nds5L* pair was found in a 82 K contig, as described below.

2-1-3-1 Cloudy catshark *WA_DS5-like*
Cloudy catshark *WA_DS5-like* sequence was found in BFAA01007584.1 (159 K contig, 159043 bp) through tblastn searches with banded houndshark WA_DS5_n1_01 sequence using whole genome shotgun (wgs) databases of cartilaginous fishes which include Cloudy catshark WGS Project BFAA01. In this 159 K contig, *WA_DS5-like* and *WB_Nds5L* genes exist as a pair (head to head configuration with respect to the transcriptional orientations; 4185 bp between the two methionine-coding start codons) as shown in Fig. S11B. Cloudy catshark *WA_DS5-like* sequence was also found in BFAA01011934.1 (82 K contig, 82266 bp) through tblastn searches with banded houndshark WA_DS5_n1_01 sequence using wgs databases of cartilaginous fishes. In this 82 K contig, *WA_DS5-like* and *WB_Nds5L* genes exist as a pair (head to head configuration with respect to the transcriptional orientations; 3059 bp between the two methionine-coding start codons) as shown in Fig. S11B.

Amino acid identity % between two WA_DS5-like sequences from two different contigs of cloudy catshark are as follows:
Between cloudy catshark WA_DS5-like_82K vs. cloudy catshark WA_DS5-like_159K, 36 % for α1 domain and 64 % for α2 domain.

Amino acid identity % between WA_DS5-like sequences of cloudy catshark and great white shark are as follows:

Between cloudy catshark WA_DS5-like_82K vs. great white shark WA_DS5-like, 63 % for α1 and 79 % for α2.
Between cloudy catshark WA_DS5-like_159K vs. great white shark WA_DS5-like, 45 % for α1 and 70 % for α2.
WA_DS5-like sequence of cloudy catshark 82 K contig showed higher amino acid identity % with those of other sharks compared to WA_DS5-like sequence of cloudy catshark 159 K contig. Similar relationships were observed in case of WB_Nds5L of two cloudy catshark contigs.

2-1-3-2 Cloudy catshark *WA_DS10-like*
Cloudy catshark *WA_DS10-like* sequence was found in BFAA01007584.1 (159 K, 159043 bp) through tblastn searches with banded houndshark WA_DS10_01 sequence using wgs databases of cartilaginous fishes. In this 159 K contig, *WA_DS10-like* and *WB_DS1-like* genes exist as a pair (head to head configuration with respect to the transcriptional orientations; 272 bp between the two methionine-coding start codons) as shown in Fig. S11B.

2-1-3-3 Cloudy catshark *WB_DS1-like*
Cloudy catshark *WA_DS1-like* sequence was found in BFAA01007584.1 (159 K, 159043 bp) through tblastn searches with banded houndshark WA_DS1_01 sequence using wgs databases of cartilaginous fishes. *WA_DS1-like* and *DS10-like* genes exist as a pair as described above.

2-1-3-4 Cloudy catshark *WB_Nds5L*
Cloudy catshark *WB_Nds5L* sequence was found in BFAA01007584.1 (159 K, 159043 bp) through tblastn searches with banded houndshark WB_DS1_01 sequence using wgs databases of cartilaginous fishes. Cloudy catshark *WB_Nds5L* sequence was also found in BFAA01011934.1 (82 K, 82266 bp; for β2 domain) through tblastn searches with banded houndshark WB_DS3_01 sequence using wgs databases of cartilaginous fishes. *WB_Nds5L* and *WA_DS5-like* genes exist as a pair in both contigs as described above.

Amino acid identity % between two WB_Nds5L sequences from two different contigs of cloudy catshark are as follows:
Between cloudy catshark WB_Nds5L_82K vs. cloudy catshark WB_Nds5L_159K, 39 % for β1 domain and 84 % for β2 domain.

Amino acid identity % between WB_Nds5L sequences of cloudy catshark and great white shark are as follows:
Between cloudy catshark WB_Nds5L_82K vs. great white shark WB_Nds5L, 63 % for β1 and 73 % for β2.
Between cloudy catshark WB_Nds5L_159K vs. great white shark WB_Nds5L, 36 % for β1 and 66 % for β2.
WB_Nds5L sequence of cloudy catshark 82 K contig showed higher amino acid identity % with those of other sharks compared with WB_Nds5L sequence of cloudy catshark 159 K contig. Similar relationships were observed in case of WA_DS5-like of two cloudy catshark contigs as described above.

2-1-4 Great white shark (*Carcharodon carcharias*)
In a 285 K contig of great white shark, three pairs of W-category genes were found: *WA_Nds3L*/*WB_DS3-like*, *WA_DS10-like* /*WB_DS1-like* and *WA_DS5-like* /*WB_Nds5L*.

2-1-4-1 Great white shark *WA_DS5-like*
Great white shark *WA_DS5-like* sequence was found in QUOW01001706.1 (285 K, 285375 bp) through tblastn searches with banded houndshark WA_DS5_n1_01 sequence using wgs databases of cartilaginous fishes. In this 285 K contig, *WA_DS5-like* and *WB_Nds5L* genes exist as a pair (head to head configuration with respect to the transcriptional orientations; 1790 bp between the two methionine-coding start codons) as shown in Fig. S11A.

2-1-4-2 Great white shark *WA_DS10-like*

Great white shark *WA_DS10-like* sequence was found in QUOW01001706.1 (285 K, 285375 bp) through tblastn searches with banded houndshark WA_DS10_01 sequence using wgs databases of cartilaginous fishes. In this 285 K contig, *WA_DS10-like* and *WB_DS1-like* genes exist as a pair (head to head configuration with respect to the transcriptional orientations; 275 bp between the two methionine-coding start codons) as shown in Fig. S11A.

2-1-4-3 Great white shark *WA_Nds3L*

Great white shark *WA_ Nds3L* sequence was found in QUOW01001706.1 (285 K, 285375 bp) through tblastn searches with banded houndshark WA_DS5_n1_01 sequence using wgs databases of cartilaginous fishes. In this 285 K contig, *WA_Nds3L* and *WB_DS3-like* genes exist as a pair (head to head configuration with respect to the transcriptional orientations; 1742 bp between the two methionine-coding start codons) as shown in Fig. S11A. *WA_Nds3L* gene in this contig lacks a single nucleotide (G) near the middle of the α1 domain exon, which produces a frame-shift, compared to the expressed sequences (e.g., SRA: SRR684727.41156647.1 of SRX228421). In Fig. S1 and Dataset S1, the corrected sequence for great white shark WA_Nds3L is presented.

2-1-4-4 Great white shark *WB_DS1-like*

Great white shark *WA_DS1-like* sequence was found in QUOW01001706.1 (285 K, 285375 bp) through tblastn searches with banded houndshark WB_DS1_ 01 sequence using wgs databases of cartilaginous fishes. *WA_DS1-like* and *DS10-like* genes exist as a pair as described above.

2-1-4-5 Great white shark *WB_DS3-like*

Great white shark *WA_DS3-like* sequence was found in QUOW01001706.1 (285 K, 285375 bp) through tblastn searches with banded houndshark WB_DS3_01 sequence using wgs databases of cartilaginous fishes. *WB_DS3-like* and *WA_Nds3L* genes exist as a pair as described above.

2-1-4-6 Great white shark *WB_Nds5L*

Great white shark *WA_Nds5L* sequence was found in QUOW01001706.1 (285 K, 285375 bp) through tblastn searches with banded houndshark WB_DS3_01 sequence using wgs databases of cartilaginous fishes. *WB_Nds5L* and *WA_DS5-like* genes exist as a pair as described above.

2-1-5 Whale shark (*Rhincodon typus*)

2-1-5-1 Whale shark *WA_DS5-like*

Whale shark *WA_DS5-like* sequences were found in LVEK01588988.1 (for α1 domain) and LVEK01625365.1 (for α2 domain) through tblastn searches with banded houndshark WA_DS5_n1_01 sequence using wgs databases of cartilaginous fishes. In Fig. S1, as a whale shark WA_DS5-like sequence, a hypothetical combination of sequences was used, which is composed of LVEK01588988.1 for the α1 domain and LVEK01625365.1 for the α2 domain.

2-1-5-2 Whale shark *WA_DS10-like*

Whale shark *WA_DS10-like* sequences were found in LVEK01757095.1 (for α1 domain) and LVEK01573532.1 (for α2 domain) through tblastn searches with banded houndshark WA_DS10_01 sequence using wgs databases of cartilaginous fishes. In Fig. S1, as a whale shark WA_DS10-like sequence, a hypothetical combination of sequences was used, which is composed of LVEK01757095.1 for the α1 domain and LVEK01573532.1 for the α2 domain.

2-1-5-3 Whale shark *WB_DS1-like*

Whale shark *WB_DS1-like* sequence was found in LVEK01262083.1 (for β2 domain) through tblastn searches with banded houndshark WB_DS1_01 sequence using wgs databases of cartilaginous fishes.

2-1-5-4 Whale shark *WB_DS3-like*

Whale shark *WB_DS3-like* sequence was found in LVEK01746520.1 (for β1 domain) through tblastn searches with banded houndshark WB_DS3_01 sequence using wgs databases of cartilaginous fishes. This β1 domain possesses a cysteine residue highly characteristic for WB_DS3.

2-1-6 Whitespotted bambooshark (*Chiloscyllium plagiosum*)

2-1-6-1 Whitespotted bambooshark *WA_DS5-like*

Whitespotted bambooshark *WA_DS5-like* sequences were found in QPFF01095956.1 (18K, 18685 bp; for α1 and α2 domains), QPFF01329347.1 (657 bp; for α2 domain), and BEZZ01383420.1 (1297 bp; for α1 domain), through tblastn searches with banded houndshark WA_DS5_n1_01 sequence using wgs databases of cartilaginous fishes.

2-1-6-2 Whitespotted bambooshark *WA_DS10-like*

Whitespotted bambooshark *WA_DS10-like* sequence was found in QPFF01486458.1 (8K, 8625 bp; for α1 and α2 domains, and CP/TM/CY region), in QPFF01329347.1 (657 bp; for α2 domain), and BEZZ01383420.1 (1297 bp; for α1 domain), through tblastn searches with banded houndshark WA_DS5_n1_01 sequence using wgs databases of cartilaginous fishes.

2-1-6-3 Whitespotted bambooshark *WA_Nds3L*

Whitespotted bambooshark *WA_Nds3L* sequence was found in QPFF01560724.1 (1417 bp; for α2 domain) through tblastn searches with great white shark WA_Nds3L sequence using wgs databases of cartilaginous fishes.

2-1-6-4 Whitespotted bambooshark *WB_DS1-like*

Whitespotted bambooshark *WB_DS1-like* sequence was found in QPFF01495858.1 (705 bp; for β2 domain) through tblastn searches with banded houndshark WB_DS1_01 sequence using wgs databases of cartilaginous fishes.

2-1-6-5 Whitespotted bambooshark *WB_DS3-like*

Whitespotted bambooshark *WB_DS3-like* sequence was found in QPFF01327377.1 (543 bp; for β1 domain) and QPFF01162766.1 (4608 bp; for β2 domain) through tblastn searches with banded houndshark WB_DS3_01 sequence using wgs databases of cartilaginous fishes.

2-1-6-6 Whitespotted bambooshark *WB_Nds5L*

Whitespotted bambooshark *WB_Nds5L* sequences were found in QPFF01130085.1 (1921 bp; for β1 domain) and QPFF01212593.1 (1887 bp; for β1 domain) through tblastn searches with great white shark WB_Nds5L sequence using wgs databases of cartilaginous fishes.

2-1-7 Brownbanded bambooshark (*Chiloscyllium punctatum*)

2-1-7-1 Brownbanded bambooshark *WA_DS5-like*

Brownbanded bambooshark *WA_DS5-like* sequences were found in BEZZ01010960.1 (3420 bp; for α1 domain), BEZZ01017577.1 (3066 bp; for α1 domain), and BEZZ01115237.1 (1187 bp; for α1 domain), through tblastn searches with banded houndshark WA_DS5_n1_01 sequence using wgs databases of cartilaginous fishes.

2-1-7-2 Brownbanded bambooshark *WA_DS10-like*

Brownbanded bambooshark *WA_DS10-like* sequence was found in BEZZ01254771.1 (544 bp; for α1 domain), and in BEZZ01004761.1 (22649 bp; for α2 domain and CP/TM/CY region) through tblastn searches with banded houndshark WA_DS10_01 sequence using wgs databases of cartilaginous fishes. This 22 K contig also contains the exons for β1 and β2 domains of *WB_DS3-like* gene.

2-1-7-3 Brownbanded bambooshark *WA_Nds3L*

Brownbanded bambooshark *WA_Nds3L* sequence was found in BEZZ01099794.1 (1357 bp; for α2 domain) through tblastn searches with great white shark WA_Nds3L sequence using wgs databases of cartilaginous fishes.

2-1-7-4 Brownbanded bambooshark *WB_DS1-like*
Brownbanded bambooshark *WB_DS1-like* sequence was found in BEZZ01084999.1 (1551 bp; for β2 domain) through tblastn searches with banded houndshark WB_DS1_01 sequence using wgs databases of cartilaginous fishes.

2-1-7-5 Brownbanded bambooshark *WB_DS3-like*
Brownbanded bambooshark *WB_DS3-like* sequence was found in BEZZ01004761.1 (22649 bp; for β1 and β2 domains) through tblastn searches with banded houndshark WB_DS3_01 sequence using wgs databases of cartilaginous fishes. This 22 K contig also contains partial *WA_DS10-like* sequence as described above.

2-1-7-6 Brownbanded bambooshark *WB_Nds5L*
Brownbanded bambooshark *WB_Nds5L* sequences were found in BEZZ01198256.1 (690 bp; for β1 domain), BEZZ01164644.1 (829 bp; for β1 domain), BEZZ01050759.1 (2168 bp; for β1 domain), BEZZ01176133.1 (775 bp; for β2 domain) and BEZZ01162851.1 (838 bp; for β2 domain) through tblastn searches with great white shark WB_Nds5L sequence using wgs databases of cartilaginous fishes.

2-1-8 Zebra bullhead shark (*Heterodontus zebra*)
2-1-8-1 Zebra bullhead shark *WA_DS5-like*
Zebra bullhead shark *WA_DS5-like* sequence was found in GGGL01449145 through tblastn searches with banded houndshark WA_DS5_n1_01 sequence using TSA databases of catilaginous fishes. This TSA sequence is an apparent readthrough transcript and also contains *WA_DS10-like* sequence (without a starting ATG codon for methionine, but with a stop codon), followed by a complete coding sequence for *WA_DS5-like*.

The sequences with the following accession numbers also contain *WA_DS5-like* sequence, and the numbers with asterisks (*) contain *WA_DS10-like* as well:
GGGL01449115*, GGGL01449117, GGGL01449119*, GGGL01449123, GGGL01449125, GGGL01449130*, GGGL01449131*, GGGL01449132*, GGGL01449136*, GGGL01449137, GGGL01449140, and GGGL01449146.

2-1-8-2 Zebra bullhead shark *WA_DS10-like*
Zebra bullhead shark *WA_DS10-like* sequence was found in GGGL01449113 through tblastn searches with banded houndshark WA_DS10_01 sequence using TSA databases of catilaginous fishes. This TSA sequence as well as the sequences described below do not contain an ATG start codon for *WA_DS10-like*.

The sequences with the following accession numbers also contain *WA_DS10-like* sequence, and the sequences with the numbers with asterisks (*) contain *WA_DS5-like* sequences which were already described in the preceding section:
GGGL01449114, GGGL01449115*, GGGL01449119*, GGGL01449130*, GGGL01449131*, GGGL01449132*, GGGL01449133, GGGL01449135, GGGL01449136*, and GGGL01449145*.

2-1-8-3 Zebra bullhead shark *WB_DS1-like*
Zebra bullhead shark *WB_DS1-like* sequence was found in GGGL01058883 through tblastn searches with banded houndshark WB_DS1_01 sequence using TSA databases of catilaginous fishes.

The sequences with the following accession numbers also contain *WA_DS1-like* sequence:
GGGL01058879, GGGL01058880, GGGL01058881, GGGL01058882, GGGL01058886, and GGGL01058887.

2-1-8-4 Zebra bullhead shark *WB_Nds5L*

Zebra bullhead shark *WB_Nds5L* sequences were found in GGGL01449143, GGGL01449112 and GGGL01449138 as three representatives through tblastn searches with great white shark WB_Nds5L sequence using TSA databases of catilaginous fishes.

2-1-9 Spiny dogfish (*Squalus acanthias*)

2-1-9-1 Spiny dogfish *WA_DS5-like*

Spiny dogfish *WA_DS5-like* sequence was found in HAGW01089906 through tblastn searches with banded houndshark WA_DS5_n1_01 sequence using TSA databases of cartilaginous fishes. This TSA sequence is an apparent readthrough transcript and also contains *WB_DS1-like* sequence, followed by *WA_DS5-like* sequence without a proper sequence for a leader region. In Fig. S1, the predicted amino acid sequence based on HAGW01089906 is shown.

The sequences with the following accession numbers also contain *WA_DS5-like* sequence, and the sequences with the numbers with asterisks (*) contain *WB_DS1-like* sequences as well: HAGW01089902*, HAGW01089904*, HAGW01089907*, HAGW01089908*, HAGW01089910*, HAGT01020445, HAGT01100681, and HAGV01095271.

The predicted amino acid sequence of HAGT01020445 is similar to banded houndshark WA_DS5_n1_01 sequence, and those of the other sequences are similar to banded houndshark WA_DS5_n1_04 sequence.

2-1-9-2 Spiny dogfish *WA_DS10-like*

Spiny dogfish *WA_DS10-like* sequence was found in HAGT01122485 (partial α1, α2 and partial TM) through tblastn searches with banded houndshark WA_DS10_01 sequence using TSA databases of cartilaginous fishes.

2-1-9-3 Spiny dogfish *WA_Nds3L*

Spiny dogfish *WA_Nds3L* sequence was found in HAGT01004242 (311bp; α2 domain) through tblastn searches with great white shark WA_Nds3L sequence using TSA databases of cartilaginous fishes.

2-1-9-4 Spiny dogfish *WB_DS1-like*

Several EST sequences of spiny dogfish were found through tblastn searches with banded houndshark WB_DS1_01 using "expressed sequence tags (est)" databases; these sequences included spiny dogfish *WB_DS1-like1* and *WB_DS1-like2* from pooled multiple tissues of spiny dogfish, and their accession numbers are listed in Table S3. All these sequences lack the 3' portion of the gene. The longer one (spiny dogfish *WB_DS1-like1*) contains a partial CP/TM/CY region.

Spiny dogfish *WB_DS1*-like sequence (*WB_DS1-like3*) was also found in HAGW01089902 through tblastn searches with banded houndshark WB_DS1_01 sequence using TSA databases of cartilaginous fishes. This longest TSA sequence is an apparent readthrough transcript and also contains *WA_DS5-like* sequence as described in the previous section. In Fig. S2, the predicted amino acid sequence based on HAGW01089902 is shown.

The sequences with the following accession numbers also contain *WB_DS1-like* sequences followed by incomplete *WA_DS5-like* sequences:
HAGW01089904, HAGW01089906, HAGW01089907, HAGW01089908, and HAGW01089910.

2-1-9-5 Spiny dogfish *WB_DS3*-like

Several EST sequences of spiny dogfish were found through tblastn searches with banded houndshark *WB_DS3_01* sequence using est databases; these sequences included spiny dogfish *WB_DS3-like1*, *WB_DS3-like2* and *WB_DS3-like3* as representatives from pooled multiple tissues of spiny dogfish, and their accession numbers are listed in Table S3. All these sequences lack most of the 3' portion of the gene. The longest one (spiny dogfish *WB_DS3-like1*) contains a partial β2 domain sequence as shown in Fig. S2.

2-1-9-6 Spiny dogfish *WB_Nds5L*

Spiny dogfish *WB_Nds5L* sequence was found in HAGT01000336 (329 bp; β1 domain) through tblastn searches with great white shark WB_Nds5L sequence using TSA databases of cartilaginous fishes.

2-1-10 Little skate (*Leucoraja erinacea*)

2-1-10-1 Little skate *WA_DS5-like*

Little skate *WA_DS5-like* sequences were found in AESE012173146 (for the α1 domain) and AESE011681578 (for the α2 domain) through tblastn search with banded houndshark WA_DS5_n1_01 sequence using wgs databases of cartilaginous fishes. One cDNA sequence (Sequence ID: gnl|SRA|SRR088619.19134478.1) was found through tblastn searches with the translated sequence of AESE012173146 using "sequence read archive (SRA)" dataset SRX036536, and this cDNA sequence contains a short overlap region between the α1 and α2 domain-exons as described above. A tentative leader sequence was obtained through tblastn searches with AESE012173146 (α1 domain) using SRX036536 mentioned above. In Fig. S1, a hypothetical combination of sequences was used based on genomic sequence information of a tentative leader sequence, the α1 domain (AESE012173146) and the α2 domain (AESE011681578).

2-1-10-2 Little skate *WA_DS10-like*

Little skate *WA_DS10-like* gene sequences corresponding to the α1 domain, the α2 domain and the CP/TM/CY region were found as follows.

Little skate *WA_DS10-like* sequence was found in AESE011710435 (for the α2 domain) through tblastn searches with banded houndshark WA_DS10_01 sequence using wgs databases of cartilaginous fishes. A partial α1 and α2 domain-corresponding cDNA sequence (LittleSkate_ TranscriptomeContig95319) was found through tblastn searches with banded houndshark WA_DS-10_01 sequence using Little Skate Transcriptomic Contigs-Build 2 at the SkateBase (42) (http://skatebase.org/skateBLAST). A complete sequence for the α1 domain of little skate *WA_DS10*-like gene was found in AESE011594527 (corresponding to LittleSkate_Consensusfrom Contig1715029 at the SkateBase) through tblastn searches with the partial α1 domain sequence using wgs database of little skate. A candidate sequence for CP/TM/CY region was found in AESE012658604 (LittleSkate_ConsensusfromContig2822493 at the SkateBase) through tblastn searches with LittleSkate_TranscriptomeContig99288 which contains a partial sequence of α2 domain and CP/TM/CY region using Little Skate Transcriptomic Contigs-Build 2 at the SkateBase. In Fig. S1, a hypothetical combination of sequences was used, which is composed of three genomic regions, namely, the α1 domain (AESE011594527), the α2 domain (AESE011710435) and CP/TM/CY region (AESE012658604).

2-1-10-3 Little skate *WB_DS1-like*

Little skate *WB_DS1-like* sequence was found in AESE011933439 (for the β2 domain) through tblastn searches with banded houndshark WB_DS1_n1_01 sequenc using wgs databases of cartilaginous fishes. A cDNA sequence corresponding to a partial β1 and β2 domain (LittleSkate_ TranscriptomeContig44319) was found through tblastn searches with banded houndshark WB_DS1_n1_01 sequence using Little Skate Transcriptomic Contigs-Build 2 at the SkateBase. In Fig. S2, a hypothetical combined sequence was used, which is composed of a cDNA sequence (LittleSkate_TranscriptomeContig44319, for the partial β1 domain) and a genomic sequence (AESE011933439, for the β2 domain).

2-1-10-4 Little skate *WB_Nds5L*

Little skate *WB_Nds5L* sequence was found in AESE011737676.1 (328 bp; for β2 domain) through tblastn search with great white shark WB_Nds5L sequence using wgs databases of cartilaginous fishes.

**2-2 Ray-finned fish - teleost fish group**

2-2-1 Japanese grenadier anchovy (*Coilia nasus*)

Japanese grenadier anchovy *WA* and *WB* sequences were found in GFON01059655.1 (encoding α1 and partial α2 domain of WA) and GFON01085854.1 (encoding WB) through tblastn searches with Atlantic herring WA_01 and WB_01 sequences, respectively, using TSA databases of bony fishes.

2-2-2 Atlantic herring (*Clupea harengus*)

Atlantic herring *WA* and *WB* sequences were initially found in 34 K contig and further recently identified in an extended 344 K contig as described below.

Atlantic herring *WA* and *WB* sequences were found in JZKK01005006 (34 K contig, 34278 bp) and also in OOIJ01000439 ("344 K contig", 344569 bp, Fig. S11C) through tblastn searches with zebrafish WA_13A and WB_13B sequences, respectively, using wgs databases of bony fishes. 344 K contig completely covers 34 K contig. *WA* and *WB* genes exist as a pair (head to head configuration with respect to the transcriptional orientations; 118 bp between the two methionine-coding start codons) as shown in Fig. S11C. Other than this *WA/WB* pair, an exon fragment of WA α2 is also detected (Fig. S11C). Notable about Atlantic herring WA molecule is that the otherwise highly conserved canonical second cysteine of the α2 domain is replaced with a phenylalanine. This replacement was also observed in the WA α2 domain fragment and observed in SRA genomic sequences (e. g., gnl|SRA|SRR611608.17870700.1 of SRX203066). cDNA sequence information of Atlantic herring W-category genes is not available at present.

2-2-3 Sardine (*Sardina pilchardus*)

Sardine *WA* sequence was found in GGSC01089055, GGSC01089060, GGSC01089061 and GGSC01089054, GGSC01089059 (corresponding to WA α2 domain) and GGSC01089058 (also corresponding to WA α2 domain) through tblastn searches with Atlantic herring WA_01 sequence using TSA databases of bony fishes.

Sardine WB partial sequences were found through tblastn searches with Atlantic herring WB_01 sequence using SRX3593722 (liver RNA) of sardine SRA. Representative sequences are as follows: SRR6505116.71659865.1, SRR6505116.16871074.2, and SRR6505116.16871074.1.

2-2-4 Allis shad (*Alosa alosa*)

Allis shad *WA* and *WB* sequences were found in GETY01010370 (for *WA*), GETY01018251 (for *WB*) and GETY01036995 (for *WB*) through tblastn searches with zebrafish WA_13A for WA and WB_13B for WB, respectively, using TSA databases of bony fishes. Allis shad WA sequence possesses the canonical second cysteine in the α2 domain, which is different from the case of Atlantic herring, although both allis shad and Atlantic herring belong to the family Clupeidae.

2-2-5 Alewife (*Alosa pseudoharengus*)

Alewife *WA* and *WB* sequences were found in GFCK01040569.1 (encoding partial α2 and CP/TM/CY of WA) and GFCK01026404.1 (encoding WB) through tblastn searches with Atlantic herring WA_01 and WB_01 sequences, respectively, using TSA databases of bony fishes.

2-2-6 Hilsa shad (*Tenualosa ilisha*)

Hilsa shad WA and WB sequences were found in QYSC01123695 ("325 K contig", 325703 bp, Fig. S11C) through tblastn searches with Atlantic herring WA_01 and WB_01 sequences using wgs databases of bony fishes. *WA* and *WB* genes exist as a pair (head to head configuration with respect to the transcriptional orientations; 11593 bp between the two methionine-coding start codons) as shown in Fig. S11C. Hilsa shad WA sequence also possesses the canonical second cysteine in the α2 domain like allis shad WA, which is different from the case of Atlantic herring,

2-2-7 Oriental weatherfish (weather loach, mud loach) (*Misgurnus anguillicaudatus*)

Oriental weatherfish *WA* and *WB* sequences were found in GAAD01002023 (encoding a partial α1 domain, a complete α2 domain and a partial CP/TM/CY region of WA) and GAAD01004277 (encoding a partial β2 domain and a complete CP/TM/CY region of WB) through tblastn searches with zebrafish WA_13A and WB_13B, respectively, using TSA databases of bony fishes. Since GAAD01004277 lacks sequences corresponding to the amino-terminal portion (eleven amino acid residues) of the β2 domain, we assembled a presumed complete β2 domain coding sequence using SRA transcriptomic database information (e. g., SRA:SRR3064024.68986258.1 of SRX1479505) and used this sequence in the analyses.

2-2-8 Spined loach (*Cobitis taenia*)

Spined loach *WA* sequence was found in GGJF01002240 (encoding partial α1, α2 and CP/TM/CY of WA) through tblastn searches with zebrafish WA_13A sequence using TSA databases of bony fishes. Spined loach *WB* sequence has not been obtained yet.

2-2-9 White sucker (*Catostomus commersonii*)

White sucker *WA* and *WB* sequences were found in GECX01063527 (for *WA*) and GECX01114064 (for *WB*) through tblastn searches with zebrafish WA_13A and WB_13B sequences, respectively, using TSA databases of bony fishes. The white sucker *WB* sequence of GECX01114064 lacks the beginning of the leader sequence and the last part of the CP/TM/CY portion.

2-2-10 Common carp (*Cyprinus carpio*)

For genomic sequence information of common carp, the NCBI database contains datasets of two whole genome sequencing projects, BioProject PRJEB7241 and BioProject PRJNA73579. The two projects sequenced the genome of common carp using different individuals and the two sources showed similar but not identical results. In the common carp genome, we could identify two *WA/WB* pairs, namely, *WA_A1/WB_B1* and *WA_A2/WB_B2*, in both datasets. Between common carp WA_A1 and WA_A2, amino acid sequence identity is 93 % in the α2 domain, and between common carp WB_B1 and WB_B2, amino acid sequence identity is 81 % in the β2 domain. In addition, fragments of *WA* and *WB* genes were identified. In Figs. S11E and S11F, the genomic locations of these common carp W-category genes and the fragments are summarized.

Below, identifications of W-category sequences in common carp are described separately for the two different BioProject sources.

Within BioProject PRJEB7241 (62), common carp *WA* and/or *WB* sequences were found in LN590696 ("26 M contig" in Fig. S11E, LG32, 26100072 bp), LN598268 ("890 K contig", 890226 bp, 26 M contig includes this 890 K contig region), LN594648 ("138 K contig" in Fig. S11E, 138244 bp) and LN590685 ("20 M contig" in Fig. S11F, LG16, 20606094 bp) through tblastn searches with zebrafish WA_13A and WB_13B sequences using the database of nucleotide collection. The 26 M contig and 890 K contig each contain a *WA_A1/WB_B1* gene pair (head to head configuration with respect to the transcriptional orientations; 294 bp between the two methionine-coding start codons), while the 138 K contig contains a *WA_A2/WB_B2* gene pair (head to head configuration with respect to the transcriptional orientations; 331 bp between the two methionine-coding start codons) (Fig. S11E). The 138 K contig additionally contains a *WB_B2* CP/TM/CY fragment (Fig. S11E) and the 20 M contig contains a *WA_A1* α2 domain exon fragment (Fig. S11F). Compared with presumed intact genes, *WA_A1* of the 26 M/890 K contigs lacks a single nucleotide in the α1 domain exon, and *WB_B1* of these contigs has an extra nucleotide in the leader exon. *WA_A2* of the 138 K contig appears intact while *WB_B2* of this contig has two extra nucleotides in the β2 domain exon. These deviations from presumed intact sequences may either represent actual gene inactivations or sequencing/assembly errors.

Within BioProject PRJNA73579 (63, 64), common carp *WA/WB* sequences were found in LHQP01015169 ("107 K contig", 107664 bp) and LHQP01028415 ("82 K contig" in Fig. S11E, 82519 bp) through tblastn searches with zebrafish WA_13A and WB_13B sequences using wgs databases of bony fishes. The 107 K contig contains the *WA_A1/WB_B1* gene pair (head to head configuration with respect to the transcriptional orientations; 294 bp between the two methionine-coding start codons) while the 82 K contig contains the *WA_A2/WB_B2* gene pair (head to head configuration with respect to the transcriptional orientations; 333 bp between the two putative start codon positions). In the middle of the α2 domain exon of *WA_A1* of the 107 K contig, inversion and other changes of DNA sequences are observed, while *WB_B1* of this contig appears intact. *WA_A2* of the 82 K contig appears to be intact while *WB_B2* of this contig has a single nucleotide change for the methionine-coding start codon. Again, these deviations from presumed intact sequences may either represent actual gene inactivations or sequencing/assembly errors.

In the present study, for comparisons with sequences of other species, apparently intact *WA_A2* of the 82 K contig was used for the common carp *WA_A2_01*, and *WB_B1* of the 107 K contig was used for the common

carp *WB_B1_01*. For the common carp *WA_A1* and *WB_B2*, putatively correct sequences were assembled as information about short genomic sequences of *WA_A1* and *WB_B2* genes are available from SRA of the common carp strain Songpu in BioProject PRJEB7241, which is the same strain as that used to make the draft genome in the same project (ref. 62) and, based on those SRA sequences, the portions of available W-category sequences of the common carp draft genome that were suggested defective appeared to be intact instead. The corrected version of *WA_A1* of the 26 M/890 K contigs was made for the common carp *WA_A1* after the confirmation with the genomic DNA sequences of the common carp strain Songpu (e. g., SRA:SRR924320.37964842.2 of SRX316954, Sp1). Similarly the corrected version of *WB_B2* of the 138 K contig was made for the common carp *WB_B2* after the confirmation with the genomic DNA sequences (e. g., SRA:SRR924320.1454377.1 of SRX316954, Sp1). There are four different SRA datasets from strain Songpu Sp1, Sp2, Sp3 and Sp4. SRA sequence information supported intactness of *WA_A1* and *WB_B2*.

2-2-11 Chinese cavefish (*Sinocyclocheilus grahami (Sg), S. rhinocerous (Sr), S.anshuiensis (Sa)*)

Chinese cavefish from which W-category genes were identified include three closely related species, *Sinocyclocheilus grahami (Sg), S. rhinocerous (Sr)* and *S. anshuiensis (Sa)*. In our study, the same abbreviations of Sg, Sr and Sa are used as in a published report (65). In Chinese cavefish, we could identify two *WA/WB* gene pairs, namely, *WA_A1/WB_B1* and *WA_A2/WB_B2*, just like common carp; the assignments of 1 or 2 were in accordance with the names of the orthologous common carp genes (Fig. S20). Because both *WA_A1* and *WA_A2* were obtained only from *S. rhinocerous (Sr)*, W-category sequences of *S. rhinocerous (Sr)* were used as the representative sequences of Chinese cavefish in the analyses.

Chinese cavefish *WA* and *WB* sequences were found to correspond to the following predicted sequences through tblastn searches with zebrafish WA_13A and WB_13B sequences using the database of nucleotide collection; XM_016288790.1 (*WA_A1* of Sg), XM_016571073.1 (*WA_A1* of Sr), XM_016474588.1 (*WA_A1* of Sa), XM_016544921.1 (*WA_A2* of Sr), XM_016288788.1 (*WB_B1* of Sg), XM_016288789.1 (*WB_B1* of Sg, partial), XM_016571072.1 (*WB_B1* of Sr), XM_016474614.1 (*WB_B1* of Sa), XM_016263664.1 (*WB_B2* of Sg), XM_016544920.1 (*WB_B2* of Sr), and XM_016486958.1 (*WB_B2* of Sa). Chinese cavefish *WA* and *WB* genomic sequences were also detected in the following contigs through tblastn searches with zebrafish WA_13A and WB_13B sequences using wgs databases of bony fishes: LCYQ01031371.1 (including a complete pair of *WA_A1/WB_B1* of Sg, 102 K contig, 102623 bp; head to head configuration with respect to the transcriptional orientations; 341 bp between the two opposing nearest methionine-coding start codons, as there are two possible WB leader exons), LCYQ01012883.1 (including a partial *WA_A2* of Sg, 29 K contig, 29450 bp), LCYQ01125997.1 (including a partial *WA_A2* and a complete *WB_B2* of Sg, 2 K genomic sequence, 2712 bp), LAVF01191476.1 (including a complete pair of *WA_A2/WB_B2* of Sr, 50 K contig, 50091 bp; head to head configuration with respect to the transcriptional orientations; 329 bp between the two methionine-coding start codons), LAVF01079966.1 (including a partial *WA_A1* and a complete *WB_B1* of Sr, 64 K contig, 64734 bp), LAVF01079967.1 (including a partial *WA_A1* of Sr, 37 K contig, 37291 bp), LAVE01180287.1 (including a partial *WA_A1* of Sa, 36 K contig, 36160 bp), LAVE01000366.1 (including a partial *WA_A2* and a complete *WB_B2* of Sa, 31 K contig, 31461 bp) and LAVE01180285.1 (including a partial *WA_A1* and a complete *WB_B1* of Sa, 36 K contig, 36027 bp). Based on those shorter contigs, longer genomic scaffolds containing Chinese cavefish W-category genes are available as follows: NW_015505413 (*WA_A1/WB_B1* of Sg, 2.6 M, 2662682 bp), NW_015641068 (*WA_A1/WB_B1* of Sr, 124 K, 124120 bp), NW_015557379 (*WA_A1/WB_B1* of Sa, 3.3 M, 3351518 bp), NW_015666971 (*WA_A2/WB_B2* of Sr, 1.2 M, 1242612 bp), NW_015536465 (pseudo [?] *WA_A2/WB_B2* of Sa, 413 K, 413061 bp). Basically, the region containing W-category genes and the surrounding genes of Chinese cavefish is similar to the relevant region of zebrafish chromosome 13 (Fig. S11E).

2-2-12 Goldfish (*Carassius auratus*)

Goldfish *WA* and *WB* sequences were isolated based on the sequence information of zebrafish and/or common carp W-category genes. At first, to isolate goldfish W-category gene fragments, RT-PCR reaction was conducted using goldfish RNA and primers based on zebrafish and/or common carp W-category sequences. Then, 5' and 3' RACE reactions were conducted using goldfish *WA*- and *WB*-specific primers. After obtaining

goldfish partial sequences for *WA* and *WB*, complete coding regions of goldfish *WA* and *WB* genes were amplified (the primers are listed in Table S2) and the sequences were determined. Because the goldfish genome experienced the same additional whole genome duplication as the common carp genome did, a duplication of *WA/WB* pair in goldfish would be expected in comparison with the zebrafish genome (66). The isolated goldfish *WA* and *WB* sequences were compared with common carp *WA_A1*, *WA_A2*, *WB_B1* and *WB_B2* and, judging from sequence similarity levels, identified goldfish *WA* and *WB* sequences probably correspond to *WA_A1* and *WB_B1*, respectively (Fig. S20). The possible existence of additional *WA* and *WB* genes in goldfish remains to be studied.

2-2-13 Catla (*Gibelion catla* or *Catla catla*)

Catla *WA* and *WB* sequences were found in GEAE01049160.1 (for *WA*) and GEAE01019557.1 (for *WB*) through tblastn searches with zebrafish WA_13A and WB_13B sequences, respectively, using TSA databases of bony fishes.

2-2-14 Tench (*Tinca tinca*)

Tench *WA* and *WB* sequences were found in GFZX01071246.1 (for *WA*) and GFZX01039606.1 (for *WB*) through tblastn searches with zebrafish WA_13A and WB_13B sequences, respectively using TSA databases of bony fishes. The beginning of WB sequence is highly divergent compared to those of other closely related species and can be genomic, therefore, this part is not included in Fig. S2D.

2-2-15 Grass carp (*Ctenopharyngodon idella*)

Grass carp *WA* and *WB* sequences were found in GEUQ01023638 (for WA), GBKA01001259 (for WB) and GEUQ01052457 (for WB) through tblastn searches with zebrafish WA_13A and WB_13B using TSA databases of bony fishes. This grass carp *WA* cDNA sequence contains intron 2 sequence (between the α1 and α2 domain-coding exons) while all the other introns were properly spliced out. The SRA transcriptome databases contain properly spliced sequences of this grass carp *WA* gene (e. g., SRX1634319). Therefore, a complete transcript for grass carp *WA* can be assumed. Accessions GBKA01001259 and GEUQ01052457 contain the same WB-coding sequence.

2-2-16 Fathead minnow (*Pimephales promelas*)

Fathead minnow *WA* and *WB* sequences were found in JNCD01006382 (for *WA/WB* pair, "111 K contig" in Fig. S11E, 111553 bp; head to head configuration with respect to the transcriptional orientations; 173 bp between the two methionine-coding start codons; Fig. 5B) and JNCE01056294 (for *WA/WB* pair, "23 K contig", 23124 bp) through tblastn searches with zebrafish WA_13A and WB_13B using wgs databases of bony fishes. The 111 K contig sequence includes the 23 K contig sequence fragment region.

2-2-17 Roach minnow (*Rutilus rutilus*)

Roach minnow *WA* and *WB* sequences were found in GEBE01046214.1 (encoding leader, α1 and partial α2 of WA), GEBE01046216.1 (encoding partial α2 and CP/TM/CY of WA), GEBE01052260.1 (encoding β1 and partial β2 domain of WB), and GEBE01052261.1 (encoding partial β2 and partial CP/TM of WB) through tblastn searches with zebrafish WA_13A (for the first two) and WB_13B (for the last two) sequences using TSA databases of bony fishes. The beginning of WB sequence is highly divergent compared to those of other closely related species and can be genomic, therefore, this part is not included in Fig. S2D.

2-2-18 Amur ide (*Leuciscus waleckii*)

Amur ide *WA* and *WB* sequences were found in FLSR01004870 (for *WA/WB* pair, "28 M contig" in Fig. S11E, LG15, 28600511 bp; head to head configuration with respect to the transcriptional orientations; 164 bp between the two methionine-coding start codons) through tblastn searches with zebrafish WA_13A and WB_13B using wgs databases of bony fishes. Compared with presumed intact genes, *WA* of this contig lacks a single nucleotide in the α1 domain exon, and *WB* of this contig lacks two nucleotides in the β1 domain exon. Presumably correct sequences were preliminarily constituted as information about short genomic sequences

of *WA* and *WB* genes are available from SRA of Amur ide in BioProject PRJEB12292, which also produced contig FLSR01004870 and, based on those sequences, the portions of available W-category sequences of Amur ide that were suggested defective appeared to be intact instead. The corrected *WA* of 28 M contigs for Amur ide *WA* was made after the confirmation with genomic SRA sequences of Amur ide (e.g., SRA:ERR1341435.99541468.2 of ERX1413017). Similarly the corrected *WB* of the same contig for Amur ide *WB* was made after the confirmation with genomic SRA sequences (e.g., SRA:ERR1341435.114433469.1 of ERX1413017). Basically, the region containing W-category genes and the surrounding genes of Amur ide is similar to the relevant region of zebrafish chromosome 13 (Fig. S11E).

2-2-19 Zebrafish (*Danio rerio*)

Zebrafish *WA/WB* genes (Fig. S11E) were the first pair of W-category genes that we recognized outside cartilaginous fish. During extensive searches for MHC genes in various teleost fish, we noticed two puzzling MHC genes on chromosome 13 of the zebrafish genome that had not been discussed in article format yet. These turned out to share characteristic features with the banded houndshark W-category genes. The sequence of zebrafish *WA* gene is NM_001098262 (for mRNA of zebrafish *WA_13A*; gene, zmp:0000001138; GeneID:100002901) and that of zebrafish *WB* gene is NM_001328089 (for mRNA of zebrafish *WB_13B*; gene, zmp:0000001006; GeneID:100002840). The zebrafish *WA/WB* gene pair displays head to head configuration with respect to the transcriptional orientations with 227 bp between the two methionine-coding start codons. In this very short region between two start codons, the promoter sequence motifs highly conserved between the classical MHC class I and class II genes (67) were not identified.

RT-PCR reactions were conducted using zebrafish RNA isolated from the anterior half of a zebrafish and primers based on the zebrafish genomic *WA* and *WB* sequences (Table S2) to obtain cDNA sequences of zebrafish W-category genes. Polymorphism of zebrafish W-category genes were investigated using different individuals (see *SI Appendix* section 5 and Fig. S19).

2-2-20 Brown ghost knifefish (*Apteronotus leptorhynchus*)

Brown ghost knifefish *WA* and *WB* sequences were found in GBKR010337083 (for *WA*) and GBKR010051454 (for *WB*) through tblastn searches with zebrafish WA_13A and WB_13B sequences, respectively, using TSA databases of bony fishes. There are twelve *WA*-containing sequences of brown ghost knifefish (GBKR010337075~ GBKR010337086) and GBKR010337083 described above contains the longest and complete WA-coding sequence. There are two *WB*-containing sequences and GBKR010051454 described above contains complete WB-coding sequence.

2-2-21 Black ghost (*Apteronotus albifrons*)

Black ghost *WA* and *WB* sequences were found in GFID01018756.1 (for *WA*) and GFID01018754.1 (for *WB*) through tblastn searches with zebrafish WA_13A and WB_13B sequences, respectively, using TSA databases of bony fishes.

2-2-22 Duckbill knifefish (*Parapteronotus hasemani*)

Duckbill knifefish *WA* and *WB* sequences were found in GGHK01230896.1 (for partial WA), GGHK01278630.1 (for partial WA) and GGHK01160239.1 (for partial WB) through tblastn searches with zebrafish WA_13A (for the first two) and WB_13B (for the last one) sequences using TSA databases of bony fishes. Two *WA* clones have an overlapping region with 11 nucleotides. In Fig. S1D, the combined sequence is shown.

2-2-23 Glass knifefish (*Eigenmannia virescens*)

Glass knifefish *WA* sequence was found in GGJF01002240 through tblastn searches with zebrafish WA_13A sequence using TSA databases of bony fishes. The beginning of this sequence appears to be in the genomic configuration with the presumed splicing signal of AG for *WA* $\alpha$1 domain exon. Glass knifefish *WB* sequence has not been obtained yet.

2-2-24 Mexican tetra (*Astyanax mexicanus*)

Mexican tetra *WA* and *WB* sequences were found to correspond to XM_007254575 (Gene ID: 103042725) (*WA*) and XM_007254556 (Gene ID: 103034283) (*WB*) through tblastn searches with zebrafish WA_13A and WB_13B sequences using the database of nucleotide collection. These Mexican tetra *WA* and *WB* genes were identified in NW_006749376.1 ("2433 K contig", 2433507 bp; head to head configuration with respect to the transcriptional orientations; 176 bp between the two methionine-coding start codons) and this contig was later integrated into chromosome 22 (Fig. S11D). Based on these genomic sequences, we amplified *WA* and *WB* cDNAs (for primers, Table S2). After polishing the results, we obtained a single cDNA sequence of *WA* gene and also of *WB* gene, which matched the genomic sequences of *WA* and of *WB* genes, respectively.

2-2-25 Tambaqui (*Colossoma macropomum*)

Tambaqui *WA* and *WB* sequences were found in GGHL01010311 (for partial *WA*) and GGHL01049603 (for *WB*) through tblastn searches with zebrafish WA_13A and WB_13B sequences, respectively using TSA databases of bony fishes. The last part of the obtained WA sequence corresponding to ten amino acid residues is highly divergent compared to those of other closely related species and can be genomic, therefore, this part is not included in Fig. S1D.

**2-3 Lobe-finned fish – coelacanth and lungfish**

2-3-1 African coelacanth (*Latimeria chalumnae*)

At first, *WB* gene was identified in the genome of African coelacanth (34, 35), and then *WA* gene was identified as a gene paired with *WB* gene (Fig. S12A).

African coelacanth *WB* sequence was found to correspond to XM_014491414.1 (Gene ID: 102352955) through tblastn searches with banded houndshark WB_DS3 using the database of nucleotide collection of coelacanth. The sequence of XM_014491414.1 corresponds to a partial β1 domain plus complete β2 domain and CP/TM/CY region. Previously, this β2 domain exon was recognized as MHC class II β chain sequence in the *Mhc* region of African coelacanth (in JH127214.1 as reported in ref. 34). In the present study, complete β1 domain exon was identified in the genomic sequence of NW_005819663.1 (1088 K contig, 1088405 bp, same as JH127214.1 mentioned above). Further, the leader-encoding exon of *WB* was identified in BAHO01266725 (28764 bp).

Next to this *WB* gene in the genome, there exists another incompletely described MHC gene (XM_006000942.2, Gene ID: 102353475, annotated as beta-2-microglobulin-like). Our analyses revealed that this gene has some similarity with *WA* genes of other animals. The sequence of XM_006000942.2 corresponds to the leader, α2 domain and CP/TM/CY regions of an α chain gene of class II-type, *WA*. *WA* α1 domain exon was found between the leader and α2 domain exons through tblastn searches with zebrafish WA_13A using the relevant region within the sequence of NW_005819663.1. African coelacanth *WA* and *WB* genes are present in head to head configuration with respect to the transcriptional orientations and with 2418 bp between the two facing methionine start codons (Fig. S12A).

The expected spliced sequences of African coelacanth *WA* and *WB* genes were found in various SRA sequences, and some of them contain exon-junctions as follows; SRA:DRR002312.90231472.1 of DRX001723 (*WA*, containing the junction between the leader and α1 domain exons), SRA:DRR002317.11828674.2 of DRX001727 (*WA*, α2 domain and CP/TM/CY exons), SRA:DRR002312.69542290.1 of DRX001723 (*WB*, leader and β1 domain exons), SRA:DRR002312.69542290.2 of DRX001723 (*WB*, β1 and β2 domain exons), SRA: DRR002312.139051261.2 of DRX001723 (*WB*, β2 domain and CP/TM/CY exons), SRA:DRR002310.108065773.1 of DRX001721 (*WB*, the first and second junctions within CP/TM/CY exons). Only sequences containing the junction between *WA* α1 and α2 domain exons remain to be found.

2-3-2 Indonesian coelacanth (*Latimeria menadoensis*)

Indonesian coelacanth W-category gene sequences were found in SRA databases as described below.

Indonesian coelacanth *WA* partial sequences were found through tblastn searches with African coelacanth WA_1_01 sequence using SRX189185 (liver transcriptome) of Indonesian coelacanth SRA. Representative sequences are as follows: SRR576100.10484394.2, SRR576100.10484394.1, SRR576100.28293161.2. Indonesian coelacanth *WA* partial sequences were also found using SRX189186 (testis transcriptome). Representative sequences are as follows: SRR576101.33151112.1, SRR576101.9789453.1, and SRR576101.33928550.1.

Indonesian coelacanth *WB* partial sequences were found through tblastn searches with African coelacanth WB_1_01 sequence using SRX189185 (liver transcriptome) of Indonesian coelacanth SRA. Representative sequences are as follows: SRR576100.12524173.1, and SRR576100.12524173.2. Indonesian coelacanth *WB* partial sequences were also found using SRX189186 (testis transcriptome). Representative sequences are as follows: SRR576101.10092538.1, SRR576101.2943170.2, and SRR576101.12703814.2.

2-3-3 West African lungfish (*Protopterus annectens*)

For this animal, SRA datasets were utilized for the initial detection of W-category genes, and then the full-length coding sequence was amplified from cDNA by PCR experiments. Candidate *WA* and *WB* short cDNA sequences of West African lungfish could be obtained through tblastn searches with zebrafish WA_13A and WB_13B using SRA datasets of West African lungfish. We constructed presumed full-length cDNAs of *WA* and *WB* using SRA datasets, starting with short candidate cDNAs (e. g., SRA:SRR2028017.36937414.2 of SRX1016238 for *WA* and SRA:SRR2028017.1854076.1 of SRX1016238 for *WB*). *WA_2_01* and *WB_2_1_01* sequences were amplified from cDNA using presumed gene-specific primers (Table S2) and their complete coding sequences were determined.

West African lungfish *WA_1* partial sequences were found through tblastn searches with South American lungfish WA_1_01 sequence using SRX1016236 (liver RNA) of West African lungfish SRA. Representative sequences are as follows:
SRR2028021.6417444.1, SRR2028021.24594841.1, and SRR2028021.5460576.1.

West African lungfish *WB_1* partial sequences were found through tblastn searches with South American lungfish WB_1_01 sequence using SRX1016236 (liver RNA) of West African lungfish SRA. Representative sequences are as follows:
SRR2028021.33310257.1, SRR2028021.24798137.1, and SRR2028021.30422763.1.

2-3-4 Slender lungfish (*Protopterus dolloi*)

Slender lungfish W-category gene sequences were found in SRA databases as described below.

Slender lungfish *WA_1* partial sequences were found through tblastn searches with South American lungfish WA_1_01 sequence using SRX895335 (pelvic fin RNA) of slender lungfish SRA. Representative sequences are as follows: SRR1823814.10055282.2, SRR1823814.5075596.2, and SRR1823814.13757613.1.

Slender lungfish *WA_2* partial sequences were found through tblastn searches with West African lungfish WA_2_01 sequence using SRX895335 (pelvic fin RNA) of slender lungfish SRA. Representative sequences are as follows: SRR1823814.5579530.2, SRR1823814.9013780.1, and SRR1823814.18055363.1.

Slender lungfish *WB_1* partial sequences were found through tblastn searches with South American lungfish WB_1_01 sequence using SRX895335 (pelvic fin RNA) of slender lungfish SRA. Representative sequences are as follows: SRR1823814.11266724.1, SRR1823814.9260428.1, and SRR1823814.1607136.2.

Slender lungfish *WB_2* partial sequences were found through tblastn searches with West African lungfish WB_2_01 sequence using SRX895335 (pelvic fin RNA) of slender lungfish SRA. Representative sequences are as follows: SRR1823814.20167303.2, SRR1823814.2617696.2, and SRR1823814.20167303.1.

2-3-5 South American lungfish (*Lepidosiren paradoxa*)

South American lungfish *WA* and *WB* sequences were found in GEHZ01032426.1 (for WA_1_01) and GEHZ01040013.1 (for WB_1_01) through tblastn searches with African coelacanth WA_1_01 and WB_1_01 sequences, respectively, using TSA databases of lungfishes.

South American lungfish WA_2 and WB_2 were not found through tblastn searches with West African lungfish WA_2_01 and WB_2_01 sequences, respectively, using TSA databases of lungfishes.

2-3-6 Australian lungfish (*Neoceratodus forsteri*)

The sequence information of Australian lungfish *WA_1*, *WB_1*, *WA_2* and *WB_2* were obtained through the studies using SRA databases and *WA_1* and *WB_2_2* presumed sequences were constructed using SRA sequences as described below.

Australian lungfish *WA_1* partial sequences were found through tblastn searches with South American lungfish WA_1_01 sequence using SRX1823846 (pectoral fin RNA) of Australian lungfish SRA. Representative sequences are as follows:
SRR3632078.33699611.1, SRR3632078.19590582.1, and SRR3632078.19723085.1.

Australian lungfish *WA_1* partial sequences were also found through tblastn searches with South American lungfish WA_1_01 sequence using SRX4952748 (dorsal fin RNA) of Australian lungfish SRA. Representative sequences are as follows:
SRR8131642.15072763.1, SRR8131642.13478427.2, and SRR8131642.2822953.1.

A presumed complete Australian lungfish *WA_1* sequence was constructed using many short partial sequences like those described above and the presumed complete amino acid sequence is included in Fig. S1E.

Australian lungfish *WA_2* partial sequences were found through tblastn searches with West African lungfish WA_2_1_01 sequence using SRX1823846 (pectoral fin RNA) of Australian lungfish SRA. Representative sequences are as follows:
SRR3632078.17728174.2, SRR3632078.16709568.1, and SRR3632078.18029890.1.

Australian lungfish *WB_1* partial sequences were found through tblastn searches with South American lungfish WB_1_01 sequence using SRX1823846 (pectoral fin RNA) of Australian lungfish SRA. Representative sequences are as follows:
SRR3632078.34014254.1, SRR3632078.36687266.1, and SRR3632078.33111091.1.

Australian lungfish *WB_1* partial sequences were also found through tblastn searches with South American lungfish WB_1_01 sequence using SRX4952748 (dorsal fin RNA) of Australian lungfish SRA. Representative sequences are as follows:
SRR8131642.6755488.1, SRR8131642.3977539.2, and SRR8131642.15778735.2.

Australian lungfish *WB_2_1* partial sequences were found through tblastn searches with West African lungfish WB_2_1_01 sequence using SRX1823846 (pectoral fin RNA) of Australian lungfish SRA. Representative sequences are as follows:
SRR3632078.37409092.1, SRR3632078.15581747.2, and SRR3632078.24092841.2.

Australian lungfish *WB_2_2* partial sequences were found through tblastn searches with West African lungfish WB_2_1_01 sequence using SRX1823846 (pectoral fin RNA) of Australian lungfish SRA. Representative sequences are as follows:
SRR3632078.38307413.1, SRR3632078.35894717.1, and SRR3632078.35767306.1.

A presumed complete Australian lungfish *WB_2_2* sequence was constructed using many short partial sequences like those described above and the presumed complete amino acid sequence is included in Fig. S2E.

**2-4 Tetrapods – salamanders**

Extant amphibians belong to the subclass Lissamphibia which contains the order Anura (e.g., frogs), the order Urodela (e.g., salamanders) and the order Gymnophiona (e.g., caecilians). Thus far, W-category genes were identified in salamanders. Within the order Urodela, two suborders, Cryptobranchoidea and Salamandroidea, diverged from each other earlier than 157 MYA (68). Both Chinese salamander and Hokkaido salamander belong to the same genus *Hynobius* of the family Hynobiidae within the suborder Cryptobranchoidea (which also includes giant salamander). Tiger salamander belongs to Salamandroidea (which also includes axolotl and cynops).

2-4-1 Chinese salamander (*Hynobius chinensis*)

Chinese salamander *WA* sequences were found in GAQK01112360 (for the leader and partial α1 domain) and GAQK01026695 (for the partial α2 domain and CP/TM/CY region) through tblastn searches with tiger salamander WA_01 sequence using TSA databases of amphibians. GAQK01112360 and GAQK01026695 are derived from mRNA of whole body of Chinese salamander larvae. Candidate sequences of the missing last part of the α1 domain and the beginning of the α2 domain were obtained from SRA sequence reports (e. g., SRA:SRR1042328.36645099.2 of SRX386518 and SRA:SRR1042328.25098594.1 of SRX386518). For Fig. S1F, we combined two TSA sequences GAQK01112360 and GAQK01026695, and the sequence between these two came from the SRA sequences.

Chinese salamander *WB* sequences were found in GAQK01101790 (for the leader and the beginning of the β1 domain) and GAQK01119707 (for the partial β1 domain plus β2 domain and partial CP/TM/CY region) through tblastn searches with tiger salamander WB_01 sequence using TSA databases of amphibians. A region corresponding to four amino acid residues is overlapped by these two sequences. Sequences corresponding to the expected last five amino acids are missing in GAQK01119707. For Fig. S2F, we combined the two TSA sequences, GAQK01101790 for the leader plus the beginning of the β1 domain, and GAQK01119707 for the rest of the molecule except the last part.

2-4-2 Hokkaido salamander (*Hynobius retardatus*)

Hokkaido salamander *WA* and *WB* sequences were found in LE079167.1 (including a complete coding sequence of WA) and LE079819.1 (including a complete coding sequence of WB) through tblastn searches with tiger salamander WA_01 and WB_01 sequence, respectively, using TSA databases of amphibians. LE079167.1 and LE079819.1 are derived from mRNA of mixture of brain, gill, head and tail of Hokkaido salamander larvae.

2-4-3 Tiger salamander (*Ambystoma tigrinum*)

Identifications of tiger salamander *WA* and *WB* genes are described below.

A candidate sequence of partial tiger salamander *WA* gene was found in CN053477 through tblastn searches with zebrafish WA_13A using est database of amphibians. 5'- and 3'-RACE reactions were conducted with the primers based on this sequence and with RNA of tiger salamander. Using 5'- and 3'-UTR gene-specific primers, two complete coding sequences (*WA_01* and *WA_02*) were amplified from a single individual, which may be alleles (Fig. S1F).

A candidate sequence of salamander *WB* gene was found in Isotig_96288 through tblastn searches with zebrafish WB_13B sequence using the transcriptome of *Ambystoma mexicanum* (assembly V4.0-Isotigs + Singletons) at the Sal-Site (*Ambystoma* research resource development: R24OD010435). 5'- and 3'-RACE reactions were conducted with primers based on the central part of the genomic sequences of a presumable WB β2 domain exon of tiger salamander, which had been isolated with the information of Isotig_96288. Using 5'- and 3'-UTR gene-specific primers, two complete coding sequences (*WB_01* and *WB_02*) could be amplified from a single tiger salamander individual, which may be alleles (Fig. S2F).

2-4-4 Axolotl (*Ambystoma mexicanum*)

Axolotl *WA* and *WB* sequences were found in GFZP01140229 (including α2 domain and CP/TM/CY region of WA) and GFZP01045381 (including a complete coding sequence of WB) through tblastn searches with tiger salamander WA_01 and WB_01 sequence, respectively, using TSA databases of amphibians.

Axolotl *WA* and *WB* sequences were also found in PGSH01013846 ("5397 K contig", 5397334 bp DNA; head to head configuration with respect to the transcriptional orientations; 536 bp between the two methionine-coding start codons) through tblastn searches with tiger salamander WA_01 and WB_01 sequences using wgs databases of *Ambystoma mexicanum* (Fig. S12B). In this sequence, the leader, the α2 domain exon and the CP/TM/CY region of *WA*, and the leader, the β1 and β2 domain exons and the partial CP/TM/CY region of *WB* could be identified. In this *WA* gene sequence, no α1 domain exon, deletions of four nucleotides in the α2 domain exon, and a deletion of a single nucleotide in the second exon of CP/TM/CY region, were recognized. In *WB* gene sequence, the sequences of the last part corresponding to twenty amino acid residues, are missing. A complete α1 domain exon of *WA* was found in PGSH01122872 (57652 bp) by tblastn searches using wgs

databases of *Ambystoma mexicanum* with tiger salamander WA_01 sequence. The DNA sequences of the surrounding regions of *WA* α1 domain exon found in PGSH01122872 partially correspond to the sequences present in PGSH01013846.1 and some repetitive sequences were recognized in these contigs, which may have produced sequencing difficulty.

For WA sequence in Fig. S1F, the leader sequence of PGSH01013846, the α1 domain sequence from PGSH01122872 and the α2 domain and CP/TM/CY region from GFZP01140229 were combined. For WB sequence in Fig. S2F, WB_01 sequence from GFZP01045381 was used.

Based on the latest information, the two genomic sequences mentioned above (PGSH01013846 and PGSH01122872) were replaced by PGSH00000000.2. However, W-category sequences could not be found in the newer axolotl wgs databases (JXRH01 and PGSH02), possibly because they may be still included in the unplaced regions and therefore not included in the chromosomal regions. As axolotl *WA* sequences were found in GFBM010788916.1 (length 1045, *WA*α1 and first half of α2, second half of α2 and CP/TM/CY portion) and GFBM010763839.1 (length 3323, *WA* leader portion) through tblastn searches using TSA databases of *Ambystoma mexicanum*, we present Fig. S12B as a useful reference.

## 3. Southern blot analyses of the banded houndshark *W-category* genes

Because many banded houndshark W-category gene sequences were determined using the banded houndshark individual N1, the Southern blot analyses using DNA of the banded houndshark individual N1 is shown in Fig. S3. In the linkage experiments of Fig. S9, the results of Southern blot analyses were shown with the probes of banded houndshark *WA_DS5*, *WB_DS1* and *WB_DS3* using banded houndshark individuals different from N1 and also using different restriction enzymes. The following numbers of loci (in parentheses) are consistent with the results of Southern blot analyses presented in Figs. S3 and S9: banded houndshark *WA_DS5* (3), *WA_DS10* (1), *WB_DS1* (2), *WB_DS3* (1) and $\beta_2$-*m* (1).

In Fig. S10, the uncropped versions of the Southern blots used in Fig. S9 are shown to indicate that there are no additional positive bands in the blots.

## 4. Banded houndshark *W-category* genes are expressed in various tissues

The expression of the banded houndshark *W-category* genes was studied using RT-PCR.

Essentially, both *WA* (*WA_DS5* and *WA_DS10*) and *WB* genes (*WB_DS1_n1* and *WB_DS3*) are expressed in spleen, liver and kidney as shown in Fig. S4. The expression of *WA_DS5* was also detected in blood.

As described in the section 2, cDNA of W-category genes could be isolated from various animals; banded houndshark (kidney, spleen and liver), goldfish (gill), zebrafish (an anterior half of the body), Mexican tetra (gill), West African lungfish (kidney) and tiger salamander (internal organs). Further we could detect W-category cDNA sequences in various transcriptomic databases. Therefore, currently identified W-category genes may be expressed in multiple tissues although W-category subgroup-specific expression patterns might not be excluded and could be observed after further analyses.

## 5. Variation of W-category molecules

In the following sections, general observations about variation of W-category molecules are described. When appropriate data are available, the extent of presumable allelic polymorphism is discussed, since the classical MHC molecules are known to possess extremely high allelic polymorphism in their peptide-binding domains (i.e. membrane-distal domains) and it should be important to know whether W-category molecules also possess such property. Although based on limited information, the available results suggest that the membrane-distal domains of W-category molecules do not possess high allelic polymorphism.

### 5-1 Variation among W-category molecules in sharks

Banded houndshark possesses two kinds of WA, namely WA_DS5 and WA_DS10, and two kinds of WB, namely WB_DS1 and WB_DS3. In some other cartilaginous fishes, in addition to these, WA_Nds3L and WB_Nds5L are also identified.

Selected amino acid identity % are as follows:
Between banded houndshark WA_DS5_n1 and banded houndshark WA_DS10, 16 % for α1 domain and 31 % for α2 domain.
Between banded houndshark WA_DS5_n4 and banded houndshark WA_DS10, 17 % for α1 and 33 % for α2.
Between banded houndshark WA_DS5_n1 and great white shark WA_Nds3L, 10 % for α1 and 36 % for α2.
Between banded houndshark WA_DS10 and great white shark WA_Nds3L, 12 % for α1 and 33 % for α2.

Between banded houndshark WA_DS5_n1 and great white shark WA_DS5-like, 84 % for α1 and 79 % for α2.
Between banded houndshark WA_DS5_n4 and great white shark WA_DS5-like, 52 % for α1 and 78 % for α2.
Between banded houndshark WA_DS10 and great white shark WA_DS10-like, 56 % for α1 and 64 % for α2.
Between blue shark WA_Nds3L and great white shark WA_Nds3L, 47 % for α1 and 56 % for α2.

Between banded houndshark WB_DS1_n1 and banded houndshark WB_DS3, 13 % for β1 and 40 % for β2.
Between banded houndshark WB_DS1 and great white shark WB_Nds5L, 14 % for β1 and 31 % for β2.
Between banded houndshark WB_DS3 and great white shark WB_Nds5L, 15 % for β1 and 26 % for β2.

Between banded houndshark WB_DS1_n1 and great white shark WB_DS1-like, 48 % for β1 and 78 % for β2.
Between banded houndshark WA_DS3 and great white shark WA_DS3-like, 64 % for β1 and 66 % for β2.
Between blue shark WB_Nds5L and great white shark WB_Nds5L, 63 % for β1 and 73 % for β2.

Variation observed in banded houndshark WA_DS5
As shown in Fig. S1A, four kinds of *WA_DS5* cDNA could be identified from the banded houndshark individual N1, namely *WA_DS5_n1_01*, *n2_01*, *n3_01* and *n4_01*. WA_DS5_n1_01, n2_01 and n3_01 possess α1 domains highly similar to each other while WA_DS5_n4_01 possesses a highly distinct one (amino acid identity % = 47 ~ 48 % between n1_01/n2_01/n3_01 and n4_01). Regarding the leader, α2 domain and CP/TM/CY region, all four possess highly similar sequences (identity = 95 ~ 99 %). Based on our preliminary genomic analyses, *WA_DS5_n4_01* may be situated at a locus (loci) distinct from those of *WA_DS5_n1_01*, *n2_01* and *n3_01*. Therefore, currently it is assumed that the variation observed between WA_DS5_n4_01 and WA_DS5_n1_01/n2_01/n3_01 is not allelic polymorphism but variation observed between distinct loci, although further studies should be necessary to clarify relationships among various WA_DS5 members.

Variation observed in banded houndshark WA_DS10
As described in section 2-1-1-2, two kinds of cDNA of *WA_DS10* were identified from the banded houndshark individual N1. The difference between the two sequences is ascribed to a single nucleotide (C or T) of the third nucleotide position of a codon in the α2 domain exon, which does not alter the encoded amino acid. This difference was confirmed with multiple clones of independent PCR reactions and also with direct sequencing of the PCR products as described in the Materials and Methods. From the simple pattern of Southern blot results (Figs. S3 and S9), and also from the specific amplification of these cDNAs using 5'- and 3'-UTR primers, it follows that these cDNAs presumably represent allelic sequences.

Variation observed in banded houndshark WB_DS1
As shown in Fig. S2A, two kinds of cDNA of banded houndshark *WB_DS1_n1* were identified from the banded houndshark individual N1. These presumably constitute allelic sequences of the *WB_DS1_n1* locus. The two sequences show disparity at only two amino acid positions in the membrane-distal β1 domain. The

expression of another *WB_DS1* gene, *WB_DS1_n2*, seems very much limited, as it was only found in an unusual transcript described in the section (2-1-1-2) of banded houndshark *WA_DS10*.

Variation observed in banded houndshark WB_DS3

As shown in Fig. S2B, thus far two kinds of sequences of banded houndshark *WB_DS3* were obtained from different individuals, *WB_DS3_01* from banded houndshark individual N2 and *WB_DS3_02* from individual N1. The two sequences show disparity at only two amino acid positions in the Ig-like domain and the CY region and no difference is observed in their membrane-distal β1 domains.

**5-2 Variation among W-category molecules in teleost fish**

5-2-1 Variation and similarity among W-category molecules in teleost fish

Thus far, in ray-finned fish, W-category genes can be identified in the teleost fish group. Generally, W-category molecules of the teleost fish group share pronounced features as shown in the phylogenetic tree (Fig. 7) and amino acid sequence comparisons (Figs. S1 and S2). Within the teleost fish group, the order Clupeiformes (e.g., Atlantic herring and allis shad) is estimated to have diverged from the superorder Ostariophysi (e.g., zebrafish and Mexican tetra) around 261 MYA (240-282 MYA; ref. 61). Teleost fish WA and WB sequences can be relatively well aligned within each group and amino acid identity percentages between the W-category molecules of Atlantic herring and Mexican tetra are obtained as follows: WA α1, 59 %; WA α2 60 %; WB β1 63 %; WB β2 57 %. As an example of comparison between closely related species, amino acid percentages between the W-category molecules of zebrafish and fathead minnow, both belonging to the family Cyprinidae, are as follows: WA α1, 79 %; WA α2 80 %; WB β1 77 %; WB β2 73 %.

Below, variations of W-category molecules in zebrafish and Chinese cavefish (both belonging to the family Cyprinidae) are described .

5-2-2 Inspection of allelic polymorphism of W-category molecules in zebrafish

To investigate possible presence of high polymorphism in the membrane-distal domains of the W-category molecules of zebrafish, variation of those domains was studied using four different strains of zebrafish with unknown relationships. Using RT-PCR method, the expressed W-category sequences were amplified from an individual zebrafish of four different strains (AB, India [IND], TL and WIK) (zebrafish WA_01~05 and zebrafish WB_01~05; Fig. S19, A and B). Analyzing five or more clones of amplified fragment per gene per zebrafish individual, two sequences were obtained from a single individual at most (Fig. S19C). Because only a single pair of *WA/WB* genes can be detected in the genome of zebrafish (Fig. S11E), each obtained sequence can be assumed to be derived from a single locus, *WA* or *WB*. Very limited variation both in the membrane-distal domain of WA (Fig. S19A) and in the membrane-distal domain of WB (Fig. S19B) was observed. It is concluded that both zebrafish WA and WB molecules exhibit very limited allelic polymorphism in the membrane-distal domains (WA α1 and WB β1).

5-2-3 Variation of W-category molecules among closely related species of Chinese cavefish

In the Chinese cavefish, *Sinocyclocheilus*, several W-category sequences can be detected. Chinese cavefish WA sequences can be classified into two, A1 and A2, based on similarity with the common carp WA_A1 and WA_A2 sequences, respectively (Fig. S20A). Similarly, Chinese cavefish WB sequences can be classified into two, B1 and B2, based on similarity with the common carp WB_B1 and WB_B2 sequences, respectively (Fig. S20B). In the common carp contig, *WA_A1* and *WB_B1* exist as a pair and are situated very close to each other. In another common carp contig, *WA_A2* and *WB_B2* similarly exist as a pair. Inspecting the Chinese cavefish contigs, we confirmed that Chinese cavefish *WA_A1* and *WB_B1* constitute a pair, and *WA_A2* and *WB_B2* constitute another pair. With these Chinese cavefish sequences, sequences of different but closely related three species of Chinese cavefish could be compared at the same locus. Even between different species of *Sinocyclocheilus*, only a limited amount of variation could be observed in the membrane-distal domains of WA and WB sequences as shown (Fig. S20).

**5-3 Variation among W-category molecules in lobe-finned fish**

In lungfish, currently two major subgroups of WA molecules were identified: WA_1 and WA_2.
Amino acid identity % are as follows:
Between South American lungfish WA_1 and Australian lungfish WA_1, 40 % for α1 domain and 70 % for α2 domain.
Between South American lungfish WA_1 and West African lungfish WA_2, 19 % for α1 and 35 % for α2.
Between Australian lungfish WA_1 and West African lungfish WA_2, 19 % for α1 and 33 % for α2.

As African coelacanth WA molecule shares some specific amino acid residues with South American lungfish and Australian lungfish WA_1 molecules (Fig. S1E), African coelacanth WA molecule is temporarily classified as WA_1 subgroup.
Amino acid identity % are as follows:
Between South American lungfish WA_1 and African coelacanth WA_1, 22 % for α1 domain and 39 % for α2 domain.
Between Australian lungfish WA_1 and African coelacanth WA_1, 33 % for α1 and 43 % for α2.
Between African coelacanth WA_1 and West African lungfish WA_2, 13 % for α1 and 32 % for α2.

In lungfish, currently two major subgroups of WB molecules were identified: WB_1 and WB_2. Temporarily, WB_2 can be further classified into two groups: WB_2_1 and WB_2_2.
Amino acid identity % are as follows:
Between South American lungfish WB_1 and West African lungfish WB_2_1, 18 % for β1 domain and 32 % for β2 domain.
Between South American lungfish WB_1 and Australian lungfish WB_2_2, 18 % for β1 and 29 % for β2.
Between West African lungfish WB_2_1 and Australian lungfish WB_2_2, 37 % for β1 and 58 % for β2.

As African coelacanth WB molecule shares some specific amino acid residues with South American lungfish WB_1 molecule (Fig. S2E), African coelacanth WB molecule is temporarily classified as WB_1 subgroup.
Amino acid identity % are as follows:
Between South American lungfish WB_1 and African coelacanth WB_1, 22 % for β1 domain and 47 % for β2 domain.
Between West African lungfish WB_2_1 and African coelacanth WB_1, 15 % for β1 and 32 % for β2.
Between Australian lungfish WB_2_2 and African coelacanth WB_1, 18 % for β1 and 32 % for β2.

As already described in the previous section 2-3 and summarized in Table S1, WA_1 sequence could be identified in West African lungfish, and WA_2 sequence could be identified in Australian lungfish based on the investigation using SRA databases. Similarly, WB_1 sequence could be identified in West African lungfish and also in Australian lungfish, WB_2_1 sequence could be identified in Australian lungfish, and WB_2_2 sequence could be identified in West African lungfish.

**5-4 Variation among W-category molecules in salamanders**

Between the Chinese salamander and the Hokkaido salamander, which both belong to the same genus *Hynobius*, only a small number of amino acid differences could be observed in the membrane-distal domains (96 % amino acid identity for WA and 97 % for WB).

Between the two suborders, Salamandroidea and Cryptobranchoidea, W-category molecules exhibit a relatively divergent nature in their membrane-distal domains while they exhibit more conserved nature in the Ig-like domains as shown in Figs. S1 and S2. For example, the amino acid identity percentages between tiger salamander WA_01 (Salamandroidea) and Hokkaido salamander (Cryptobranchoidea) WA_01 are as follows: 52 % in WA α1 domain and 76 % in WA α2 domain. Those between tiger salamander WB_01 and Hokkaido salamander (Cryptobranchoidea) WB_01 are as follows: 35 % in WB β1 domain and 64 % in WB β2 domain.

From a single individual tiger salamander, presumed alleles of two WA and also presumed alleles of two WB sequences could be isolated as shown in Figs. S1 and S2. In the membrane-distal domains, they show a small number of amino acid differences (95 % amino acid identity for WA and 98 % for WB).

## 6. Conserved features at the Iα3/$\beta_2$-m interface

Iα3 P57 and $\beta_2$-m Y8 are highly conserved in class I molecules at the Iα3/$\beta_2$-m interface (e. g., human, 1DLH of PDB ID; mouse, 2VAA; chicken, 3BEV; and grass carp, 5Y91) and these residues are highly conserved at the corresponding positions of W-category molecules (in the WB β2 domain and WA α2 domain). In Fig. S6A, the positions of Iα3 P57 and $\beta_2$-m Y8 in HLA-A2, which interact through a hydrogen bond, are shown at the Iα3/$\beta_2$-m interface. In Fig. S6B, the corresponding interface in the MHC class II molecule, namely, the IIBβ2/IIAα2 interface is shown. Although some class II molecules possess Y8 in IIAα2, there is no conserved P57 in IIBβ2 (Fig. 3; Dataset S2).

## 7. $\beta_2$-m K67 can form an intra-domain hydrogen bond

$\beta_2$-m K67 is one of the amino acid residues shared between the WA α2 domain and $\beta_2$-m, which are shaded in red color in Fig. 3 and Dataset S2. Because phylogenetically relatively primitive jawed vertebrates such as grass carp possess a lysine (K) at this position in their $\beta_2$-m molecules, the structural features of $\beta_2$-m K67 can be studied for grass carp $\beta_2$-m (69) (PDB: 3GBL and 5Y91; Fig. S7). As reported previously (69), a hydrogen atom from the ε-amino group of grass carp $\beta_2$-m K67 forms hydrogen bonds with a main chain carbonyl oxygen of $\beta_2$-m I35 [Fig. S7A, length of hydrogen bond = 2.75 Å] and also with a γ-carboxyl oxygen of $\beta_2$-m E36 [Fig. S7B, length of hydrogen bond = 3.54 Å]. At position 35 of the WA α2 domain and also of $\beta_2$-m, an isoleucine (I) is often replaced by other amino acid residues. Because a main chain carbonyl oxygen is involved in the hydrogen bonds between $\beta_2$-m I35 and $\beta_2$-m K67, the conservation of this hydrogen bond is assumed in the WA α2 domain as well as in $\beta_2$-m of other phylogenetically relatively primitive vertebrates. In addition, as seen in Fig. S7, grass carp $\beta_2$-m L37, which also corresponds with residues shaded in red color in the $\beta_2$-m and WA α2 domain sequences (Fig. 3 and Dataset S2), is positioned close to $\beta_2$-m K67 in the three-dimensional structure (69). It is notable that the classical class I α3 domain of all cartilaginous fish (Dataset S2) possess both I α3L37 and I α3K/R68, and independent acquisitions of L37 plus K/R68 might have occurred in $\beta_2$-m and in the classical class I α3 domain of cartilaginous fish.

## 8. Linkage between the banded houndshark *$\beta_2$-m* gene and the *Mhc* region

The banded houndshark *$\beta_2$-m* gene was isolated using PCR based on information of cartilaginous *$\beta_2$-m* genes, and has been deposited in GenBank (HQ630063 for the *Triakis scyllium* $\beta_2$-m mRNA and HQ634972 for the *Triakis scyllium $\beta_2$-m* gene). The primer sequences for the amplification of the transcript of *$\beta_2$-m* are listed in Table S2.

Linkage analysis was conducted using a previously described panel of seventeen littermate sharks (17). The PCR products (~3.8 kb) of banded houndshark *$\beta_2$-m* gene, amplified with two primers (F11 and R10, Table S2), were digested with the restriction enzyme, *Mbo*II, to detect distribution of allelic variation among the littermates and their mother.

Figure S15A shows an additional band in six samples, indicated with an arrow. Classification with or without the additional band is in complete concordance with the haplotype classification obtained for the classical MHC genes (Fig. S9; 17). This pattern also matches those reported for complement *C4* and *Bf* genes of banded houndshark which were concluded to be linked with the classical MHC genes (70). Using sample No. 12, the region of interest was sequenced (Fig. S15B) and seven nucleotides were revealed as responsible for the additional band.

In conclusion, the results indicate that the banded houndshark *$\beta_2$-m* gene is linked with the *Mhc* region, as reported previously for nurse shark (28).

**9. Specific interaction between WA and WB**

As W-category *WA* and *WB* genes are present close to each other as a pair in the genome of sharks, teleost fish, coelacanth and salamander like MHC class II genes (Figs. S11 and S12; *SI Appendix*), the protein products of these genes are expected to form a heterodimer (2, 3). Both classical MHC class I and class II molecules form a heterodimer in the endoplasmic reticulum, and after they bind appropriate peptide ligands at their respective intracellular locations, they are transported and expressed on the cell surface. Although it is not clear whether W-category molecules bind any ligands, which might be necessary for stabilization and efficient transport, possible intracellular processing and cell surface expression of recombinant W-category proteins of tiger salamander was investigated using Western blotting and flow cytometry. Total protein lysates of the cells used for the flow cytometry experiments were also analyzed by Western blotting. The results shown in Fig. 6 and Figs. S13 and S14 are representatives of several independent experiments with similar results.

*Processing of recombinant α and β chain proteins of a tiger salamander W-category molecule*

Figure 6 confirmed the production of recombinant WA (Fig. 6A) and WB (Fig. 6B) proteins by transfected cells. Further, apparent higher molecular weight species were observed only when both WA and WB of tiger salamander were simultaneously introduced into cells [Fig. S6A (d) for WA; Fig. S6B (d) for WB], compared to the controls [Fig. S6A (b) and (f) for WA; Fig. S6B (c) for WB]. The apparent size differences can be ascribed to different N-glycosylations of proteins as shown by the digestion of the samples with Endo H [Fig. 6C (b) and (d)] or GPF [Fig. 6D (b) and (d)]. In case of the transfectants with both WA and WB of tiger salamander, the WA protein fractions of relatively lower molecular weight could be digested with Endo H while the protein fractions of higher molecular weight could not be [Fig. 6C (d)], suggesting that those undigested proteins possess an Endo H-resistant complex glycan structure. This was confirmed by the experiments which showed that those proteins of higher molecular weight actually could be digested with GPF [Fig. 6D (d)]. In contrast, in the controls in which tiger salamander WA plus empty PA vector [Fig. 6C (b)] or tiger salamander WA plus Mexican tetra WB [Fig. 6C (f)] were present, all WA proteins could be digested with Endo H. Regarding the additional band of higher molecular weight of WB protein detected in Fig. 6B (d), this particular band became obscure (possibly due to protein aggregation) with a digestion protocol without addition of enzymes (mock treatment) (Fig. S14). Therefore, in case of WB proteins, a conclusion could not be drawn about its detailed glycosylation state.

Thus, when both WA and WB of a tiger salamander were introduced into cells, the molecular species of higher molecular weight were observed for both WA and WB. In case of WA, these molecular species were apparently produced by the advanced glycosylation processing.

For the possible N-glycosylation sites, the following multiple asparagines could be mentioned solely based on the sequence information of tiger salamander WA_01 and WB_01:

WAα1, N26, N119 (numbers are based on Dataset S1); WAα2, N60, N97 (based on Dataset S2); WA CP region, N14 (based on Dataset S3); WBβ2, N34, N60, N97 (based on Dataset S2).

*Cell surface expression of recombinant α and β chain proteins of a tiger salamander W-category molecule*

Figure 6E and F shows that the recombinant WA (α chain) and WB (β chain) of a tiger salamander W-category molecule could be observed on the cell surface only when these two chains were simultaneously introduced into cells. Namely, for the detection of α chains, low but reproducible binding of anti-FLAG antibody to FLAG-tagged WA on the cell surface could be observed only in the presence of both tiger salamander WA and WB [Fig. 6E (d)] in contrast to the controls in which tiger salamander WA plus empty PA vector [Fig. 6E (b)] or tiger salamander WA plus Mexican tetra WB [Fig. 6E (f)] were introduced. For the detection of β chains, significant binding of anti-PA antibody to PA-tagged WB on the cell surface could be observed only in the presence of both tiger salamander WA and WB [Fig. 6F (d)] in contrast to the controls in which empty FLAG vector plus tiger salamander WB [Fig. 6F (c)] or tiger salamander WA plus Mexican tetra WB [Fig. 6F (f)] were introduced.

Taken together, both the recombinant WA and WB proteins of a tiger salamander W-category molecule were processed differently from controls and could be detected on the cell surface, only when these two tiger

salamander chains were simultaneously introduced into cells. These results indicate a specific interaction between recombinant WA and WB chains of a tiger salamander W-category molecule.

## 10. Conservation profile of the teleost fish W-category membrane-distal domains and molecular modeling of the extracellular domains of W-category molecule

### 10-1 The teleost fish W-category membrane-distal domains show a unique conservation profile

To gain insight into the nature of W-category molecules, the conservation profile was investigated in the membrane-distal domains of teleost fish W-category molecules. The membrane-distal domains of the classical MHC class I and class II molecules are known to be highly polymorphic and critically responsible for peptide ligand-binding. The present investigation became possible because a large number of sequences of the teleost fish W-category genes could be identified from various fish species.

More than twenty sequences of WA and WB were compared (Figs. S1 and S2) and the Wu-Kabat variability (described in the Materials and Methods) was calculated (Table S4). Originally Wu-Kabat variability was used to study the variable nature of immunoglobulins, but later also used to study the polymorphic nature of the membrane-distal domains of MHC molecules (e. g., 17, 71, 72). The conservation profile, i. e., the patterns of positions of highly conserved and variable residues were found to be remarkably similar between the teleost fish W-category molecules and MHC-Z molecules (Fig. S21). MHC-Z molecules are ancient nonclassical class I molecules which possess most of the peptide-termini-binding amino acid residues of the classical MHC class I molecules; compared to most classical MHC class I molecules in non-mammalian jawed vertebrates, they possess seven out of eight such residues, although their possible (peptide) ligand(s) has not been clarified yet (36-38). In contrast, these eight amino acid residues are not conserved in the teleost fish W-category molecules (Fig. S21). Previously, the positions of the conserved residues among MHC-Z molecules have been revealed to correspond to the peptide-binding positions of the classical MHC class I molecules (38). In the present study, the positions of conserved residues among the teleost fish W-category molecules (Table S4) were found to correspond to those of peptide-binding residues of the classical MHC class I molecules and also of the classical MHC class II molecules (Fig. S21). Based on Fig. S21 and the structure of HLA-A2, the hypothetical membrane-distal domains of the teleost fish W-category molecule are shown in Fig. S22. More than 80 % of the peptide binding positions of the HLA-A2 molecule correspond to highly conserved positions of the teleost fish W-category molecules (Figs. S21 and S22). In the α-helical regions, many positions of the HLA-A2 residues that point away from the binding groove (25) correspond to highly variable residues in the teleost fish W-category molecules (Fig. S22 and Table S4).

The present study suggests that the teleost fish W-category subgroup molecules may bind some conserved ligands in their presumed groove, although in the teleost fish W-category molecules, neither the eight amino acid residues of the classical MHC class I molecules which interact with the peptide termini of a bound peptide nor the four amino acid residues of the classical MHC class II molecules which interact with the main chain residues of a bound peptide are conserved (Fig. S21).

### 10-2 Molecular modeling of the extracellular domains of W-category molecule

For the prediction of the protein structure of the W-category molecules, we used protein modeling tools such as Phyre2 (90) and SWISS-MODEL (91), although there exist various limitations for such analyses. We briefly show here some selected results obtained with Phyre2 and SWISS-MODEL, and compared to our predicted alignment and structure (Figs. S21 and S22) of the membrane-distal domains of the teleost fish W-category molecule which was obtained based on the conservation profile.

For both protein modeling softwares, we used five query sequences.

1. allis shad WA α1 (a single domain)
2. allis shad WA α2 (a single domain)
3. allis shad WA all (a whole sequence including signal peptide and CP/TM/CY regions)
4. allis shad WB all (a whole sequence including signal peptide and CP/TM/CY regions)

5. allis shad WA α1 + WB β1β2 (artificially combined three-domains sequence)

Further, for SWISS-MODEL, we used the following sequences for hetero oligomeric protein analyses.
6. allis shad WA all / WB all (two sequences, four extracellular domains, class II-type model)
7. allis shad (WA α1 + WB β1β2) / WA α2 (two sequences, four extracellular domains, class I-type model)

In the last part of this section, we present the following results obtained with the modeling programs in this order.

## Representative results of the modeling analyses using Phyre2 or SWISS-MODEL
## Representative results of the 3D modeling in the Phyre2 analyses
## Representative results of the alignments in the Phyre2 analyses
## Representative results of the 3D modeling in the SWISS-MODEL analyses
## Representative results of the alignments in the SWISS-MODEL analyses

10-2-1 Overall comparison

Phyre2 and SWISS-MODEL produced multiple predicted structural models of the teleost fish W-category molecule. The models of the teleost fish W-category molecule are basically similar to those of the classical MHC class I and also to those of the classical MHC class II molecules. In the two membrane-proximal Ig-like domains, namely, WA α2 and WB β2 domains, especially high similarity and highly probable alignments were obtained in various model cases. In the membrane-distal domains, highly probable alignment in WB β1 domain were obtained whereas especially the second half of the WA α1 domain (namely, α-helix region) showed variations.

With the [allis shad WB all] sequence or with the [allis shad WAα1WBβ1β2] sequence as a query sequence, the α2 and α3 domains of various class I sequences were obtained as templates for the corresponding WBβ1β2 sequence. The alignment for the WB β1 sequence including the α-helix region is highly similar between those obtained with the models (both Phyre2 and SWISS-MODEL) and that of Fig. S21. Therefore, the proposed alignment shown in Fig. S21 was basically similar to the models except for the α-helix region of WA α1 domain. Further, even for WA α1 domain, some models showed the alignments similar to that of Fig. S21 in the α-helix region to some extent. One example was obtained in the following model, in which the consecutive 28 amino acid positions of the last part of the WA α1 domain are consistent with the alignment of Fig. S21: allis shad WA all / WB all, SWISS-MODEL No. 1 template 3pdo.1 Human MHC class I HLA-DR1 (class II-type model).

If the two presumed α-helix structures are reasonably apart from each other and there exists a “groove”, some conserved ligand may be expected. As described above, W-category molecule possesses neither the eight amino acids highly conserved in the classical MHC class I for the binding to the bound peptide termini nor the four amino acids highly conserved in the classical MHC class II for the binding to the main chain of a bound peptide. However, W-category could bind a peptide with the principle different from the classical MHC class I and also different from the classical MHC class II. Clarification of possible ligand(s) including peptides remains to be investigated.

10-2-2 Molecular modeling of the inter-domain interfaces of W-category molecule

In the model of [allis shad WA all/WB all] and [allis shad (WAα1 +WBβ1β2/WAα2)], amino acid residues like WAα2W61 and Y57 can be found in the interface between WAα1/WBβ1 and WAα2 domains (in the pictures shown below). This has been expected because α1 and α2 domains of class II molecule superimpose closely on the corresponding α1 domain and the $\beta_2$-m, respectively, of class I, and β1 and β 2 domains of class II superimpose on the α2 and less closely on the α3, respectively, of class I, as described by Brown et al. (27), and in our analyses, [allis shad WA all/WB all] sequence has class II-type domain architecture and [allis shad (WAα1 + WBβ1β2/WAα2)] sequence has class I-type domain architecture. However, the existence

of those amino acid residues like W61 in the relevant interface, should be checked with the model, which can consider structural distortions, unfavorable interactions and clashes.

In the class I molecules, $\beta_2$-m W61 interacts with $\alpha$2Q6 and $\alpha$2D37 through hydrogen bonds. Although in the class II-type model of [allis shad WA all/WB all], the oxygen of WB$\beta$1D37 is not close to the nitrogen of WA$\alpha$2W61, they are very closely located to each other in the class I-type model of [allis shad (WA$\alpha$1 +WB$\beta$1$\beta$2/WA$\alpha$2)]. In both models, however, the nitrogen of WB $\beta$1Q6 is very close to the oxygen of main chain of WA$\alpha$2W61. For the modeling of W-category molecule, class I-type modeling appear to produce a better model with respect to the domain-interfaces.

In the $\alpha$3/ $\beta_2$-m interface of a class I molecule, $\beta_2$-m Y8 interacts with $\alpha$3P57 through hydrogen-bonding. In the corresponding WB$\beta$2/ WA$\alpha$2 interface of the model, WB$\beta$2P57 can also be found in the positions very close to WA$\alpha$2Y8 in case of class I-type model and not class II-type model.

Apparently, currently there is no highly appropriate template for the modeling which fulfills requirements for both domain architecture and domain-interfaces.

Future structural determination of W-category molecules should reveal the details of the inter-domain interfaces and the structure of the membrane-distal domains, and further possible ligand(s).

## Representative results of the modeling analyses using Phyre2 or SWISS-MODEL

Some explanations in the softwares:

"Rank" in Phyre2 means that "models are ranked according to raw alignment score".

"Confidence" in Phyre2 is "the probability that the query sequence and the template are homologous".

"GMQE" in SWISS-MODEL means "Global Model Quality Estimate".

Numbers in red, shown in the columns of "Rank" or "No.", indicate the modeling results with the alignments and 3D models shown later.

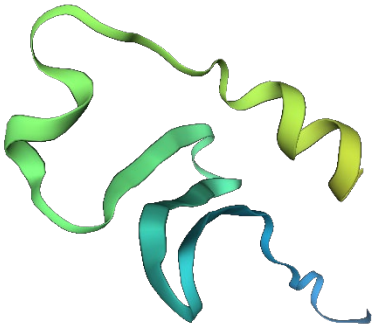
Representative results of the 3D modeling in the SWISS-MODEL analyses

1. allis shad WA α1

SWISS-MODEL No. 1 template 6blr.1.A Mouse MHC class II IA α1

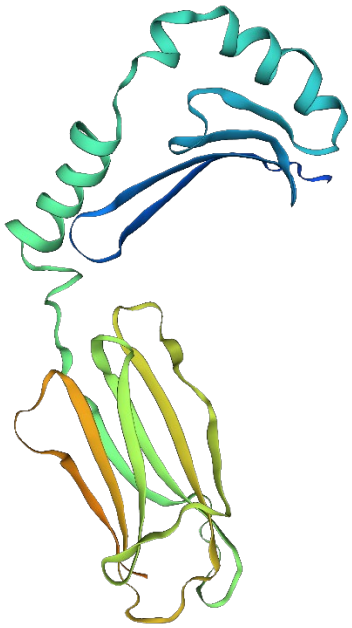


2. allis shad WA α2

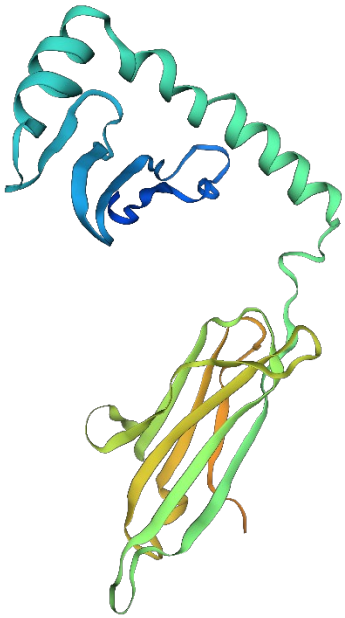
SWISS-MODEL No. 1 template 2qri.2.A Mouse MHC class I H-2 Kb $\beta_2$-m

3. allis shad WA all

SWISS-MODEL No.1 template 1aqd.1.B Human MHC class II HLA-DR1

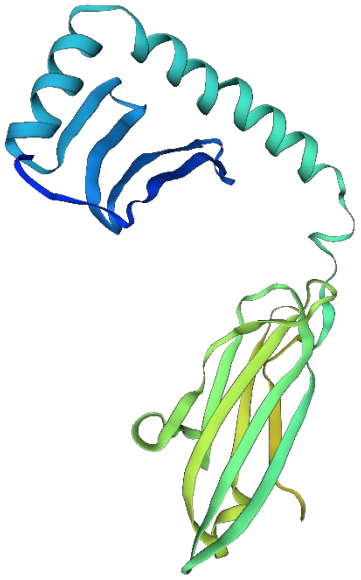


SWISS-MODEL No.6 template 6h6d.1.A Mouse MHC class I H-2 D-B



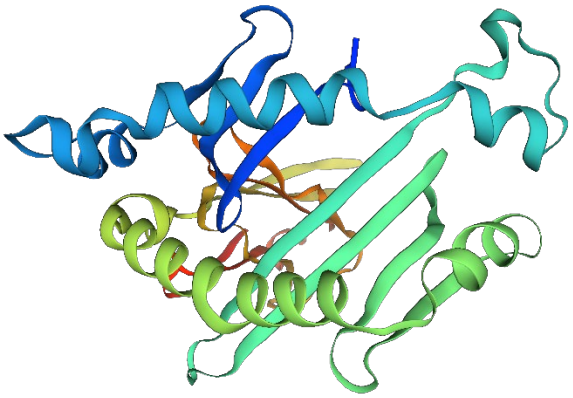
4. allis shad WB all

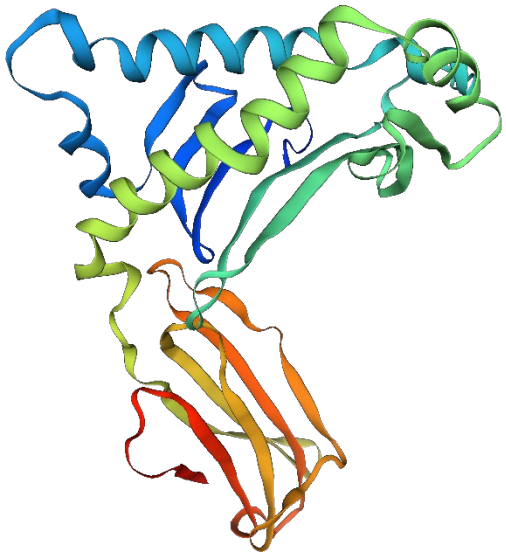
SWISS-MODEL No. 1 template  3p77.1.A  Chicken MHC class I Rfp-Y α2α3



5. allis shad (WA α1 + WB β1β2)

SWISS-MODEL No. 1 template  7cpo.1.A  Anolis MHC class I α1α2α3

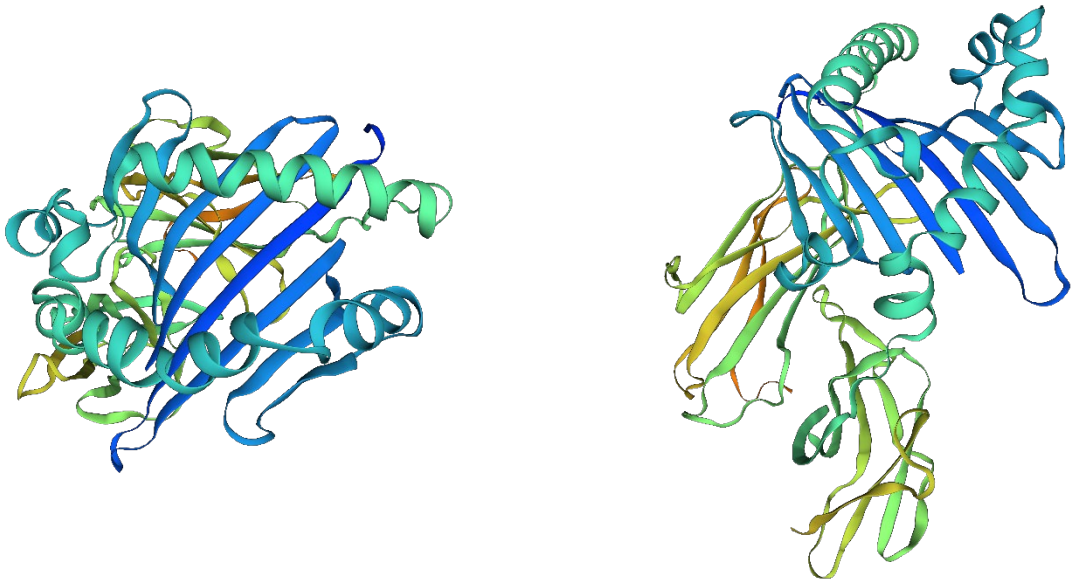




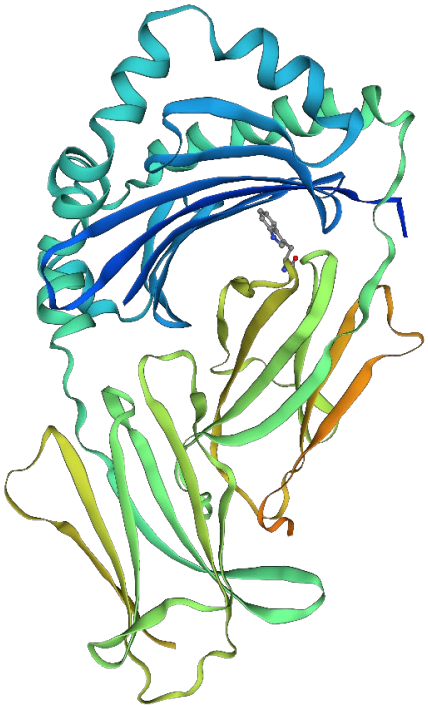
6. allis shad WA / WB

SWISS-MODEL No. 1 template 3pdo.1　Human MHC class I HLA-DR1　　(class II-type model)

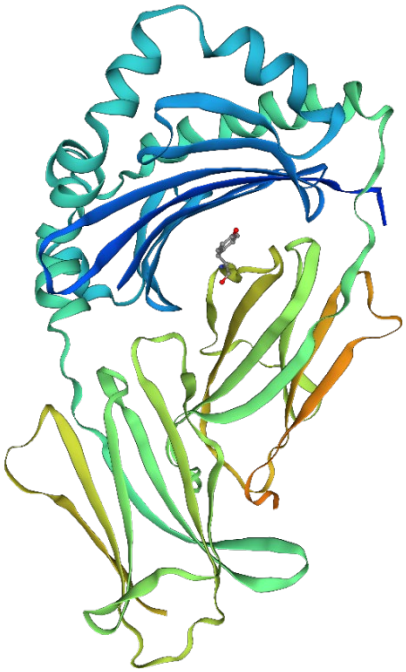
Within the first half of the α-helix of the WA α1 domain is not formed well.
The template MHC class II molecules generally possess deletions of residues at the corresponding region (Fig. S21).



SWISS-MODEL No. 1 template 3pdo.1 Human MHC class I HLA-DR1 (class II-type model)



WA α2 W61



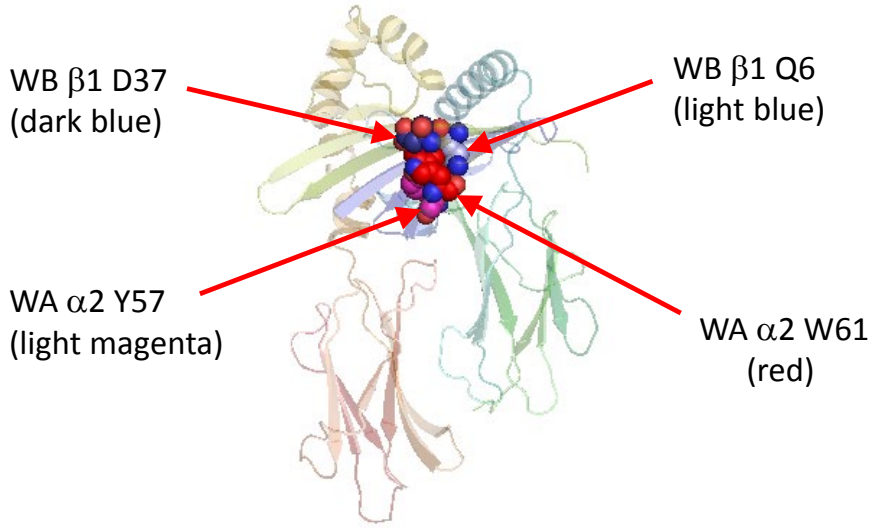
WA α2 Y57

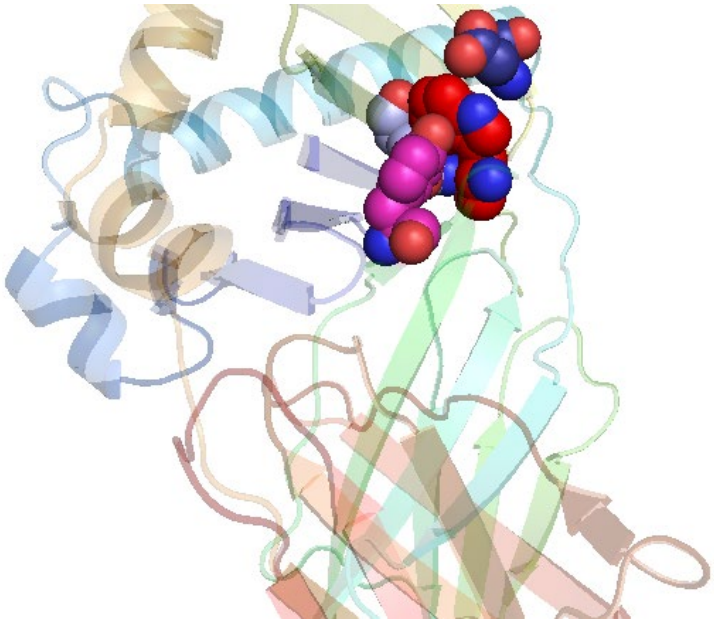
SWISS-MODEL No. 1 template 3pdo.1　Human MHC class I HLA-DR1　(class II-type model)

showing Tryptophan (W)-61 and Tyrosine (Y)-57 of WA α2 domain in the model
together with glutamine (Q)-6 and aspartic acid (D)-37 of WB β1 domain.
$\beta_2$-m possesses conserved phenylalanine (F)-57 instead of tyrosine.
$\beta_2$-m W61 interacts with Q6 and D37 of the class I α2 domain through hydrogen-bonding.
$\beta_2$-m F57 also interacts with Q6 of the class I α2 domain.

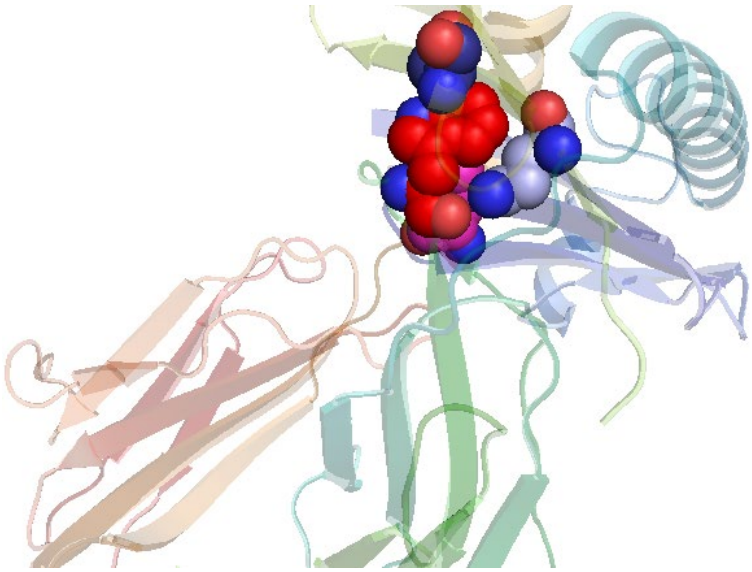
Even in the model of the class II-type molecule composed of WA α chain (WA α1α2) and WB β chain (WB β1β2), WB β1 Q6 and WB β1 D37 are situated close to WA α2 W61.

Oxygen: light red
Nitrogen: blue

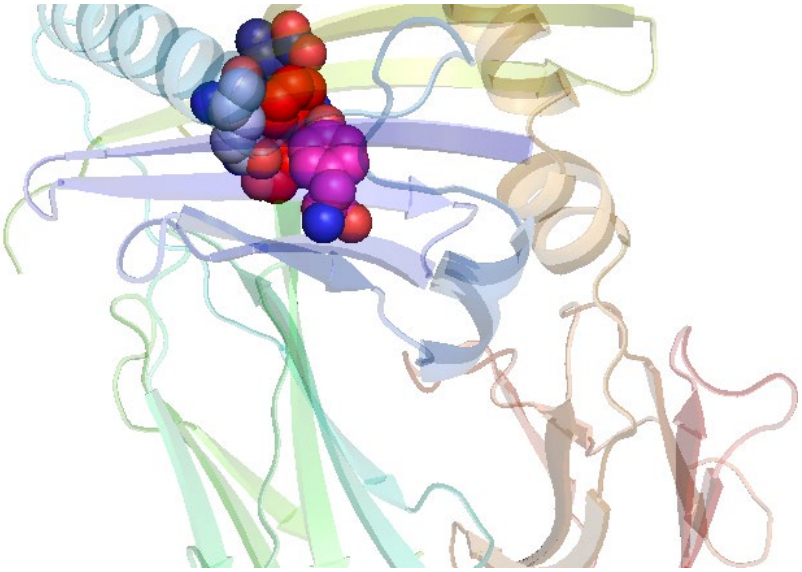




The nitrogen of WAα2 W61 is not so close to the oxygen of WB β1 D37.



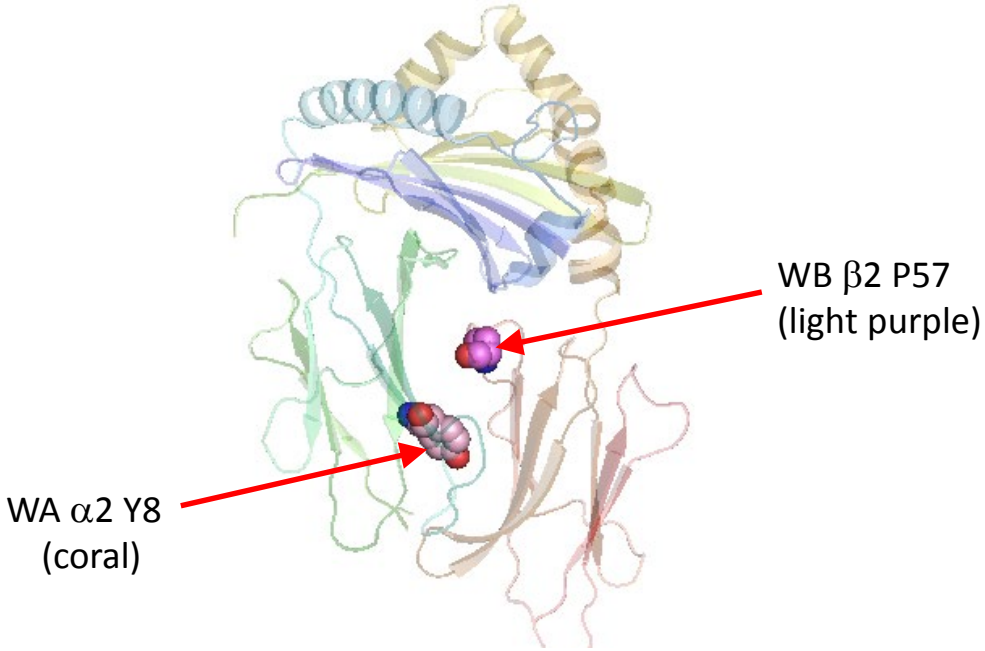
The oxygen of main chain of WAα2 W61 is very close to the nitrogen of WB β1 Q6.



WAα2 Y57 and WB β1 Q6.

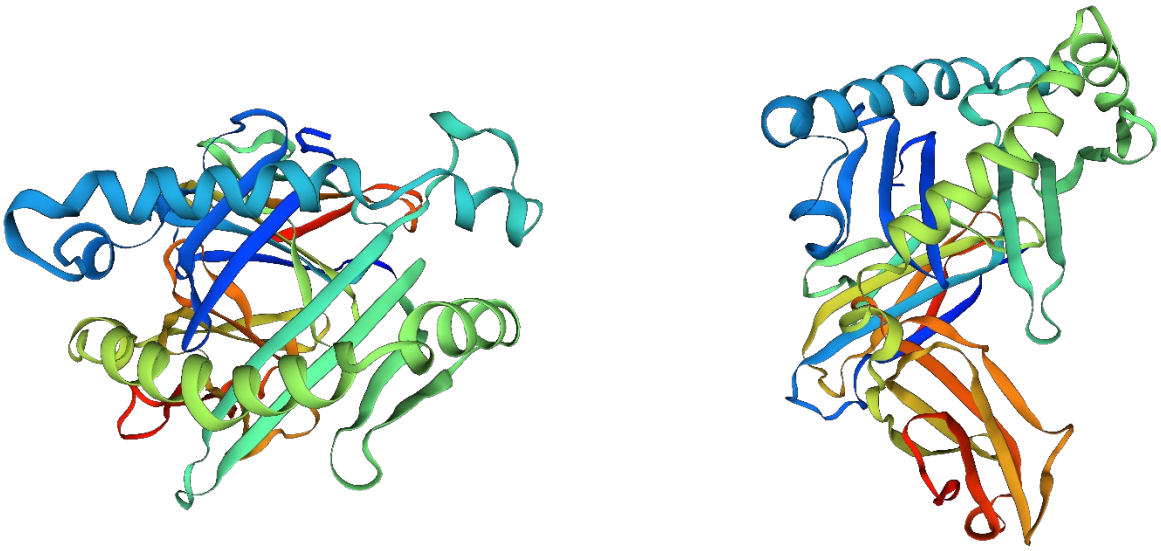
SWISS-MODEL No. 1 template 3pdo.1　Human MHC class I HLA-DR1　(class II-type model)

In α3/$\beta_2$-m interface of MHC class I molecule, the oxygen of main chain of α3P57 and the hydroxy group of $\beta_2$-m Y8 form the conserved hydrogen bond.
In this model of W-category molecule, the oxygen of main chain of WBβ2 P57 and the hydroxy group of WAα2 Y8 are distantly located.
Oxygen: light red,　Nitrogen: blue

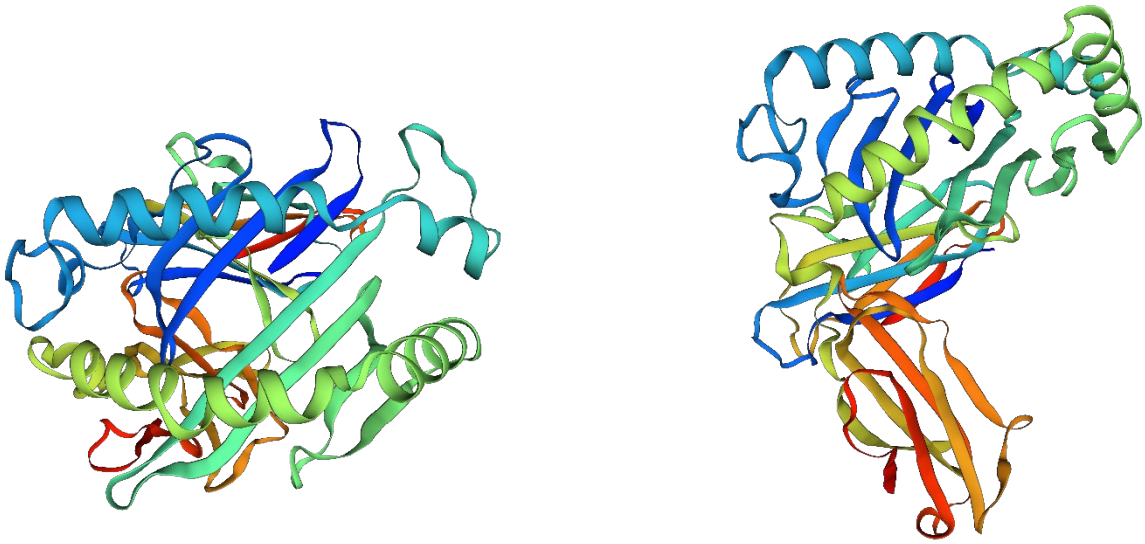


7. allis shad (WA α1 + WB β1β2) / WA α2

SWISS-MODEL No. 1 template  6lhf.1  Chicken MHC class I BF2  (class I-type model)



SWISS-MODEL No. 10 template  3wuw.1  Human MHC class I HLA-B57  (class I-type model)



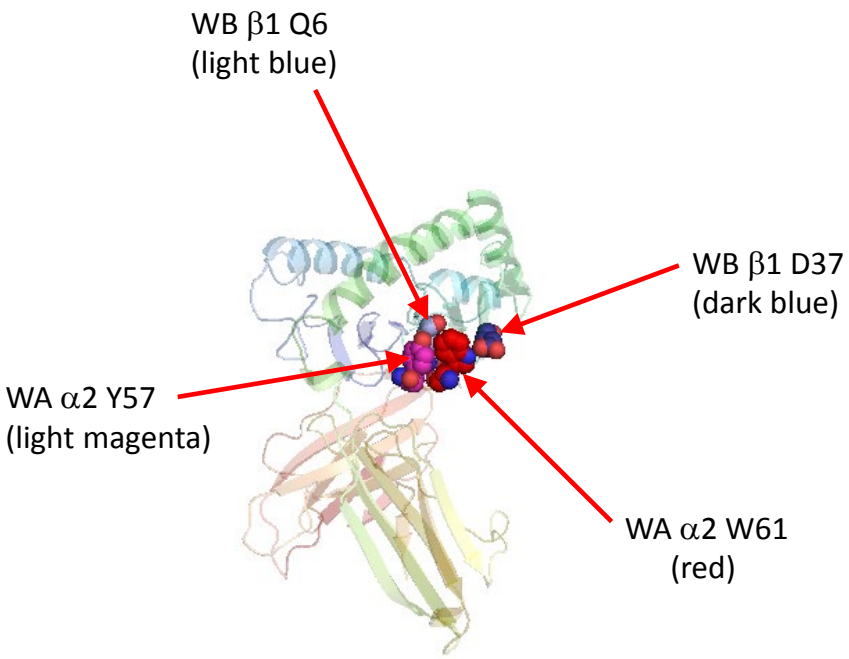
SWISS-MODEL No. 10 template 3wuw.1 Human MHC class I HLA-B57 (class I-type model)

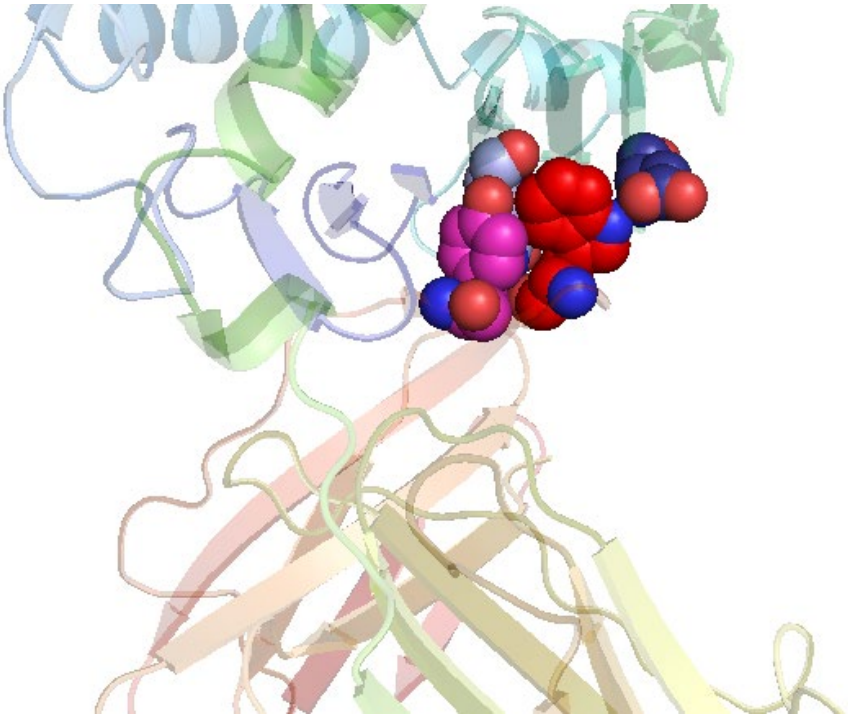
WA α2 W61

WA α2 Y57

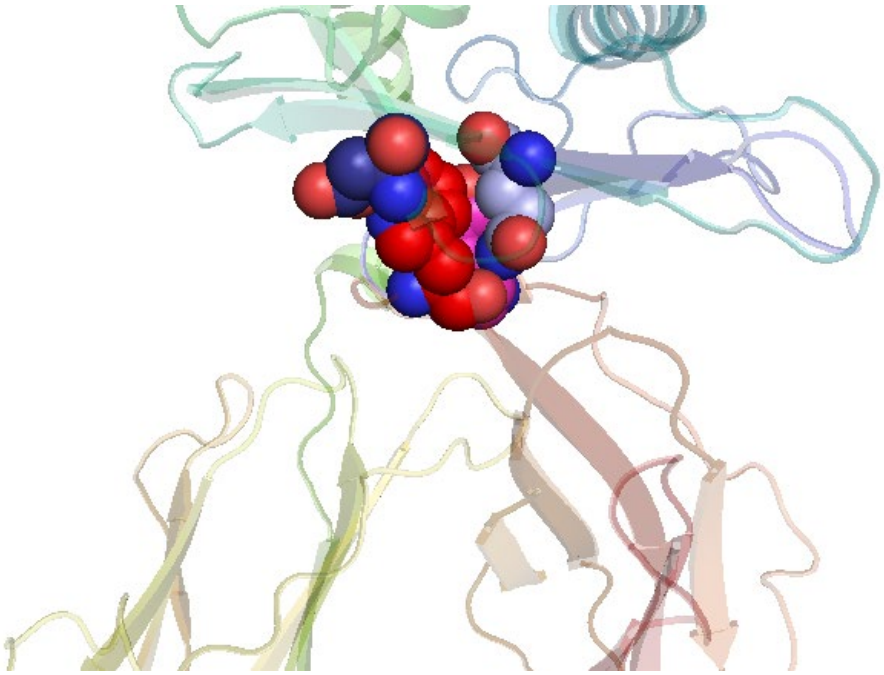
SWISS-MODEL No. 10 template 3wuw.1 Human MHC class I HLA-B57 (class I-type model)

showing Tryptophan (W)-61 and Tyrosine (Y)-57 of WA α2 domain in the model
together with glutamine (Q)-6 and aspartic acid (D)-37 of WB β1 domain.
$\beta_2$-m possesses conserved phenylalanine (F)-57 instead of tyrosine.
$\beta_2$-m W61 interacts with Q6 and D37 of the class I α2 domain through hydrogen-bonding.
$\beta_2$-m F57 also interacts with Q6 of the class I α2 domain.
Oxygen: light red, Nitrogen: blue

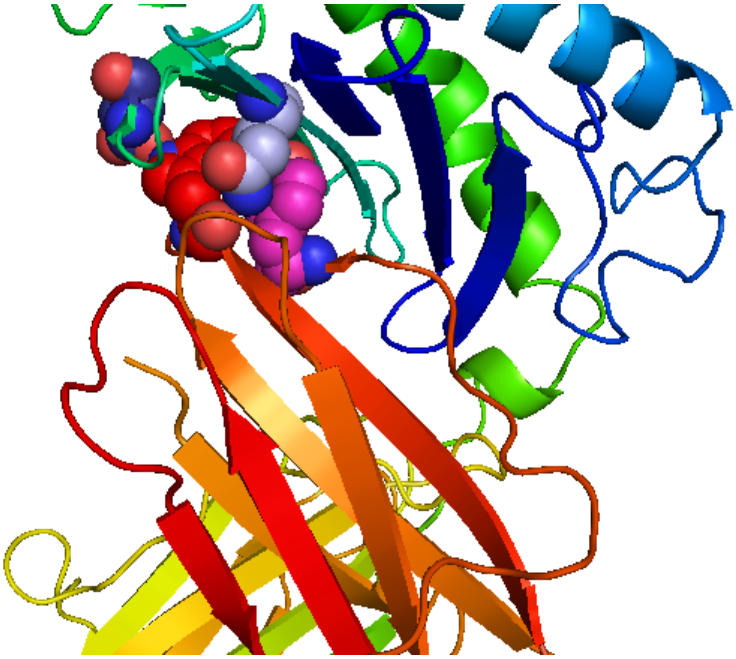


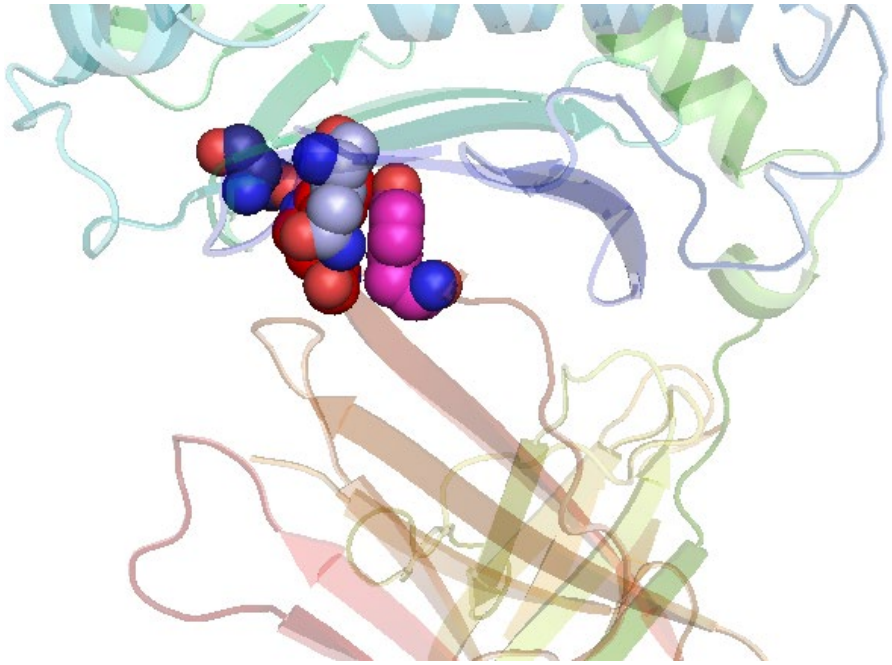


The nitrogen of WAα2 W61 is very close to the oxygen of WB β1 D37.

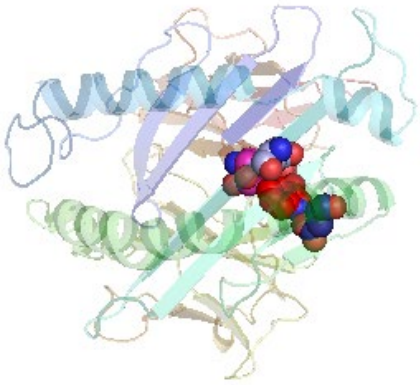


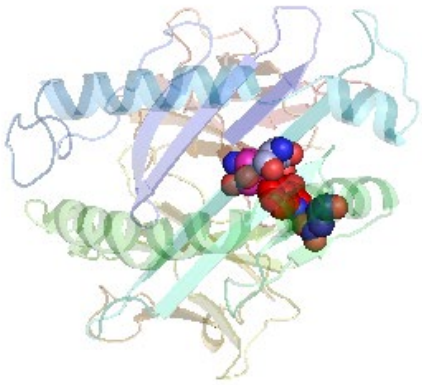
The oxygen of main chain of WAα2 W61 is very close to the nitrogen of WB β1 Q6.

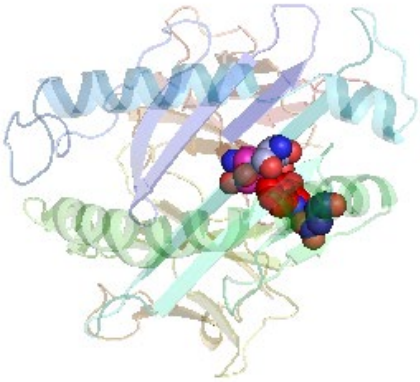


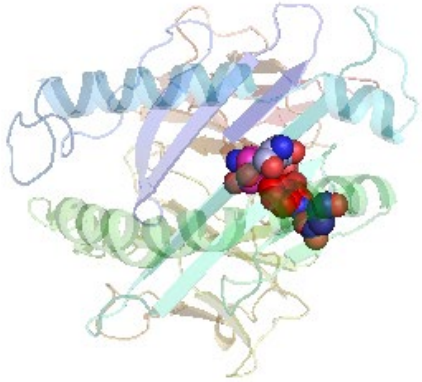


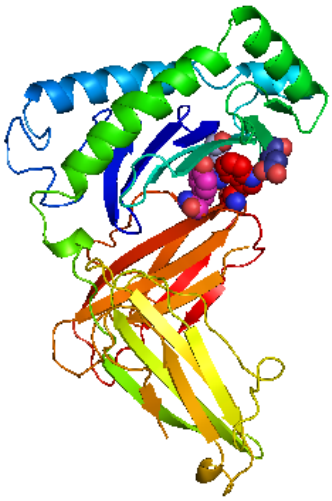
WAα2 Y57 is also close to WB β1 Q6.











SWISS-MODEL No. 10 template 3wuw.1 Human MHC class I HLA-B57 (class I-type model)

In α3/$\beta_2$-m interface of MHC class I molecule, the oxygen of main chain of α3P57 and the hydroxy group of $\beta_2$-m Y8 form the conserved hydrogen bond.
In this model of W-category molecule, the oxygen of main chain of WBβ2 P57 and the hydroxy group of WAα2 Y8 are very close to each other.
Oxygen: light red, Nitrogen: blue

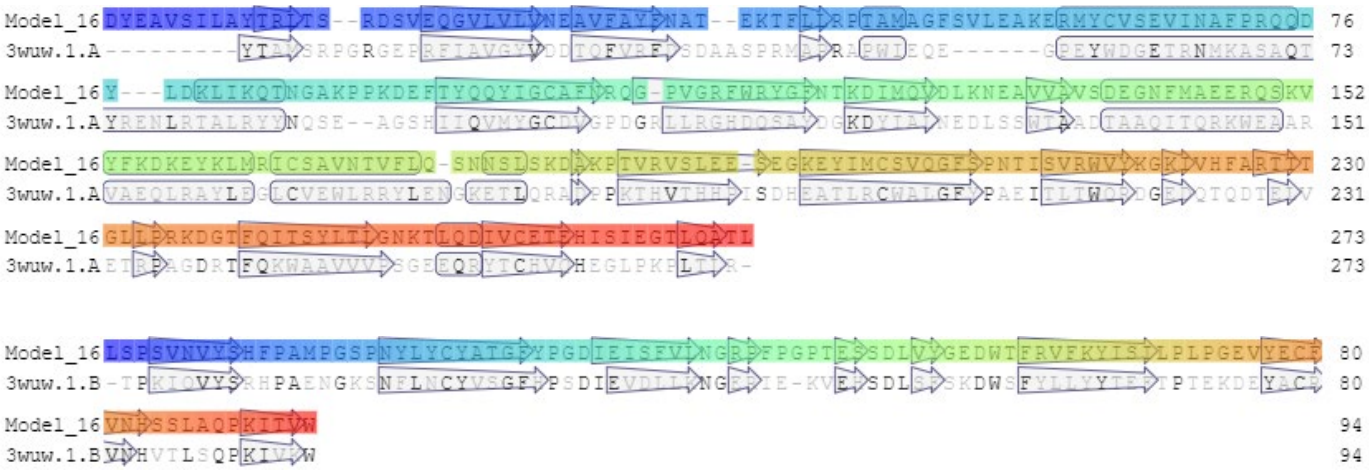
SWISS-MODEL No. 10 template 3wuw.1 Human MHC class I HLA-B57



## 11. Additional explanations for Fig. S5

**Figure S5**

**A**

At the corresponding position of $\beta_2$-m [Y]67, WA α2 and $\beta_2$-m molecules of phylogenetically more primitive animals often possess a lysine or an arginine, and indeed a lysine can be seen at this position in the structure of grass carp $\beta_2$-m (PDB ID: 3GBL and 5Y91) forming intra-domain hydrogen bonds (69) (*SI Appendix* and Fig. S7). At the corresponding position of I α3[T]55, many WB β2 and several class I α3 domains possess an isoleucine, and at the corresponding position of I α3[P]95, many WB β2 and several class I α3 possess a lysine.

**B**

The class II α1 residues described in the preceding part of this legend are not conserved in the corresponding positions of W-category and class I molecules (Dataset S1). However, for inter-domain interactions between the membrane-distal and the membrane-proximal domains, MHC class II molecules use regions roughly corresponding to those used by MHC class I molecules (31). The amino acid residues of HLA-DR1 described above are located in these regions. All the residues of HLA-DR1 involved in the interface interaction between the membrane-distal and the membrane-proximal domains according to ref. 31 are described in the legends of Datasets S1 and S2.

**C**

Among the residues described hitherto in this legend, several (color-shaded) are involved in inter-domain interactions as follows (29): I α2Q6, I α2A32, I α2G35 and I α2D37 interact with $\beta_2$-m W61, I α2Q6 also interacts with $\beta_2$-m F57, I α1V30 interacts with the main chain of $\beta_2$-m L55 and I α1 R60 interacts with $\beta_2$-m D54. I α2K36 interacts with the first residue (an isoleucine) of the mature $\beta_2$-m peptide, which is not included in Fig. 3 and Dataset S2 and not conserved among $\beta_2$-m. This figure does not show all the residues involved in inter-domain interaction between $\beta_2$-m and the membrane-distal domains. In HLA-A2, $\beta_2$-m W61 interacts with two more residues of the α2 domain (I α2Q30 and I α2Y31) in addition to those described above. $\beta_2$-m W61 appears to play an important role at the interface with such many interactions (two of them are hydrogen bonds, $\beta_2$-m W61 to I α2Q6 and $\beta_2$-m W61 to I α2D37). All the residues of HLA-A2 involved in the interface interaction between the membrane-distal and the membrane-proximal domains according to ref. 29 are described in the legends of Datasets S1 and S2.

In the MHC class I structure, the $\beta_2$-m and class I α3 domains, which are classified as C1-set Ig-like domains, unexpectedly possess asymmetrical structural arrangements (25) as shown in A, namely, they are not related by a dyad (180°) symmetry, whereas several other molecules such as antibodies and T cell receptors show a dyad symmetry in the arrangements of their dimeric C1-set Ig-like domains [e.g., $C_H1$ and $C_L$ in an Fab, and $C_H3$ dimer in Fc in case of antibodies (73); Cα and Cβ in case of T cell receptors (74)]. This special asymmetrical structural organization of MHC class I Ig-like domains is essentially also observed for the two Ig-like domains (class II α2 and β2 domains) of an MHC class II molecule (27) (see B). An MHC class I molecule can superimpose onto an MHC class II molecule although there is a small difference in angle for the arrangements between the class I α3 and class II β2 domains (27).

In this figure, human HLA-A2 (PDB ID: 1AO7) and human HLA-DR1 (PDB ID: 1DLH) are used as representative MHC class I and conventional class II molecules, respectively. For class I molecules, overall structures largely similar to that of HLA-A2 have been reported for other classical class I molecules, e.g., mouse (30) (PDB ID: 2VAA), chicken (75) (PDB ID: 3BEV) and grass carp (PDB ID: 5Y91). Topologically similar overall structures also have been found for highly divergent class I molecules including, for example, mouse CD1 (76) (PDB ID: 1CD1), chicken CD1 (77) (PDB ID: 3DBX) and rat FcRn (78) (PDB ID: 1EXU). In these class I structures, several conserved residues can be observed at the interface between the membrane-distal and the membrane-proximal domains described in this legend including $\beta_2$-m W61. Also for class II molecules, largely similar overall structures with highly conserved W61 in the β2 domain have been reported

for the DM molecules of human (PDB ID: 1HDM) and mouse (PDB ID: 1K8I), whose sequences are highly divergent from the classical MHC class II molecules (Datasets S1 and S2).

In the figure, only for the residues relevant for the discussion, their side chains are shown as a ball-and-stick representation. The MHC class I domains are colored as follows: yellow, green, blue and red for α1, α2, α3 and $\beta_2$-m, respectively. The MHC class II domains are colored as follows: salmon pink, magenta, light green and light blue for II A α1, II A α2, II B β1 and II B β2, respectively. Each pair of corresponding domains of MHC class I and class II molecules (class I α1/class II α1, $\beta_2$-m/class II α2, class I α2/class II β1 and class I α3/class II β2, see Fig. 8) possesses related colors. The highlighted amino acid residues with a ball-and-stick representation have colors similar to those of the domain to which the relevant residue belongs. Bound peptides are shown in the color purple. Disulfide bridges formed by two cysteine residues are shown in dark brown color.

The numbers of amino acid positions are based on Dataset S1 for the membrane-distal domains, and Fig. 3/ Dataset S2 for the Ig-like domains. The corresponding amino acid numbers in HLA-A2 (ref. 29) or the respective chain of HLA-DR1 (ref. 31) for the residues used in the figure are as follows: the numbers in HLA-A2 are shown in parentheses, I α1S4 (4), I α1R21 (17), I α1G22 (18), I α1V30 (25), I α1V33 (28), I α1T36 (31), I α1F38 (33), I α1F41 (36), I α1R60 (48), I α2H3 (93), I α2Q6 (96), I α2G11 (100), I α2A32 (117), I α2G35 (120), I α2K36 (121), I α2D37 (122), I α3T55 (233), I α3P57 (235), I α3G61 (239), I α3P95 (269), $\beta_2$-m L37 (39), $\beta_2$-m L55 (54), $\beta_2$-m F57 (56), $\beta_2$-m W61 (60), $\beta_2$-mY67 (66); the numbers in HLA-DR1 are shown in parentheses, IIA α1F34 (26), IIA α1L72 (45), IIA α1F75 (48), IIA α2H61 (143). IIB β2W61 (153).

## 12. Notes for Datasets

**Dataset S1: Amino acid comparison of the membrane-distal domains of W-category and other MHC molecules.**

The classification of molecules is shown in the first column. The following classification is used:
WA α1 (W-category α chain α1 domain), I α1 (class I α1 domain), I nc α1 (nonclassical class I α1 domain), IIA α1 (class II α chain α1 domain), DOA α1 (α1 domain of HLA-DO α chain related), DMA α1 (α1 domain of HLA-DM α chain related), IIA nc α1 teleost (nonclassical class II α chain α1 domain of teleost fish), WB β1 (W-category β chain β1 domain), I α2 (class I α2 domain), I nc α2 (nonclassical class I α2 domain), IIB β1 (class II β chain β1 domain), DOB β1 (β1 domain of HLA-DO β chain related), DMB β1 (β1 domain of HLA-DM β chain related), IIB nc β1teleost (nonclassical class II β chain β1 domain of teleost fish).

The shading principles are as follows:
Red, residues which are shared between WA α1 and class I α1 domains but very uncommon in classical class II α1 domains;
Blue, residues which are shared between WB β1 and class I α2 domains but very uncommon in classical class II β1 domains;
Purple, conserved residues interacting with bound peptide termini in classical class I (the same residues at the same position in most of the other aligned domain types are also shaded with purple color for comparison, but in case of irrelevant class I domains, those are shaded with pale orange color);
Moss green, conserved residues interacting with a bound peptide in classical class II (the same residues at the same position in most of the other aligned domain types are also shaded with moss green color for comparison, but in case of irrelevant class II domains, those are shaded with pale orange color);
Dark gray, conserved tryptophans in class I α1 domains (position 73) and class I α2 domains (position 57);
Light green, residues found in many teleost WB and classical class II β1 domains;
Pale gray, N-glycosylation motif NX(S/T) found in the last part of domains, all residues of N and/or (S/T) at the same positions are shaded irrespective of the completeness of the motif;
Orange, residues frequently observed in WB β1, class I α2 and class II β1 but not in WA α1, class I α1 and also not in class II α1 except position 33;
Pink and magenta, specific for WA α1 domain (F57) and WB β1 domain (Q7, C27 and W29), respectively;
Black, highly conserved cysteines in class I α2 and class II β1 domains, and also in DM α1 domains and bony fish and some cartilaginous fish class II α1 domains;
Yellow, commonly observed in various MHC membrane-distal domains;
Bright purple, "LN" motif observed in banded houndshark WB_DS1 and WB_DS3;
Dark brown, conserved tryptophan in class II α1 domain (position 59), which is important for the interaction with DM molecules (79);
Pale blue, three residues with this color-shading in the last part of domains are highly conserved in class I α2 domains.

The amino acid residues in the membrane-distal domains of the human classical MHC class I HLA-A2 molecule which participate in the inter-domain interactions between the membrane-distal domains and the Ig-like domains are as follows (ref. 29) (for convenience, in the following listing, not only the residue numbering of this figure but also, in parentheses, the residue numbering of HLA-A2 in ref. 29 is shown):
I α1/α2 with $\beta_2$-m, I α1F8 (8), I α1F10 (9), I α1T11 (10), I α1V13 (12), I α1I28 (23), I α1V30 (25), I α1Y32 (27), I α1Q37 (32), I α1R40 (35), I α1R60 (48), I α2T4 (94), I α2Q6 (96), I α2Q30 (115), I α2Y31 (116), I α2A32 (117), I α2D34 (119), I α2G35 (120), I α2K36 (121), I α2D37(122); I α1/α2 with I α3, I α1D34 (29), I α1D35 (30), I α1T36 (31), I α2L124 (179), I α2R126 (181), I α2T127 (182).

In case of human classical MHC class II HLA-DR1 molecule, the amino acid residues in the membrane-distal domains which participate in the inter-domain interactions between the membrane-distal domains and the Ig-like domains are as follows (ref. 31) (for convenience, in the following listing, not only the residue numbering of this figure but also, in parentheses, the residue numbering of the respective chain of HLA-DR1 in ref. 31 is shown):

II α1/β1 with II α2/II β2, II α1I6 (8), II α1A8 (10), II α1F11(12), II α1L13 (14), II α1D16 (17), II α1E28 (21), II α1M30 (23), II α1F33 (26), II α1D34 (27), II α1G35 (28), II α1D36 (29), II α1E37 (30), II α1I38 (31), II α1H40 (33), II α1R60 (44), II α1L71 (45), II α1F74 (48), II β1R2 (6), II β1L4 (8), II β1Q6 (10), II β1K8 (12), II β1R30 (29), II β1F32 (31), II β1Q35 (34).

The sequences used in this figure are listed in Table S3.

**Dataset S2: Amino acid comparison of the membrane-proximal, Ig-like domains of W-category and other MHC molecules.**

The classification of molecules is shown in the first column. The following classification is used:
WA α2 (W-category α chain α2 domain), $\beta_2$-m ($\beta_2$-microglobulin), IIA α2 (class II α chain α2 domain), DOA α2 (α2 domain of HLA-DO α chain related), DMA α2 (α2 domain of HLA-DM α chain related), IIA nc α2 teleost (nonclassical class II α chain α2 domain of teleost fish), WB β2 (W-category β chain β2 domain), I α3 (class I α3 domain), I nc α3 (nonclassical class I α3 domain), IIB β2 (class II β chain β2 domain), DOB β2 (β2 domain of HLA-DO β chain related), DMB β2 (β2 domain of HLA-DM β chain related), IIB nc β2 teleost (nonclassical class II β chain β2 domain of teleost fish).

The shading principles are as follows:
Red, residues which are shared between WA α2 and $\beta_2$-m domains but very uncommon in classical class II α2 domains;
Blue, residues which are shared between WB β2 and class I α3 domains but very uncommon in classical class II β2 domains;
Green, often found in WA α2, $\beta_2$-m and class IIA α2;
Light blue, a tryptophan (position 37) conserved in many Ig-superfamily members and observed except WA α2, $\beta_2$-m, and some class I α3;
Orange, observed in class I α3 and class IIB β2;
Purple, a leucine residue (position 70) conserved in conventional class II α2 and β2 domains;
Black, highly conserved cysteines in Ig-like domains;

For the co-receptor CD8 binding to classical MHC class I molecule, I α3Q48 [226 in HLA-A2 (ref. 29)] is the most important residue (80, 81). This glutamine residue is generally not conserved in I α3-corresponding WB sequences. Only banded houndshark WB_DS1 and WB_DS3 possess a glutamine residue at this position.

For the co-receptor CD4 binding to a classical MHC class II molecule, the following residues of the class II molecule have been reported to interact with CD4 (82) (for convenience, in the following listing, not only the residue numbering of this figure but also, in parentheses, the residue numbering of the respective chain of HLA-DR1 in ref. 31 is shown): II α2E4(88), II α2T6(90), II α2K99(176), II β2S10(104), II β2L20(114), II β2V22(116), II β2M50(142), II β2V51(143), II β2S52(144), II β2T54(145), II β2I57(148), II β2L67(158), II β2M69(160), II β2E71(162).

The amino acid residues in the Ig-like domains of the human classical MHC class I HLA-A2 molecule which participate in the inter-domain interactions between the membrane-distal and the membrane-proximal Ig-like domains are as follows (ref. 29) (for convenience, in the following listing, not only the residue numbering of this figure but also, in parentheses, the residue numbering of HLA-A2 heavy chain and $\beta_2$-m in ref. 29 is shown): $\beta_2$-m with I α1/α2, $\beta_2$-m I (not included) (1), $\beta_2$-m R1 (3), $\beta_2$-m H29 (31), $\beta_2$-m S31 (33), $\beta_2$-m D54 (53), $\beta_2$-m L55 (54), $\beta_2$-m S56 (55), $\beta_2$-m F57 (56), $\beta_2$-m W61 (60), $\beta_2$-m F63 (62), $\beta_2$-m Y64 (63); α3 with I α1/α2, I α3D1 (183), I α3Y29 (209), I α3P30 (210), I α3A31 (211), I α3F63 (241), I α3E89 (264).

In case of human classical MHC class II HLA-DR1 molecule, the amino acid residues in the Ig-like domains which participate in the inter-domain interactions between the membrane-distal and the membrane-proximal Ig-like domains are as follows (ref. 31) (for convenience, in the following listing, not only the residue numbering of this figure but also, in parentheses, the residue numbering of the respective chain of HLA-DR1 in ref. 31 is shown): II α2 with II α1/β1, II α2T29 (113), II α2P30 (114), II α2P31 (115), II α2V32 (116), II

α2T53 (135), II α2V54 (136), II α2F55 (137), II α2L56 (138), II α2P57 (139), II α2R58 (140), II α2E59 (141), II α2D60 (142), II α2H61 (143), II α2L62 (144), II α2F63 (145), II α2R64 (146), II α2Y68 (150), II α2W89 (168); II β2 with II α1/β1, II β2Y29 (123), II β2Q57 (149), II β2G59 (151), II β2D60 (152), II β2W61 (153).

At position 61, several C1-set Ig-like domains of other molecules, such as tapasin (57), some B7 members (83), antibodies (e.g., 57, 78) and signal-regulatory protein (SIRP) α (84), possess a glycine. Thus, a glycine is one of the candidate residues at position 61 in the primordial class II molecule.

In the oriental weatherfish WB_01 sequence, two amino acid residues (SW) between positions 37 and 38 are not included.

In the outgroup sequences used in the phylogenetic analyses, the following amino acid residue(s) are not included after the amino acid position numbers indicated. In the house mouse IgM sequence: 15, N; 39, R; 59, GA; 77, N. In the human IgM sequence: 15, N; 39, R; 59, QA; 77, N. In the house mouse TCRB sequence: 11, KA; 55, A; 74, FW; 75, N; 91, SEEDKWPEGSPKPV. In the human TCRB sequence: 11, EA; 55, P; 59, PALN; 74, FW; 75, N; 91, SENDEWTQDRAKPV. In the house mouse tapasin: 15, AP; 32, G; 40, GGPGGSS; 77, KQ. In the human tapasin: 15, AP; 32, G; 40, GGPGGRS; 77, EQ.

For the phylogenetic tree analyses, the following three regions in which the three outgroup molecules exhibit high structural variations compared to the MHC molecules were not included: the amino acid position numbers 11-18, 73-80 and 92-93.

The sequences used in this figure are listed in Table S3. The numbers of amino acid positions shown at the top equal those in Fig. 3 and the positions with asterisks are not included for numbering.

**Dataset S3: Conservation of α chain or β chain-specific motifs in the TM region of the W-category molecules.**

CP/TM/CY region sequences of W-category and other class II molecules are compared. The classifications of molecules are indicated in the first column. In the TM region, W-category sequences possess heptad repeats of glycine residues reported previously for conventional class II sequences (24, 79, 85, 86). MHC class I molecules do not display these features. Other small amino acid residues, e.g., an alanine (A) or a serine (S), can often replace a glycine. Notable differences between class II α and β chains are those at positions 21 and 31. Three residues (F, L, A) between positions 27 and 28 of fat head minnow WB_01 are not included. The shading colors are used as follows: purple, cysteine (C); brown, glycine (G); green, alanine (A) or serine (S).

**13. Detailed Author Contributions**

K.O. contributed to experiments including isolation of cDNA library clones of banded houndshark *WB_DS1* and *WB_DS3*, isolation of *WB_DS3* genomic clones and their initial sequence determination, isolation of *WA_DS10*, isolation of salamander W-category cDNAs, Southern blot analyses, linkage and expression experiments for banded houndshark W-category genes, and experiments regarding $\beta_2$-*m*. J.M.D. contributed to the planning for the expansion of the study with identification of W-category genes from various animals including little skate, various teleost fish, coelacanth, lungfish and salamander, isolated cDNAs from lungfish, goldfish, Mexican tetra, salamander and zebrafish, determined their sequences, and performed the study on polymorphism of zebrafish W-category genes. K.T. contributed to the identification and isolation of cDNAs of banded houndshark *WA_DS5*, isolated cDNAs of banded houndshark *WB_DS1* and *WB_DS3* using RT-PCR, performed intensive study of determination of the genomic organizations of banded houndshark *WA_DS5*, *WA_DS10* and *WB_DS3*, determined the partial genomic organization of *WB_DS1_n1*, and conducted experiments using recombinant proteins of W-category molecules. U.G. performed extensive searches for MHC sequences in the teleost fish genome databases and identified unclassified MHC sequences from the zebrafish database. G.F.W. performed the study of the sequences of the common carp genome and identified the duplicated common carp W-category genes. A.K. performed the experiments of the expression of the zebrafish W-category genes and studied salamander class I sequences for comparison. H.Y. performed comparative structural analyses of MHC sequences using Chimera program for the basis of sequence alignments. K.H. conceived the study, performed the initial experiments including isolation of DNA fragments of banded houndshark *WA_DS5* and *WB_DS3*, and banded houndshark genomic library screening, contributed to the identification of banded houndshark *WA_DS10*, identified *WA_Nds3L* and *WB_Nds5L*, analyzed conservation profile of teleost fish W-category molecules, conducted database searches, phylogenetic estimation, and molecular modeling, analyzed the results, and wrote the manuscript with great helps from J.M.D., K.T., K.O., U. G. and G. F. W.

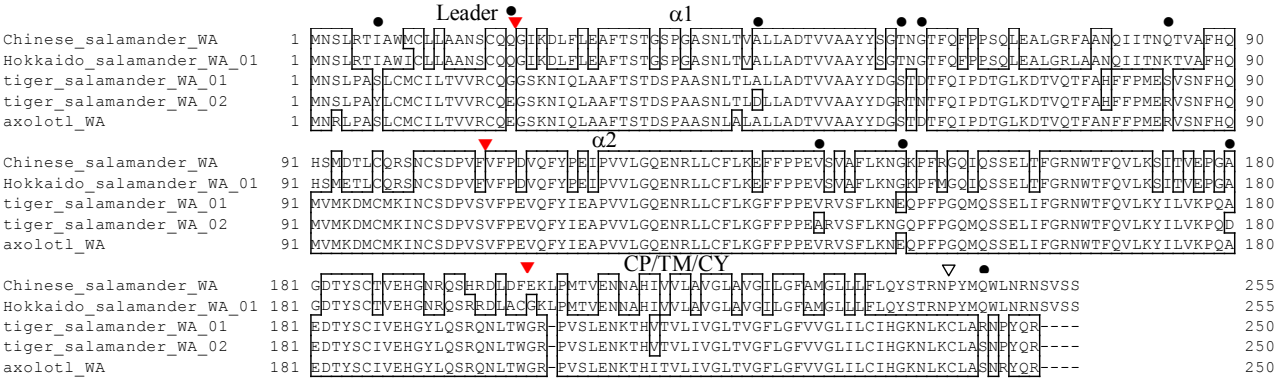

**Fig. S1. Representative W-category α chain (WA) sequences from cartilaginous fish, teleost fish, lobe-finned fish and salamanders.**

**A**, banded houndshark WA_DS5 and closely-related sequences of other cartilaginous fish. From a single individual banded houndshark, four kinds of WA_DS5 cDNA sequences were obtained. Currently, the allelic relationship of these sequences is not clear. **B**, banded houndshark WA_DS10 and closely-related sequences of other cartilaginous fish. **C**, blue shark and great white shark WA_Nds3L sequences. **D**, WA sequences of teleost fish. Information of the oriental weatherfish WA sequence is currently incomplete. The additional twenty-two residues in the last part of sardine WA_01 and the additional two residues in the last part of Hilsa shad WA_01 are not included. **E**, WA sequences of lobe-finned fish including African coelacanth and three kinds of lungfish. **F**, WA sequences of salamanders. The positions where the two tiger salamander WA sequences (obtained from a single individual and presumable alleles) show disparity are shown by black circles above the sequences.

The borders of the corresponding exons are shown by red arrowheads. Additional borders within the CP/TM/CY region are shown by open arrowheads. All sequences used in this figure are listed in Table S3 and composite or corrected sequences are described in *SI Appendix*.

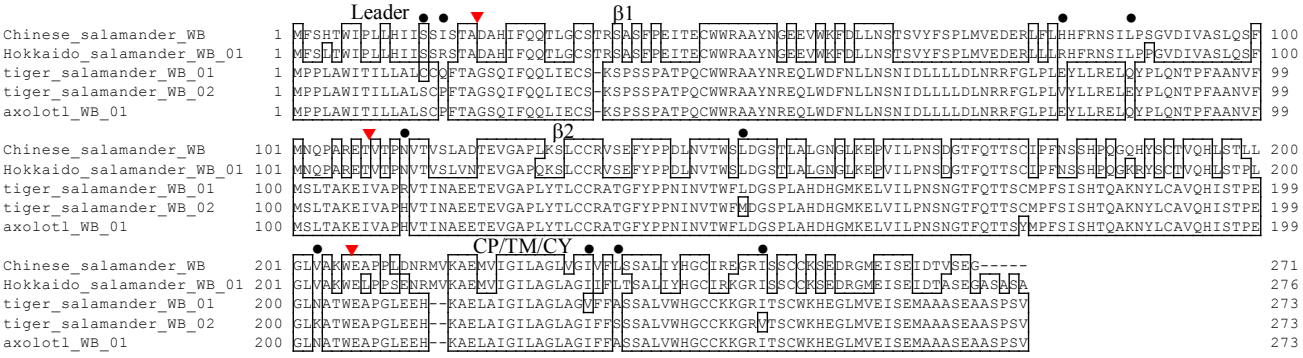

**Fig. S2. Representative W-category β chain (WB) sequences from cartilaginous fish, teleost fish, lobe-finned fish and salamanders.**

**A**, banded houndshark WB_DS1 and closely-related sequences of other cartilaginous fish. The positions where the two banded houndshark WB_DS1 sequences (presumable alleles) show disparity are shown by filled circles above the sequences. The additional twenty-two residues in the last part of zebra bullhead shark WB_DS1-like are not included. **B**, banded houndshark WB_DS3 and closely-related sequences of other cartilaginous fish. The positions where the two banded houndshark WB_DS3 sequences (found in different individuals) show disparity are shown by filled circles above the sequences. **C**, cloudy catshark, great white shark and zebra bullhead shark WB_Nds5L sequences. **D**, WB sequences of teleost fish. Information of the oriental weatherfish and white sucker WB sequences is currently incomplete. **E**, WB sequences of lobe-finned fish including African coelacanth and three kinds of lungfish. **F**, WB sequences of salamanders. The positions where the two tiger salamander WB sequences (obtained from a single individual and presumable alleles) show disparity are shown by black circles above the sequences. Information on the last residues of the Chinese salamander WB sequence is currently incomplete.

The borders of the corresponding exons are shown by red arrowheads. Additional borders within the CP/TM/CY region are shown by open arrowheads. All sequences used in this figure are listed in Table S3 and composite sequences are described in *SI Appendix*.

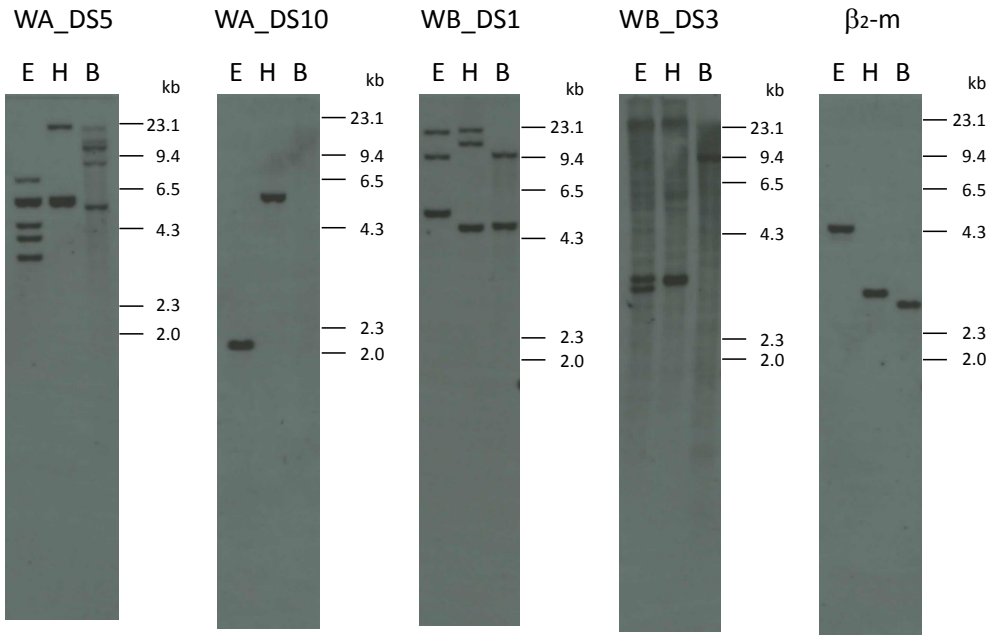

**Fig. S3. Southern blot analyses for the banded houndshark *W-category* and *β2-m* genes.** Banded houndshark genomic DNA was digested with either *Eco*RI (E), *Hin*dIII (H) or *Bam*HI (B) as described in the Materials and Methods. The primer sequences for the probes in the analyses are listed in Table S2. Clearly-positive bands could not be observed in *Bam*HI-digests probed with *WA_DS10* in several independent experiments. Background bands in the blot of *WB_DS3* were not observed in other independent experiments (e. g., Fig. S10). Agarose gels of 1.2 % were used.

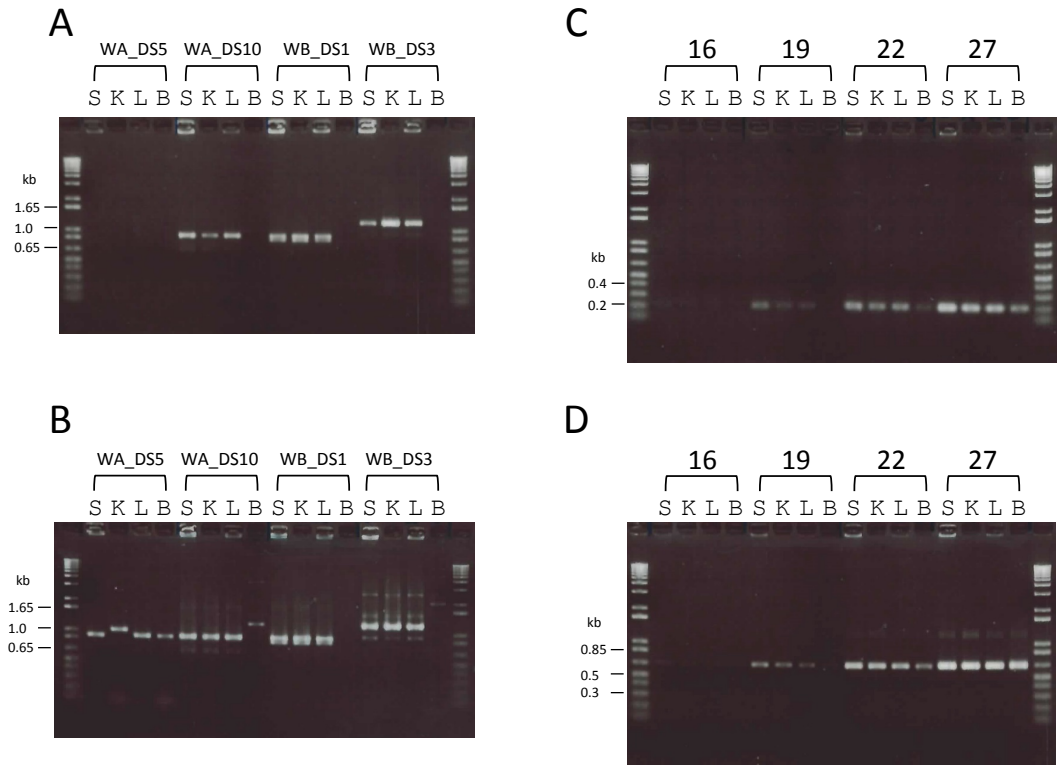

**Fig. S4. Expression of various WA and WB genes of a banded houndshark individual (N1).**
**A**, Amplification of various W-category genes with 32 cycles of RT-PCR. S, K, L and B are abbreviations of spleen, kidney, liver and blood, respectively. Using RNA of spleen, kidney and liver, cDNA fragments of expected lengths were amplified in case of WA_DS10, WB_DS1 and WB_DS3. The primers used are described in Table S2. The primers for *WA_DS5* used in this experiment did not discriminate among *WA_DS5_n1~n4*. **B**, Amplification of various W-category genes with 42 cycles of RT-PCR. Compared to the results of 32 cycles in A, some irrelevant bands became apparent and the amount of amplified cDNA of *WA_DS5* increased. In the amplified products of *WA_DS5* using the kidney sample (K), a fragment with a length longer than expected was noticed. Sequencing of this fragment revealed it to be an alternatively spliced product which includes an extra region found in the intron 1 of *WA_DS5* gene and produces a frame-shift in the open reading frame. In a separate experiment, using a different RT-PCR protocol (protocol No. 2) described in the Materials and Methods, we could amplify cDNA fragments of *WA_DS5* with lengths expected from canonical type sequences using the same kidney sample. cDNA fragments with lengths longer than expected in case of WA_DS10 with blood sample (B) have not been investigated yet. **C**, RT-PCR amplification of β-actin cDNA (a short fragment) with various cycles (16, 19, 22 and 27 cycles as indicated on top). **D**, RT-PCR amplification of β-actin cDNA (a longer fragment) with various cycles (16, 19, 22 and 27 cycles as indicated on top). With more PCR cycles, the number of irrelevant bands increased. The primers used for C and D are listed in Table S2. Agarose gels of 1.5 % were used for all experiments in this figure.

**Fig. S5. The structural positions of amino acid residues which are shared between W-category and class I molecules.**

In A, an overall structure of an MHC class I molecule, HLA-A2, is shown. The positions of amino acid residues often shared between W-category and class I molecules in the Ig-like domains are indicated. In B, an overall structure of an MHC class II molecule, HLA-DR1, is shown for comparison. In C, the interface between $\beta_2$-m and the membrane-distal domains of HLA-A2 is shown highlighting positions of several residues shared between W-category and class I molecules.

**A**, Five amino acid positions of $\beta_2$-m (with red frames) and four positions of the class I α3 domain (with blue frames) highlighted in Fig. 3 with red and blue shadings, respectively, are indicated. The residues in brackets are different from those shared between W-category and other class I molecules. In the figure, the position of I α3W37, which corresponds to the highly conserved tryptophan in the Ig superfamily and is indicated with an open square in Fig. 3, is shown. The position of $\beta_2$-m Y8 (with a light green frame), which interacts with I α3P57 (Fig. S6), is also shown.

**B**, Two amino acid positions, H61 of the class IIA α2 domain (IIA α2H61, with a yellow frame) and IIB β2W61 (with a magenta frame), are indicated. These residues possess the same position 61 in the sequence alignment (Fig. 3) and correspond to $\beta_2$-m W61 and I α3G61 (shown in A), respectively. IIA α2H61 is not conserved among classical MHC class II molecules. Highly conserved IIB β2W61 forms a hydrogen bond with the main chain carbonyl oxygen of IIA α1E37 and further interacts with the three conserved hydrophobic amino acid residues of the class II α1 domain (IIA α1F33, IIA α1L71 and IIA α1F74) (*31*) as shown. In the figure, the positions of IIA α2W37 and IIB β2W37, which correspond to the highly conserved tryptophan in the Ig superfamily and is indicated with an open square in Fig. 3, are also shown.

**C**, The positions of amino acid residues frequently shared between W-category and class I molecules but not shared with the classical class II molecule at the interface between the membrane-distal and the membrane-proximal domains of HLA-A2. These comprise eight positions of the class I α1 domain (with red frames) and six positions of the class I α2 domain (with blue frames). I α2Q6 (with light blue frame), I α1R60 and $\beta_2$-m D54 (both with light green frames) are also indicated, although these can be observed in the corresponding positions of some classical class II molecules (Datasets S1 and S2). A glutamine corresponding to I α2Q6 is highly conserved in WB β1 domains, and an arginine corresponding to I α1R60 plus an aspartic acid corresponding to $\beta_2$-m D54 can be found in teleost fish and lungfish WA. $\beta_2$-m L55, $\beta_2$-m F57 and $\beta_2$-m W61, three residues of $\beta_2$-m at the interface shared between W-category and class I molecules are also indicated.

Additional explanations for this figure are described in the section 11 of *SI Appendix*.

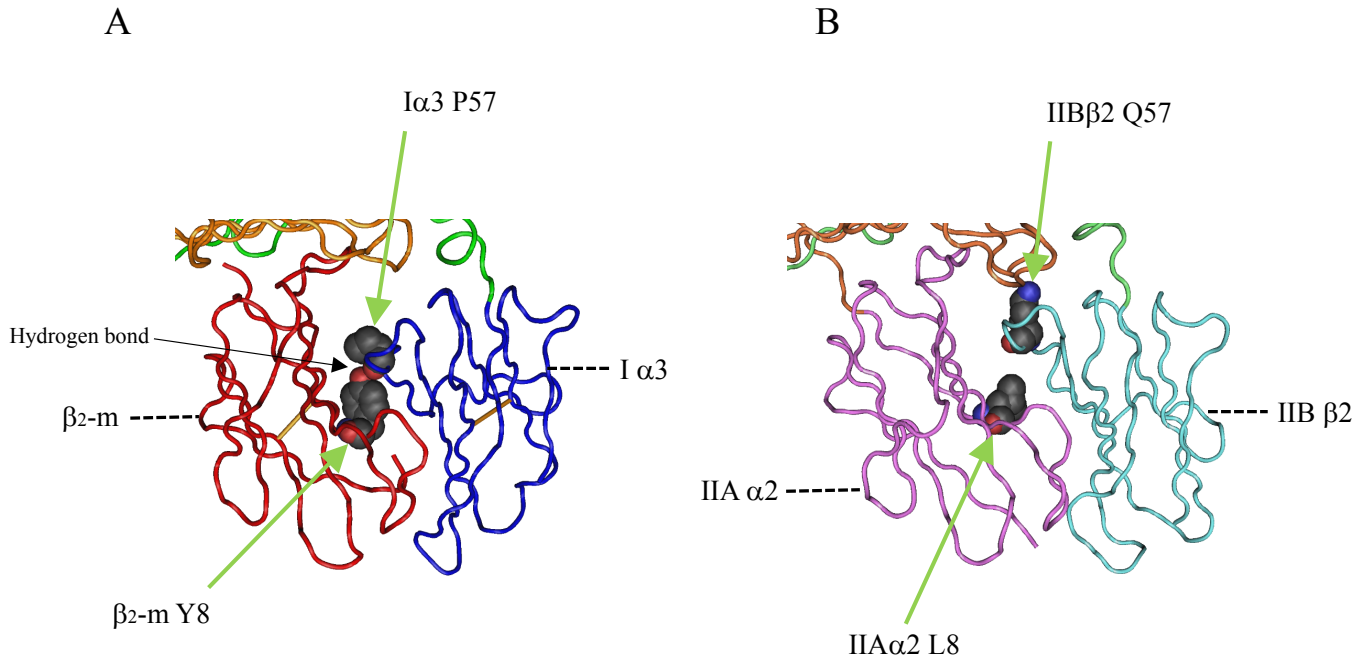

**Fig. S6. MHC class I α3 domain P57 interacts with Y8 of $\beta_2$-m.**
**A.** The main chain carbonyl oxygen of MHC class I α3 P57 interacts with a hydrogen atom of a hydroxyl group of $\beta_2$-m Y8 through a hydrogen bond (29).
**B.** The residues of the classical MHC class II molecule whose positions are corresponding to class I α3 P57 and Y8 of $\beta_2$-m are shown.
HLA-A2 (PDB ID: 1QSF) and HLA-DR1 (PDB ID: 1DLH) were used for MHC class I and class II molecules, respectively. The relevant amino acid residues with their side- and main-chains are presented using the space-filling model representation. Oxygen: red, nitrogen: blue, and carbon: black.

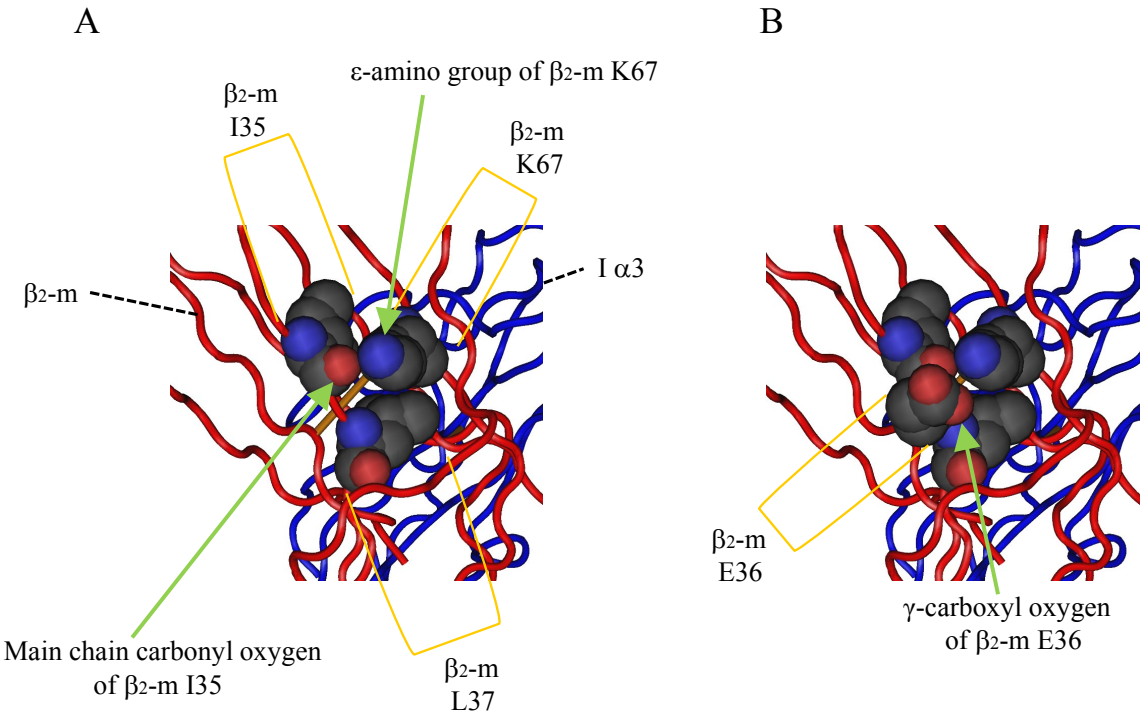

**Fig. S7. β2-m K67 can form intra-domain hydrogen bonds.**
**A**, A structural drawing centered on grass carp β2-m K67 is shown. A hydrogen atom from ε-amino group of grass carp β2-m K67 forms a hydrogen bond with a main chain carbonyl oxygen of β2-m I35 (69). The ε-amino group of grass carp β2-m K67 and the main chain carbonyl oxygen of β2-m I35 are indicated with green arrows. In addition to β2-m K67 and β2-m I35, β2-m L37 whose sequence position is corresponding to that of the conserved W37 of the Ig-superfamily, is also shown. The relevant three amino acid residues with their side- and main-chains are shown as the space-filling model and their approximate locations are indicated with yellow brackets. β2-m (red) and class I α3 domain (blue) are indicated. **B,** The same structure from the same angle as shown in A, but also showing the space-filling model of β2-m E36 (indicated with a yellow bracket). β2-m K67 forms a hydrogen bond to a γ-carboxyl oxygen of β2-m E36 (69).

Grass carp class I molecule (PDB ID: 5Y91) was used for the drawing. Oxygen: red, nitrogen: blue, and carbon: black.

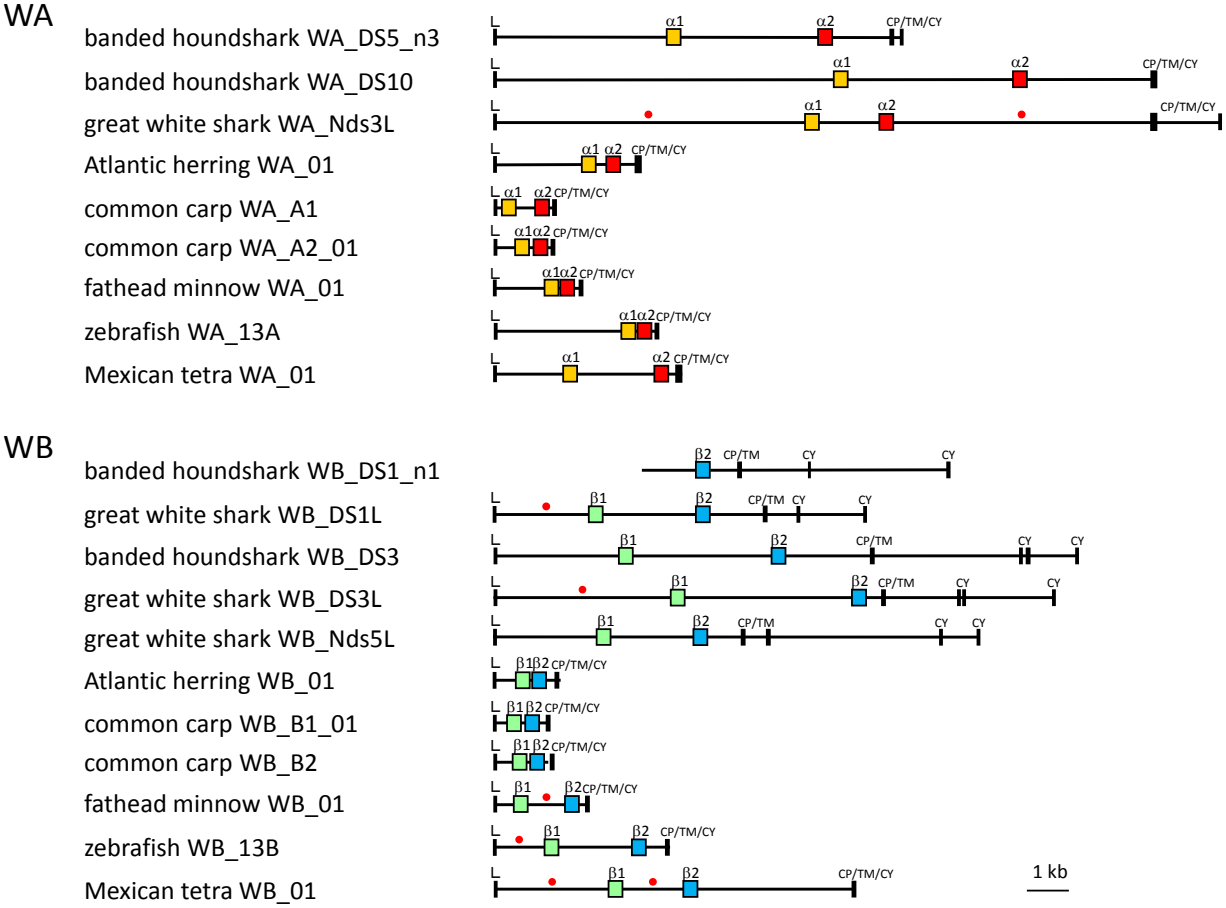

**Fig. S8. The genomic structures of additional W-category genes with class II domain architectures.** The genomic structures of coding exons and introns of additional *WA* and *WB* genes are shown. The genomic sequence of banded houndshark *WB_DS1_n1* was partially determined and its 5' side has not yet been clarified. The genomic sequence of banded houndshark *WB_DS3* was determined using two parts which contain the first four and the last three exons, respectively. Colored boxes are explained in the legend to Fig. 5. Within some intron sequences, undetermined regions in the database information exist and those introns are indicated by red filled circles.

**Fig. S9. All four investigated types of banded houndshark W-category genes belong to the same linkage group.** Panel A, C and D show Southern blots for linkage analyses of DNA samples from seventeen littermates and their mother using *WA_DS5*, *WB_DS1* and *WB_DS3* probes, respectively. Panel B shows PCR amplification of *WA_DS10* for linkage analyses because of a limitation of the shark DNA samples. Panel E shows the summary of the linkage analyses.

**A**, Southern blot analysis using banded houndshark *WA_DS5* as probe. Left: Positive bands of seventeen littermates exhibit four patterns, which are shown with the represented haplotype symbol combination (e-h, indicated on top) with lane numbers as follows: (1, 4, 6, 8, 9, 11, 17; eg), (2, 5, 7, 10, 16; fg), (3, 14, 15; eh) and (12, 13; fh). Based on similar arguments as in the previous studies (17, 33), these four patterns could represent four distinct haplotype patterns produced by total of four different haplotypes of their parents (maternal, e and f; paternal, g and h) through Mendelian inheritance. Positive bands were assigned to one of the haplotypes (indicated on the right), in some cases with difficulties because of limited resolution. The DNA lengths of the size markers in kilo-bases (kb) are indicated on the left side. Right: Southern blot analysis of mothers's DNA along with representative littermates. The experiment described in the left picture did not contain mother's DNA.

**B**, PCR amplification of banded houndshark *WA_DS10*. Left: DNA fragments amplified from the seventeen littermates and their mother's DNA with two primers (forward: HhaI-group F1, reverse: HhaI-group R1 described in Table S2) were digested with the restriction enzyme *Hha*I and the products analyzed with agarose gel (3 %) electrophoresis. All samples with an additional band (as indicated with an arrow on the right hand side) are indicated by arrowheads (on top). The seventeen littermates could be classified into two groups; an HhaI-group "i" and an HhaI-group "j" with the latter showing an additional band. Right: DNA fragments amplified from seventeen littermates and their mother's DNA with two primers (forward: Amp-group F1, reverse: Amp-group R1), analyzed with agarose gel (1 %) electrophoresis. All samples with amplification of DNA fragments of approximately 8 kb in size (as indicated with an arrow on the right hand side) are indicated by arrowheads (on top). The seventeen littermates could be classified into two groups; an Amp-group "k" and an Amp-group "l" with the latter showing an 8 kb band. Variations observed in the results of the left and right experiments are considered to represent haplotype variations. Combining these results indicates four patterns, shown with the represented group (haplotype) symbol combinations along with lane numbers as follows: (1, 4, 6, 8, 9, 11, 17; ik), (2, 5, 7, 10, 16; jk), (3, 14, 15; il) and (12, 13; jl).

**C**, Southern blot analysis using banded houndshark *WB_DS1* as probe. Like in A, positive bands of seventeen littermates exhibit four patterns, which are shown with the represented haplotype symbol combination with lane numbers as follows: (1, 4, 6, 8, 9, 11, 17; mo), (2, 5, 7, 10, 16; no), (3, 14, 15; mp) and (12, 13; np).

**D**, Southern blot analysis using banded houndshark *WB_DS3* as probe. Like in A, positive bands of seventeen littermates exhibit four patterns, which are shown with the represented haplotype symbol combination with lane numbers as follows: (1, 4, 6, 8, 9, 11, 17; qs), (2, 5, 7, 10, 16; rs), (3, 14, 15; qt) and (12, 13; rt).

**E**, Summary of the haplotype classification of W-category and classical MHC genes. The number of the banded houndshark individual littermate, mother (M) and father (F) are shown on top. In the first row, previously published haplotype classifications of classical MHC genes (17, 33) are shown with four different colors (purple, light blue, orange and pale yellow). In the following rows, haplotype classifications of banded houndshark *W-category* genes are shown in addition to the deduced haplotype of the father. Identical patterns are observed for *WA_DS5*, *WA_DS10*, *WB_DS1* and *WB_DS3* as shown with four different colors (red, green, yellow and blue). This indicates that in banded houndshark all four investigated types of W-category genes belong to the same linkage group. The distribution of the four W-category haplotypes (red, green, yellow and blue) over the littermates is completely different from the distribution of the classical MHC genes haplotypes (purple, light blue, orange and pale yellow), indicating that the four investigated W-category genes are not linked with the classical MHC genes. Linkage analysis of banded houndshark $\beta_2$-*m* gene was conducted

separately and shown to be linked with the classical MHC genes (*SI Appendix* and Fig. S15) as also reported for another shark species (28).

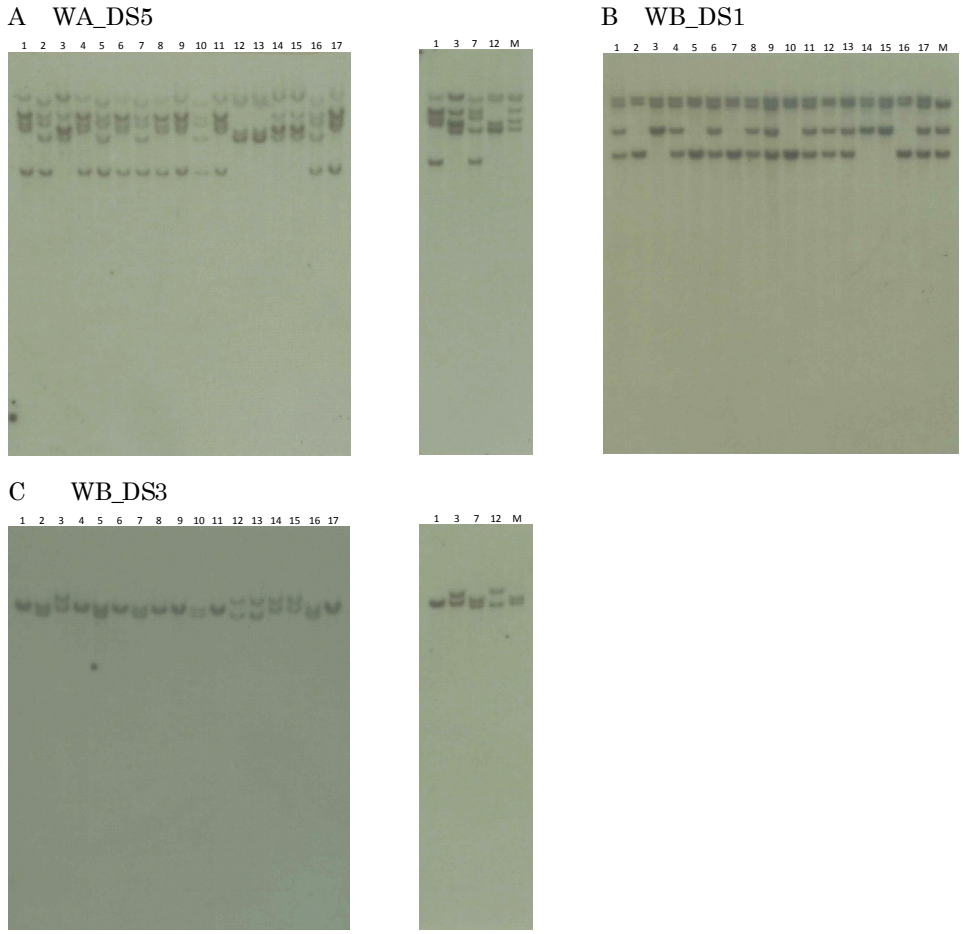

**Fig. S10. Full pictures of the Southern blots used for linkage analyses in Fig. S9.**
**A**, probe: banded houndshark *WA_DS5*, **B**, probe: banded houndshark *WB_DS1*, **C**, probe: banded houndshark *WB_DS3*. The numbers indicate individual sharks and "M" indicates their mother as in Fig. S9. There are no positive bands in the blots other than those shown in Fig. S9. Agarose gels of 0.8 % were used.

**Fig. S11. Genomic locations of W-category genes of cartilaginous fish and of teleost fish.**
**A**, Great white shark 285 K contig containing three *WA* (red) and three *WB* (blue) genes. There are three *WA*/*WB* pairs with head-to-head configurations, although the pairing remains to be studied at the protein level. The three pairs are: *WA_Nds3L*/*WB_DS3L*, *WA_DS10L*/*WB_DS1L*, and *WA_DS5L*/*WB_Nds5L*. In the same contig, in addition to the *WA* and *WB* genes, some gene fragment sequences were identified in the surrounding regions of *WA*/*WB* genes as described below.

*SEMA3F*-like sequence (~144 bp), corresponding to the coding sixteenth exon (total 19 exons) sequence of human *SEMA3F* (chromosome 3p21.31, 50 M 155 K) transcript variant 1 (NM_004186). A blast search of the Mexican tetra genome with this *SEMA3F*-like sequence revealed the *sema3f* gene situated near the W-category genes (see D) as the top match.

*FTSJ1*-like sequences of ~69 bp and ~93 bp corresponding to the fourth and the eleventh coding exon sequences, respectively, of human *FTSJ1* (chromosome Xp11.23, 48 M 476 K) transcript variant 1 (NM_012280).

*WDR13*-like sequences (length: ~94 to ~316 bp with mixed orientations) corresponding to six coding exon sequences including the exons 4 and 6-10 of human *WDR13* (chromosome Xp11.23, 48 M 590 K) transcript variant 4 (NM_001347217). The closest relative of human *WDR13* gene, *WDR5*, is present at the human chromosome 9q34.2 that was previously regarded as an *Mhc* paralogous region (87, 88). *WDR5B*, a sequence homologous to *WDR5*, is located on human chromosome 1 (~122 M) close to the *CASR* gene (see the axolotl W-category contig; Fig. S12B) and close to other *Mhc* region-related genes.

**B**, Cloudy catshark 159 K and 82 K contigs containing *WA* (red) and *WB* (blue) genes. The order of the genes is the same as that of great white shark in A. *WA_DS5L*/*WB_Nds5L* gene pairs of the two contigs are distinct from each other (*SI Appendix*).

**C**, Atlantic herring 344 K contig and Hilsa shad 325 K contig containing *WA* (red) and *WB* (blue) genes.

Genes which are homologous to the sequences (depicted with red color) in the surrounding regions of the *WA*/*WB* gene pair in these contigs can be found in the human chromosome 15 (shown on the right), which is closely related to the *Mhc* region (28, 87, 88) and where the $\beta_2$-microglobulin ($\beta_2$-m) gene and many other *Mhc* related genes are present. Some selected sequences in the surrounding regions of the *WA*/*WB* gene pair and their homologies with the human genes are described below.

In the Atlantic herring 344 K contig:

*MEGF11*-like sequences correspond to a part of the coding sixth exon of human *MEGF11* (chromosome 15q22.31, 66 M 253 K) mRNA sequence (NM_032445) with 73 % identity (176/240), to a part of the coding twenty-second exon with 86 % identity (95/110), and to a part of the coding eighth and ninth exons with 83 % identity (87/105). These sequences also show similarity to a part of human *MEGF10* gene (chromosome 5q23.2, 127 M 229 K).

A *SLC24A1*-like sequence corresponds to a part of the coding fourth exon of human *SLC24A1* (chromosome 15q22.31, 65 M 611 K) transcript variant 5 (NM_001301033.2) with 77 % identity (414/539). Another *SLC24A1*-like sequence corresponds to the coding tenth exon with 84 % identity (148/177). These sequences also show similarity with a part of human *SLC24A2* (chromosome 9p22.1-p21.3), *SLC24A3* (chromosome 20p11.23) and *SLC24A4* (chromosome 14q32.12) sequences.

In both Atlantic herring and Hilsa shad contigs (described using the results of Atlantic herring):

*DENND4B*-like sequence stretch corresponds to a part of the coding sixth exon of human *DENND4B* (chromosome 1q21.3, 153 M 946 K) transcript variant 2 (NM_001367466) with 84 % identity (118/140 or 108/129), to the coding twelfth exon with 76 % identity (139/184), to the coding seventeenth and eighteenth exon with 72 % identity (156/217), and to the coding twenty-fourth exon with 76 % identity (108/142).

Some *DENND4B* -like sequences are also *DENND4A*-like, and *DENND4A*-like sequences correspond to various portions of human *DENND4A* (chromosome 15q22.31, 65 M 792 K).

*ZBED9*-like sequence corresponds to the non-coding sequence of human *ZBED9* (chromosome 6p22.1, 28M 616K, in the *Mhc* region) transcript vatiant X2 mRNA sequence (XM_011514285) with 90 % identity (65/72). A blastn search of the human genome with the Atlantic herring *ZBED9*-like noncoding 72 bases revealed the sequences of chromosome 6, 15 and 17 as the top matches: chromosome 6, 18 M 836 K, 27 M 519 K, 28 M 941 K; chromosome 15, 65 M 869 K; chromosome 17, 8 M 119 K. On human chromosome 6, the locations of some MHC class I genes are as follows: HFE (26 M 87 K), HLA-F (29 M 723 K), HLA-G (29 M 826 K), HLA-A (29 M 942 K), HLA-E (30 M 489 K), HLA-C (31 M 272 K), HLA-B (31 M 357 K), MICA (31 M 400 K), MICB (31 M 494 K). The location of the homologous sequence of *ZBED9*-like noncoding sequence on human chromosome 15 (65 M 869 K) is indicated in the figure.

*GNPAT*-like sequence corresponds to the coding seventh exon of human *GNPAT* (chromosome 1q42.2, 231 M 241 K) transcript variant 1 mRNA sequence with 69 % identity (88/127). Near the W-category genes of zebrafish, fourteen genes that are homologous to the genes found in the human chromosome 1 (~231 M) exist.

A *NR2E3*-like sequence corresponds to the coding second exon of human *NR2E3* (chromosome 15q23, 71 M 810 K) transcript variant 1 mRNA sequence (NM_016346) with 82 % identity (106/129). Another *NR2E3*-like sequence corresponds to a part of the coding fifth exon with 90 % identity (77/86).

*ARIH1*-like sequences correspond to the coding tenth exon of human *ARIH1* (chromosome 15q24.1, 72 M 474 K) mRNA sequence (NM_005744) with 81 % identity (113/139) and to the twelfth exon with 87 % identity (228/263).

In the Hilsa shad 325 K contig:

*RHCG*-like sequences correspond to the coding second exon of human *RHCG* (chromosome 15q26.1, 89 M 496 K) transcript variant 3 mRNA sequence (NM_001321041) with 88 % identity (137/155), to the coding sixth exon with 79 % identity (97/123), to the coding fifth exon with 74 % identity (120/175), to the coding fourth exon with 73 % identity (108/147), and to the coding seventh exon with 70 % identity (84/120).

Some *RHCG*-like sequences are also *RHBG*-like, and these *RHBG*-like sequences correspond to the coding third exon of human RHBG (chromosome 1q22, 156 M 366 K) transcript variant 3 mRNA sequence (NM_001256396) with 78 % identity (124/159), to the coding fifth exon with 71 % identity (103/146), to a part of the coding sixth exon with 75 % identity (63/84), and to a part of the coding eighth exon with 81 % identity (44/54).

*FES*-like sequences correspond to the coding fifteenth exon of human FES (chromosome 15q26.1, 90 M 884 K) transcript variant 4 mRNA sequence (NM_001143785) with 78 % identity (123/158), to the coding sixteenth exon with 78 % identity (102/131), to the coding thirteenth exon with 83 % identity (81/98), to the coding twelfth exon with 72 % identity (89/124), and to a part of the coding fourteenth exon with 84 % identity (38/45).

*FURIN*-like sequences correspond to the coding ninth exon of human FURIN (chromosome 15q26.1, 90 M 868 K) transcript variant 1 mRNA sequence (NM_002569) with 85 % identity (185/217), to the coding eighth exon with 77 % identity (137/179), to a part of the coding thirteenth exon with 81 % identity (88/108), to the coding tenth exon with 81 % identity (82/101), to the coding fourteenth exon with 81 % identity (80/99), to the coding twelfth exon with 80 % identity (80/100), to the coding sixth exon with 82 % identity (67/82), to the coding seventh exon with 79 % identity (73/92), to the coding fourth exon with 78 % identity (69/89), and to the coding eleventh exon with 74 % identity (79/107).

*PCSK4*-like sequences correspond to the coding eighth exon of human *PCSK4* (chromosome 19p13.3, 1 M 490 K) transcript variant X22 mRNA sequence (XM_024451556) with 81 % identity (152/188), to the coding seventh exon with 76 % identity (134/176), to a part of the coding twelfth exon with 76 % identity (90/118), and to the coding tenth exon with 74 % identity (72/97). Identification of exons are based on *PCSK4* mRNA sequence (NM_017573).

Some *PCSK4*-like sequences are also *PCSK6*-like, and these *PCSK6*-like sequences correspond to the coding eighth exon of human *PCSK6* (chromosome 15q26.3, 101 M 489 K) transcript variant 3 mRNA

sequence (NM_138322) with 77 % identity (137/177), to the coding seventh exon with 77 % identity (115/150), and to the coding fourth exon with 76 % identity (71/94).

**D**, Mexican tetra chromosome 22 containing *WA* (red) and *WB* (blue) genes. The pair of *WA*/*WB* genes is sandwiched in between *slc38a3* and *cacna1d3* genes.

On human chromosome 3 (shown on the left of the Mexican tetra's), homologous genes for many surrounding genes of the Mexican tetra *WA*/*WB* gene pair can be found (indicated by blue lines).

In the corresponding region of zebrafish chromosome 11 (shown on the right of the Mexican tetra's), *WA* and *WB* genes are not present, but present on zebrafish chromosome 13 (see E).

In the region of the human chromosome 1 previously regarded as the *Mhc* paralogous regions (87, 88) (second from the right), homologous genes or closely related genes for some surrounding genes of the Mexican tetra *WA*/*WB* gene pair can be found (shown in red color), and these are also indicated in the figure of the Mexican tetra and zebrafish chromosomal regions.

In the region of 80 M~100 M of human chromosome 7 which includes MHC nonclassical MHC class I gene (*AZGP1*) (shown on the far right), closely related genes for some surrounding genes of the Mexican tetra *WA*/*WB* gene pair can be found (shown in red or green color). VPS50 and COL1A2 genes are present near *AZGP1*. In the human *Mhc* region, VPS52 (chromosome 6p21.32, 33 M 271 K) and COL11A2 (chromosome 6p21.32, 33 M 193 K) are located close to each other like VPS50 and COL1A2 shown in the figure.

In the surrounding region of the Mexican tetra *WA*/*WB* gene pair, *sema3f* gene, whose related gene fragment can be found near the great white shark W-category genes (shown in A), is highlighted in light blue color. On human chromosome 7 (on the far right), closely related genes for this *sema3f* gene are also highlighted in light blue color.

**E**, Zebrafish chromosome 13 containing *WA* (red) and *WB* (blue) genes. Genomic regions of zebrafish relatives, e. g., Amur ide, fathead minnow and common carp, also containing a *WA*/*WB* gene pair.
The *WA/WB* pair of zebrafish and its relatives is located between *fibulin* 7 gene (*fbln7*) and *zinc finger CCCH-type containing 6* gene (*zc3h6*).

On human chromosome 2 (shown on the left of the zebrafish's), homologous genes for many surrounding genes of the zebrafish *WA*/*WB* gene pair can be found (indicated by blue lines).

In the region of zebrafish chromosome 13 shown, homologous genes for several genes in green color are located on human chromosome 6: *TMEM63B* (6p21.1, 44 M 126 K), *SLC29A1* (6p21.1, 44 M 219 K), *MTRF1L* (6q25.2, 153 M 3 K), *FBXO5* (6q25.2, 152 M 983 K), and *VIP* (6q25.2, 152 M 750 K). Near human chromosome 6q25.2, several MHC related genes are present, including *ULBP1~3*, e. g., *ULBP3* (6q25.1, 150 M 69 K). Homologous genes for several genes in red color are located on human chromosome 1: *NTPCR* (1q42.2, 232 M 950 K), *SIPA1L2* (1q42.2, 232 M 630 K), *DISC1* (1q42.2, 231 M 626 K), *TSNAX* (1q42.2, 231 M 528 K), and *EGLN1* (1q42.2, 231 M 425 K). Near human chromosome 1q42.2, some *Mhc* region-related genes are present, including *AKT3* (1q43-q44, 243 M 851 K).

Amur ide 28 M contig and fathead minnow 111 K contig contain a *WA*/*WB* pair at the genomic region corresponding to the zebrafish chromosome 13.

In case of common carp, two pairs of *WA* and *WB* genes exist, namely, a pair of *WA_A1* and *WB_B1* and another pair of *WA_A2* and *WB_B2*. The common carp contig containing *WA_A1* and *WB_B1* comes in two forms with different genomic configuration, depending on the genomic source: in one form (common carp 107 K contig, *SI Appendix*), an inversion including a partial *WA_A1* was observed. The common carp contigs containing *WA_A2* and *WB_B2* also comes in two forms with different genomic configuration, depending on the genomic source (the difference indicated by a bracket): in one form (common carp 138 K contig), there exists a *WB_B2* gene fragment at around 100 kb distant from the full-length *WB_B2* gene, as shown in the figure.

Mexican tetra chromosome 25, containing *fibulin-7* gene and corresponding to the zebrafish chromosome 13 region, is shown (on the far right).

**F**, Common carp W-category gene fragment maps close to the nonclassical class I and class II genes. *WA* α2 domain gene fragment (red) exists near MHC class I (light blue) and class II (orange for IIA and green for IIB) genes in the common carp genome. Left, a portion of a common carp 20 M contig on which *WA_A1* α2 fragment is present. Close to this sequence, nonclassical lineage class I and nonclassical lineage class II genes are present. The genomic environment of this region partly resembles the zebrafish chromosome 8 (right) where several nonclassical class I (L-lineage), nonclassical class II genes and some other genes are located (89). Right, the region of 40M~45M of the zebrafish chromosome 8 with selected genes. "Ca ch" stands for "calcium release-activated calcium channel protein 1-like".

Additional information is described in Supplementary Information. Information on the contigs in this figure is listed in Table S3. Only selected genes are shown, and the genomic maps are schematic and not proportional to the actual distances of DNA.

**Fig. S12. Genomic locations of W-category genes of coelacanth and of salamander axolotl.**
**A**, Coelacanth *WA/WB* gene pair maps within the *Mhc* region.
In the *Mhc* region of the African coelacanth, *WA_1* (red) and *WB_1* (blue) genes were identified (*SI Appendix*). The locations of various genes present in this region (34, 35) were compared with those of the corresponding human genes situated at the human *Mhc* region (chromosome 6p21.3) as shown on the right-hand side. Colors indications are as follows: MHC class I, light blue; MHC class II α chain, orange; MHC class II β chain, green.

**B**, Salamander axolotl *WA/WB* gene pair exists together with genes related to the *Mhc* regions.
Axolotl *WA* (red) and *WB* (blue) gene sequences were identified in one contig. The genes are not intact which may be due to some difficulties in sequencing this region (Supplementary Information).
In addition to the W-category sequences, in the surrounding regions there are notable sequences related to the *Mhc* region as described below:

*ZNF420*-like sequences (length ~1628 bp) covering partial coding sequences (666-2294) of the fifth exon (399-3639) of human *ZNF420* transcript variant 2 (NM_144689) with around 65 % identity. The human *ZNF420* gene exists on chromosome 19q13.12 (37 M 7 K, far right in the figure) in a region previously regarded as *Mhc* paralogous (28). In this region, the nonclassical MHC class I gene *FCGRT* (encoding FcRn protein) is located as shown. A gene homologous to the *ZNF112* gene (near the center of the region shown) was reported to exist next to the $\beta_2$-microglobulin gene in the nurse shark (28).

*CASR*-like sequence (length ~157 bp) corresponding to partial coding sequences (~2837-2994) of the seventh exon (2208-10150) of human *CASR* transcript variant 1 (NM_001178065) with 71 % identity (113/159). The human *CASR* gene exists on chromosome 3q13.33-q21.1 (122 M 183 K) near some *Mhc* region-related genes, e. g., *CD86* (122 M 55 K), *CD80* (119 M 559 K), *SEMA5B* (123 M 28 K) and *WDR5B* (122 M 416 K) genes. CD80 and CD86 belong to B7 family, whose members are found in the *Mhc*-related regions. *WDR5B* is closely related with *WDR13* (chromosome Xp11.23, 48 M 590 K). *WDR13*-like sequences were found near W-category genes of great white shark (Fig. S11A). The human *WDR5* gene, the homolog of *WDR5B*, exists on chromosome 9q34.2 (134 M 135 K) which was previously regarded as the *Mhc* paralogous region (87, 88).

*SLC12A*-like sequences are present in the region of 2.5 ~3.5 M of this contig. Examples are as follows. One *SLC12A*-like sequence corresponds to a partial coding sequence (~804-940) of the first exon (1-945) of human *SLC12A2* (chromosome 5q23.3, 128 M 83 K) transcript variant 1 (NM_001046) with 75 % identity (104/139). Another *SLC12A*-like sequence corresponds to a coding sequence (~1900-2023) including the fourteenth exon (1901-2002) of human *SLC12A1* (chromosome 15q21.1, 48 M 206 K) transcript variant 1 (NM_000338) with 80 % identity (100/125). The human *SLC12A1* and *FBN1* genes exist near $\beta_2$-microglobulin ($\beta_2$-m) gene on chromosome 15.

*FBN*-like sequences are present in the region of 3.5 ~ 3.9 M of this contig. *FBN*-like sequences in this contig correspond to many coding exon sequences of the human *FBN2*, *FBN3* and *FBN1* sequences. Examples are as follows. One *FBN*-like sequence corresponds to a coding sequence (~1269-1468) including the sixth exon (1271-1468) of human *FBN2* mRNA (NM_001999) with 85 % identity (170/200). Another *FBN*-like sequence corresponds to a coding sequence (~8087-8218) including the sixty-third exon (8095-8214) of human *FBN1* mRNA (NM_000138) with 82 % identity (108/132). The homologs of *FBN* genes exist on human chromosome 15q21.1, 48 M 645 K (*FBN1*), 5q23.3, 128 M 538 K (*FBN2*) and 19p13.2, 8 M 149 K (*FBN3*) which are previously regarded as *Mhc* related regions (87, 88). Both the human *SLC12A* and *FBN* homologs are present on human chromosomes 5 and 15 as shown.

The axolotl contig also contains human *TCAF1*/*TCAF2*-like and *RPL27*-like sequences as shown. The locations of these human genes on human chromosomes are: *TCAF1* and *TCAF2*, 7q35 (~143 M); *RPL27*, 17q21.31 (~43 M).

Information on the contigs in this figure is listed in Table S3. Only selected genes are shown, and the genomic maps are schematic and not proportional to the actual distances of DNA. Some annotated pseudogenes are included. Within the African coelacanth 1088 K contig, additional class I gene (fragment) sequences are present, but not indicated.

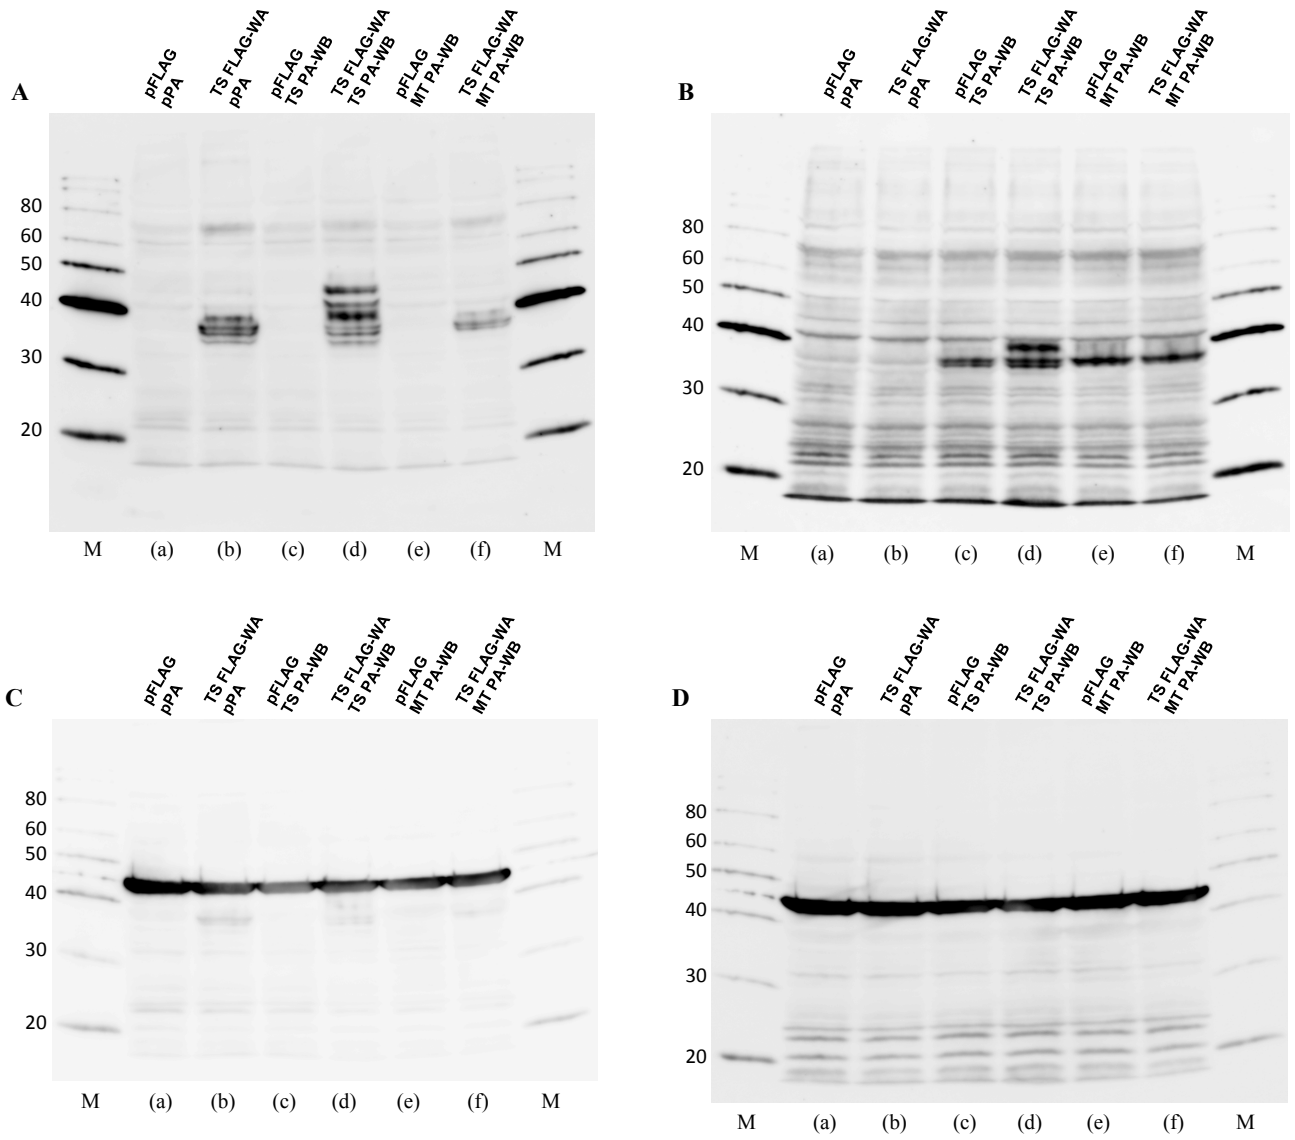

**Fig. S13. Production of recombinant WA and WB proteins in transfected cells with β-actin control.** Total proteins from CHO K-1 transfected cells were investigated by Western blot analyses. The panels (A) and (B) are the same as those in Fig. 6. (*A*) FLAG-tagged WA detected by anti-FLAG antibody. (*B*) PA-tagged WB detected by anti-PA antibody. (*C*) $\beta$ -actin controls using the membrane in *A*. (*D*) $\beta$ -actin controls using the membrane in *B*. Apparent molecular weights of protein size markers are indicated in kilo Dalton. Abbreviations are the same as those in Fig. 6. See *SI Appendix* for details.

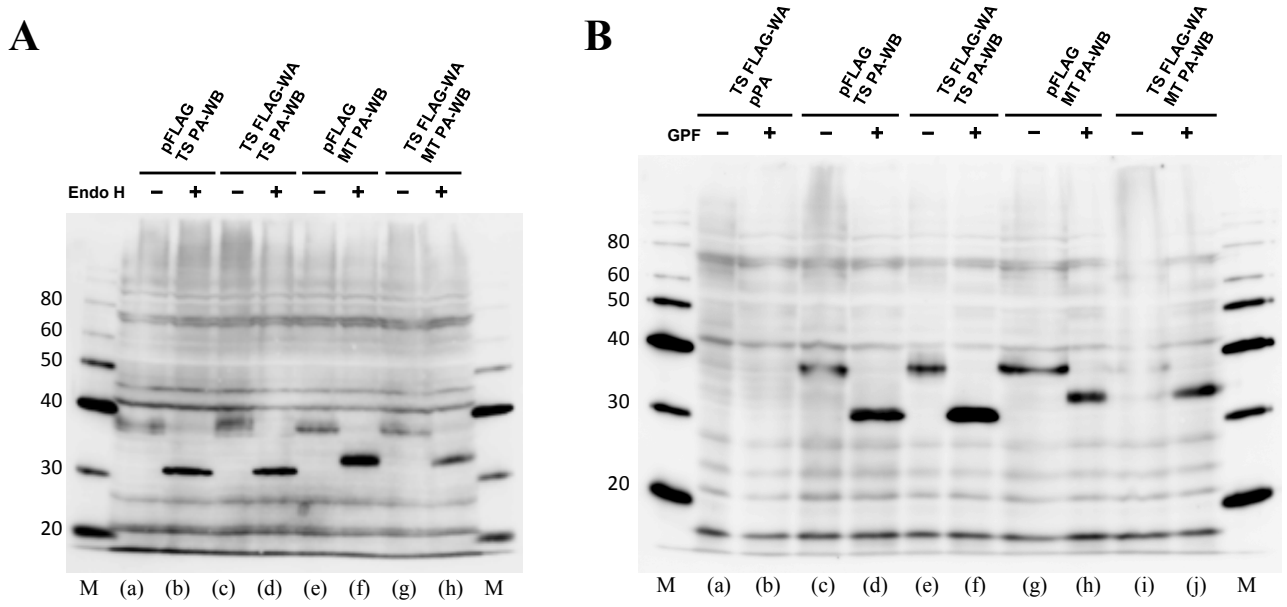

**Fig. S14. Digestion of recombinant WB protein by Endoglycosidase H (Endo H) or Glycopeptidase F (GPF).** Enzyme-digested total protein from transfected CHO-K1 cells were investigated by Western blot analyses. (A) PA-tagged WB with/without (+/-) Endo H digestion detected by anti-PA antibody. (B) PA-tagged WB with/without (+/-) GPF digestion detected by anti-PA antibody.
Apparent molecular weights of protein size markers are indicated in kilo Dalton. Abbreviations are the same as those in Fig. 6. See *SI Appendix* for details.

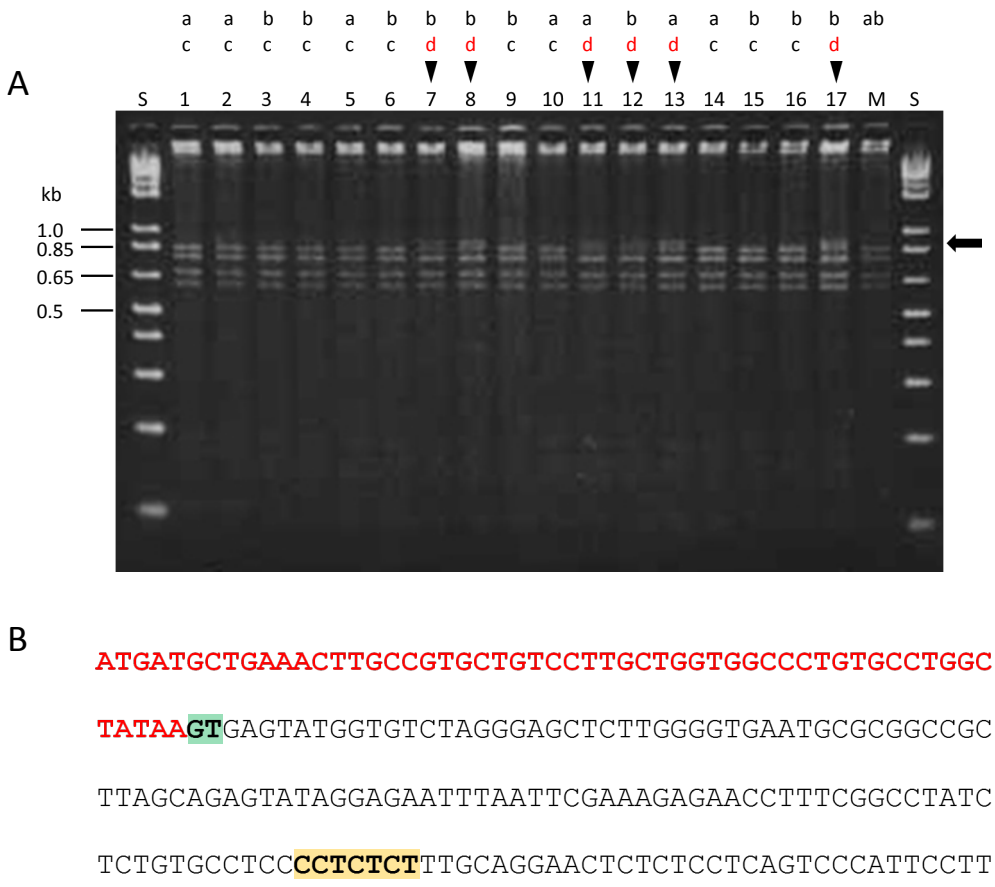

**Fig. S15. Linkage analysis of banded houndshark *β₂-m* gene.**
**A**, Banded houndshark *β₂-m* gene is linked with the classical MHC genes. The PCR products amplified with forward (F11) and reverse (R10) primers were digested with the restriction enzyme *Mbo*II and the products were analyzed using agarose gel electrophoresis. Arrowheads (on top) indicate the samples in which an additional band (indicated by an arrow on the right hand side) of slightly larger than 850 bp can be observed. The distribution of this additional band among the seventeen littermate sharks perfectly matches with that of the paternal haplotype "d" described in case of the classical MHC genes (Fig. S9; 17). Assumed classical MHC haplotype classifications are shown on top ("d" in red). The lengths of size markers (S) are indicated on the left. An agarose gel of 4 % was used. **B**, The genomic sequence near the leader-coding exon of the banded houndshark *β₂-m* gene reveals haplotype variation. Red letters show the leader-encoding nucleotides starting with a methionine start codon, ATG. Green shading indicates a splicing signal sequence. Yellow shading indicates the seven nucleotides which are present in the paternal haplotype "d" of the banded houndshark individual No.12. The maternal haplotype "b" does not possess these seven nucleotides based on the analysis of the banded houndshark individual No.12 (haplotype "bd"). The maternal haplotype "a" and paternal haplotype "c" also do not appear to possess these seven nucleotides based on the result described in A. Additional information is described in *SI Appendix*.

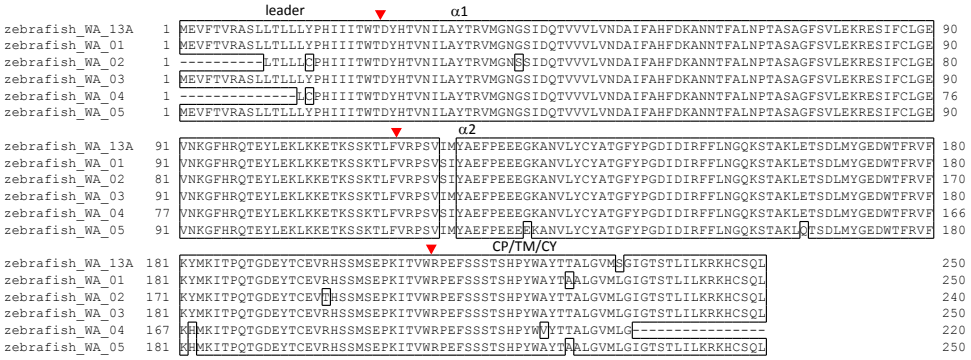
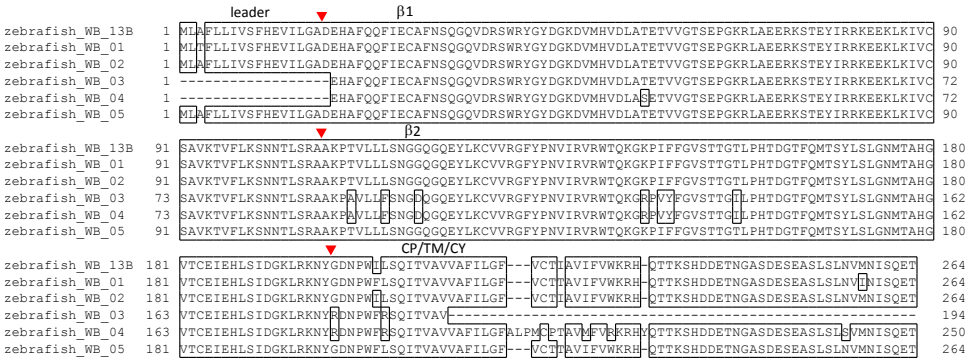
**Fig. S18. Phylogenetic tree analysis of W-category and MHC class I and class II molecules including nonclassical molecules.** The phylogenetic tree was constructed with membrane-proximal Ig-like C1-set domains of selected MHC molecules using Maximum Likelihood. Several nonclassical class I and class II molecules are included in this analysis. The percentage of trees (bootstrap value, 50 or greater) in which respective sequences clustered together is shown next to the nodes. The bootstrap value at the WA$\alpha$2/$\beta_2$-m node is shown in red. A more detailed explanation is described in the Materials and Methods. The alignment used for this analysis is shown in Dataset S2. Red dots mark WA $\alpha$2 sequences and blue dots mark WB $\beta$2 sequences.

A Zebrafish WA



B Zebrafish WB



C

| strain | individual | WA | | WB | |
|---|---|---|---|---|---|
| AB | AB-1 | WA-01 | | WB-01 | |
| | AB-2 | WA-01 | | WB-01 | |

| WIK | WIK-1 | WA-05 | | WB-05 | |
| | WIK-2 | WA-05 | | WB-05 | |

**Fig. S19. Variations in W-category molecules observed for zebrafish.**
**A**, Zebrafish WA sequences. **B**, Zebrafish WB sequences. Sequences labeled 01~05 were identified in individuals of four different zebrafish strains (AB, IND, TL and WIK) as summarized in C. WA_13A and WB_13B are taken from zebrafish genomic sequences. The primer sequences used to amplify zebrafish W-category cDNA are listed in Table S2. Red arrowheads indicate the corresponding positions of exon/intron borders in the genome. For some sequences, the amino and/or carboxyl terminal side(s) are not available because of the primer positions chosen. **C**, Distribution of zebrafish W-category sequences among various strains. One or two sequences for WA and for WB per individual could be identified using our procedure.

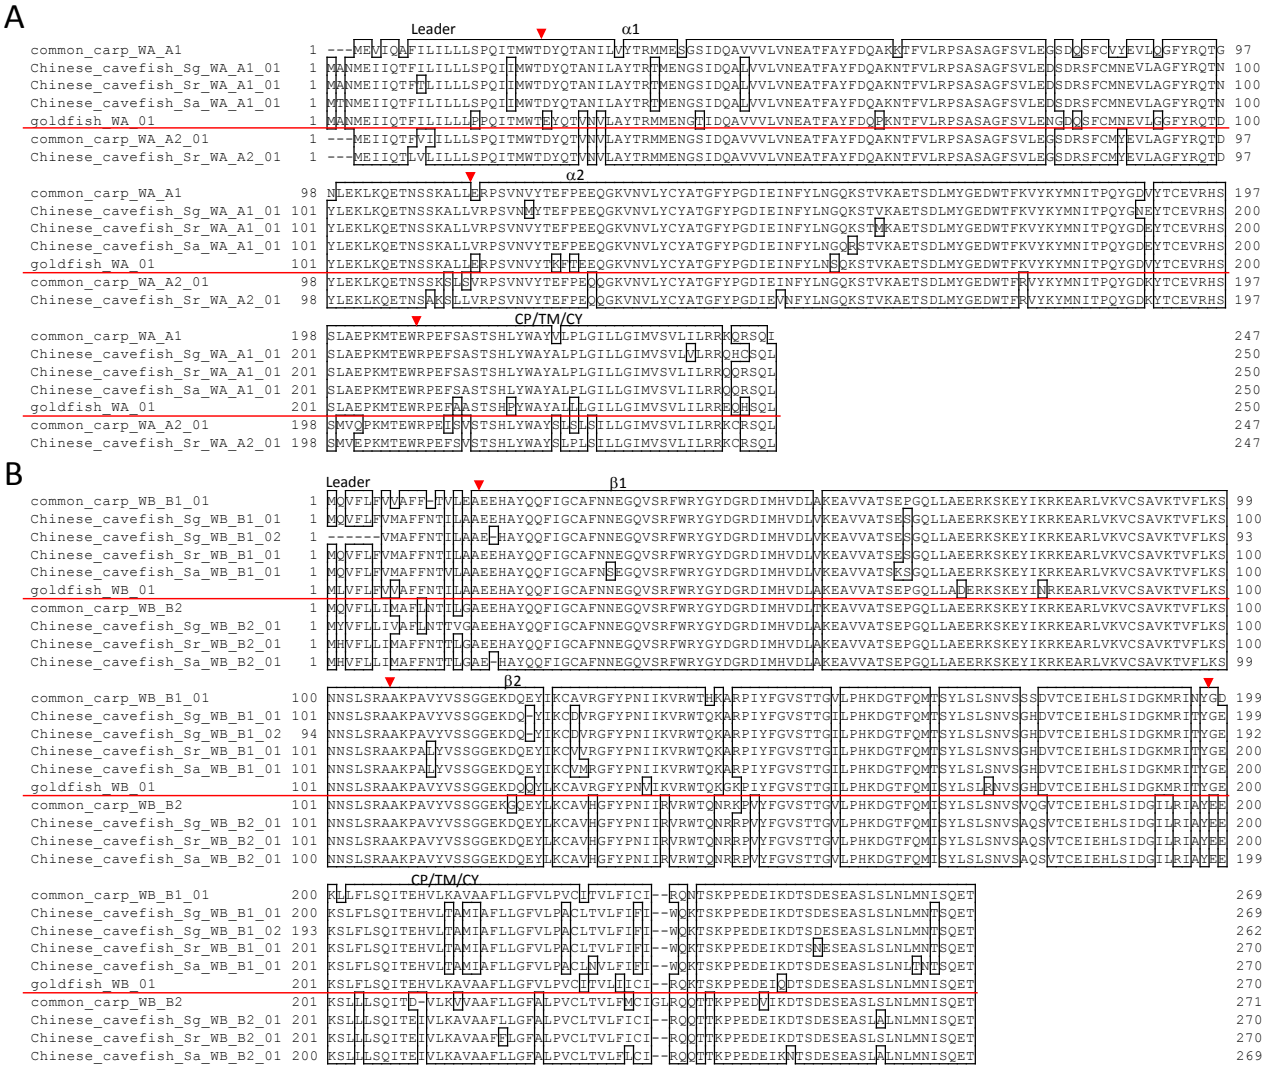

**Fig. S20. Variations in W-category molecules of Chinese cavefish in comparison with common carp and goldfish molecules.**

**A**, WA_A1 and WA_A2 sequences of different Chinese cavefish species, common carp and goldfish. A1 and A2 groups are separated with a red line. **B**, WB_B1 and WB_B2 sequences of Chinese cavefish, common carp and goldfish. B1 and B2 groups are separated with a red line. Goldfish WA_01 and WB_01 are also included in A and B, respectively. Goldfish WA_01 and WB_01 are similar to WA_A1 and WB_B1 of the other compared fishes, respectively. Chinese cavefish Sg = *Sinocyclocheilus graham,* Sr = *Sinocyclocheilus rhinocerous,* Sa = *Sinocyclocheilus anshuiensis.* Red arrowheads indicate the positions of exon/intron borders in the genome.

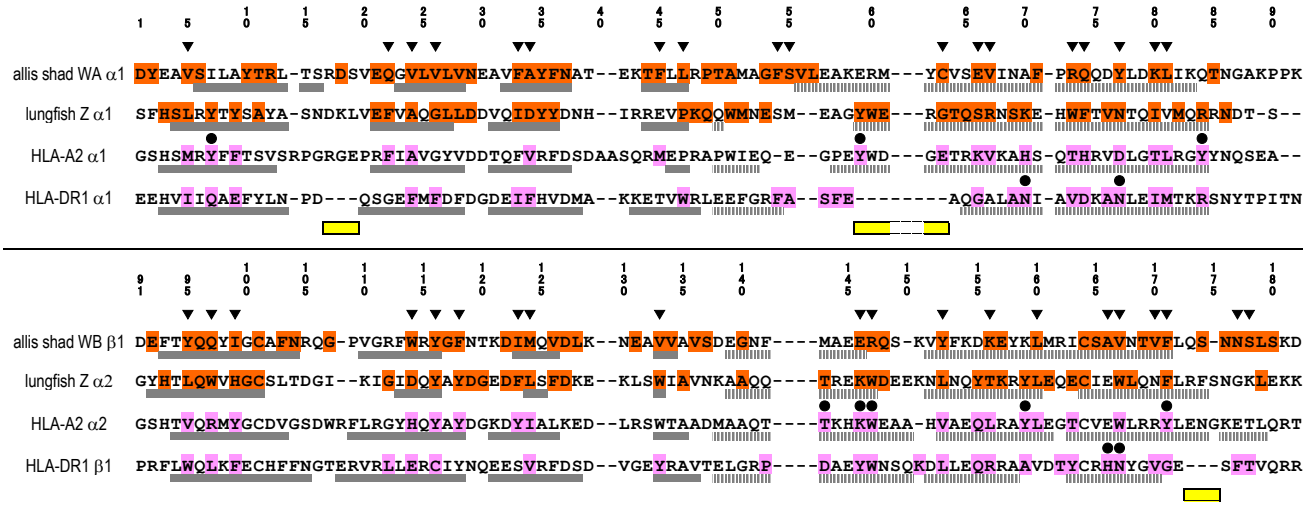

**Fig. S21. Highly conserved positions in the membrane-distal domains of the teleost fish W-category molecules: similarity with those of MHC-Z molecules and with peptide-binding positions of the classical MHC molecules.**

W-category amino acid residues of allis shad (*Alosa alosa*, Clupeidae, as a representative of the teleost fish) compared with lungfish MHC-Z molecule and with the classical MHC class I, HLA-A2 and the classical MHC class II, HLA-DR1. Orange-shaded residues of allis shad are invariable or highly conserved at the respective positions as verified among more than twenty teleost fish W-category sequences (Table S4). Orange-shaded residues of lungfish MHC-Z are invariable or highly conserved at the respective positions among MHC-Z molecules of lungfish and teleost fish (38). Magenta-shaded residues of HLA-A2 and of HLA-DR1 can interact with bound peptide antigens according to the references 29 and 31, respectively. Arrowheads indicate the amino acid positions where both the highly conserved teleost fish W-category amino acid positions and the peptide antigen binding positions of HLA-A2 and/or HLA-DR1 can be found. Large black dots above HLA-A2 sequence indicate amino acid residues highly conserved among the classical MHC class I molecules which interact with peptide termini of a bound peptide. Large black dots above HLA-DR1 sequence indicate amino acid residues highly conserved among the classical MHC class II molecules which interact with main chain residues of a bound peptide. Grey bars indicate positions of β-strands whereas dotted grey bars indicate positions of helical structures. For allis shad and lungfish molecules, these secondary structures were predicted as described in the Materials and Methods. Yellow boxes indicate gaps in class II molecules compared to class I molecules (Dataset S1). The residue numbers in this figure are based on those of HLA-A2 (29).

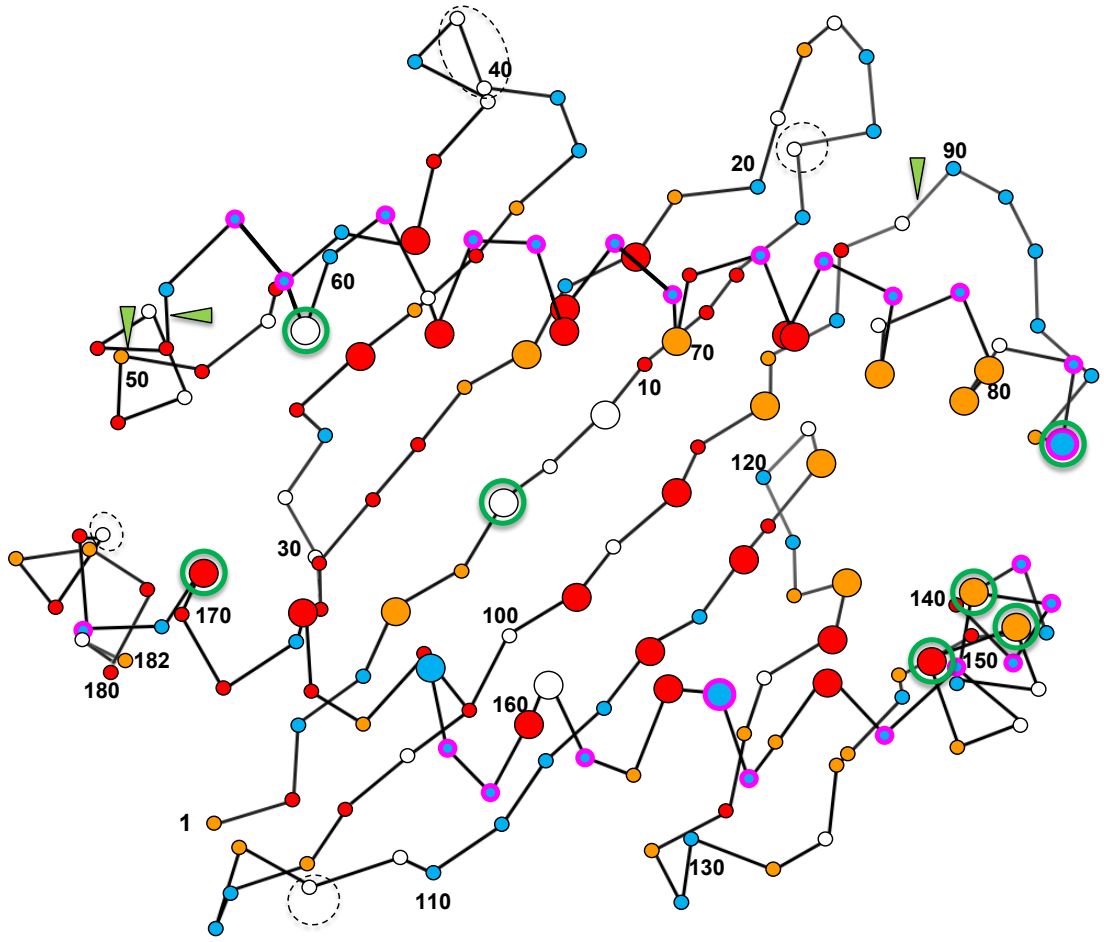

**Fig. S22. Conservation profile in the hypothetical membrane-distal domains of the teleost fish W-category molecule based on the structure of HLA-A2: the highly conserved positions in the teleost fish W-category molecule largely correspond to the peptide-binding positions of HLA-A2.**

Circles indicate positions of main chain Cα of HLA-A2. Large circles (total 37) indicate peptide-binding positions of HLA-A2. For the respective amino acid positions of teleost fish W-category molecules, Wu-Kabat variability was calculated (Table S4), and the obtained values are classified with various colors as follows: red, 1.0 (invariable); orange, 2.1 - 2.5 (relatively highly conserved); white, 2.5 < and </= 4; blue, 4 < (highly variable). The number of peptide-binding positions labeled with different colors are as follows: red, 19; orange, 11; white, 4; and blue, 3. In the α-helical regions, the positions with blue colors with especially high Wu-Kabat values (= or > 6) are labeled with magenta boundary lines, and many of them are positions on an α-helix that are away from the site including those toward TCR. In HLA-A2 molecule, three peptide-binding residues at positions 146 (orange), 155 (blue) and 163 (blue) are classified as residues with intermediate positions on an α-helix that point both into the peptide-binding site and away from the site (25). The eight positions with large green circles indicate the highly conserved amino acid positions of the classical MHC class I molecule, which interact with the N- or C-terminal of the bound peptide (the numbers of the positions are: Y7, Y59, (Y or R)84, T143, K146, W147, Y159, and Y171). In Fig. S21, these positions are shown with large black dots above the HLA-A2 sequence. The residues 1 to 90 correspond to WA α1 domain, and the residues 91 to 182 correspond to WB β1 domain. Dotted lines indicate presumed absence of residue(s) in case of teleost fish W-category molecules compared to HLA-A2. Green triangles indicate presumed locations of

the presence of additional position(s) of teleost fish W-category molecule compared to HLA-A2. The structure is based on HLA-A2 of Protein Data Bank ID: 3HLA (29).

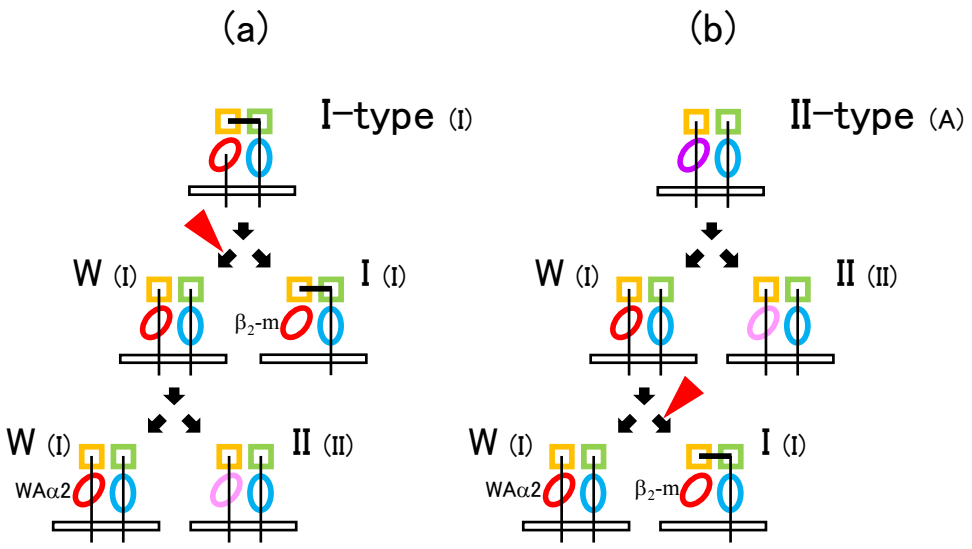

**Fig. S23. Models for MHC class divergence with W-category as an intermediate.**
(a) Class I-first model with W-category. The previous model (9) is modified with W-category as an intermediate. In this model, at the change from W (I) to II (II), inter-domain interfaces of W-category molecule should change into those of the conventional class II, including the loss of W61 of WAα2 (corresponding to IIAα2) and the acquisition of W61 of WBβ2 (corresponding to IIBβ2). Further, (F/L)37 of WAα2 should change back to W37 of IIAα2, which is highly conserved among many Ig superfamily members.
(b) Class II-first model with W-category. The previous model (7, 15) is modified with W-category as an intermediate. This is the same as Fig. 8C, but shown for comparison with (a).
Red arrowheads indicate the stages when alterations of domain architectures take place. The class I-type and the class II-type inter-domain interfaces are indicated by (I) and (II), respectively, and (A) indicates the ancestral state of the inter-domain interface.

**Table S1. Summary of representative species from which W-category genes (*WA* and *WB*) were identified.** In cloudy catshark, two *WA_DS5L* (*WA_DS5L_159K* and *WA_DS5L_82K*) and two *WB_Nds5L* (*WB_Nds5L_159K* and *WB_Nds5L_82K*) were identified. Plus (+) symbols following the animals' name indicate that the W-category genomic and/or cDNA sequences from the relevant animals were experimentally determined in the present study. Hash (#) symbols indicate that the gene fragments were identified in SRA (Sequence Read Archive; see *SI Appendix*). Asterisks (*) in the last column indicate that the *WA/WB* gene pairing situations are as follows: *WA_DS5L*/*WB_Nds5L* and *WA_DS10L*/*WB_DS1L* in cloudy catshark, *WA_DS5L*/*WB_Nds5L*, *WA_DS10L*/*WB_DS1L* and *WA_Nds3L*/*WB_DS3L* in great white shark, *WA_A1*/*WB_B1* and *WA_A2*/*WB_B2* in common carp and also in Chinese cavefish.

**Table S4. Conservation profile of the membrane-distal domains of W-category molecules in the teleost fish.**

Variabilities of the WA α1 domain (left, positions 1-90c) and WB β1 domain (right, positions 91-182) are shown. Wu-Kabat variability (V) is defined as the number of different amino acids at a given position (Nd) divided by the frequency of the most common amino acid at that position (Nc/N; Nc, the number of the most common amino acid at that position; N, the number of sequences studied at that position) as described in the Materials and Methods. The position numbers are based on those of the HLA-A2 molecule (29; Fig. S21). Position numbers with a, b or c are used where sequence length disparities are present between the HLA-A2 and teleost fish W-category molecules. The sequence alignment is based on Dataset S1. The values of Wu-Kabat variability are classified with various colors as follows: red, 1.0 (invariable); orange, 2.1 - 2.5(relatively highly conserved); white, 2.6 =/< and </= 4 (moderately conserved/variable); blue, 4 < (highly variable).
