

BMJ Open

BMJ Open is committed to open peer review. As part of this commitment we make the peer review history of every article we publish publicly available.

When an article is published we post the peer reviewers' comments and the authors' responses online. We also post the versions of the paper that were used during peer review. These are the versions that the peer review comments apply to.

The versions of the paper that follow are the versions that were submitted during the peer review process. They are not the versions of record or the final published versions. They should not be cited or distributed as the published version of this manuscript.

BMJ Open is an open access journal and the full, final, typeset and author-corrected version of record of the manuscript is available on our site with no access controls, subscription charges or pay-per-view fees (<http://bmjopen.bmj.com>).

If you have any questions on BMJ Open's open peer review process please email info.bmjopen@bmj.com

Abstract

Objective To determine whether geographical variations in outcomes are accounted for by baseline clinical risk factors and stroke prevention strategies.

Design GARFIELD-AF is a prospective non-interventional registry of patients with newly diagnosed AF. A total of 52,018 patients were enrolled (2010- 2016).

Setting Investigator sites (n=1317) are representative of the care settings/locations in each of the 35 participating countries.

Participants A total of 52,018 patients 18 years and older with newly diagnosed AF and at least 1 investigator-determined stroke risk factor were included.

Main outcomes and measures Observed 1-year Kaplan-Meier event rates and national risk-standardised rates derived.

Results Despite similar conventional measures of stroke risk (CHA₂DS₂-VASc 3.0 in each region), anticoagulant treatment varied three-fold and rates of non-haemorrhagic stroke/SE and mortality differed substantially, even after adjustment for baseline factors and treatments. High observed mortality rates in Canada, France and Germany were largely accounted for by clinical case mix, but countries with some of the lowest Healthcare Access and Quality (HAQ) indices (India, Ukraine, Argentina and Brazil) had the highest mortality, even after risk adjustment. The lowest observed rates of mortality in Japan and South Korea persisted after risk adjustment. The lowest risk-standardised rates of non-haemorrhagic stroke/SE were seen in Germany, Czech Republic and Canada and the highest risk-standardized rates of major bleeding in the Netherlands and USA. Patients from countries with the highest rates of cardiovascular mortality and stroke were among the least likely to receive oral anticoagulants. However, differences in antithrombotic regimens account for only part of the substantial geographic variations in outcomes.

1
2
3
4
5 **Conclusion** Only part of the variability in outcomes among countries is accounted for by
6
7 baseline demographics, modifiable cardiovascular risk factors, comorbidities and
8
9 antithrombotic regimens. The potential exists to improve outcomes by addressing modifiable
10
11 risk factors and the gap between evidence based guidelines and clinical practice among patients
12
13 with AF.

Strengths and limitations of this study

- Marked geographic variations in outcomes (up to two-fold differences in mortality, and in bleeding) are attenuated, but persist after accounting for demographic and clinical characteristics of patients with incident AF.
- The potential exists to improve outcomes among patients with newly diagnosed AF, and to diminish geographic disparities, not only through guideline appropriate stroke prevention, but also by addressing potentially modifiable risk factors.
- The mortality data from GARFIELD-AF reflect the life expectancy in countries with highest and lowest mortality rates, and there is a significant ($p<0.001$) inverse association with the choice of antithrombotic regimen, multinationality, and the Healthcare Access and Quality Indices derived from national data
- Ascertainment bias may have been responsible for the apparently high rates of bleeding in some countries but rates of anticoagulation and combined treatment with antiplatelets may also have contributed to the observed rates of bleeding.

INTRODUCTION

The 2015 Global Burden of Disease (GDB) report of 195 countries and territories suggests that AF prevalence is highest in Northern and Central Europe, and the United States ¹, and is projected to rise globally because of aging and population growth worldwide ².

The gains in cardiovascular health in high-income countries are related, at least in part, to modification of cardiovascular risk factors as well as improved disease management. In the context of atrial fibrillation, the changes include the availability of treatment strategies for stroke prophylaxis, and/or rhythm or rate control ³⁻⁷. However, the extent to which baseline characteristics and treatment strategies account for geographic variations in outcomes is unclear.

The Global Anticoagulant Registry in the FIELD-Atrial Fibrillation (GARFIELD-AF) aimed to define geographical variations in all-cause mortality, stroke/systemic embolism (SE) and major bleeding in patients with newly diagnosed AF. The primary aim of this report was to determine whether variations in outcomes of AF are accounted for by baseline clinical risk characteristics. A secondary aim was to consider the impact of other factors including national differences in life expectancy, access to quality healthcare, and stroke prevention strategies.

MATERIALS AND METHODS

Design

GARFIELD-AF is the largest multinational prospective registry in AF ⁸. The study recruited patients from >1,000 investigational sites (identified nationally as representative) in 35 countries. Patients were recruited from: Europe (Finland, Norway, Sweden, Denmark, United Kingdom, Netherlands, Belgium, Germany, Switzerland, France, Spain, Italy, Austria, Hungary, Russia, Poland, Czech Republic, Ukraine and Turkey), Asia (Singapore, China, Japan, South Korea, Thailand and India), North America (USA and Canada), Latin America

1
2
3 (Mexico, Brazil, Argentina and Chile) and other countries including Egypt, United Arab
4
5 Emirates, South Africa and Australia.
6
7

8 Adults ≥ 18 years were eligible for inclusion if they were diagnosed with non-valvular AF within
9
10 6 weeks of study entry. Patients with AF were required to have at least one risk factor for stroke,
11
12 as judged by the investigator (entry to GARFIELD-AF did not require performance of a stroke
13
14 risk predictor, nor a specific threshold if such a score was performed). Patients were enrolled
15
16 prospectively and consecutively at sites that aimed to reflect diverse care settings (including
17
18 office/outpatient practice; hospital departments including neurology, cardiology, geriatrics,
19
20 internal medicine and emergency; anticoagulation clinics; and general practice) ^{8,9}.
21
22
23
24

25 Independent ethics committee and hospital-based institutional review board approvals were
26
27 obtained. The registry was conducted in accordance with the principles of the Declaration of
28
29 Helsinki, local regulatory requirements, and the International Conference on Harmonisation–
30
31 Good Pharmacoepidemiological and Clinical Practice guidelines. Written informed consent
32
33 was obtained from all study participants.
34
35
36

37 GARFIELD-AF data were captured using an electronic case report form (eCRF). Submitted
38
39 data were examined for completeness and accuracy by the coordinating centre (Thrombosis
40
41 Research Institute, London, UK), and data queries were sent to study sites. An audit and quality
42
43 control programme was implemented, and this included source documentation (20% of all
44
45 eCRFs were monitored against source records) ¹⁰. This paper adheres to the guidelines from
46
47 STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) ¹¹.
48
49
50

52
53
54
55
56

57 **Patient and Public Involvement**

58
59
60

1
2
3 Patients and/or the public were not involved in the design, conduct, reporting, or dissemination
4
5 plans of this research.
6
7

8 **Procedures and outcome measures**

9
10 Baseline characteristics collected at study entry included: medical history, care setting, type of
11
12 AF, date and method of diagnosis of AF, symptoms, antithrombotic treatment (vitamin K
13
14 antagonists [VKAs], non-vitamin K antagonist oral anticoagulants [NOACs] and antiplatelet
15
16 [AP] treatment), as well as all cardiovascular drugs. Race was classified by the investigator in
17
18 agreement with the patient⁸. Vascular disease included coronary artery disease (CAD) with a
19
20 history of acute coronary syndromes (ACS) and/or peripheral artery disease. Chronic kidney
21
22 disease (CKD) was classified according to National Kidney Foundation guidelines into
23
24 moderate-to-severe (stages 3–5), mild (stages 1 and 2) or none. Data on components of the
25
26 CHA₂DS₂-VASc and HAS-BLED risk stratification schemes were collected and calculated
27
28 retrospectively. HAS-BLED scores were calculated excluding fluctuations in international
29
30 normalised ratio. In addition, the risk of death, non-haemorrhagic stroke/SE and major bleeding
31
32 was evaluated with the GARFIELD-AF risk calculator¹².
33
34
35
36
37
38

39 Patients were followed over a minimum of 24 months or until death or loss to follow-up,
40
41 whichever occurred first. As reported previously, standardised definitions for clinical events,
42
43 death (cardiovascular and non-cardiovascular), non-hemorrhagic stroke/SE and major
44
45 bleeding) were used^{8,9}. Data for this report were extracted from the study database on 30th June
46
47 2019.
48
49

50 **Statistical analysis**

51
52 Univariate data are presented as medians (1st and 3rd quartile) for continuous variables and as
53
54 absolute frequencies with percentages for categorical variables.
55
56
57
58
59
60

1
2
3 “Time at risk” for each event was calculated over the first year after enrolment up to the first
4 occurrence of an event or last follow-up or at 365 days, whichever occurred earlier. All-cause
5 mortality, non-haemorrhagic stroke/SE and major bleeding were described as the number of
6 events and the Kaplan-Meier event rate with 95% confidence intervals.
7
8
9
10
11

12
13 In this study, national risk-standardised measures of event rates were calculated to compare the
14 observed event rates based on case mix (i.e. the clinical characteristics of patients) in each
15 country, with the expected rates for a similar case mix. The risk-standardised event rates were
16 calculated using the following equation:
17
18
19
20
21

$$\frac{\text{Observed event rate}}{\text{Expected event rate}} \times \text{Global event rate} = \text{Risk standardized rate}$$

22
23
24
25
26 Where the **Observed event rate** was the crude rate calculated for each country using the
27 Kaplan-Meier estimator (1 minus event-free survival probability at 1 year after enrolment).
28
29

30
31 **Expected event rate** was calculated (using multivariable Cox regression with a series of
32 demographic and clinical characteristics as covariates) for every patient and the national
33 average computed.
34
35
36
37

38
39 **Global (and regional) event rates** were the crude rate calculated with the Kaplan-Meier rate
40 across all countries in GARFIELD-AF without exclusion.
41
42
43

44
45 When the observed and expected rates were the same, the risk-standardised rate equalled the
46 global event rates. However, when the observed event rate was greater or less than the expected
47 rate, then the country had more or less events than expected, based on its case mix. Hence, the
48 observed to expected ratio was greater or less than 1.0, making the risk-standardised rate higher
49 or lower than the global rate.
50
51
52
53
54

55
56 Patients' characteristics included in the initial Cox model were: age, gender, type of AF, history
57 of hypertension, blood pressure (systolic and diastolic) and pulse rate (at enrolment),
58
59
60

1
2
3 hypercholesterolemia, smoking status (never/ex/current) and heavy alcohol consumption,
4
5 diabetes mellitus (type 1 or 2), ACS, coronary artery bypass graft (CABG), vascular disease,
6
7 carotid occlusive disease, venous thromboembolism (VTE), history of stroke/transient
8
9 ischaemic attack (TIA)/SE, history of bleeding, heart failure, moderate-to-severe CKD and
10
11 cirrhosis. Confidence intervals for the risk-standardized measures were computed using
12
13 estimates extracted from 1000 bootstrap samples. Patients with missing values were not
14
15 removed from the study; single imputation was applied.
16
17

18
19
20 Both baseline risk factors and antithrombotic regimens (with oral AC and/or AP) at the time of
21
22 diagnosis of AF (baseline) were included in the Cox model.
23
24

25 The observed rates in a contemporary US registry, the ORBIT-AF II, were derived to assess the
26
27 representability of the US patients in GARFIELD-AF.
28
29

30 All analyses were performed with SAS version 9.4 (SAS Institute Inc., Cary, NC, USA).
31
32

33 RESULTS

34 Baseline demographics and clinical characteristics

35
36 Baseline characteristics were analysed for the 52,018 patients with newly diagnosed AF,
37
38 enrolled consecutively into GARFIELD-AF between March 2010 and August 2016, in 35
39
40 countries. The largest cohort was recruited from Europe (57.4%), followed by Asia (26.6%),
41
42 Latin America (8.2%), “Other” countries (4.7%) (including South Africa, Egypt, United Arab
43
44 Emirates and Australia) and North America (3.1%).
45
46
47
48
49

50
51 The observed variability in patients’ baseline characteristics among regions in GARFIELD-AF
52
53 is reported in **table 1**. Patients from Asia compared with Europe tended to be younger, had a
54
55 lower body mass index, a lower prevalence of hypertension, hypercholesterolemia, vascular
56
57 disease and CKD. By contrast, patients from North America in GARFIELD-AF had the highest
58
59
60

1
2
3 proportion of patients aged ≥ 75 , together with the highest prevalence of diabetes,
4 hypercholesterolemia and prior/current smokers from any region (except “Other Region” where
5 the highest prevalence of diabetes was observed). The prevalence of heart failure was consistent
6 and approximately one in five of patients in every region. Approximately 70% of patients
7 overall (and 91.6% of patients in North America) were categorised as having paroxysmal or
8 unclassified AF at enrolment in this study (**Table 1**).

9
10
11
12
13
14
15
16
17
18
19 Standard risk assessment scores (including the GARFIELD-AF risk score) found that the
20 calculated risks of stroke or major bleeding were similar across regions (median CHA₂DS₂-
21 VASc score 3.0 in all regions). The GARFIELD-AF risk model for death revealed regional
22 differences, with a lower expected rate of death in patients from Asia and highest in those from
23 Latin America (**Table 1**).

32 33 **Treatment setting**

34
35
36 In Asia and Latin America, patients were predominantly diagnosed and managed by
37 cardiologists (83.7% and 75.0%, respectively), while in Europe and North America, the role of
38 managing patients with AF was shared between cardiologists (in approximately 60% of cases),
39 internists (~20%) and primary care (~20%). The likelihood of being diagnosed and treated in
40 the emergency care setting was highest in North America (38.0% of patients) followed by Latin
41 America (24.7%), “Other” countries (13.4%), Europe (11.5%) and Asia (2.5%).

50 51 **Observed global and regional outcomes**

52
53
54 In GARFIELD-AF, the lowest observed rate of death at one year was recorded in Asia (2.8;
55 95% CI: 2.6-3.1) with rates less than half those observed in “Other” countries (6.0; 95% CI:
56 5.1-7.0) (namely, South Africa, Egypt, United Arab Emirates and Australia). Non-
57
58
59
60

1
2
3 haemorrhagic stroke/SE rates showed less regional variability, but once again, the lowest
4 observed rates were reported in Asia (1.0; 95% CI: 0.9-1.2). For major bleeding, the highest
5 observed rates were recorded in North America (2.9; 95% CI: 2.2-3.8) and the lowest in Asia
6 (0.9; 95% CI: 0.7-1.0). Reflecting the high proportion of patients from Europe, the global rates
7 across all countries in GARFIELD-AF were similar to European event rates for mortality, non-
8 haemorrhagic stroke/SE and major bleeding (**Table 2**).

19 **Observed and risk-standardised outcomes by country**

21
22 **Figures 1 to 3** depict the observed and risk-standardised rates of mortality, non-haemorrhagic
23 stroke/SE and major bleeding for countries that enrolled more than 90% of the patients into
24 GARFIELD-AF, i.e. omitting countries with potentially unrepresentative findings due to low
25 enrolment. Full details of the observed rates from all countries, including those omitted from
26 the figures, i.e. South Africa (n=639), Denmark (n=532), Egypt (n=527), Austria (n=460),
27 United Arab Emirates (n=397), Finland (n=359), Singapore (n=306), Norway (n=270), and
28 Switzerland (n=89), are reported in **Supplement Tables S1-S3**.

39
40 **Figures 1-3** show the marked variations in observed event rates by country. This variability
41 persisted even after adjusting for all 22 baseline factors (demographics, modifiable
42 cardiovascular risk factors and comorbidities).

49 India and Ukraine experienced the highest risk-standardised mortality rates, primarily driven
50 by cardiovascular events. Marked differences were also observed for the USA, where the rate
51 of non-cardiovascular mortality was more than 3-fold higher compared to cardiovascular
52 mortality. Within most other countries the rates of cardiovascular and non-cardiovascular
53 mortality were similar (**Supplementary Table S1**).

1
2
3
4
5 To display the relation between healthcare access and outcomes in more detail, we colour-coded
6 each country according to the Healthcare Access and Quality (HAQ) Index (overall score on a
7 scale of 0–100) from the Global Burden of Disease Study 2016¹⁴. The results show that some
8 of the countries with highest risk-standardised mortality rates (i.e. India, Mexico, Argentina and
9 Brazil) had some of the lowest HAQ indices (HAQ: <70); only Thailand had a similarly low
10 HAQ and a mortality rate. Conversely, the three countries with the lowest risk-standardised
11 mortality rate (South Korea, Japan, and Sweden) all obtained a high HAQ score (HAQ: ≥90).
12
13
14
15
16
17
18
19
20
21
22

23
24 The observed mortality rate from the US study, ORBIT-AF II, was similar to the GARFIELD-
25 AF global rate (4.3 [95% CI: 3.7-4.9] vs 4.2 [95% CI: 4.0-4.4] respectively) and below the
26 global rate for non-haemorrhagic stroke/SE (ORBIT-AF-II 0.8 [95% CI: 0.6-1.1] vs
27 GARFIELD-AF 1.2 [95% CI: 1.1-1.3]). Nevertheless, both GARFIELD-AF and ORBIT-AF
28 II reported high rates of major bleeding in the US: 3.4 (95% CI: 2.3-5.0) [GARFIELD-AF] and
29 3.3 (95% CI: 2.8-3.8) [ORBIT-AF II] relative to the global rate of 1.2(95% CI: 1.1-1.3) in
30 GARFIELD-AF.
31
32
33
34
35
36
37
38
39
40
41

42 The rates of each type of outcome differed by country. For instance, the lowest risk-standardised
43 mortality rates were observed for South Korea, Japan and Sweden, while the lowest risk-
44 standardised rates of non-haemorrhagic stroke/SE were observed in Germany, Czech Republic
45 and Canada. The highest risk-standardised rates non-haemorrhagic stroke/SE were reported in
46 Ukraine and Australia, and the highest risk-standardised rates of major bleeding in the
47 Netherlands and the USA.
48

57

58 **Antithrombotic regimen for stroke prevention at baseline**

59
60

1
2
3 GARFIELD-AF recorded substantial differences in the overall rate of anticoagulation by region
4 (from 73% in Europe to 56% in Asia, **Supplementary Figure S1a**), as well as large variations
5 within countries (**Supplementary Figure S1b**). At the time of diagnosis of AF, the highest
6 proportion of patients receiving NOACs was in North America (44.8%). This included 14.4%
7 of patients who received NOAC in combination with APs. VKAs were most commonly
8 prescribed in Europe, Latin America and "Other" countries (in 44.4%, 39.8% and 41.1% of
9 patients, respectively) (**Figure S1a**).

18
19
20
21 Even though CHA₂DS₂-VASc scores were similar across countries (**Supplementary Table**
22 **S2**), anticoagulant treatment varied three-fold among countries (30% to 90%) (**Figure S1b**).
23 The highest rate of anticoagulation was in the Netherlands and Switzerland (90%) and lowest
24 in China (30%), India (35%) and Ukraine (48%) (Figure 4b). More than 40% of newly
25 diagnosed patients with AF in China and India received anti-platelet therapy only and a further
26 20%, approximately, received no anti-thrombotic therapy. Across all countries, we found a
27 significant ($p<0.001$) association with the choice of antithrombotic regimen and HAQ index,
28 i.e. with a greater likelihood of AC and NOAC prescribing (and lower likelihood of AP therapy
29 alone) with increasing HAQ score (**Figure 4**).

ACs (with or without AP therapy) were prescribed to more than 70% of patients in 18 of 35 countries.

The choice of stroke prevention strategy by region and country was analysed and included in the Cox model. Even after adjustment for baseline risk factors and antithrombotic regimen (AC and/or AP treatment), substantial inter-country differences remained in the rate of non-haemorrhagic stroke/SE (**Supplementary table S4**).

DISCUSSION

Analysis of the 52,018 prospectively enrolled patients from the GARFIELD-AF registry shows that after adjusting for the baseline demographics and clinical characteristics (including modifiable cardiovascular risk factors and comorbidities) variability in outcomes among countries is attenuated, but persists. This finding highlights the importance of identifying factors beyond those collected in conventional risk prediction tools to estimate outcomes in patients with AF. Such factors may include practice patterns, access to quality health care, and numerous environmental and epigenetic characteristics to account for the substantial differences in risk-standardised event rates among countries ¹⁵.

The findings show that the apparently high observed rates of mortality (relative to the global average) in countries such as Canada, USA, France and Germany could be largely accounted for by clinical patient characteristics at enrolment. By contrast, countries with some of the lowest Healthcare Access and Quality (HAQ) indices in GARFIELD-AF (India, Ukraine, Argentina and Brazil) had the highest risk-standardised mortality rates. Conversely, the lowest observed rates of mortality in Japan and South Korea persisted even after risk adjustment.

The risk-standardised mortality rates in GARFIELD-AF appear to be a reflection of average national life expectancy, with the lowest mortality rates in this population with newly diagnosed AF in countries with life-expectancies (in years) of 82.2, 83.8, 82.6, 78.2 and 81.6, whereas countries with the highest mortalities in this AF population have life expectancies (in years) of 68.3, 71.2, 76.3, 78.7 and 74.7 ¹⁶.

Patients from participating centres with the highest rates of mortality and non-haemorrhagic stroke/SE and were among the least likely to receive oral ACs for stroke prevention over the 5

1
2
3 years of recruitment into GARFIELD-AF (**Figure S1b**). This is consistent with the observed
4
5 higher rates of cardiovascular (vs non-cardiovascular) mortality in such countries and where
6
7 AP therapy or no antithrombotic therapy for AF is most prevalent (**Table 2**).
8
9

10
11
12 It is possible that the higher rates of major bleeding at participating centres in the Netherlands
13
14 (GARFIELD-AF) and the USA (GARFIELD-AF and ORBIT-AF II) are a reflection of
15
16 prescribing practice (e.g. high use of anticoagulation in the Netherlands [90%]; and the frequent
17
18 use of combined NOAC+ AP therapy in the USA [20.7%]) as well as possible ascertainment
19
20 bias.
21
22

23
24
25
26 It is notable that further analyses of stroke rates revealed that differences in OAC and AP
27
28 treatment regimens account for only some of the differences among countries, and substantial
29
30 differences remain (**Supplementary Figure S1**).
31
32

33
34
35 Achieving population-wide control of modifiable risk factors (including tobacco use, diet,
36
37 physical inactivity, plasma glucose and hypertension) could abrogate a substantial part of the
38
39 global stroke burden, irrespective of age, gender or ethnicity^{17,18}. Even small changes in the
40
41 distribution of these risk factors could lead to clinically relevant reductions in the risks of
42
43 cardiovascular disease, stroke, and mortality¹⁹⁻²¹. The findings from GARFIELD-AF and other
44
45 recently published global and regional studies^{7,22-26} suggest that high rates of potentially
46
47 modifiable metabolic disorders and smoking persist. Thus there remains considerable scope to
48
49 improve the outcomes of patients with newly diagnosed AF, even in high- and middle-income
50
51 countries.
52
53
54
55
56
57
58
59
60

1
2
3 Substantially higher than global rates of antiplatelet therapy (without anticoagulation), are
4 prescribed in China and India than in Thailand, South Korea, Singapore and Japan (Figure 1b).
5
6 Fewer older patients were recruited from India, (26% vs 37% of patients were ≥ 75 years) but
7
8 there were more diabetics (36% vs 22%) and CAD patients (28% vs 22%) compared with global
9
10 average ²⁷. By contrast, patients from Japan were older than the global average (42% vs 37%
11
12 of patients were ≥ 75 years) with a lower prevalence of hypercholesterolemia (29.2% and
13
14 42.9%) and CAD (10.3% and 22.8%) at the time of diagnosis of AF ²⁸.

15
16
17
18
19
20
21 GARFIELD-AF has demonstrated major disparities in the rate of anticoagulation for AF
22
23 (Figure 1b) and these are not accounted for by conventional measures of stroke risk ²⁹. Such
24
25 findings are consistent with other observational studies, including: PINNACLE (Practice
26
27 Innovation and Clinical Excellence) ³⁰, EORP-AF (EUR Observational Research Programme-
28
29 Atrial Fibrillation) ³¹ and GLORIA-AF (Global Registry on Long-Term Antithrombotic
30
31 Treatments in Patients with Atrial Fibrillation) ³². However, in GARFIELD-AF there were
32
33 geographic disparities, not only in antithrombotic regimens for AF, but also in other
34
35 cardiovascular and lifestyle management measures. These may account to a substantial part of
36
37 the remaining geographic differences in outcomes. The clear relation of outcomes with indices
38
39 of healthcare access (HAQ indices) supports this concept.

40 41 42 43 44 45 46 47 **Strengths and limitations**

48
49 GARFIELD-AF is a non-interventional registry, and it provided a record of consecutively
50
51 enrolled patients with newly diagnosed AF who were treated, according to local standards of
52
53 care, in each participating centre without exclusion of participants by age, risk profile or
54
55 concomitant disease. GARFIELD-AF mitigated some of the limitations inherent to
56
57 observational studies through the standardisation of clinical definitions and the rigorous audit
58
59
60

1
2
3 (using both remote and onsite monitoring) to ensure the completeness and accuracy of the data
4
5 collected. However, reported rates will be influenced by the characteristics of recruiting centres
6
7 and treatment settings. Nevertheless, the mortality data from GARFIELD-AF reflect the life
8
9 expectancy in countries with highest and lowest mortality rates, and there is a significant
10
11 ($p<0.001$) inverse association with the choice of antithrombotic regimen in GARFIELD-AF
12
13 and average HAQ index (derived from national data). Ascertainment bias may have been
14
15 responsible for the apparently high rates of bleeding in some countries (e.g. Netherlands and
16
17 USA) but rates of anticoagulation and combined treatment with antiplatelets may also have
18
19 contributed to the observed rates of bleeding. It is also possible that there was lower
20
21 ascertainment of outcomes in some countries.
22
23
24

25 26 **CONCLUSIONS**

27
28 Despite similar conventional measures of stroke risk (CHA₂DS₂-VASc equalled 3.0 in each
29
30 region), anticoagulant treatment varied three-fold across countries and the observed rates of
31
32 stroke/SE and mortality differed substantially by region, even after adjustment for baseline
33
34 factors and antithrombotic treatments. The new diagnosis of AF signals an increased risk of
35
36 diverse adverse cardiovascular outcomes, but with striking geographic variations. The
37
38 variations persisted after adjusting for CHA₂DS₂-VASc risk factors and other baseline and risk
39
40 characteristics (e.g., smoking, type of AF and moderate-to-severe CKD). Other factors,
41
42 including variations in clinical practice, organization and access to quality healthcare (as
43
44 measured by HAQ) as well as patient-related factors may be responsible for the substantial
45
46 differences in the rates of mortality, stroke/SE and major bleeding across countries.
47
48 Conventional stroke and cardiovascular risk factors and antithrombotic treatments do not
49
50 explain the substantial national and regional disparities in outcomes for patients with newly
51
52 diagnosed AF.

*Showing only countries with more than 700 patients enrolled. Horizontal dashed line represents overall observed global rate calculated from all 35 countries. Measures of performance are based on the Healthcare Access and Quality Index for 195 countries and territories from the Global Burden of Disease Study [reference 20].

Figure 4. Baseline antithrombotic treatment distribution by Healthcare Access and Quality (HAQ) index¹

¹As HAQ index is a country measure, all patients enrolled within a specific country are assigned the same HAQ index

HAQ index of OAC+AP or AP only: <70=46.7%; 70-79=52.5%; 80-89=30.1%; ≥90=28.6%

Table 1. Baseline demographics and clinical characteristics of patients stratified by region

| Baseline characteristics | Region | | | | |
|---|------------------------|----------------------|-----------------------------|--------------------------------|-------------------------------|
| | Europe (N = 29,876) | Asia (N = 13,821) | Latin America (N = 4247) | North America (N = 1619) | Other countries (N = 2455) |
| Gender female, n (%) | 13,563 (45.4) | 5622 (40.7) | 2016 (47.5) | 734 (45.3) | 1051 (42.8) |
| Age, median (Q1; Q3), years | 72.0 (64.0; 79.0) | 69.0 (60.0; 76.0) | 71.0 (63.0; 79.0) | 72.0 (64.0; 80.0) | 67.0 (59.0; 75.0) |
| Age group, n (%) | | | | | |
| <65 years | 8016 (26.8) | 4980 (36.0) | 1258 (29.6) | 441 (27.2) | 996 (40.6) |
| 65-74 years | 9761(32.7) | 4564 (33.0) | 1336 (31.5) | 494 (30.5) | 791 (32.2) |
| ≥75 years | 12,099 (40.5) | 4277 (30.9) | 1653 (38.9) | 684 (42.2) | 668 (27.2) |
| Race/Ethnicity, n (%) | | | | | |
| Caucasian | 27934 (96.9) | 13 (0.1) | 957 (23.1) | 1421 (90.5) | 1672 (70.3) |
| Hispanic/Latino | 344 (1.2) | 0 (0.0) | 3000 (72.5) | 35 (2.2) | 14 (0.6) |
| Asian | 160 (0.6) | 13789 (99.8) | 11 (0.3) | 11 (0.7) | 305 (12.8) |
| Black/Mixed/Other | 394 (1.4) | 16 (0.1) | 172 (4.2) | 103 (6.6) | 386 (16.2) |
| Prior/current smoker, n (%) | 9558 (35.2) | 3833 (31.2) | 1348 (32.9) | 709 (47.6) | 949 (40.4) |
| Heavy alcohol use, n (%) | 486 (1.9) | 365 (3.2) | 72 (1.8) | 36 (2.7) | 69 (3.1) |
| Body mass index, median (Q1; Q3), kg/m ² | 28.0 (25.1;31.8) | 24.2 (22.0;26.6) | 27.9 (24.8;31.6) | 29.4 (25.4;34.0) | 29.8 (26.0;34.3) |
| Pulse, median (Q1; Q3), bpm | 85.0 (70.0; 108.0) | 82.0 (70.0; 98.0) | 80.0 (70.0; 102.0) | 89.0 (72.0; 117.0) | 98.0 (80.0; 122.0) |
| SBP, median (Q1; Q3), mm Hg | 135 (120.0;147.0) | 130 (118.0;140.0) | 130(120.0;141.0) | 130 (118.0;143.0) | 133 (120.0;148.0) |
| DBP, median (Q1; Q3), mm Hg | 80.0 (71.0;90.0) | 78.0 (70.0;86.0) | 80.0 (70.0;86.0) | 78.0 (68.0;86.0) | 80.0 (70.0;90.0) |

| | | | | | |
|--|----------------|----------------|----------------|----------------|----------------|
| Type of atrial fibrillation, n (%) | | | | | |
| Permanent | 4587 (15.4) | 1108 (8.0) | 666 (15.7) | 35 (2.2) | 234 (9.5) |
| Persistent | 4313 (14.4) | 2505 (18.1) | 625 (14.7) | 100 (6.2) | 210 (8.6) |
| Paroxysmal | 7375 (24.7) | 5165 (37.4) | 1086 (25.6) | 345 (21.3) | 333 (13.6) |
| Unclassified | 13598 (45.5) | 5042 (36.5) | 1870 (44.0) | 1137 (70.3) | 1678 (68.4) |

| Risk scores | | | | | |
| CHA₂DS₂-VASc score, median (Q1; Q3) | 3.0 (2.0; 4.0) | 3.0 (2.0; 4.0) | 3.0 (2.0; 4.0) | 3.0 (2.0; 4.0) | 3.0 (2.0; 4.0) |

| | | | | | |
|---|----------------|----------------|----------------|----------------|----------------|
| HAS-BLED score, median (Q1; Q3)* | 1.0 (1.0; 2.0) | 1.0 (1.0; 2.0) | 1.0 (1.0; 2.0) | 2.0 (1.0; 2.0) | 1.0 (1.0; 2.0) |
| GARFIELD-AF risk score, median (IQR) | | | | | |
| All-cause mortality | 5.3 (3.1;9.4) | 3.1 (1.8;6.0) | 6.0 (3.5;10.9) | 5.8 (3.1;10.9) | 4.3 (2.5;8.5) |
| Non-haemorrhagic stroke/SE | 1.6 (1.1;2.4) | 1.5 (1.0;2.3) | 1.6 (1.1;2.4) | 1.6 (1.1;2.4) | 1.4 (0.9;2.3) |
| Major bleeding | 1.7 (1.1;2.6) | 1.3 (0.9;2.0) | 1.6 (1.0;2.4) | 1.6 (1.0;2.6) | 1.6 (1.0;2.4) |

*The risk factor 'Labile INRs' is not included in the HAS-BLED score as it is not collected at baseline. As a result, the maximum HAS-BLED score at baseline is 8 points (not 9).

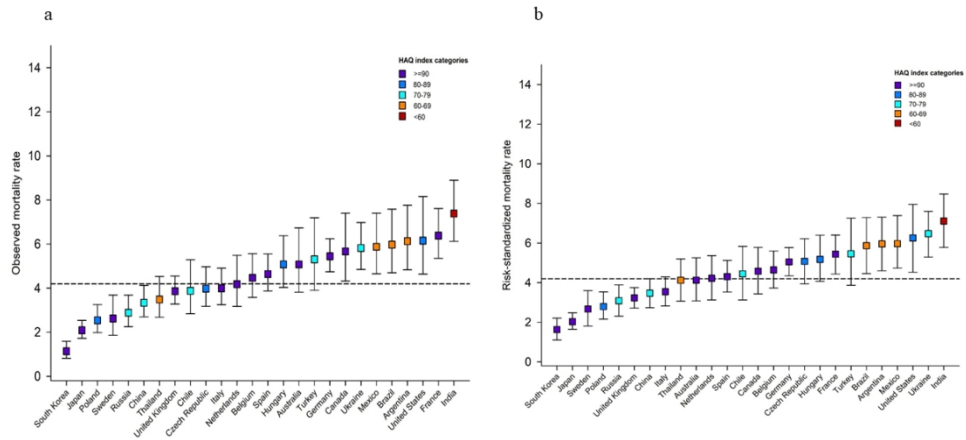

BPM, beats per minute; DBP, diastolic blood pressure; SBP, systolic blood pressure, Q1, 1st quartile, Q3, 3rd quartile, SE, systemic embolism

Countries in each region are as follows: Europe (Finland, Norway, Sweden, Denmark, United Kingdom, Netherlands, Belgium, Germany, Switzerland, France, Spain, Italy, Austria, Hungary, Russia, Poland, Czech Republic, Ukraine and Turkey), Asia (Singapore, China, Japan, South Korea, Thailand and India), North America (USA and Canada), Latin America (Mexico, Brazil, Argentina and Chile) and Other countries (Egypt, United Arab Emirates, South Africa and Australia)

Table 2. Observed rate and corresponding 95% confidence interval for all-cause mortality, non-haemorrhagic stroke/SE and major bleeding by region and in all 35 countries in GARFIELD-AF

| Region | Outcome | | |
|-----------------|---------------|-------------------------------|----------------|
| | Mortality | Non-haemorrhagic Stroke/SE | Major bleeding |
| Europe | 4.4 (4.2-4.6) | 1.2 (1.1-1.3) | 1.3 (1.2-1.4) |
| Asia | 2.8 (2.6-3.1) | 1.0 (0.9-1.2) | 0.9 (0.7-1.0) |
| Latin America | 5.5 (4.8-6.2) | 1.4 (1.1-1.8) | 1.3 (1.0-1.7) |
| North America | 5.9 (4.8-7.2) | 1.0 (0.6-1.6) | 2.9 (2.2-3.8) |
| Other countries | 6.0 (5.1-7.0) | 1.8 (1.3-2.4) | 1.3 (0.9-1.9) |
| All countries | 4.2 (4.0-4.4) | 1.2 (1.1-1.3) | 1.2 (1.1-1.3) |

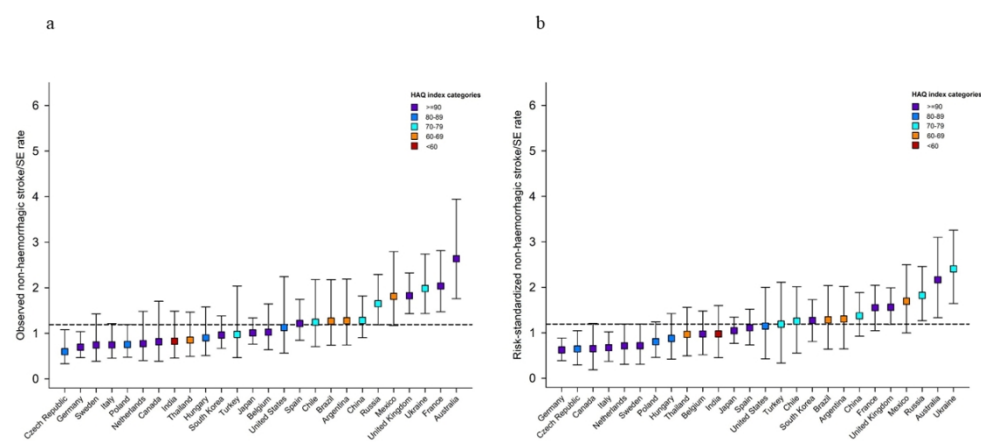

SE: Systemic embolism

Observed (a) and risk-standardized (b) one-year mortality rates with 95% confidence intervals by country. *
 *Showing only countries with more than 700 patients enrolled. Horizontal dashed line represents overall
 observed global rate calculated from all 35 countries. Measures of performance are based on the Healthcare
 Access and Quality Index for 195 countries and territories from the Global Burden of Disease Study
 [reference 20].

United States

Michael Cox, Scott Beach, Peter Duffy, Stephen Falkowski, Kevin Ferrick, Miguel Franco, W. Michael Kutayli, Annette Quick, Niraj Sharma, Vance Wilson, Stephen Miller, Mark Alberts, Edwin Blumberg, Roddy Canosa, Ted Gutowski, Rodney Ison, Jorge Garcia, Paul Mullen, Howard Noveck, Pamela Rama, Rajneesh Reddy, Marcus Williams, Daniel Nishijima, Keith Ferdinand, Ihsan Haque, Robert Mendelson, Sridevi Pitta, Daniel Theodoro, Charles Treasure, Moustafa Moustafa, Cas Cader, Walter Pharr, Alisha Oropallo, George Platt, Jaspal Gujral, James Welker, Firas Koura.

STROBE Statement—checklist of items that should be included in reports of observational studies

| Item No | Recommendation |
|------------------------------|---|
| 1 | (a) Indicate the study's design with a commonly used term in the title or the abstract- title page 1 (b) Provide in the abstract an informative and balanced summary of what was done and what was found- page 4 &5 |
| Introduction | |
| Background/rationale | 2 Explain the scientific background and rationale for the investigation being reported- page 6 |
| Objectives | 3 State specific objectives, including any prespecified hypotheses- page 6 |
| Methods | |
| Study design | 4 Present key elements of study design early in the paper- Page 6-7 |
| Setting | 5 Describe the setting, locations, and relevant dates, including periods of recruitment, exposure, follow-up, and data collection – pages 6-8 |
| Participants | 6 (a) <i>Cohort study</i> —Give the eligibility criteria, and the sources and methods of selection of participants. Describe methods of follow-up- page 6-7 <i>Case-control study</i> —Give the eligibility criteria, and the sources and methods of case ascertainment and control selection. Give the rationale for the choice of cases and controls <i>Cross-sectional study</i> —Give the eligibility criteria, and the sources and methods of selection of participants (b) <i>Cohort study</i> —For matched studies, give matching criteria and number of exposed and unexposed <i>Case-control study</i> —For matched studies, give matching criteria and the number of controls per case |
| Variables | 7 Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable- page 7 |
| Data sources/ measurement | 8* For each variable of interest, give sources of data and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group- page 8-10 |
| Bias | 9 Describe any efforts to address potential sources of bias |
| Study size | 10 Explain how the study size was arrived at |
| Quantitative variables | 11 Explain how quantitative variables were handled in the analyses. If applicable, describe which groupings were chosen and why |
| Statistical methods | (a) Describe all statistical methods, including those used to control for confounding- page 8-10 (b) Describe any methods used to examine subgroups and interactions (c) Explain how missing data were addressed (d) <i>Cohort study</i> —If applicable, explain how loss to follow-up was addressed <i>Case-control study</i> —If applicable, explain how matching of cases and controls was addressed <i>Cross-sectional study</i> —If applicable, describe analytical methods taking account of sampling strategy (e) Describe any sensitivity analyses |

| Results | | |
|--------------------------|-----|--|
| Participants | 13* | (a) Report numbers of individuals at each stage of study—eg numbers potentially eligible, examined for eligibility, confirmed eligible, included in the study, completing follow-up, and analysed page 10 (b) Give reasons for non-participation at each stage (c) Consider use of a flow diagram |
| Descriptive data | 14* | (a) Give characteristics of study participants (eg demographic, clinical, social) and information on exposures and potential confounders page 10-11 (b) Indicate number of participants with missing data for each variable of interest (c) <i>Cohort study</i> —Summarise follow-up time (eg, average and total amount) |
| Outcome data | 15* | <i>Cohort study</i> —Report numbers of outcome events or summary measures over time page 11-13 <i>Case-control study</i> —Report numbers in each exposure category, or summary measures of exposure <i>Cross-sectional study</i> —Report numbers of outcome events or summary measures |
| Main results | 16 | (a) Give unadjusted estimates and, if applicable, confounder-adjusted estimates and their precision (eg, 95% confidence interval). Make clear which confounders were adjusted for and why they were included page 9-10 (b) Report category boundaries when continuous variables were categorized (c) If relevant, consider translating estimates of relative risk into absolute risk for a meaningful time period |
| Other analyses | 17 | Report other analyses done—eg analyses of subgroups and interactions, and sensitivity analyses page 13-14 |
| Discussion | | |
| Key results | 18 | Summarise key results with reference to study objectives- page 14-15 |
| Limitations | 19 | Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss both direction and magnitude of any potential bias- page 17-18 |
| Interpretation | 20 | Give a cautious overall interpretation of results considering objectives, limitations, multiplicity of analyses, results from similar studies, and other relevant evidence- page 14-18 |
| Generalisability | 21 | Discuss the generalisability (external validity) of the study results |
| Other information | | |
| Funding | 22 | Give the source of funding and the role of the funders for the present study and, if applicable, for the original study on which the present article is based- page 19 |

*Give information separately for cases and controls in case-control studies and, if applicable, for exposed and unexposed groups in cohort and cross-sectional studies.

Note: An Explanation and Elaboration article discusses each checklist item and gives methodological background and published examples of transparent reporting. The STROBE checklist is best used in conjunction with this article (freely available on the Web sites of PLoS Medicine at <http://www.plosmedicine.org/>, Annals of Internal Medicine at <http://www.annals.org/>, and Epidemiology at <http://www.epidem.com/>). Information on the STROBE Initiative is available at www.strobe-statement.org.

Abstract

Objective In patients with newly diagnosed AF, do baseline risk factors and stroke prevention strategies account for the geographically diverse outcomes.

Design GARFIELD-AF is a prospective multinational non-interventional registry of patients with newly diagnosed AF (n=52,018 patients).

Setting Investigator sites (n=1317) were representative of the care settings/locations in each of the 35 participating countries. Treatment decisions were all determined by the local responsible clinicians.

Participants The patients (18 years and over) with newly diagnosed AF had at least 1 investigator-determined stroke risk factor and patients were not required to meet specific thresholds of risk score for anticoagulant treatment.

Main outcomes and measures Observed 1-year event rates and risk-standardised rates were derived.

Results Rates of death, non-haemorrhagic stroke/SE and major bleeding varied more than three-to-four fold across countries even after adjustment for baseline factors and antithrombotic treatments. Rates of anticoagulation and antithrombotic treatment varied widely. Patients from countries with the highest rates of cardiovascular mortality and stroke were among the least likely to receive oral anticoagulants. Beyond anticoagulant treatment, variations in the treatment of comorbidities and lifestyle factors may have contributed to the variations in outcomes. Countries with the lowest healthcare Access and Quality indices (India, Ukraine, Argentina, Brazil) had the highest risk-standardized mortality.

Conclusion The variability in outcomes across countries for patients with newly diagnosed AF is not accounted for by baseline characteristics and antithrombotic treatments. Residual

1
2
3 mortality rates were correlated with Healthcare Access and Quality indices. The findings
4
5 suggest the management of patients with AF needs to not only address guideline indicated and
6
7 sustained anticoagulation, but also the treatment of comorbidities and lifestyle factors.

Strengths and limitations of this study

- This is a prospective observational study where patients with newly diagnosed AF were identified and followed and outcomes evaluated.
- All patients were managed according to local standards of care.
- Remote and onsite monitoring and robust quality control methods were used.
- As in any observational study the findings may have been influenced by unmeasured confounders.
- Ascertainment of bleeding outcomes was according to local standards of care and thus ascertainment criteria, locally, may have influenced observed rates of bleeding.

For peer review only

INTRODUCTION

The 2015 Global Burden of Disease (GDB) report of 195 countries and territories suggests that AF prevalence is highest in Northern and Central Europe, and the United States ¹, and is projected to rise globally because of aging and population growth worldwide ². However, whether the diverse outcomes of patients with newly diagnosed AF are accounted for by baseline risk characteristics and antithrombotic therapies is uncertain.

The gains in cardiovascular health in high-income countries are related, at least in part, to modification of cardiovascular risk factors as well as improved disease management. In the context of atrial fibrillation, the changes include the availability of treatment strategies for stroke prophylaxis, and/or rhythm or rate control ³⁻⁷. However, the extent to which baseline characteristics and treatment strategies account for geographic variations in outcomes is unclear.

The Global Anticoagulant Registry in the FIELD-Atrial Fibrillation (GARFIELD-AF) aimed to define geographical variations in all-cause mortality, stroke/systemic embolism (SE) and major bleeding in patients with newly diagnosed AF. The primary aim of this report was to determine whether variations in outcomes of AF are accounted for by baseline clinical risk characteristics. A secondary aim was to consider the impact of other factors including national differences in life expectancy, access to quality healthcare, and stroke prevention strategies.

METHODS

Design

GARFIELD-AF is the largest multinational prospective registry in AF ⁸. The study recruited patients from >1,000 investigational sites (identified nationally as representative) in 35 countries. Patients were recruited from: Europe (Finland, Norway, Sweden, Denmark, United Kingdom, Netherlands, Belgium, Germany, Switzerland, France, Spain, Italy, Austria,

1
2
3 Hungary, Russia, Poland, Czech Republic, Ukraine and Turkey), Asia (Singapore, China,
4 Japan, South Korea, Thailand and India), North America (USA and Canada), Latin America
5 (Mexico, Brazil, Argentina and Chile) and other countries including Egypt, United Arab
6 Emirates, South Africa and Australia.
7
8
9

10
11
12
13 Adults ≥ 18 years were eligible for inclusion if they were diagnosed with non-valvular AF within
14 6 weeks of study entry. Patients with AF were required to have at least one risk factor for stroke,
15 as judged by the investigator (entry to GARFIELD-AF did not require performance of a stroke
16 risk predictor, nor a specific threshold if such a score was performed). Patients were enrolled
17 prospectively and consecutively at sites that aimed to reflect diverse care settings (including
18 office/outpatient practice; hospital departments including neurology, cardiology, geriatrics,
19 internal medicine and emergency; anticoagulation clinics; and general practice)^{8,9}.
20
21

28
29

30 **Ethics statement**

31
32
33 Independent ethics committee and hospital-based institutional review board approvals were
34 obtained, as necessary, for the registry protocol. Additional approvals were obtained from
35 individual study sites. The registry is being conducted in accordance with the principles of the
36 Declaration of Helsinki, local regulatory requirements, and the International Conference on
37 Harmonisation Good Pharmacoeconomic and Clinical Practice Guidelines. Written
38 informed consent was obtained from all study participants. Confidentiality and anonymity of
39 all enrolled patients was maintained.
40

GARFIELD-AF data were captured using an electronic case report form (eCRF). Submitted
data were examined for completeness and accuracy by the coordinating centre (Thrombosis
Research Institute, London, UK), and data queries were sent to study sites. An audit and quality
control programme was implemented, and this included source documentation (20% of all

1
2
3 eCRFs were monitored against source records) ¹⁰. This paper adheres to the guidelines from
4
5 STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) ¹¹.
6
7

8 **Patient and Public Involvement**

9

10
11 Patients and/or the public were not involved in the design, conduct, reporting, or dissemination
12
13 plans of this research.
14

15 **Procedures and outcome measures**

16

17
18 Baseline characteristics collected at study entry included: medical history, care setting, type of
19
20 AF, date and method of diagnosis of AF, symptoms, antithrombotic treatment (vitamin K
21
22 antagonists [VKAs], non-vitamin K antagonist oral anticoagulants [NOACs] and antiplatelet
23
24 [AP] treatment), as well as all cardiovascular drugs. Race was classified by the investigator in
25
26 agreement with the patient ⁸. Vascular disease included coronary artery disease (CAD) with a
27
28 history of acute coronary syndromes (ACS) and/or peripheral artery disease. Chronic kidney
29
30 disease (CKD) was classified according to National Kidney Foundation guidelines into
31
32 moderate-to-severe (stages 3–5), mild (stages 1 and 2) or none. Data on components of the
33
34 CHA₂DS₂-VASc and HAS-BLED risk stratification schemes were collected and calculated
35
36 retrospectively. HAS-BLED scores were calculated excluding fluctuations in international
37
38 normalised ratio. In addition, the risk of death, non-haemorrhagic stroke/SE and major bleeding
39
40 was evaluated with the GARFIELD-AF risk calculator ¹².
41
42
43
44
45

46
47 Patients were followed over a minimum of 24 months or until death or loss to follow-up,
48
49 whichever occurred first. As reported previously, standardised definitions for clinical events,
50
51 death (cardiovascular and non-cardiovascular), non-hemorrhagic stroke/SE and major
52
53 bleeding) were used ^{8,9}. Outcome events were not centrally adjudicated.
54
55
56
57
58
59
60

1
2
3 Data for this report were extracted from the study database on 30th June 2019.
4
5

6 **Statistical analysis**

7

8 Univariate data are presented as medians (1st and 3rd quartile) for continuous variables and as
9 absolute frequencies with percentages for categorical variables.
10
11

12
13 “Time at risk” for each event was calculated over the first year after enrolment up to the first
14 occurrence of an event or last follow-up or at 365 days, whichever occurred earlier. All-cause
15 mortality, non-haemorrhagic stroke/SE and major bleeding were described as the number of
16 events and the Kaplan-Meier event rate with 95% confidence intervals.
17
18

19
20 In this study, national risk-standardised measures of event rates were calculated to compare the
21 observed event rates based on case mix (i.e. the clinical characteristics of patients) in each
22 country, with the expected rates for a similar case mix. The risk-standardised event rates were
23 calculated using the following equation:
24
25

$$26 \frac{\text{Observed event rate}}{\text{Expected event rate}} \times \text{Global event rate} = \text{Risk standardized rate}$$

27
28

29 Where the **Observed event rate** was the crude rate calculated for each country using the
30 Kaplan-Meier estimator (1 *minus* event-free survival probability at 1 year after enrolment).
31
32

33
34 **Expected event rate** was calculated (using multivariable Cox regression with a series of
35 demographic and clinical characteristics as covariates) for every patient and the national
36 average computed.
37
38

39
40 **Global (and regional) event rates** were the crude rate calculated with the Kaplan-Meier rate
41 across all countries in GARFIELD-AF without exclusion.
42
43

44
45 When the observed and expected rates were the same, the risk-standardised rate equalled the
46 global event rates. However, when the observed event rate was greater or less than the expected
47 rate, then the country had more or less events than expected, based on its case mix. Hence, the
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 observed to expected ratio was greater or less than 1.0, making the risk-standardised rate higher
4
5 or lower than the global rate.
6
7

8
9 Patients' characteristics included in the initial Cox model were: age, gender, type of AF, history
10
11 of hypertension, blood pressure (systolic and diastolic) and pulse rate (at enrolment),
12
13 hypercholesterolemia, smoking status (never/ex/current) and heavy alcohol consumption,
14
15 diabetes mellitus (type 1 or 2), ACS, coronary artery bypass graft (CABG), vascular disease,
16
17 carotid occlusive disease, venous thromboembolism (VTE), history of stroke/transient
18
19 ischaemic attack (TIA)/SE, history of bleeding, heart failure, moderate-to-severe CKD and
20
21 cirrhosis. Fine-Gray modelling was applied to the outcomes of non-haemorrhagic stroke/SE
22
23 and major bleeding with death as the competing risk. Confidence intervals for the risk-
24
25 standardized measures were computed using estimates extracted from 1000 bootstrap samples.
26
27 Patients with missing values were not removed from the study; single imputation was applied.
28
29

30
31
32 Both baseline risk factors and antithrombotic regimens (with oral AC and/or AP) at the time of
33
34 diagnosis of AF (baseline) were included in the Cox model.
35
36

37
38 The observed rates in a contemporary US registry, the ORBIT-AF II, were derived to assess the
39
40 representability of the US patients in GARFIELD-AF.
41
42

43 All analyses were performed with SAS version 9.4 (SAS Institute Inc., Cary, NC, USA).
44

45 RESULTS

46 Baseline demographics and clinical characteristics

47
48
49 Baseline characteristics were analysed for the 52,018 patients with newly diagnosed AF,
50
51 enrolled consecutively into GARFIELD-AF between March 2010 and August 2016, in 35
52
53 countries. The largest cohort was recruited from Europe (57.4%), followed by Asia (26.6%),
54
55 Latin America (8.2%), "Other" countries (4.7%) (including South Africa, Egypt, United Arab
56
57 Emirates and Australia) and North America (3.1%). The rate of missing data was below <3%,
58
59
60

1
2
3 with the exception of lifestyle information, BMI and some vital signs. Loss to follow-up was
4
5 about 1% for all world regions except Asia (4.3%).
6

7
8 The observed variability in patients' baseline characteristics among regions in GARFIELD-AF
9
10 is reported in **table 1**. Patients from Asia compared with Europe tended to be younger, had a
11
12 lower body mass index, a lower prevalence of hypertension, hypercholesterolemia, vascular
13
14 disease and CKD. By contrast, patients from North America in GARFIELD-AF had the highest
15
16 proportion of patients aged ≥ 75 , together with the highest prevalence of diabetes,
17
18 hypercholesterolemia and prior/current smokers from any region (except "Other Region" where
19
20 the highest prevalence of diabetes was observed). The prevalence of heart failure was consistent
21
22 and approximately one in five of patients in every region. Approximately 70% of patients
23
24 overall (and 91.6% of patients in North America) were categorised as having paroxysmal or
25
26 unclassified AF at enrolment in this study (**Table 1**).
27
28
29

30
31 Standard risk assessment scores (including the GARFIELD-AF risk score) found that the
32
33 calculated risks of stroke or major bleeding were similar across regions (median CHA₂DS₂-
34
35 VASc score 3.0 in all regions). However, the GARFIELD-AF risk model for death revealed
36
37 regional differences, with a lower expected rate of death in patients from Asia and highest in
38
39 those from Latin America (**Table 1**).
40

41 42 **Treatment setting** 43

44
45 In Asia and Latin America, patients were predominantly diagnosed and managed by
46
47 cardiologists (83.7% and 75.0%, respectively), while in Europe and North America, the role of
48
49 managing patients with AF was shared between cardiologists (in approximately 60% of cases),
50
51 internists (~20%) and primary care (~20%). The likelihood of being diagnosed and treated in
52
53 the emergency care setting was highest in North America (38.0% of patients) followed by Latin
54
55 America (24.7%), "Other" countries (13.4%), Europe (11.5%) and Asia (2.5%).
56
57
58
59
60

Observed global and regional outcomes

In GARFIELD-AF, the lowest observed rate of death at one year was recorded in Asia (2.8; 95% CI: 2.6-3.1) with rates less than half those observed in “Other” countries (6.0; 95% CI: 5.1-7.0) (namely, South Africa, Egypt, United Arab Emirates and Australia). Non-haemorrhagic stroke/SE rates showed less regional variability, but once again, the lowest observed rates were reported in Asia (1.0; 95% CI: 0.9-1.2). For major bleeding, the highest observed rates were recorded in North America (2.9; 95% CI: 2.2-3.8) and the lowest in Asia (0.9; 95% CI: 0.7-1.0). Reflecting the high proportion of patients from Europe, the global rates across all countries in GARFIELD-AF were similar to European event rates for mortality, non-haemorrhagic stroke/SE and major bleeding (**Table 2**).

Observed and risk-standardised outcomes by country

Figures 1 to 3 depict the observed and risk-standardised rates of mortality, non-haemorrhagic stroke/SE and major bleeding for countries that enrolled more than 90% of the patients into GARFIELD-AF, i.e. omitting countries with potentially unrepresentative findings due to low enrolment. Full details of the observed rates from all countries, including those omitted from the figures, i.e. South Africa (n=639), Denmark (n=532), Egypt (n=527), Austria (n=460), United Arab Emirates (n=397), Finland (n=359), Singapore (n=306), Norway (n=270), and Switzerland (n=89), are reported in **Supplement Tables S1-S3**.

Figures 1-3 show the marked variations in observed event rates by country. This variability persisted even after adjusting for all 22 baseline factors (demographics, modifiable cardiovascular risk factors and comorbidities).

India and Ukraine experienced the highest risk-standardised mortality rates, primarily driven by cardiovascular events. Marked differences were also observed for the USA, where the rate of non-cardiovascular mortality was more than 3-fold higher compared to cardiovascular

1
2
3 mortality. Within most other countries the rates of cardiovascular and non-cardiovascular
4 mortality were similar (**Supplementary Table S1**).

5
6
7 To display the relation between healthcare access and outcomes in more detail, we colour-coded
8 each country according to the Healthcare Access and Quality (HAQ) Index (overall score on a
9 scale of 0–100) from the Global Burden of Disease Study 2016¹³. The results show that some
10 of the countries with highest risk-standardised mortality rates (i.e. India, Mexico, Argentina and
11 Brazil) had some of the lowest HAQ indices (HAQ: <70); only Thailand had a similarly low
12 HAQ and a mortality rate. Conversely, the three countries with the lowest risk-standardised
13 mortality rate (South Korea, Japan, and Sweden) all obtained a high HAQ score (HAQ: ≥90).

14
15
16 The observed mortality rate from the US study, ORBIT-AF II, was similar to the GARFIELD-
17 AF global rate (4.3 [95% CI: 3.7-4.9] vs 4.2 [95% CI: 4.0-4.4] respectively) and below the
18 global rate for non-haemorrhagic stroke/SE (ORBIT-AF-II 0.8 [95% CI: 0.6-1.1] vs
19 GARFIELD-AF 1.2 [95% CI: 1.1-1.3]). Nevertheless, both GARFIELD-AF and ORBIT-AF
20 II reported high rates of major bleeding in the US: 3.4 (95% CI: 2.3-5.0) [GARFIELD-AF] and
21 3.3 (95% CI: 2.8-3.8) [ORBIT-AF II] relative to the global rate of 1.2 (95% CI: 1.1-1.3) in
22 GARFIELD-AF.

23
24
25 The rates of each type of outcome differed by country. For instance, the lowest risk-standardised
26 mortality rates were observed for South Korea, Japan and Sweden, while the lowest risk-
27 standardised rates of non-haemorrhagic stroke/SE were observed in Germany, Czech Republic
28 and Canada. The highest risk-standardised rates non-haemorrhagic stroke/SE were reported in
29 Ukraine and Australia, and the highest risk-standardised rates of major bleeding in the
30 Netherlands and the USA.

31 **Antithrombotic regimen for stroke prevention at baseline**

32
33
34 GARFIELD-AF recorded substantial differences in the overall rate of anticoagulation by region
35 (from 73% in Europe to 56% in Asia, **Supplementary Figure S1a**), as well as large variations
36
37
38
39

56
57
58
59
60

1
2
3 within countries (**Supplementary Figure S1b**). At the time of diagnosis of AF, the highest
4 proportion of patients receiving NOACs was in North America (44.8%). This included 14.4%
5 of patients who received NOAC in combination with APs. VKAs were most commonly
6 prescribed in Europe, Latin America and "Other" countries (in 44.4%, 39.8% and 41.1% of
7 patients, respectively) (**Figure S1a**).

8
9
10 Even though CHA₂DS₂-VASc scores were similar across countries (**Supplementary Table**
11 **S2**), anticoagulant treatment varied three-fold among countries (30% to 90%) (**Figure S1b**).
12 The highest rate of anticoagulation was in the Netherlands and Switzerland (90%) and lowest
13 in China (30%), India (35%) and Ukraine (48%) (**Figure S1b**). More than 40% of newly
14 diagnosed patients with AF in China and India received anti-platelet therapy only and a further
15 20%, approximately, received no anti-thrombotic therapy. Across all countries, we found a
16 significant ($p < 0.001$) association with the choice of antithrombotic regimen and HAQ index,
17 i.e. with a greater likelihood of AC and NOAC prescribing (and lower likelihood of AP therapy
18 alone) with increasing HAQ score (**Figure 4**).

ACs (with or without AP therapy) were prescribed to more than 70% of patients in 18 of 35 countries.

The choice of stroke prevention strategy by region and country was analysed and included in the Cox model. Even after adjustment for baseline risk factors and antithrombotic regimen (AC and/or AP treatment), substantial inter-country differences remained in the rate of non-haemorrhagic stroke/SE (**Supplementary table S4**).

DISCUSSION

Our analysis revealed a wide variability in standardized rates of all-cause mortality, non-haemorrhagic stroke/SE and major bleeding across regions and countries. It also showed a wide variability in baseline characteristics and treatment patterns across regions and countries. Asians had a lower risk profile than patients of any other regions, with lower mean age, BMI,

1
2
3 systolic and diastolic blood pressure, and pulse rate. They had lower rates of comorbidities,
4 particularly history of ACS, vascular disease, stroke/SE, hypertension, high blood cholesterol,
5 moderate to severe chronic kidney disease, and much lower risk of death according to the
6 GARFIELD-AF risk score. With few exceptions, patients of non-Asian regions had
7 substantially higher rates of any of these variables and higher risk of death according to
8 GARFIELD-AF mortality risk score, though median CHA₂DS₂-VASc score and GARFIELD-
9 AF stroke risk score were similar across regions.

10
11
12 In addition, there was a wide variability in treatment patterns as regards stroke prevention that
13 was not accounted for by conventional measures of stroke risk, namely CHA₂DS₂-VASc score

14. Such findings are consistent with other observational studies, including PINNACLE
(Practice Innovation and Clinical Excellence)¹⁵, EORP-AF (EUR Observational Research
Programme-Atrial Fibrillation)¹⁶ and GLORIA-AF (Global Registry on Long-Term
Antithrombotic Treatments in Patients with Atrial Fibrillation)¹⁷. In our population, there were
also wide variations across countries in antithrombotic therapy prescription. The rate of
prescription of OAC w/wo antiplatelet agent was in the range of 70% in Europe, North America
and Other Countries but approximately 60% in Latin America, and 56% in Asia. In China,
India, South Korea, Singapore, Russia, United Arab Emirates, Mexico, Ukraine patients had
substantially higher than global rates of antiplatelet therapy (without anticoagulation) (over
30%), and substantially lower than global average rates of OAC prescription (range 22% to
58%), and a higher proportion of patients with no antithrombotic at all.

After adjusting for the baseline demographics and clinical characteristics (including modifiable
cardiovascular risk factors and comorbidities), the variability in all three major outcomes
among countries persisted, though attenuated. Even after including antithrombotic regimen as
a model covariate, substantial differences in the expected rates of events across countries
remained. OAC treatment was shown to be associated with 30% and 28% lower risks of death

1
2
3 and stroke/SE in a previous report¹⁸. However, type and quality of OAC matter. NOAC instead
4 of VKA, appropriateness of NOAC dosing and quality of VKA monitoring had significant
5 impact on outcomes ^{19,20}, as well as adherence to treatment ²¹. This was not accounted for in
6 this analysis and may explain that the differences in outcomes were only partly attenuated after
7 adjustment.
8
9

10
11
12 In GARFIELD-AF there were geographic disparities, not only in antithrombotic regimens for
13 AF, but also in other cardiovascular management measures. Indeed, AF is no longer considered
14 as an isolated arrhythmia as it is associated with comorbidities that all need a specific
15 therapeutic approach in other words a comprehensive management is now recommended. There
16 may be wide geographic variations in the management of comorbidities such as CHF, diabetes,
17 hypertension, high total and LDL cholesterol, as well as other non-cardiovascular comorbidities
18 such as respiratory failure, sepsis and malignancy. Non-cardiovascular death accounts for at
19 least 50% of all cause death. In some regions more comprehensive treatment of comorbidities
20 in patients with AF may have influenced cardiovascular and non-cardiovascular outcomes and
21 may have accounted, at least in part, for the residual geographic variation in outcomes. The
22 demonstrated clear relation of outcomes with indices of healthcare access (HAQ indices)
23 supports this concept.
24
25

26
27
28 The observed differences in stroke rates, by country and by region, are not explained by the risk
29 predictors within commonly used stroke prediction tools. These findings highlight the
30 importance of identifying factors beyond those collected in conventional risk prediction tools
31 to estimate outcomes in patients with AF. Such factors may include practice patterns (e.g.
32 anticoagulation quality and adherence to treatment, statin use, LDL cholesterol management,
33 diabetes control), access to quality health care, and environmental, lifestyle and epigenetic
34 characteristics. The sum impact may account for the substantial differences in risk-standardised
35 event rates among countries ²². Achieving population-wide control of modifiable risk factors

1
2
3 (including tobacco use, diet, physical inactivity, plasma glucose and hypertension) could
4
5 abrogate a substantial part of the global stroke burden, irrespective of age, gender or ethnicity
6
7
8 ^{23,24}. Even small changes in the distribution of these risk factors could lead to clinically relevant
9
10 reductions in the risks of cardiovascular disease, stroke, and mortality ²⁵⁻²⁷. The findings from
11
12 GARFIELD-AF and other recently published global and regional studies ^{7,28-32} suggest that high
13
14 rates of potentially modifiable metabolic disorders and smoking persist. Thus, there remains
15
16 considerable scope to improve the outcomes of patients with newly diagnosed AF, even in high-
17
18 and middle-income countries.

21
22 Across countries huge variations in outcomes may also be influenced by factors beyond
23
24 baseline characteristics, stroke prevention and management. Outcomes may depend on access
25
26 to good quality care and may reflect standardized mortality rates per country. In GARFIELD-
27
28 AF, the proportion of anticoagulated patients was highly correlated with the average HAQ index
29
30 (derived from national data). And it was not surprising to observe that both these measures were
31
32 found to be high in most countries with low risk-standardized mortality rates. Countries with
33
34 some of the lowest Healthcare Access and Quality (HAQ) indices in GARFIELD-AF (India,
35
36 Ukraine, Argentina and Brazil) had the highest risk-standardised mortality rates. Conversely,
37
38 the lowest observed rates of mortality in Japan and South Korea persisted even after risk
39
40 adjustment. Not all countries fit in this frame though. High observed mortality rates (relative to
41
42 the global average) were found in countries with high Healthcare Access and Quality (HAQ)
43
44 indices such as USA, France, and Germany, which remained greater than average even after
45
46 risk adjustment.

51
52 The risk-standardised mortality rates in GARFIELD-AF appeared to be a reflection of average
53
54 national life expectancy, with the lowest mortality rates in this population with newly diagnosed
55
56 AF in countries with life-expectancies (in years) of 82.2, 83.8, 82.6, 78.2 and 81.6, whereas
57
58
59
60

1
2
3 countries with the highest mortalities in this AF population have life expectancies (in years) of
4
5 68.3, 71.2, 76.3, 78.7 and 74.7³³.
6

7
8 Patients from participating centres with the highest rates of mortality and non-haemorrhagic
9
10 stroke/SE were among the least likely to receive OAC for stroke prevention over the 5 years of
11
12 recruitment into GARFIELD-AF. This is consistent with the observed higher rates of
13
14 cardiovascular (vs non-cardiovascular) mortality in such countries and where AP therapy or no
15
16 antithrombotic therapy for AF is most prevalent. However, higher rates of major bleeding were
17
18 observed in the Netherlands (GARFIELD-AF) and the USA (GARFIELD-AF and ORBIT-AF
19
20 II). These findings may reflect prescribing practice as in the US where combination therapy,
21
22 OAC+ AP was more often used (28%) than in other countries. In the Netherlands the rate of
23
24 OAC prescription is very high, in the range of 90%, chiefly with VKA (78%) and far less with
25
26 NOAC (28%). These factors may account for the higher-than-expected rates of major bleeding
27
28 in these two countries.
29
30
31
32
33
34

35 **CLINICAL IMPLICATIONS**

36
37 Implications are twofold: firstly, that cardiovascular secondary prevention measures, including
38
39 lifestyle measures need to be systematically addressed and anticoagulation measures applied
40
41 and maintained. Secondly, that additional factors, beyond those in commonly used risk
42
43 prediction tools (like CHADS₂VASc) need to be evaluated, including renal dysfunction,
44
45 smoking status and the extent of vascular disease. Such comorbidities require additional
46
47 management.
48
49
50
51
52

53 **CONCLUSIONS**

54
55 Antithrombotic regimens varied substantially across countries as well as the observed rates of
56
57 death, stroke/SE and bleeding. Differences in the event rates persisted even after adjustment for
58
59
60

1
2
3 baseline characteristics and antithrombotic treatments. Other factors, including variations in
4 clinical practice and access to quality healthcare, as well as unobserved patient-related factors,
5 may be responsible for the substantial differences in the rates of mortality, stroke/SE and major
6 bleeding across countries. The comprehensive management of patients with AF extends beyond
7 anticoagulation.

Figure Legends:

Figure 1. Observed (a) and risk-standardized¹ (b) mortality rates by country.

¹Computed as the ratio of observed and predicted rate for each country, multiplied by the global observed rate. The predicted rate estimated from a Cox model with the following covariates: age, sex, type of AF, systolic and diastolic blood pressure, pulse, BMI, hypertension, diabetes, heart failure, history of stroke/TIA/SE, history of bleeding, vascular disease, acute coronary syndromes, moderate to severe CKD, hypercholesterolemia, cirrhosis, carotid occlusive disease, VTE, dementia, smoking status, heavy alcohol consumption. Confidence intervals for risk-standardized rates are calculated through bootstrap sampling with 1000 replications. Showing only countries with more than 700 patients enrolled. Horizontal dashed line represents overall observed global rate.

Figure 2. Observed (a) and risk-standardized¹ (b) non-haemorrhagic stroke/SE rates by country.

¹Computed as the ratio of observed and predicted rate for each country, multiplied by the global observed rate. The predicted rate estimated from a Fine-Gray model with the following covariates: age, sex, type of AF, systolic and diastolic blood pressure, pulse, BMI, hypertension, diabetes, heart failure, history of stroke/TIA/SE, history of bleeding, vascular disease, acute coronary syndromes, moderate to severe CKD, hypercholesterolemia, cirrhosis, carotid occlusive disease, VTE, dementia, smoking status, heavy alcohol consumption. Confidence intervals for risk-standardized rates are calculated through bootstrap sampling with 1000 replications. Showing only countries with more than 700 patients enrolled. Horizontal dashed line represents overall observed global rate.

Figure 3. Observed (a) and risk-standardized¹ (b) major bleeding rates by country.

¹Computed as the ratio of observed and predicted rate for each country, multiplied by the global observed rate. The predicted rate estimated from a Fine-Gray model with the following covariates: age, sex, type of AF, systolic and diastolic blood pressure, pulse, BMI, hypertension, diabetes, heart failure, history of stroke/TIA/SE, history of bleeding, vascular disease, acute coronary syndromes, moderate to severe CKD, hypercholesterolemia, cirrhosis, carotid occlusive disease, VTE, dementia, smoking status, heavy alcohol consumption. Confidence intervals for risk-standardized rates are calculated through bootstrap sampling with 1000 replications. Showing only countries with more than 700 patients enrolled. Horizontal dashed line represents overall observed global rate.

Figure 4. Baseline antithrombotic treatment distribution by Healthcare Access and Quality (HAQ) index¹

¹As HAQ index is a country measure, all patients enrolled within a specific country are assigned the same HAQ index

HAQ index of OAC+AP or AP only: <70=46.7%; 70-79=52.5%; 80-89=30.1%; ≥90=28.6%

Table 1. Baseline characteristics distribution by region of enrolment

| Variable | Region | | | | | P-value ¹ |
|---|-----------------------|------------------------|-----------------------------|-----------------------------|-------------------------------|----------------------|
| | Europe (N = 29876) | Asia (N = 13821) | Latin America (N = 4247) | North America (N = 1619) | Other countries (N = 2455) | |
| Sex, n (%) | | | | | | |
| Male | 16313 (54.6) | 8199 (59.3) | 2231 (52.5) | 885 (54.7) | 1403 (57.2) | <0.001 |
| Female | 13563 (45.4) | 5622 (40.7) | 2016 (47.5) | 734 (45.3) | 1051 (42.8) | |
| Age, median (Q1; Q3), years | 72.0 (64.0;79.0) | 69.0 (60.0;76.0) | 71.0 (63.0;79.0) | 72.0 (64.0;80.0) | 67.0 (59.0;75.0) | <0.001 |
| Age, n (%), years | | | | | | |
| <65 | 8016 (26.8) | 4980 (36.0) | 1258 (29.6) | 441 (27.2) | 996 (40.6) | <0.001 |
| 65-69 | 4578 (15.3) | 2165 (15.7) | 628 (14.8) | 237 (14.6) | 407 (16.6) | |
| 70-74 | 5183 (17.3) | 2399 (17.4) | 708 (16.7) | 257 (15.9) | 384 (15.6) | |
| ≥75 | 12099 (40.5) | 4277 (30.9) | 1653 (38.9) | 684 (42.2) | 668 (27.2) | |
| Race/Ethnicity, n (%) | | | | | | |
| Caucasian | 27934 (96.9) | 13 (0.1) | 957 (23.1) | 1421 (90.5) | 1672 (70.3) | <0.001 |

¹P-values for categorical variables obtained from Chi-square or Fisher's exact test, as appropriate. P-value for continuous variables obtained from one-way ANOVA or Kruskal-Wallis test, as appropriate;

²The risk factor 'Labile INRs' is not included in the HAS-BLED score as it is not collected at baseline. As a result, the maximum HAS-BLED score at baseline is 8 points (not 9);

³Represent the risk of mortality within 2 years;

⁴Represent the risk of non-haemorrhagic stroke/SE within 2 years;

⁵Represent the risk of major bleeding within 2 years.

Table 2. Observed 1-year rates and corresponding 95% confidence intervals for all-cause mortality, non-haemorrhagic stroke/SE and major bleeding by region and in all 35 countries in GARFIELD-AF

| Region | Outcome | | |
|-----------------|---------------|-------------------------------|----------------|
| | Mortality | Non-haemorrhagic Stroke/SE | Major bleeding |
| Europe | 4.4 (4.2-4.6) | 1.2 (1.1-1.3) | 1.3 (1.2-1.4) |
| Asia | 2.8 (2.6-3.1) | 1.0 (0.9-1.2) | 0.9 (0.7-1.0) |
| Latin America | 5.5 (4.8-6.2) | 1.4 (1.1-1.8) | 1.3 (1.0-1.7) |
| North America | 5.9 (4.8-7.2) | 1.0 (0.6-1.6) | 2.9 (2.2-3.8) |
| Other countries | 6.0 (5.1-7.0) | 1.8 (1.3-2.4) | 1.3 (0.9-1.9) |
| All countries | 4.2 (4.0-4.4) | 1.2 (1.1-1.3) | 1.2 (1.1-1.3) |

SE: Systemic embolism

For peer review only

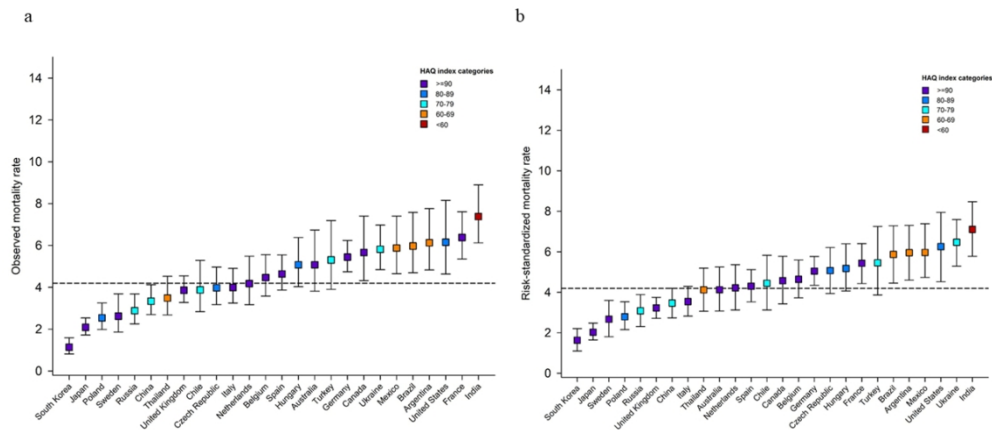

Figure 1. Observed (a) and risk-standardized¹ (b) mortality rates by country.

¹Computed as the ratio of observed and predicted rate for each country, multiplied by the global observed rate. The predicted rate estimated from a Cox model with the following covariates: age, sex, type of AF, systolic and diastolic blood pressure, pulse, BMI, hypertension, diabetes, heart failure, history of stroke/TIA/SE, history of bleeding, vascular disease, acute coronary syndromes, moderate to severe CKD, hypercholesterolemia, cirrhosis, carotid occlusive disease, VTE, dementia, smoking status, heavy alcohol consumption. Confidence intervals for risk-standardized rates are calculated through bootstrap sampling with 1000 replications. Showing only countries with more than 700 patients enrolled. Horizontal dashed line represents overall observed global rate.

108x60mm (300 x 300 DPI)

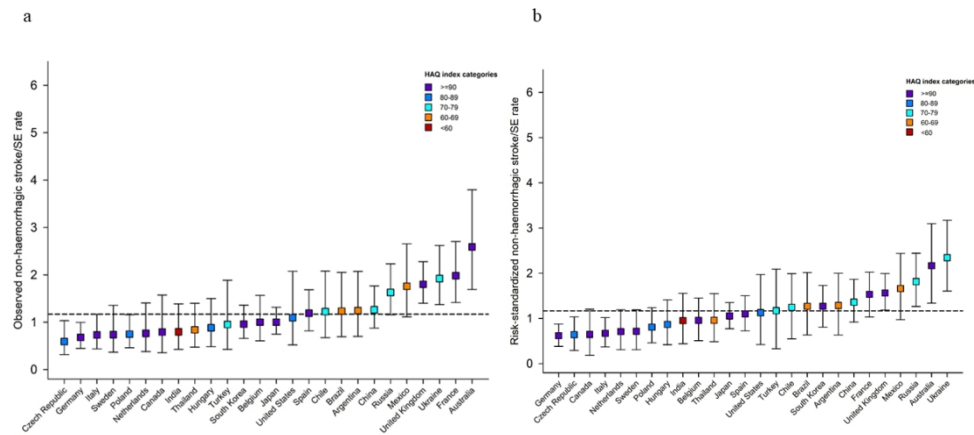

Figure 2. Observed (a) and risk-standardized¹ (b) non-haemorrhagic stroke/SE rates by country.

¹Computed as the ratio of observed and predicted rate for each country, multiplied by the global observed rate. The predicted rate estimated from a Fine-Gray model with the following covariates: age, sex, type of AF, systolic and diastolic blood pressure, pulse, BMI, hypertension, diabetes, heart failure, history of stroke/TIA/SE, history of bleeding, vascular disease, acute coronary syndromes, moderate to severe CKD, hypercholesterolemia, cirrhosis, carotid occlusive disease, VTE, dementia, smoking status, heavy alcohol consumption. Confidence intervals for risk-standardized rates are calculated through bootstrap sampling with 1000 replications. Showing only countries with more than 700 patients enrolled. Horizontal dashed line represents overall observed global rate.

108x60mm (300 x 300 DPI)

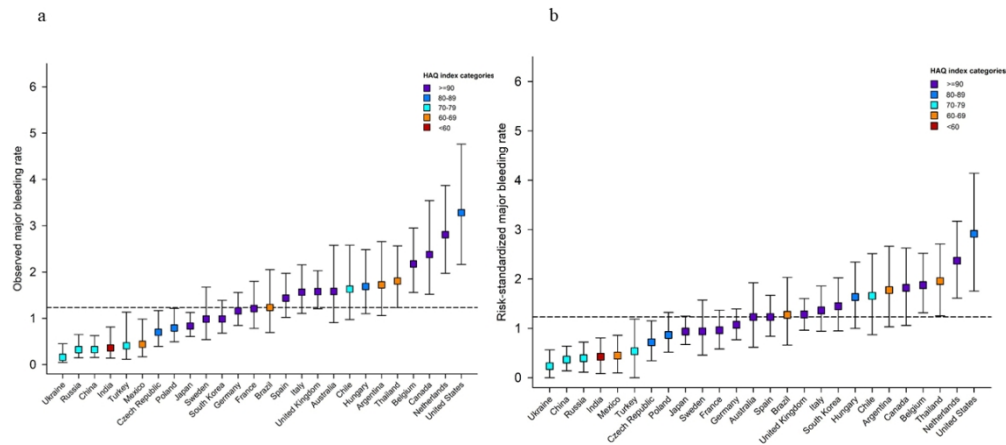

Figure 3. Observed (a) and risk-standardized¹ (b) major bleeding rates by country.

¹Computed as the ratio of observed and predicted rate for each country, multiplied by the global observed rate. The predicted rate estimated from a Fine-Gray model with the following covariates: age, sex, type of AF, systolic and diastolic blood pressure, pulse, BMI, hypertension, diabetes, heart failure, history of stroke/TIA/SE, history of bleeding, vascular disease, acute coronary syndromes, moderate to severe CKD, hypercholesterolemia, cirrhosis, carotid occlusive disease, VTE, dementia, smoking status, heavy alcohol consumption. Confidence intervals for risk-standardized rates are calculated through bootstrap sampling with 1000 replications. Showing only countries with more than 700 patients enrolled. Horizontal dashed line represents overall observed global rate.

108x60mm (300 x 300 DPI)

Baseline antithrombotic treatment distribution by Healthcare Access and Quality (HAQ) index¹
 1As HAQ index is a country measure, all patients enrolled within a specific country are assigned the same HAQ index

HAQ index of OAC+AP or AP only: <70=46.7%; 70-79=52.5%; 80-89=30.1%; ≥90=28.6%

108x60mm (300 x 300 DPI)

Supplementary Tables and Figures

Table S1. Observed and risk-standardized¹ all-cause mortality rates by country in GARFIELD-AF

| Country | Observed mortality rate (95% CI) | | | Risk standardized mortality rate (95% CI) |
|---------------------------------|----------------------------------|---------------------------|-------------------------------|---|
| | All-cause mortality | Cardiovascular mortality* | Non-cardiovascular mortality* | |
| Global (all GARFIELD-AF) | 4.2 (4.0-4.4) | | | - |
| Argentina | 6.1 (4.8-7.8) | 2.7 (1.9-3.9) | 2.6 (1.8-3.8) | 6.0 (4.6-7.3) |
| Australia | 5.1 (3.8-6.7) | 1.8 (1.1-3.0) | 2.2 (1.4-3.4) | 4.1 (3.1-5.3) |

| Thailand | 3.5 (2.7-4.5) | 0.3 (0.1-0.8) | 2.5 (1.9-3.4) | 4.1 (3.1-5.2) |
| Turkey | 5.3 (3.9-7.2) | 3.4 (2.3 - 5.0) | 1.7 (1.0-2.9) | 5.5 (3.9-7.3) |
| Ukraine | 5.8 (4.8-7.0) | 3.0 (2.3-3.9) | 0.2 (0.1 - 0.6) | 6.5 (5.3-7.6) |
| United Arab Emirates | 6.5 (4.5-9.5) | 2.3 (1.2-4.4) | 3.6 (2.1-6.0) | 5.4 (3.6-7.5) |
| United Kingdom | 3.9 (3.3-4.5) | 1.1 (0.8 - 1.5) | 2.0 (1.6-2.5) | 3.2 (2.7-3.7) |
| United States | 6.2 (4.6-8.2) | 0.8 (0.4-1.9) | 2.9 (1.9-4.4) | 6.3 (4.5-7.9) |

¹Computed as the ratio of observed and predicted rate for each country, multiplied by the global observed rate. The predicted rate estimated from a Cox model with the following covariates: age, sex, type of AF, systolic and diastolic blood pressure, pulse, BMI, hypertension, diabetes, heart failure, history of stroke/TIA/SE, history of bleeding, vascular disease, acute coronary syndromes, moderate to severe CKD, hypercholesterolemia, cirrhosis, carotid occlusive disease, VTE, dementia, smoking status, heavy alcohol consumption. Confidence intervals for risk-standardized rates are calculated through bootstrap sampling with 1000 replications.

*Note the rate of cardiovascular and non-cardiovascular mortality do not add up to the total because the cause of death is not known in some cases.

Table S2. Observed and risk-standardized non-haemorrhagic stroke/systemic embolism (SE) rates by country in GARFIELD-AF

| Country | CHA ₂ DS ₂ -VASC | | Observed stroke/SE rate (95% CI) | Risk standardized stroke/SE rate (95% CI) |
|---------------------------------|--|-----------|----------------------------------|---|
| | Median (Q1; Q3) | Mean (SD) | | |
| Global (all GARFIELD-AF) | | | 1.2 (1.1-1.3) | - |
| Argentina | 3.0 (2.0; 4.0) | 3.1 (1.5) | 1.2 (0.7-2.1) | 1.3 (0.6-2.0) |
| Australia | 3.0 (2.0; 4.0) | 3.3 (1.6) | 2.6 (1.7-3.8) | 2.2 (1.3-3.1) |
| Austria | 3.0 (2.0; 4.0) | 3.5 (1.5) | 1.8 (0.8-3.3) | 1.6 (0.6-2.7) |

¹Computed as the ratio of observed and predicted rate for each country, multiplied by the global observed rate. The predicted rate estimated from a Cox model for all-cause mortality or Fine-Gray model for non-haemorrhagic stroke/SE and major bleeding with the following covariates: age, sex, type of AF, systolic and diastolic blood pressure, pulse, BMI, hypertension, diabetes, heart failure, history of stroke/TIA/SE, history of bleeding, vascular disease, acute coronary syndromes, moderate to severe CKD, hypercholesterolemia, cirrhosis, carotid occlusive disease, VTE, dementia, smoking status, heavy alcohol consumption, OAC treatment and AP treatment. Confidence intervals for risk-standardized rates are calculated through bootstrap sampling with 1000 replications.

STROBE Statement—checklist of items that should be included in reports of observational studies

| Item No | Recommendation |
|------------------------------|---|
| 1 | (a) Indicate the study's design with a commonly used term in the title or the abstract- title page 1 (b) Provide in the abstract an informative and balanced summary of what was done and what was found- page 4 &5 |
| Introduction | |
| Background/rationale | 2 Explain the scientific background and rationale for the investigation being reported- page 6 |
| Objectives | 3 State specific objectives, including any prespecified hypotheses- page 6 |
| Methods | |
| Study design | 4 Present key elements of study design early in the paper- Page 6-7 |
| Setting | 5 Describe the setting, locations, and relevant dates, including periods of recruitment, exposure, follow-up, and data collection – pages 6-8 |
| Participants | 6 (a) <i>Cohort study</i> —Give the eligibility criteria, and the sources and methods of selection of participants. Describe methods of follow-up- page 6-7 <i>Case-control study</i> —Give the eligibility criteria, and the sources and methods of case ascertainment and control selection. Give the rationale for the choice of cases and controls <i>Cross-sectional study</i> —Give the eligibility criteria, and the sources and methods of selection of participants (b) <i>Cohort study</i> —For matched studies, give matching criteria and number of exposed and unexposed <i>Case-control study</i> —For matched studies, give matching criteria and the number of controls per case |
| Variables | 7 Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable- page 7 |
| Data sources/ measurement | 8* For each variable of interest, give sources of data and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group- page 8-10 |
| Bias | 9 Describe any efforts to address potential sources of bias |
| Study size | 10 Explain how the study size was arrived at |
| Quantitative variables | 11 Explain how quantitative variables were handled in the analyses. If applicable, describe which groupings were chosen and why |
| Statistical methods | (a) Describe all statistical methods, including those used to control for confounding- page 8-10 (b) Describe any methods used to examine subgroups and interactions (c) Explain how missing data were addressed (d) <i>Cohort study</i> —If applicable, explain how loss to follow-up was addressed <i>Case-control study</i> —If applicable, explain how matching of cases and controls was addressed <i>Cross-sectional study</i> —If applicable, describe analytical methods taking account of sampling strategy (e) Describe any sensitivity analyses |

| Results | | |
|--------------------------|-----|--|
| Participants | 13* | (a) Report numbers of individuals at each stage of study—eg numbers potentially eligible, examined for eligibility, confirmed eligible, included in the study, completing follow-up, and analysed page 10 (b) Give reasons for non-participation at each stage (c) Consider use of a flow diagram |
| Descriptive data | 14* | (a) Give characteristics of study participants (eg demographic, clinical, social) and information on exposures and potential confounders page 10-11 (b) Indicate number of participants with missing data for each variable of interest (c) <i>Cohort study</i> —Summarise follow-up time (eg, average and total amount) |
| Outcome data | 15* | <i>Cohort study</i> —Report numbers of outcome events or summary measures over time page 11-13 <i>Case-control study</i> —Report numbers in each exposure category, or summary measures of exposure <i>Cross-sectional study</i> —Report numbers of outcome events or summary measures |
| Main results | 16 | (a) Give unadjusted estimates and, if applicable, confounder-adjusted estimates and their precision (eg, 95% confidence interval). Make clear which confounders were adjusted for and why they were included page 9-10 (b) Report category boundaries when continuous variables were categorized (c) If relevant, consider translating estimates of relative risk into absolute risk for a meaningful time period |
| Other analyses | 17 | Report other analyses done—eg analyses of subgroups and interactions, and sensitivity analyses page 13-14 |
| Discussion | | |
| Key results | 18 | Summarise key results with reference to study objectives- page 14-15 |
| Limitations | 19 | Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss both direction and magnitude of any potential bias- page 17-18 |
| Interpretation | 20 | Give a cautious overall interpretation of results considering objectives, limitations, multiplicity of analyses, results from similar studies, and other relevant evidence- page 14-18 |
| Generalisability | 21 | Discuss the generalisability (external validity) of the study results |
| Other information | | |
| Funding | 22 | Give the source of funding and the role of the funders for the present study and, if applicable, for the original study on which the present article is based- page 19 |

*Give information separately for cases and controls in case-control studies and, if applicable, for exposed and unexposed groups in cohort and cross-sectional studies.

Note: An Explanation and Elaboration article discusses each checklist item and gives methodological background and published examples of transparent reporting. The STROBE checklist is best used in conjunction with this article (freely available on the Web sites of PLoS Medicine at <http://www.plosmedicine.org/>, Annals of Internal Medicine at <http://www.annals.org/>, and Epidemiology at <http://www.epidem.com/>). Information on the STROBE Initiative is available at www.strobe-statement.org.
