

Supporting Information

Appendix S1. Imaging Procedure

For pre-processing data, the Data Analysis, Informatics, and Resources Center (DAIRC) of ABCD utilizes the Multi-Modal Processing Stream (MMPS) which consists of a toolbox of MATLAB functions; Python, sh, and csh scripts; and C++ compiled executables. In addition, MMPS incorporates several software packages, including FreeSurfer (1), AFNI (2), and FSL (3, 4). The T₁w acquisition (1 mm isotropic) was a 3D T₁w inversion prepared RF-spoiled gradient echo scan using prospective motion correction, when available (currently only on Siemens and GE scanners) (5, 6). T₁w structural images were corrected for gradient nonlinearity distortions using scanner-specific, nonlinear transformations provided by MRI scanner manufacturers (7, 8). Intensity inhomogeneity correction was performed by applying smoothly varying, estimated B₁-bias fields (9, 10). Images were rigidly registered and resampled into alignment with an averaged in-house reference brain in standard space (1.0 mm isotropic voxels, roughly aligned with the anterior commissure/posterior commissure axis), facilitating standardized viewing and analysis of brain structure.

Cortical surface reconstruction and subcortical segmentation were performed using FreeSurfer v5.3 (11, 12). To ensure high quality of derived measures, trained technicians reviewed the accuracy of cortical surface reconstruction. For each cortical surface reconstruction, reviewers examined the severity of five categories of MRI artifact or reconstruction inaccuracy, including motion, intensity inhomogeneity, white matter underestimation, pial overestimation, and magnetic susceptibility artifact. Quality values were assigned on a scale of 0–3, indicating absent, mild, moderate, or severe levels of each type of artifact, respectively. The reviewers then assigned an overall quality score which indicated whether the cortical surface reconstruction was recommended for use or for exclusion. Exclusion was recommended if any of the five categories were rated as severe.

1
2
3 Based on this criteria, 863 participants were excluded from the structural MRI analyses
4
5 (n=10,858).
6
7

9 **Appendix S2. Confirmatory factor analysis**

10 *Methods*

11 To delineate the structure of psychopathology in the current sample, three
12
13 confirmatory factor analysis (CFA) models were fit: 1) a one factor model with all indicators
14
15 loading on a single latent factor representing general psychopathology; 2) a bifactor model
16
17 with all indicators of psychopathology loading on a single factor representing general
18
19 psychopathology as well as the residual variance from three indicators representing
20
21 externalizing (attention deficit hyperactivity disorder, oppositional defiance disorder, conduct
22
23 disorder), six indicators representing internalizing (major depressive disorder, generalised
24
25 anxiety disorder, panic disorder, separation anxiety disorder, social anxiety disorder, post-
26
27 traumatic stress disorder), and four indicators representing thought disorder pathology
28
29 (hallucinations, delusions, obsessive-compulsive disorder, bipolar disorder); and 3) a higher-
30
31 order model with three lower-order factors representing externalizing, internalizing, and
32
33 thought disorder pathology (as described in the bifactor model), and a single higher order
34
35 factor representing general psychopathology that accounts for correlations among lower order
36
37 factors.
38
39
40
41
42
43

44 All models were estimated using a robust maximum likelihood estimator (MLR) with
45
46 numerical integration, suitable for binary indicators, as implemented in MPlus Version 8.4
47
48 (13). Models were compared based on the Bayesian Information Criterion (BIC) and the
49
50 sample size adjusted Bayesian Information Criterion (ssaBIC), with lower values indicating
51
52 better model fit (14). For the specific factors from the bifactor model, OmegaHS coefficients
53
54 were derived from the standardized factor loadings (15). OmegaHS indicates whether the
55
56 specific factors from the bifactor model reflect reliable variance that is independent from the
57
58 general psychopathology factor. The lower-order/specific factors from the higher-order and
59
60

1
2
3 bifactor factor models, respectively, were compared using the H coefficient, given recent
4
5 simulations demonstrating that model fit statistics like BIC and ssaBIC tend to be biased
6
7 towards selection of bifactor models (16). The H coefficient provides an indication of the
8
9 construct replicability (i.e., reliability) of the latent factors with values ranging from 0 to 1
10
11 and estimates $> .8$ indicating well-defined latent variables (Rodriguez et al., 2016). Finally,
12
13 the CFA models were re-run using a weighted least squares estimator (WLSMV) to generate
14
15 the Comparative Fit Index (CFI), Tucker-Lewis Index (TLI), and the root mean square error
16
17 of approximation (RMSEA). Prior empirically derived cut-points were used to determine
18
19 close fit (CFI and TLI > 0.95 and RMSEA < 0.05) (17). The confirmatory factor analysis
20
21 described above was conducted before the study was preregistered (as described here:
22
23 <https://osf.io/qxegb>).

24 25 26 27 28 *Results*

29
30 Tetrachoric correlations for all the binary indicators of psychopathology are provided
31
32 in Table S1. Confirmatory factor analysis model fit statistics are presented in Table S2. The
33
34 bifactor model as specified above had a Heywood case (i.e., negative residual variance) for
35
36 the hallucinations indicator, indicating that the model was not valid. Inspection of the results
37
38 indicated that the thought disorder factor was subsumed by the general psychopathology
39
40 factor: whilst these indicators loaded highly on general psychopathology, they did not form a
41
42 separate thought disorder factor independent of the general psychopathology factor. The
43
44 bifactor model was then re-specified removing the thought disorder specific factor, with the
45
46 fit statistics reported in Table S2 (Model B': modified bifactor model). All three models fit
47
48 the data well, with both the higher-order model and the modified bifactor model
49
50 outperforming the one factor model. However, the reliability of the specific factors in the
51
52 modified bifactor model was low (H coefficient externalizing = 0.50; H coefficient
53
54 internalizing = 0.53). Whereas reliability was higher and within the acceptable range for the
55
56
57
58
59
60

1
2
3 lower order factors in the higher-order model (H coefficient externalizing: 0.84; H coefficient
4 internalizing: 0.91, H coefficient thought disorder: 0.74). The internalizing specific factor
5
6 from the bifactor model had an OmegaHS of 0.22, while externalizing had an OmegaHS of
7
8 0.39, indicating that the specific factors provide little unique, reliable variance.
9
10
11
12
13

14 **Appendix S3. Estimation of Bayesian plausible values**

15
16
17 In order to estimate Bayesian plausible values, the SVALUES output option was included in
18
19 the final best fitting model estimated using the MLR estimator. The SVALUES option
20
21 generates a model command with final estimates used as starting values. The best fitting
22
23 model was then re-estimated with the Bayes estimator and included the model command with
24
25 final estimates as starting values from the previously estimated measurement model. The data
26
27 imputation command was also included, with a total of 100 datasets imputed and saved. Each
28
29 of the 100 imputations contained different plausible values for the externalizing,
30
31 internalizing, thought disorder and general psychopathology dimensions. The following
32
33 analysis example was highly informative as a practical guide for estimating these values:
34
35 https://www.lesahoffman.com/PSYC948/948_Example11_SEM.pdf. The MPlus code for
36
37 generating Bayesian plausible values, including starting values, is appended below.

Figure S1. Empirical distributions of factor scores and Bayesian plausible values.

Empirical distributions of factor scores (a; using the WLSMV estimator in MPlus) and the first imputation of Bayesian plausible values (b; using the BAYES estimator in MPlus) for general psychopathology. All participants reporting zero indicators have the same factor score, resulting in a distribution that is positively skewed in general population samples. As plausible values are random draws from the participant's posterior distribution, those reporting the same pattern of indicators have a range of different plausible values, resulting in a smooth, normal distribution of general psychopathology.

Table S1. Comparison of baseline demographic and clinical characteristics of the participants included and excluded from the structural imaging analyses

	High quality structural MRI data (n=10,858)		Low quality structural MRI data (n = 863)		<i>p</i>
