Supplementary material

Supplementary time-dependent global sensitivity analysis (GSA) results from the "Model output sensitivity for low initial glucose level" section in the main article are presented in Figure S1 and explained in "GSA results for low initial glucose level, [G](0)=0.02 mM". Supplementary time-dependent global GSA results from the "Model output sensitivity for higher initial glucose level" section in the main article are presented in Figure S2 and explained in "GSA results for higher initial glucose level, [G](0)=2 mM". PRCC sensitivity analysis time series data generated during this study are presented in Tables S1 through S8. eFAST sensitivity analysis time series data generated during this study are presented in Tables S9 through S16.

GSA results for low initial glucose level, [G](0)=0.02 mM

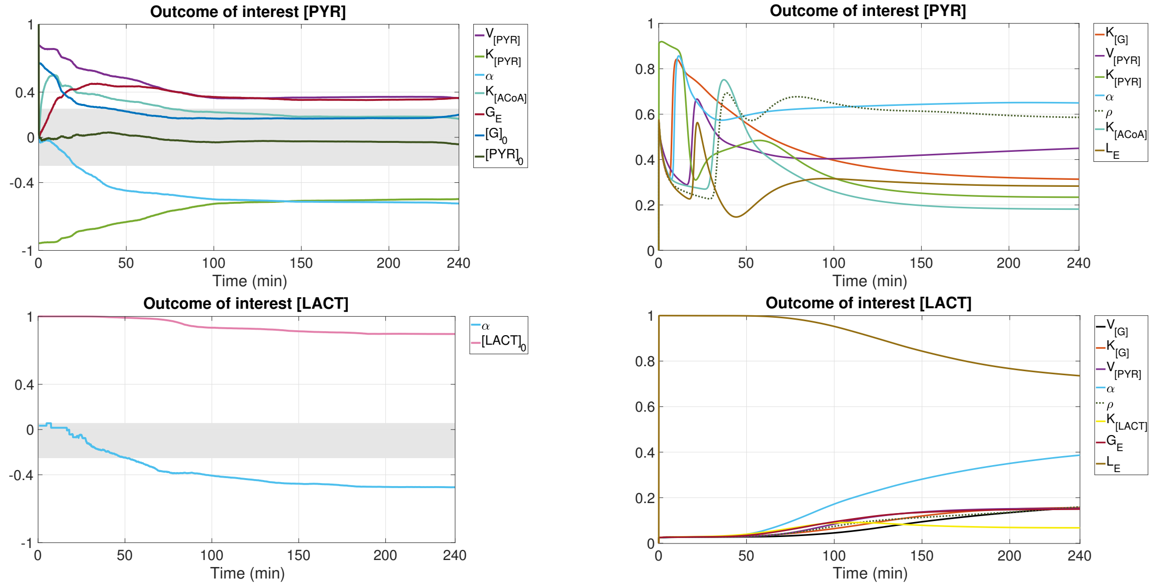

Figure S1: **Time-dependent global sensitivity analysis results for low initial glucose level.** Left panels present time-dependent results of PRCC and right panels present time-dependent results of eFAST, both for initial glucose concentration of $[G](0) = 0.02$ mM. Outcome of interest: row 1 - pyruvate ([PYR]); row 2 - lactate ([LACT]). The gray bands on the left panels indicate PRCC values which are not statistically significant (p-value ≥ 0.001).

PRCC, [PYR]. The PRCC analysis shows that the input factors which significantly affect the pyruvate level initially are $V_{[\mathrm{PYR}]}$, $K_{[\mathrm{PYR}]}$, $K_{[\mathrm{ACoA}]}$, $[\mathrm{G}]_0$, and $[\mathrm{PYR}]_0$ (the initial pyruvate concentration) (Figure 1, top left panel). By approximately 40 minutes the last three are no longer important, and [PYR] becomes sensitive to G_E and α. After about 75 minutes, $K_{[\mathrm{PYR}]}$ and α are the only influential factors. These results indicate that as the temporal dynamics of the metabolic system evolve, the ACoA biochemical reaction, external glucose, the maximal rate of pyruvate production and the initial glucose and pyruvate concentration lose their impact, but the half-limiting value of pyruvate synthesis from glucose as well as G3P utilization and oxidation of fatty acids remain essential for the pyruvate level.

eFAST, [PYR]. Similar to PRCC, eFAST highlights $V_{[\mathrm{PYR}]}$, $K_{[\mathrm{PYR}]}$, $K_{[\mathrm{ACoA}]}$ and α as important (Figure 1, top right panel). Additional factors to which [PYR] is sensitive include $K_{[\mathrm{G}]}$, ρ, and L_E. In the first 100 minutes of the simulation, the sensitivity indices of all parameters exhibit transient dynamics, reaching a peak before 50 minutes. As the indices settle to stable levels, toward the end of the simulation α, ρ and $V_{[\mathrm{PYR}]}$ stand out as the three most important parameters. These findings suggest that RdCVF-stimulated glucose uptake, the half-limiting values of the pyruvate and ACoA biochemical reactions, external lactate, G3P utilization and oxidation of fatty acids, diversion of pyruvate to OXPHOS, and the maximal rate of puruvate production are all influential in the beginning. However, later on the last three processes contribute most to variability in the pyruvate concentration.

PRCC, [LACT]. PRCC shows that [LACT] is sensitive to just two factors: $[\mathrm{LACT}]_0$, which is influential throughout the whole time window, and α, which becomes influential at about 75 minutes (Figure 1, bottom left). This means that with low initial glucose, only changes in the initial lactate concentration and changes in G3P utilization and oxidation of fatty acids affect the level of internal lactate.

eFAST, [LACT]. For the variability of internal lactate, eFAST identifies as most important L_E, which controls the lactate gradient-based gating mechanisms for flow into and out of the cell (Figure 1, bottom right). After 50 minutes, [LACT] also becomes sensitive to uncertainties other parameters: α, $V_{[\mathrm{G}]}$, $K_{[\mathrm{G}]}$, $V_{[\mathrm{PYR}]}$, ρ, G_E, and $K_{[\mathrm{LACT}]}$ (half-limiting value of lactate production from pyruvate). Among those, α has the most pronounced effect. These findings indicate that as the metabolic system dynamics evolve, in addition to the lactate gating mechanisms, other processes, most notably G3P utilization and oxidation of fatty acids, become important in relation to the variability of the internal lactate concentration.

GSA results for higher initial glucose level, [G](0)=2 mM

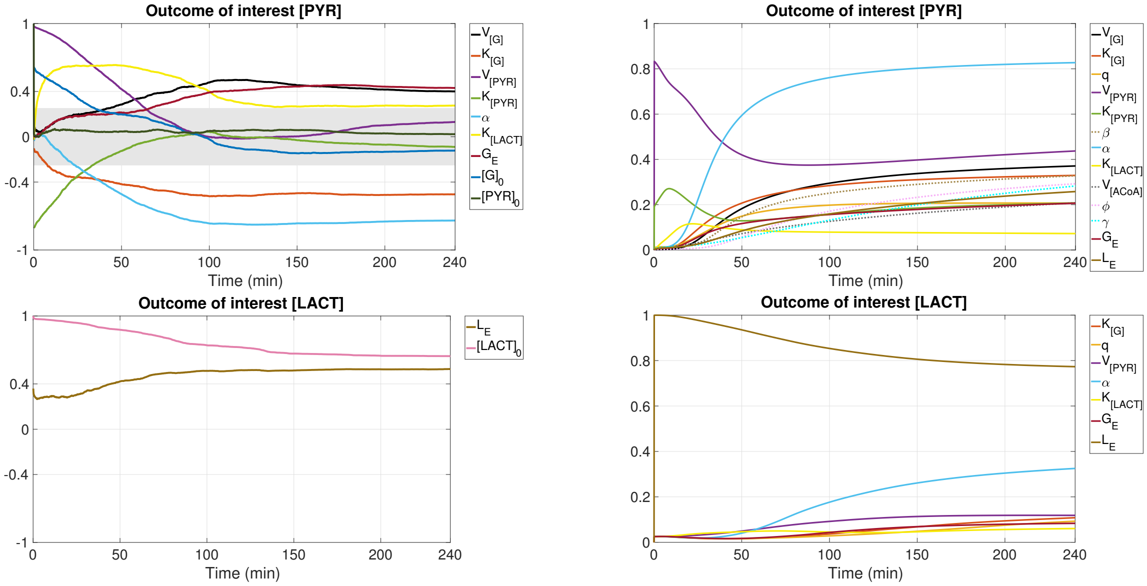

Figure S2: **Time-dependent global sensitivity analysis results for higher initial glucose level.** Left panels present time-dependent results of PRCC and right panels present time-dependent results of eFAST, both for initial glucose concentration of $[\mathrm{G}](0) = 2$ mM. Outcome of interest: row 1 - pyruvate ([PYR]); row 2 - lactate ([LACT]). The gray bands on the left panels indicate PRCC values which are not statistically significant (p-value ≥ 0.001); no gray band means that the PRCC values are statistically significant throughout the whole time frame (left-bottom panel).

PRCC, [PYR]. PRCC reveals that initially the pyruvate level is sensitive to $V_{[\mathrm{PYR}]}$, $K_{[\mathrm{PYR}]}$, $[\mathrm{G}]_0$ and $[\mathrm{PYR}]_0$, but these factors are no longer important after 50 minutes (Figure 2, top left). On the other hand, $K_{[\mathrm{LACT}]}$ has an impact between 5 and 100 minutes. Also, [PYR] is initially insensitive to changes in α, $K_{[\mathrm{G}]}$, $V_{[\mathrm{G}]}$, and G_E, but becomes sensitive at about 40, 50, 75, and 10 minutes, respectively. These results suggest that while in the beginning the pyruvate biochemical dynamics and the initial glucose and pyruvate concentrations influence the pyruvate level the most, as time progresses other factors become dominant, such as lactate synthesis, RdCVF-stimulated glucose uptake, external glucose, and G3P utilization and oxidation of fatty acids.

eFAST, [PYR]. In addition to $V_{[\mathrm{G}]}$, $K_{[\mathrm{G}]}$, $V_{[\mathrm{PYR}]}$, $K_{[\mathrm{PYR}]}$, α, $K_{[\mathrm{LACT}]}$, and G_E, which were highlighted as important with PRCC, eFAST identifies several new parameters as contributing to the variability of pyruvate: q, β (the rate of CIT inhibition of glycolysis), $V_{[\mathrm{ACoA}]}$, ϕ, γ (the maximum velocity of lactate transport contributing to ACoA production), and L_E (Figure 2, top right). Among all of those, the parameters with the greatest sensitivity indices are $V_{[\mathrm{PYR}]}$, dominating until 40 minutes, and α, dominating from 40 minutes until the end of the simulation. These findings indicate that apart from uncertainty in the production of PYR, uncertainty in other processes, such as external glucose, RdCVF-stimulated glucose uptake, glycolysis inhibition, external lactate, G3P synthesis, LACT and ACoA production, CIT conversion to ATP and G3P utilization and oxidation of fatty acids, also play an important role in the variability of pyruvate.

PRCC, [LACT]. PRCC shows that the internal lactate level is sensitive to only $[\mathrm{LACT}]_0$ and L_E (Figure 2, bottom left). $[\mathrm{LACT}]_0$ is influential throughout the entire simulation window, and L_E becomes influential after 50. This means that with higher initial glucose, only changes in the initial lactate concentration and external lactate affect the level of internal lactate.

eFAST, [LACT]. eFAST shows that L_E has the greatest impact on the variability of internal lactate (Figure 2, bottom right). After 50 minutes, several other parameters, including α, $K_{[\mathrm{G}]}$, q, $V_{[\mathrm{PYR}]}$, $K_{[\mathrm{LACT}]}$, and G_E, emerge as important, but to a lower extent compared to L_E. Among those, α has the most pronounced effect. These findings suggest that over time, apart from uncertainty in external lactate, uncertainties in additional processes, most notably G3P utilization and oxidation of fatty acids, make a sizable contribution to the variability of internal lactate.

Comparing the GSA results with the two different initial glucose levels, we make the following observations. PRCC reveals that when [G](0) is low, G_E plays a role in the level of pyruvate earlier compared to the case of higher [G](0). With PRCC we also see that [PYR] is sensitive to $V_{[\mathrm{PYR}]}$ for both levels of initial glucose, but becomes insensitive faster for higher levels of initial glucose. Additionally, while $K_{[\mathrm{PYR}]}$ is important throughout the whole time frame with low initial glucose, it is only important in the first 25 minutes with higher initial glucose. This indicates that when there is more glucose present initially, the pyruvate level is not strongly affected by the maximal velocity and half-saturation value of the glucose conversion to pyruvate. Finally, with low initial glucose, [PYR] is sensitive to $K_{[\mathrm{ACoA}]}$, but for higher initial glucose, $K_{[\mathrm{LACT}]}$ appears as influential. This suggests that the pyruvate-to-ACoA pathway plays a role for low initial glucose, while the pyruvate-to-lactate pathway gains importance for higher initial glucose.

When intracellular lactate is the outcome of interest, PRCC identifies $[\mathrm{LACT}]_0$ as a factor influencing the lactate level whether [G](0) is low or higher. For low [G](0), [LACT] is sensitive to α, whereas for higher [G](0), [LACT] is sensitive to L_E. With the low [G](0), the cell may not have enough material to produce ample lactate, so the internal lactate concentration will possibly never exceed or only slightly exceed the external lactate level. Since the gating mechanisms for lactate leaving the cell is governed by the gradient between internal and external lactate, the gate would remain closed or be open with very minimal flux, which explains why the internal lactate level is not sensitive to L_E for low [G](0). With higher [G](0), PRCC shows that an increase in L_E will result in higher level of lactate inside the cell. This is because with more initial glucose, the cell can produce sufficient amount of lactate allowing the gate for lactate exit to be open with strong flux. Thus, increasing L_E beyond the intracellular lactate level will cause the gate to close, promoting an increase of lactate inside the cell.

PRCC and eFAST sensitivity analysis data

The rest of this document contains the time series data generated during this study by conducting PRCC and eFAST sensitivity analysis in the temporal window 0–240 minutes with [G](0)=0.02 mM and [G](0)=2 mM. The tables show the time discretization and include only the parameters to which the level and variability of the model outputs are sensitive to. In Tables S1 through S8, the sensitivity analysis data from PRCC for [G], [G3P], [PYR] and [LACT] is presented (PRCC sensitivity indices followed by their corresponding p-values). In Tables S9 through S16, the sensitivity analysis data from eFAST for [G], [G3P], [PYR] and [LACT] is shown.

Table S1: PRCC analysis data for [G] with [G](0)=0.02 mM: PRCC sensitivity indices and their corresponding p-values

Sensitivity analysis data from PRCC for [G] with [G](0)=0.02 mM (only the parameters to which [G]'s level is sensitive to appear)

Table S2: PRCC analysis data for [G] with [G](0)=2 mM: PRCC sensitivity indices and their corresponding p-values

Sensitivity analysis data from PRCC for [G] with [G](0)=2 mM (only the parameters to which [G]'s level is sensitive to appear)

Time discretization	V_{[G]}	K_{[G]}	V_{[PYR]}	K_{[PYR]}	alpha	G_E	[G]_0

Table S3: PRCC analysis data for [G3P] with [G](0)=0.02 mM: PRCC sensitivity indices and their corresponding p-values

Sensitivity analysis data from PRCC for [G3P] with [G](0)=0.02 mM (only the parameters to which [G3P]'s level is sensitive to appear)
