Appendix 1. Detailed methods

Setting

The study was conducted in Ghana, Rwanda and South Africa. One rural and one urban area in each country was purposively selected to allow feasibility whilst being as representative of the general population as possible.

Ghana is a lower middle income country, it has an estimated population of 30.4 million people (2019), life expectancy is 63.8 years, and 7.56% of deaths and 7.24% of disability-adjusted life years (DALYs) are estimated to be due to trauma.[15] While health service delivery is largely provided by government, private institutions provide substantial health services to the population.[16] The National Ambulance Service (NAS) provides 24-hour prehospital care for accidents and emergencies. [16] Until 2020, the NAS had only 55 active ambulances serving the entire nation. Recently, 307 new ambulances and a new hotline for emergency services to support the operations of the NAS have been added.[17] Inequality in Ghana is high,[15] as is out of pocket (OOP) health expenditure (37.69% of total health expenditure is OOP).[15] Tamale Metropolitan Area and Yendi Municipal District were the urban and rural study areas chosen; both are in the north of Ghana.

Rwanda is a low income country of 12.6 million people, with a life expectancy of 68.7 years; 9% of all deaths are due to trauma.[15] Community-Based Health Insurance (CBHI) was introduced in 1999/2000 to enable citizens in rural populations and the informal sector to access healthcare.[18] Despite this, the health system is still challenged with deficiencies and inequalities.[19] In Rwanda's national plan, the government has recognised the need to strengthen health systems to reduce the burden of avoidable mortality and morbidity after trauma.[20] The ambulance system has an emergency free call number and over 300

ambulances are in operation throughout the country. This study was conducted in the metropolitan area of the capital, Kigali, and the rural area of Burera.

South Africa is an upper middle-income country, with a population of 60.1 million and a life expectancy of 62.0 years. Injuries are estimated to be responsible for 10% of deaths and 11% of DALYs.[21] Interpersonal violence is seven times higher and road traffic collisions are double the global rate. South Africa has the third biggest economy in Africa, although it is one of the most unequal societies in the world.[15] Access to health care is also inequitable with 86% of the population served by the public sector which has a disproportionately low proportion of the human resources for health.[22] Prehospital emergency care is delivered by both government-funded and private emergency medical services (EMS). Government-funded EMS service is available to everyone, reached via a toll-free national emergency number, and free of charge to all those earning below a threshold.[23] An air medical service with helicopter evacuation is available if needed.[24] This study was conducted in the urban township of Khayelitsha and the rural area of Worcester, both located in the Western Cape province.

Conceptual frameworks

On appraising the literature on frameworks for conceptualising access to quality healthcare, we did not find a developed framework that suited our aims exhaustively. However, three we considered would, in combination, comprehensively cover the dimensions of access to quality healthcare for injured people in LMICs. These were the four-delay framework to access to care as described above,[14 25] the IoM framework for quality healthcare,[26] and the WHO health systems building blocks.[27] The IoM's framework for quality healthcare conceptualises quality of care as effective, safe, efficient, timely, patient centred, and equitable. The WHO building blocks include leadership/governance, financing, medicines

and equipment, information, human resources, and service delivery. Data collection and analysis were based on the domains in these frameworks.

Study design

The same methodologies were employed in each country. Data on barriers to equitable access of quality care were collected between June 2020 and May 2021 by trained local researchers. Data were analysed separately by in-country research teams, with support from the central investigator team (JC, JD, MLO, AI, AMAL). The results were then discussed, compared and integrated during a two-day investigator meeting held in Tamale, Ghana in May 2021. A summary of the methods for this study is presented in Table 1.

Data sources

1) Workshops with policy makers, infrastructure providers, service users, and healthcare workers to identify barriers to access to quality injury care and prioritise solutions to overcome these barriers.

We conducted a two-day workshop in each of the study countries. The workshops were designed as round table workshops (5-8 people per table) and plenary discussions. Methods are described for the Rwanda workshop in more detail elsewhere.[25] In brief, the process was informed by the four-delay framework with small working groups discussing and listing barriers occurring at each delay stage before presenting and discussing results in plenary and agreeing on the barriers. Working groups were formed of participants of similar backgrounds to prevent hierarchies limiting expression of opinions; participants were seated at tables relevant to their delay. Discussions were facilitated by study team members and

translators were used when needed. Outputs were captured as listed barriers. At the end of each workshop, barriers were prioritised by participant voting to identify the top prioritised barriers in each country.

2) Qualitative interviews and focus groups discussions with injured patients and community leaders

In each country, individual interviews (IDIs) and focus groups discussions (FGDs) were undertaken each with rural and urban residents who had accessed injury care for themselves in the past 6 months. Numbers of interviews continued until saturation of themes occurred. Two focus group discussions with community leaders and prominent members of the communities, one in urban and one in rural area, were also undertaken.

The IDIs and FGDs were undertaken by trained bilingual researchers in the appropriate languages. A topic guide was developed in English with questions structured around the four-delay framework, and open questions were asked with prompts given when necessary to explore replies of interest. Interviews and FGDs were audio recorded, transcribed and translated into English for analysis.

Data from each country were analysed thematically using Nvivo qualitative data analysis Software (2015, QSR International Pty Ltd). Coding was done deductively focusing on the domains of the four delays, IoM, and WHO building block frameworks and inductively, allowing additional themes to emerge from the data. A sample of interview transcripts was first read to identify the initial set of codes by local investigators and investigators from the

UK team. This generated a coding framework that was discussed between the data collectors, relevant country team members and investigators, and then used to code all remaining interview and focus group transcripts. Codes were gradually built into broader categories and themes through comparison across transcripts. The same process was repeated for all countries, generating three coding frameworks. Findings were written as a narrative summary. From that, an overall list of barriers across three countries was created. Key themes for each country can be found in appendices.

3) Surveys about experiences with the healthcare services, either as inpatients (the Inpatient Assessment of Health Care (I-PAHC)) or outpatients (the Outpatient Users Assessment of Health Care (O-PAHC)).

The I-PAHC and O-PAHC are brief (25 or 23 question, respectively) survey tools that have been developed and validated to explore experiences of care in low-income settings.[28] They were administered in each country to the persons who took part in the interviews or focus group discussions with the choice of tool dependent on whether participants had been in or outpatient users, or both. Surveys were administered in the local language by trained bilingual investigators after ensuring that the surveys were contextually appropriate. Most responses were captured as a four-part Likert scale from strongly agree (4 points) to strongly disagree (1 point), others were captured as a binary response, yes (2 points) or no, with each response given a score (1 point). We categorised questions into the following domains, based upon previous research and investigator discussions:[28] respectful care, communication, patients would recommend services, cleanliness of facilities, and pain control (captured in the I-PAHC survey only). Scores for each category were created by

dividing the total score achieved for all questions in each category by the total possible score for that category, and presented as a percentage. We selected a threshold of below 80% to indicate presence of a barrier to quality injury care, based upon the median score for the survey responses.

4) Survey for assessing the governance of the health system, based on the framework for healthcare governance developed by Siddiqi et al.[29]

We adapted Siddiqi et al's survey for the injury care context on discussion between authors. The resultant survey contained 37 questions about presence or absence of a structure or function within 10 domains that reflect the health system context for injury care (Appendix 5). Domains were: strategic vision; participation and consensus orientation; rule of law; transparency; responsiveness; equity and inclusiveness; effectiveness and efficiency; accountability; intelligence and information; and ethics.

The survey was sent to policy makers, trauma opinion leaders, and lead trauma care providers. Initial participants were selected based upon investigator contacts and snowball sampling used to identify further participants. Questions from each domain were scored based on a pre-agreed scoring system, deriving an investigator assessed score calculated independently by two investigators (AMAL, MLO) and considering the participant's original score, their background, investigator knowledge, and evidence available. For example, if a trauma care provider stated that a policy was not available, but a policymaker stated that it

was, or the investigators had seen a copy of the policy, we prioritised the policymaker's response. Where investigators disagreed, cases were arbitrated by a third investigator (AI).

Appendix 2. List of the 121 barriers identified in Ghana, Rwanda and South Africa, and the number of methods used to identify them

Original framework	Category of barrier	Institute of Medicine Domain if relevant	Barrier	Ghana		South Africa		Rwanda

	Mitigating factors		Alcohol/substance abuse	y	1	y	1	s	0

*Areas too dangerous to enter without police because of crime

**Stigma around rehabilitation and mental health (I think this should read "stigma around rehabilitation for mental health". The barrier is related to those who require mental health services following injury. They may be reluctant to go for this follow-up due to the fear of being stigmatised)

Green indicates that the barrier is present in a country and the shade of green indicates using how many methods
Dark grey indicates that the barrier is not present in the country and shade of green indicates using how many methods

Light grey indicates the barrier has not been mentioned using any of the data collection methods in the country

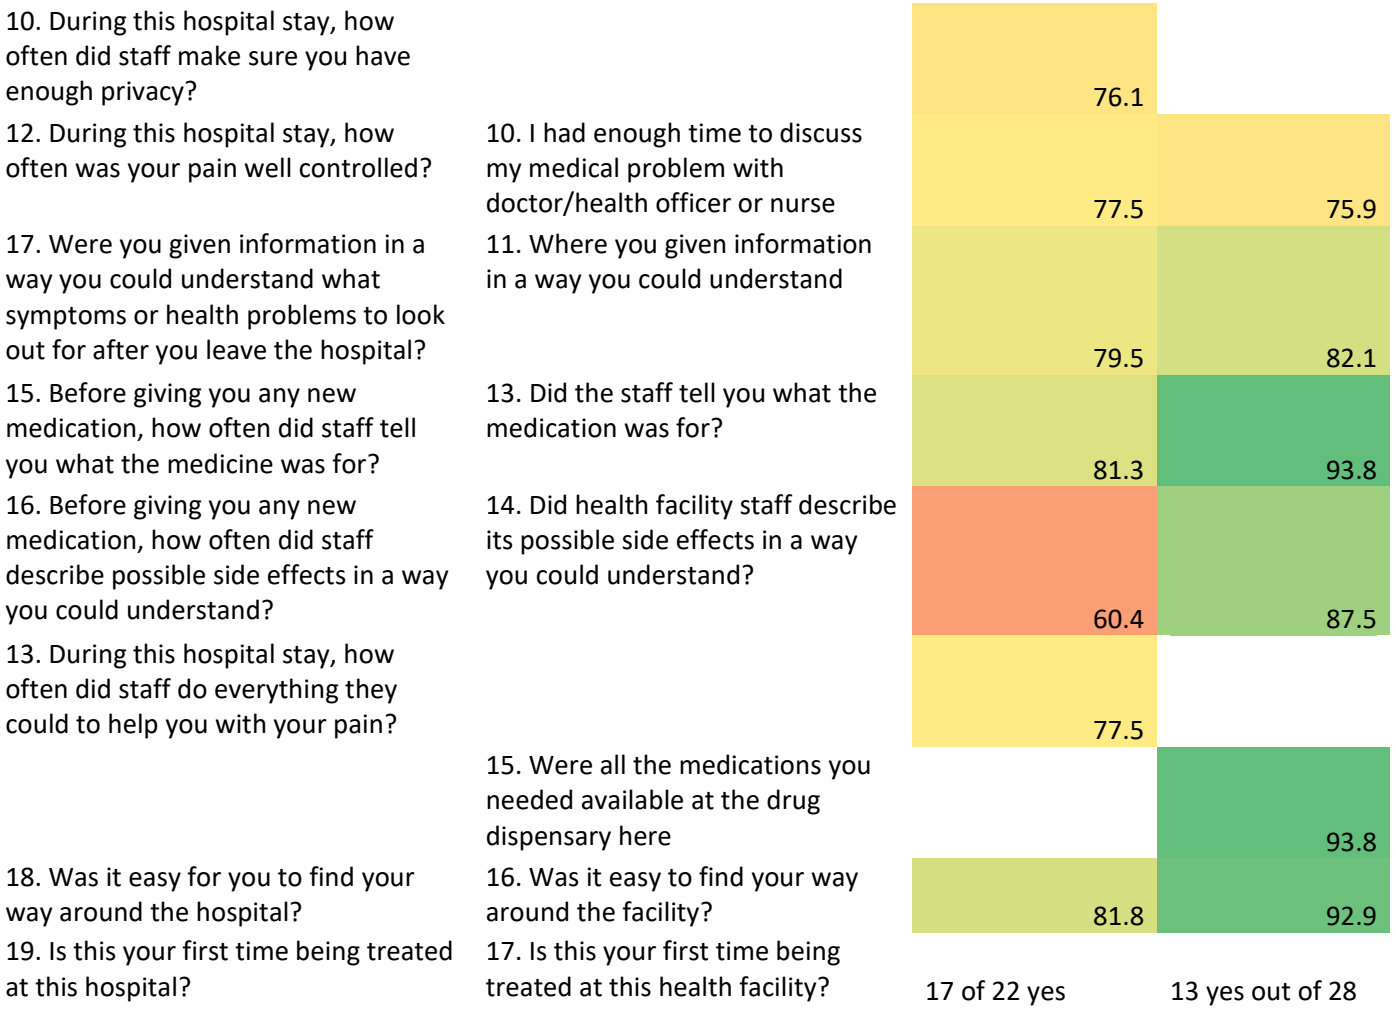
Appendix 4a Percentage scores from I-PAHC and O-PAHC from South Africa

Question I-PAHC	Question	Percentage score I-PAHC	Percentage score O-PAHC
1. During this hospital stay, how often did nurses treat you with courtesy and respect?	1. During this visit, nurses treated me with courtesy and respect?	78.4	75.0
2. During this hospital stay, how often did the nurses listen carefully to you?	2. During this visit nurses listened carefully to me?	81.8	72.2
3. During this visit hospital stay, how often did nurses explain things in a way you could understand?	3. During this visit nurses explained things in a way I could understand?	71.6	67.6
4. During this hospital stay, how often did doctors/health officers treat you with courtesy and respect?	4. During this visit, doctors/health officers treated me with courtesy and respect?	92.0	72.2
5. During this hospital stay, how often did doctors/health officers listen carefully to you?	5. During this visit doctors/health officers listened carefully to me?	79.5	68.5
6. During this hospital stay, how often did doctors/health officers explain things in a way you could understand	6. During visit doctors/health officers explained things in a way I could understand	77.3	66.7
7. I could distinguish between doctors/health officers and nurses	7. I could distinguish between doctors/health officers and nurses	81.8	83.3
8. During this hospital stay, how often was the room you were sleeping in kept clean?	8. The outpatient department was clean	89.8	48.1
9. During this hospital stay, how often was the area around you quiet at night?	9. The bathrooms/latrines were clean	81.8	75.9



10. During this hospital stay, how often did staff make sure you have enough privacy?
76.1
12. During this hospital stay, how often was your pain well controlled?
10. I had enough time to discuss my medical problem with doctor/health officer or nurse
77.5
75.9
17. Were you given information in a way you could understand what symptoms or health problems to look out for after you leave the hospital?
11. Where you given information in a way you could understand
79.5
82.1
15. Before giving you any new medication, how often did staff tell you what the medicine was for?
13. Did the staff tell you what the medication was for?
81.3
93.8
16. Before giving you any new medication, how often did staff describe possible side effects in a way you could understand?
14. Did health facility staff describe its possible side effects in a way you could understand?
60.4
87.5
13. During this hospital stay, how often did staff do everything they could to help you with your pain?
77.5
15. Were all the medications you needed available at the drug dispensary here
93.8
18. Was it easy for you to find your way around the hospital?
16. Was it easy to find your way around the facility?
81.8
92.9
19. Is this your first time being treated at this hospital?
17. Is this your first time being treated at this health facility?
17 of 22 yes
13 yes out of 28

20. On a scale 0-10 (0 being the worst hospital, 10 being the best hospital), how would you rate this hospital?	18. On a scale of 0-10, how would you rate this facility?	72.7 / 56.1
21. Would you recommend this hospital to your friends and family?	19. Would you recommend this outpatient department/clinic to your friends and family?	76.1 / 64.3
22. Did you have to pay for this hospital stay? (if 1 skip 23)	20. Did you have to pay for this outpatient visit? (if not skip 21)	7 yes skip pattern Q / 4 yes out of 28
23. Do you consider this hospital stay too expensive?	21. Do you consider this outpatient visit too expensive?	85.7 / 87.5
