Supplementary Figures

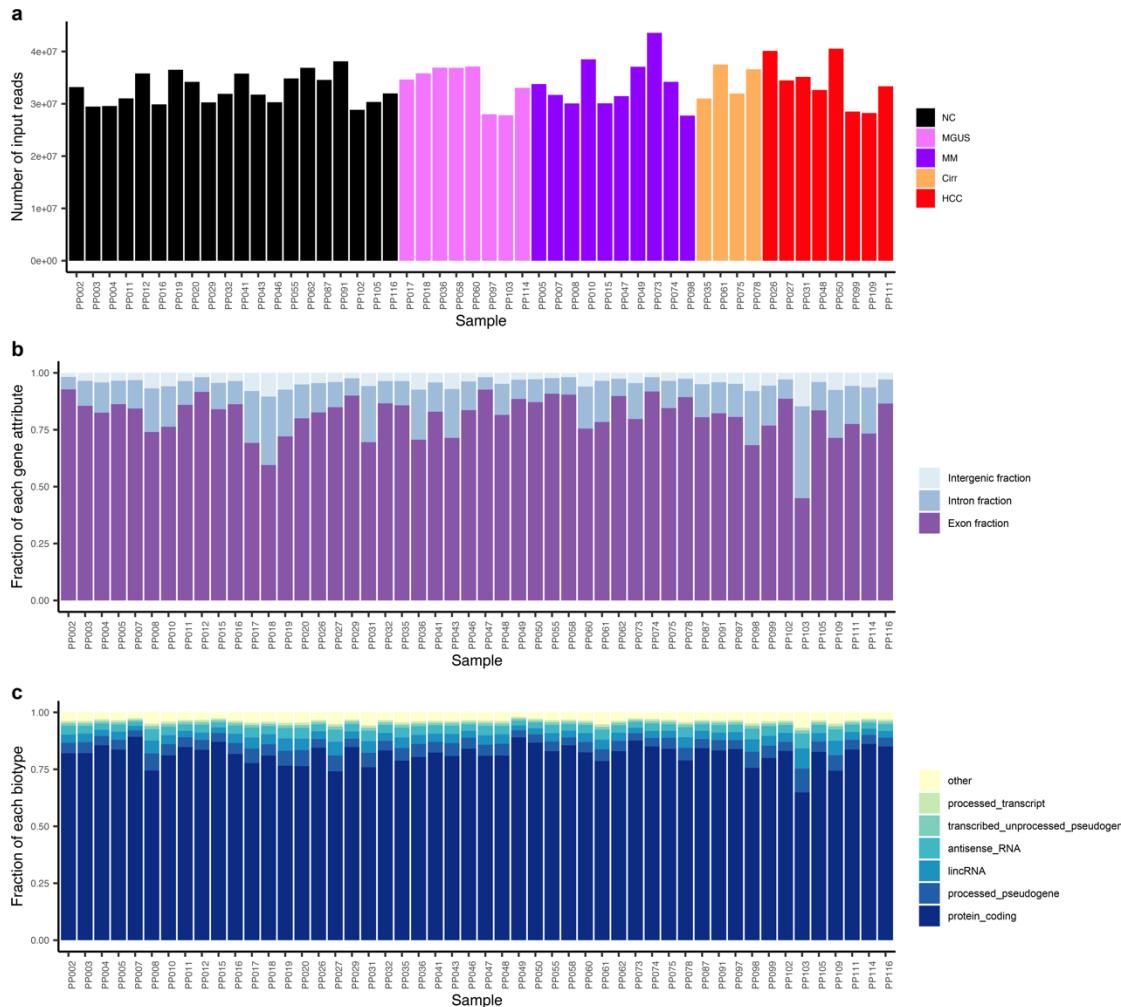

a

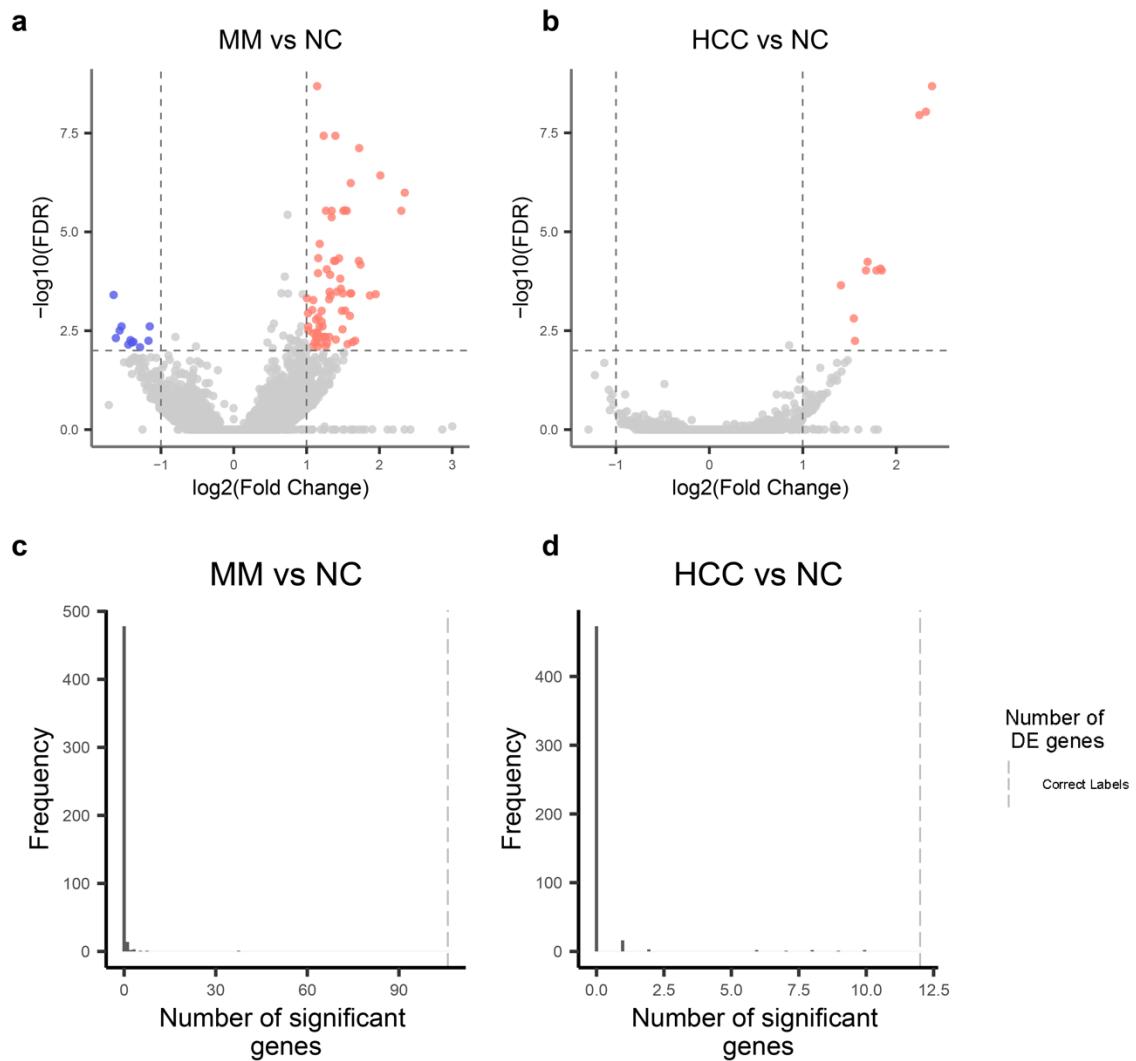

Supplementary Figure 1 | Illustration of overall sample sets and analytic methods used in this study.

a

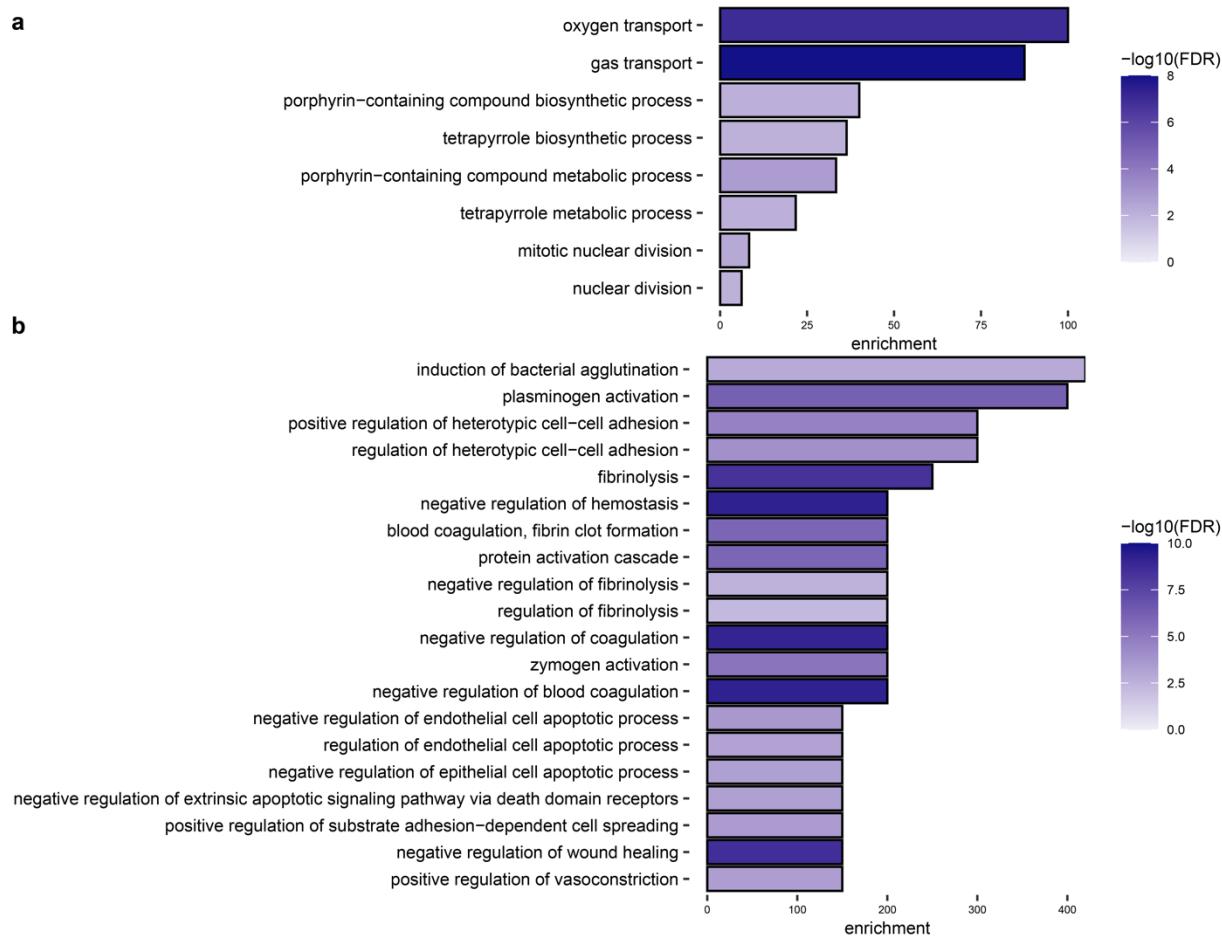

Supplementary Figure 2 | Sequencing saturation analysis of all 50 samples in the pilot cohort. Total reads for each sample were subsampled (x-axis) and the number of genes detected at that read depth is reported (y-axis).

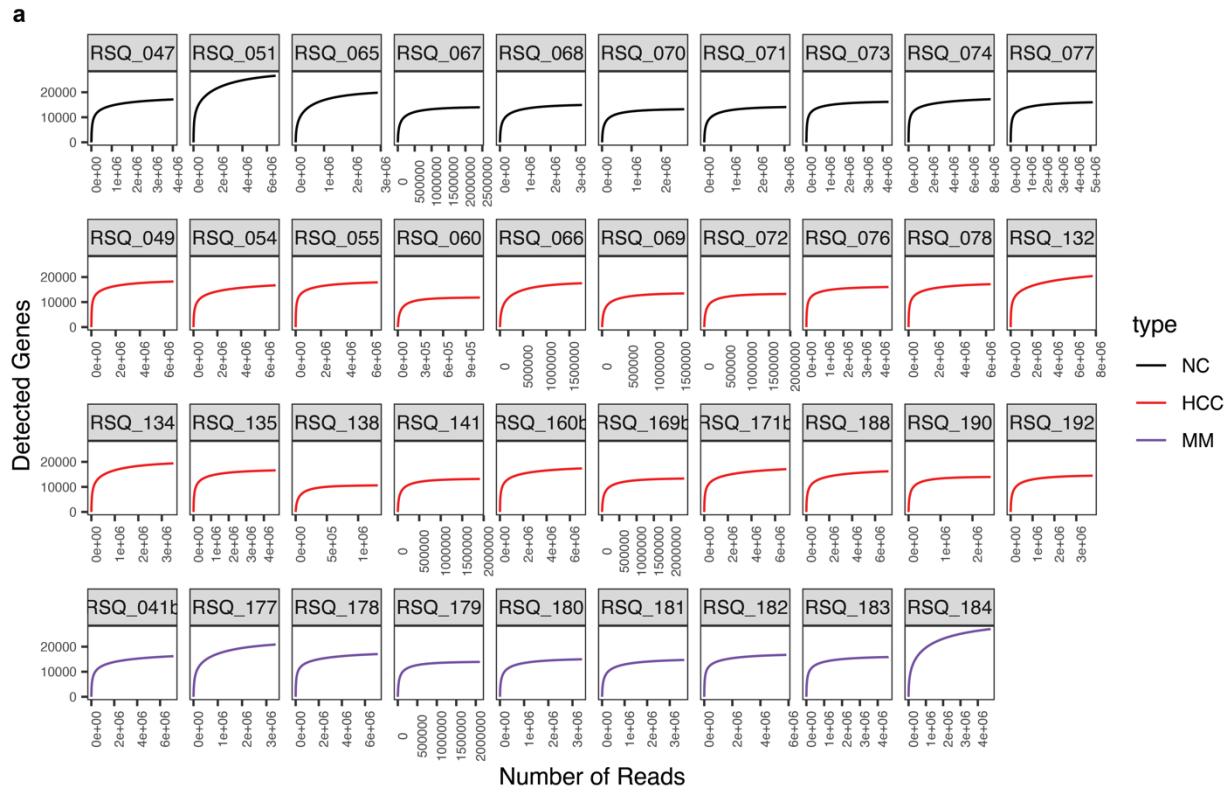

Supplementary Figure 3 | Distribution of (a) sequencing reads, (b) exon/intron and intergenic fractions, and (c) coverage of the transcriptome across all 50 samples in the pilot cohort.

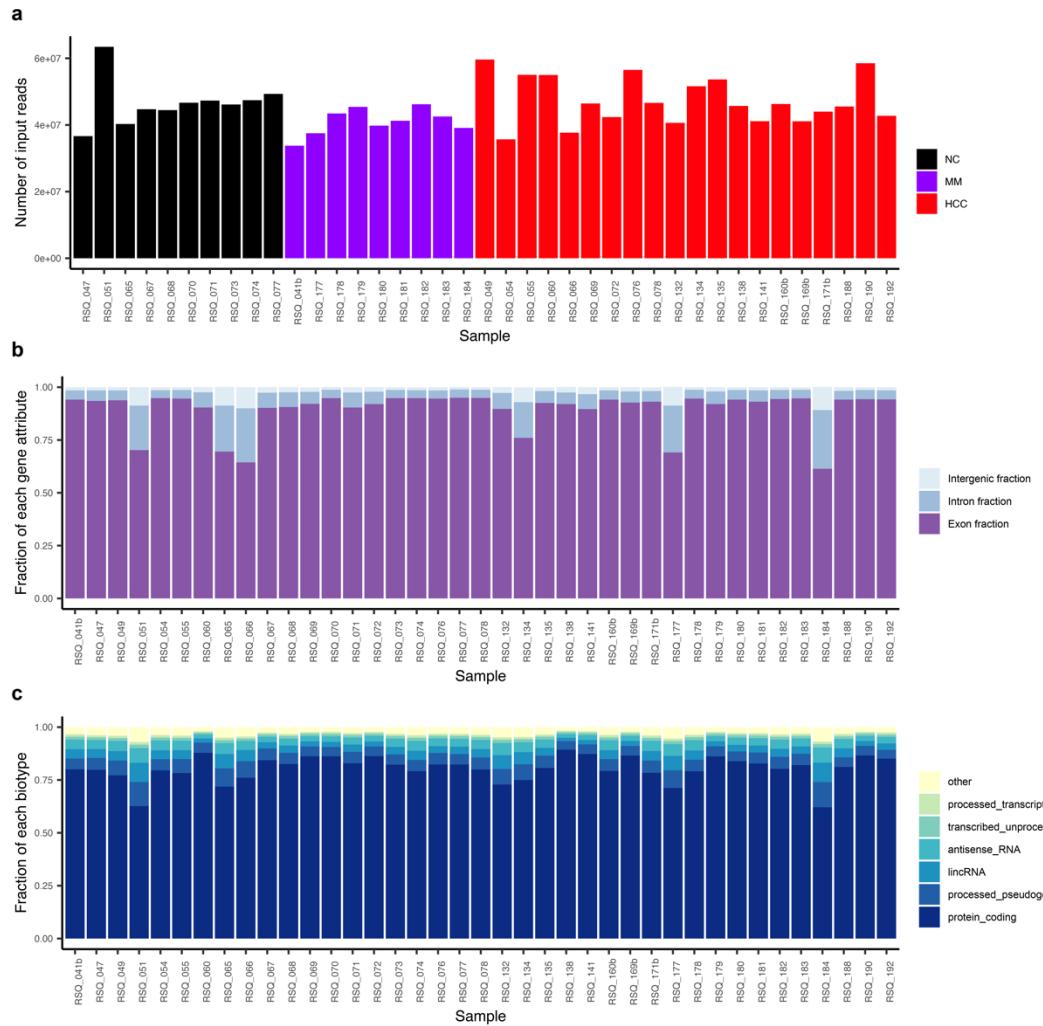

Supplementary Figure 4 | Volcano plots between false discovery rate (FDR) and fold changes for all genes in pairwise comparison between non-cancer (NC) donors and (a) multiple myeloma (MM) and (b) liver cancer (HCC) analyzed by DESeq2. Histograms of number of significant genes differentiating two groups from random permutation between samples across non-cancer donors and (c) multiple myeloma or (c) liver cancer. Differential expression analysis was performed using DESeq2 with Wald test and adjusted p-value cutoff at 0.01. Here we report the results from pairwise comparisons in the pilot cohort.

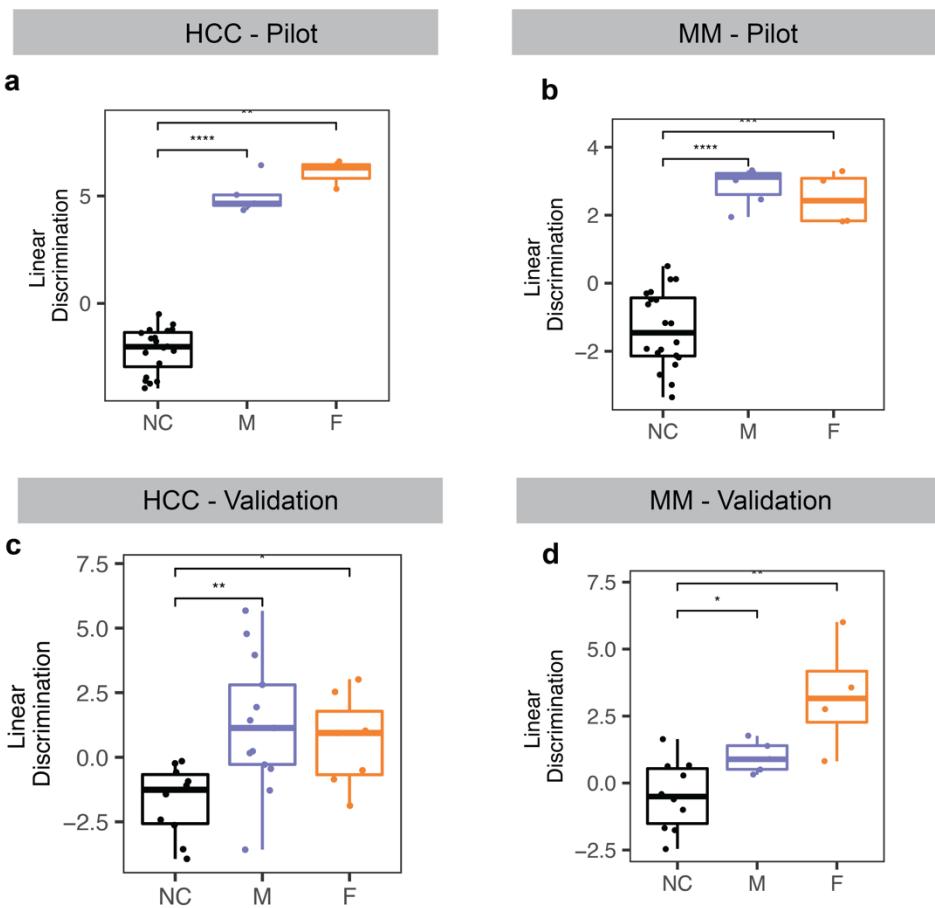

Supplementary Figure 5 | Gene Ontology analysis shows enrichment of biological processes for the significant gene panels identified by DESeq2 analysis for each pairwise comparison between the non-cancer group and (a) multiple myeloma and (b) liver cancer groups in the pilot cohort.

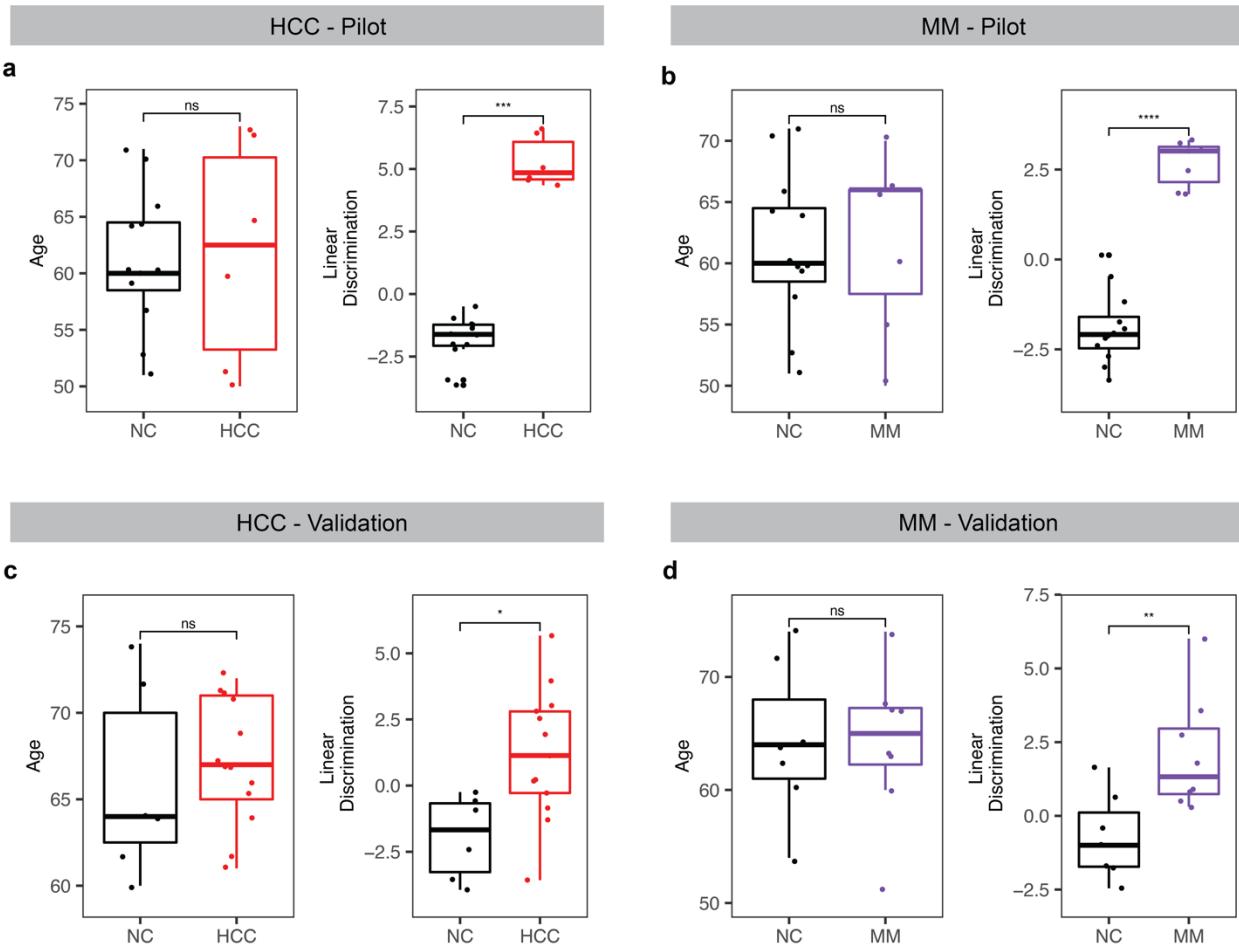

Supplementary Figure 6 | Sequencing saturation analysis of all 39 samples in the independent validation cohort. Total reads for each sample were subsampled (x-axis) and the number of genes detected at that read depth is reported (y-axis).

Supplementary Figure 7 | Distribution of (a) sequencing reads, (b) exon/intron and intergenic fractions, and (c) coverage of the transcriptome across all 39 samples in the independent validation cohort.

Supplementary Figure 8 | Linear Discriminant Analysis (LDA) across males and females in HCC and MM in our pilot cohort (**a, b**). Using the models trained on our pilot cohort, we also tested discrimination by LDA in our external validation set for both HCC and MM across males and females (**c, d**). P-values for each pair are calculated by the Wilcoxon rank sum test. Centre-line indicates the median value across all patients in that group, and the hinges represent the lower (Q1) and upper (Q3) quartile, with whiskers extending to the minimum and maximum of the resulting distribution.

Supplementary Figure 9 | Linear Discriminant for the subset of the samples in which cases and controls had comparable median age and standard deviation. In this reduced sample set, we show that when a difference in age between cases and controls is not significant, discrimination by Linear Discriminant Analysis (LDA) is still significant. This was done with the models trained on our pilot cohort, and tested for each pairwise comparison of NC – HCC (**a**), NC – MM (**b**) in our pilot cohort, and our validation cohort (**c,d**). P-values for each pair are calculated by the Wilcoxon rank sum test. Centre-line indicates the median value across all patients in that group, and the hinges represent the lower (Q1) and upper (Q3) quartile, with whiskers extending to the minimum and maximum of the resulting distribution.
