eMethods 1. Constructing Mortality Measures

In the surveys, age at death was usually recorded in days, months, or years for children that died at 24 months or older. Therefore, we used age at death in months, as imputed in the DHS and MICS, where ages reported in days were converted to months, ages reported in months were used directly, and ages reported in years were truncated to months (ie, three years as 36 months). Missing age at death was imputed using a quasi-random "hot deck" method, based on the age at death for the closest preceding observation in the data with the same birth interval and, if available, the same form of reporting for age at death (ie, days, months, or years). Date of birth was randomly imputed after imposing certain logical ranges (eg, based on other dates, birth intervals, and maternal age at birth, duration of amenorrhea, and abstinence) and constraints (eg, age or age at death) [1].

We used a direct method for calculating mortality rates. Direct methods are preferable to indirect methods, which only use information on births and deaths for cohorts of mothers as opposed to data on date of birth and age at death of deceased children. Indirect methods rely on a broader set of assumptions than direct methods, such as stable fertility levels and patterns, no change or linear change in mortality, and a pattern of mortality derived from other populations, often European. We followed the United Nations Population Division's recommendation for calculation and presentation of mortality rates to facilitate comparison to other sources [2]. Mortality rates were estimated using the same approach used in reports from the DHS and MICS: a synthetic cohort life table approach [3–6]. (Note that under-5 mortality rates in the DHS reports may differ since we restricted the period to ten years before a survey while the DHS usually limits it to five years for national-level estimates.)

A synthetic cohort life table was constructed and component mortality probabilities for small age intervals estimated, which were then combined to calculate a mortality probability for the age group of interest. (As such, it is similar to a product limit estimator.) This approach differs from a vital statistics approach, where deaths over a period are divided by births over the same period, in that the vital statistics approach produces true rates, rather than probabilities, and the variation in the number of births over time is not accounted for. The synthetic cohort life table approach also differs from a true life table approach, where the number of deaths in a specific birth cohort is divided by the number of deaths in that specific birth cohort, so all children must have lived through the risk period, which in this study would mean that only children born more than five years before each survey would be included. The synthetic cohort life table approach allows the use of most recent births and is also specific to a period (ie, the ten years preceding the survey in our study).

First, component mortality probabilities were constructed for the age intervals less than one month, 1–2 months, 3–5 months, 6–11 months, 12–23 months, 24–35 months, 36–47 months, and 48–59 months. (Note that here we use *age groups* to refer to the broader age groups which are of primary interest—under-5, under-2, and neonatal—and *age interval* to refer to the age segments used to calculate the component mortality probabilities, which are then used for estimating mortality rates for the broader age groups.) eFigure 5 shows a Lexis diagram which illustrates the three cohorts of children included in the component mortality probability for a specific age interval and period: the y-axis shows an age interval for a specific component mortality probability which ranges from a_1 to a_2 (0 to < 1 month, 1–2 months, 3–5 months, etc.) and the x-axis shows the period for which the component mortality probability is being calculated, ranging from t_1 (120 months before the survey in our study) to t_2 (one month before the survey). t_1 and t_2 can vary, but in this study, we use a single period. The component mortality probability for the specific age interval includes three cohorts of children: B, who are exposed to the entire period, reaching the (hypothetical) ages a_1 and a_2 within the period t_1 to t_2 (ie, born between $t_1 - a_1$ and $t_2 - a_2$); A who reach age a_1 before the period starts at t_1 and age a_2 before the period ends at t_2 (ie, born between $t_1 - a_2$ and $t_1 - a_1$); and C who reach age a_1 after the period starts at t_1 but do not reach age a_2 before the period ends at t_2 (ie, born between $t_2 - a_2$ and $t_2 - a_1$).

It was assumed that half of the exposures occurred in the relevant age interval for only partially exposed children in cohorts A and C and half the deaths for partially exposed children in cohort A. Note that all deaths of children in the relevant age interval for children in cohort C were included in this study since the end of the period t_2 was the date of the interview and those deaths must have occurred before the interview. The events occurring in the month of the interview were excluded since they did not contribute an entire month of deaths and exposures. The component probability q_i for each age interval i was then calculated as:

$$q_i = \frac{0.5 \times Ad_i + Bd_i + Cd_i}{0.5 \times Ac_i + Bc_i + 0.5 \times Cc_i} \quad \text{Eq.1}$$

or half the deaths of children in cohort A (Ad) and all deaths in cohorts B (Bd) and C (Cd) occurring in age interval i divided by half the cases in cohorts A (Ac) and C (Cc) and all cases in cohort B (Bc) exposed to age interval i . These component mortality probabilities were converted to survival probabilities by subtracting them from one ($1 - q_i$).

$${}_nq_x = 1 - \prod_{i=n}^{i=x+n} (1 - q_i) \quad \text{Eq.2}$$

The mortality rates (${}_nq_x \times 1000$) for the age groups (n to x)—ages 0 to < 1 month, 0 to 23, and 0 to 59—were calculated by subtracting the product of the component probabilities across the relevant age group from one [6].

eTable 4 demonstrates the synthetic cohort life table for our pooled sample. Each component (mortality) probability in the second last column was obtained by dividing half the deaths of children in cohort A and all deaths in cohorts B and C by half the cases in cohorts A and C and all cases in cohort B (as in Eq.1). The under-5 mortality rate was obtained by multiplying together all rows in the last column and further multiplying by 1000 (as in Eq.2). The under-2 mortality rate was obtained by multiplying the first five rows of the last column together and further multiplying by 1000. The neonatal mortality rate was $q_0 \times 1000$ for the first age interval shown in the first row second last column.

Mortality for children 1–23 months old was calculated by subtracting the neonatal mortality rate from mortality rate of children aged 0–23 months old (as neonatal mortality rate is subtracted from the infant mortality rate to construct postneonatal mortality rate in the reports from the DHS [5,6]). Similarly, mortality for children 24–59 months old was calculated by subtracting the mortality rate for children 0–23 months old from the under-5 mortality rate. Therefore, the mortality measures for neonates, children 1–23 months old, and children 24–59 months old, sum up to the under-5 mortality rate. The share measures were then calculated by dividing the mortality measures for mortality at 0–23 months, <1 month, 1–23 months, and 24–59 months by the under-5 mortality rate and multiplying by 100 to obtain percentages of under-5 deaths occurring in each age group.

eMethods 2. Measure for Household Living Standards

A household wealth index was constructed (by the DHS and MICS) using information on the household's ownership of assets (eg, car, television, refrigerator) and amenities (eg, type of toilet facility, electricity access, source of water) using principal component analysis [7]. Households were divided into five equally sized groups, each containing 20% of households (quintiles), based on the household wealth index. We show results comparing the top quintile (20% of households with the best living standards) to the bottom quintile (20% of households with the worst living standards) within each country.

Notes: Observations refer to children that were under five years old at any point during the 120 months before each survey (excluding children born in the month of survey). The Population Division of the United Nations provides data on the number of births for five-year periods: two five-year periods are summed and interpolated to a yearly series and then linked to the survey year in each country and used to rescale the sampling weights. Acronyms and abbreviations: Republic (Rep.), Democratic Republic (DR), Low-Income Countries (LIC), Lower-Middle-Income Countries (LMIC), Upper-Middle-Income Countries (UMIC)

eTable 2. Mortality and the Share of Deaths Among Children Younger Than 5 Years by Age: Period Restricted to 5 Years Before Survey Instead of 10 Years

	Mortality (deaths per 1000)					Share (%)			
	0–59 months	0–23 months	Neonates	1–23 months	24–59 months	0–23 months	Neonates	1–23 months	24–59 months

Notes: 95% confidence intervals are shown in brackets. 'Worst' refers to children in the 20% of households with the worst living standards and 'Best' refers to children in the 20% of households with the best living standards, within each country.

eTable 8. Shares of Deaths Among Children Younger Than 5 Years Occurring at Different Ages by Living Standards

Notes: 95% confidence intervals are shown in brackets.

eFigure 1. Mortality Rate Among Children Younger Than 5 Years and Share of These Deaths Occurring at Different Ages: Pooled, Least Developed Countries, Regions, and World Bank Income Groups: Period Restricted to 5 Years Before Survey Instead of 10 Years

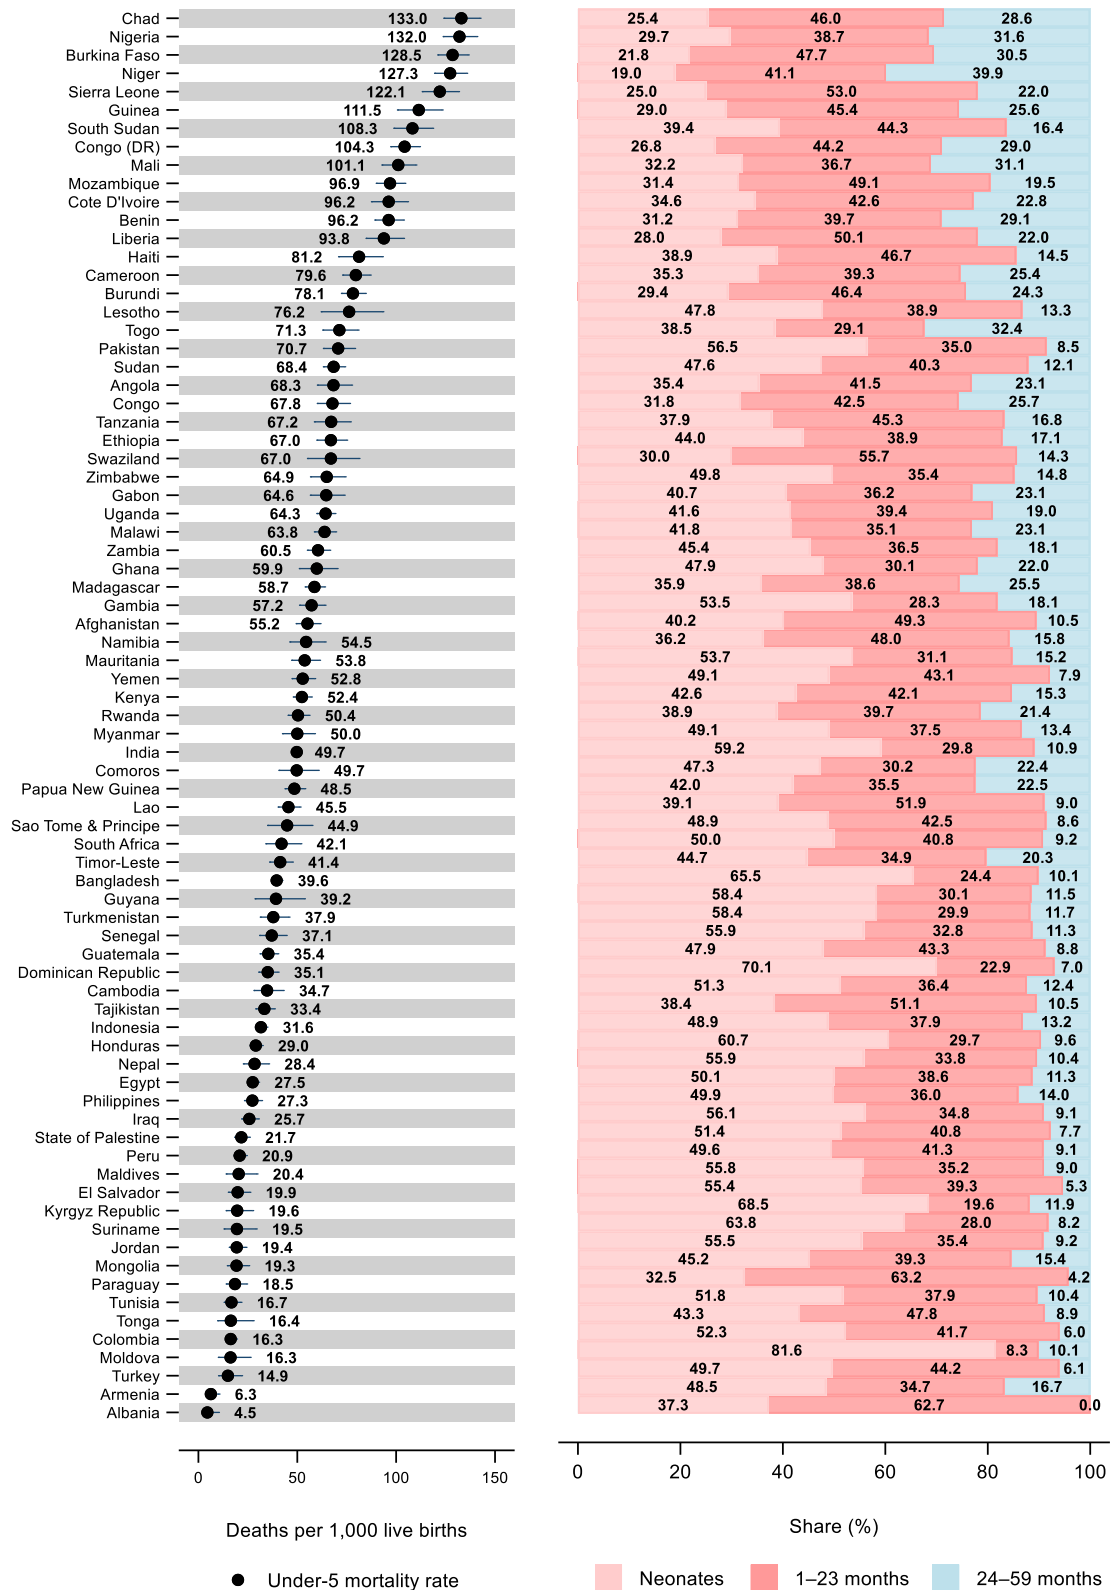

Notes: 95% confidence intervals are shown for mortality rates (some confidence intervals may be narrower than symbols). See eTable 2 in the Supplement for tabulated estimates and confidence intervals.

eFigure 2. Share of Deaths Among Children Younger Than 5 Years Occurring at Different Ages Using Detailed Age Intervals: Pooled, Least Developed Countries, Regions, and World Bank Income Groups: Period Restricted to 5 Years Before Survey Instead of 10 Years

Notes: See eTable 3 in the Supplement for tabulated estimates and confidence intervals.

eFigure 3. Mortality Rate Among Children Younger Than 5 Years and Share of These Deaths Occurring at Different Ages by Country: Period Restricted to 5 Years Before Survey Instead of 10 Years

Notes: 95% confidence intervals are shown for mortality rates (some confidence intervals may be narrower than symbols). See eTable 2 in the Supplement for tabulated estimates and confidence intervals.

eFigure 4. Share of Deaths Among Children Younger Than 5 Years Occurring at Different Ages Using Detailed Age Intervals by Countries: Period Restricted to 5 Years Before Survey Instead of 10 Years

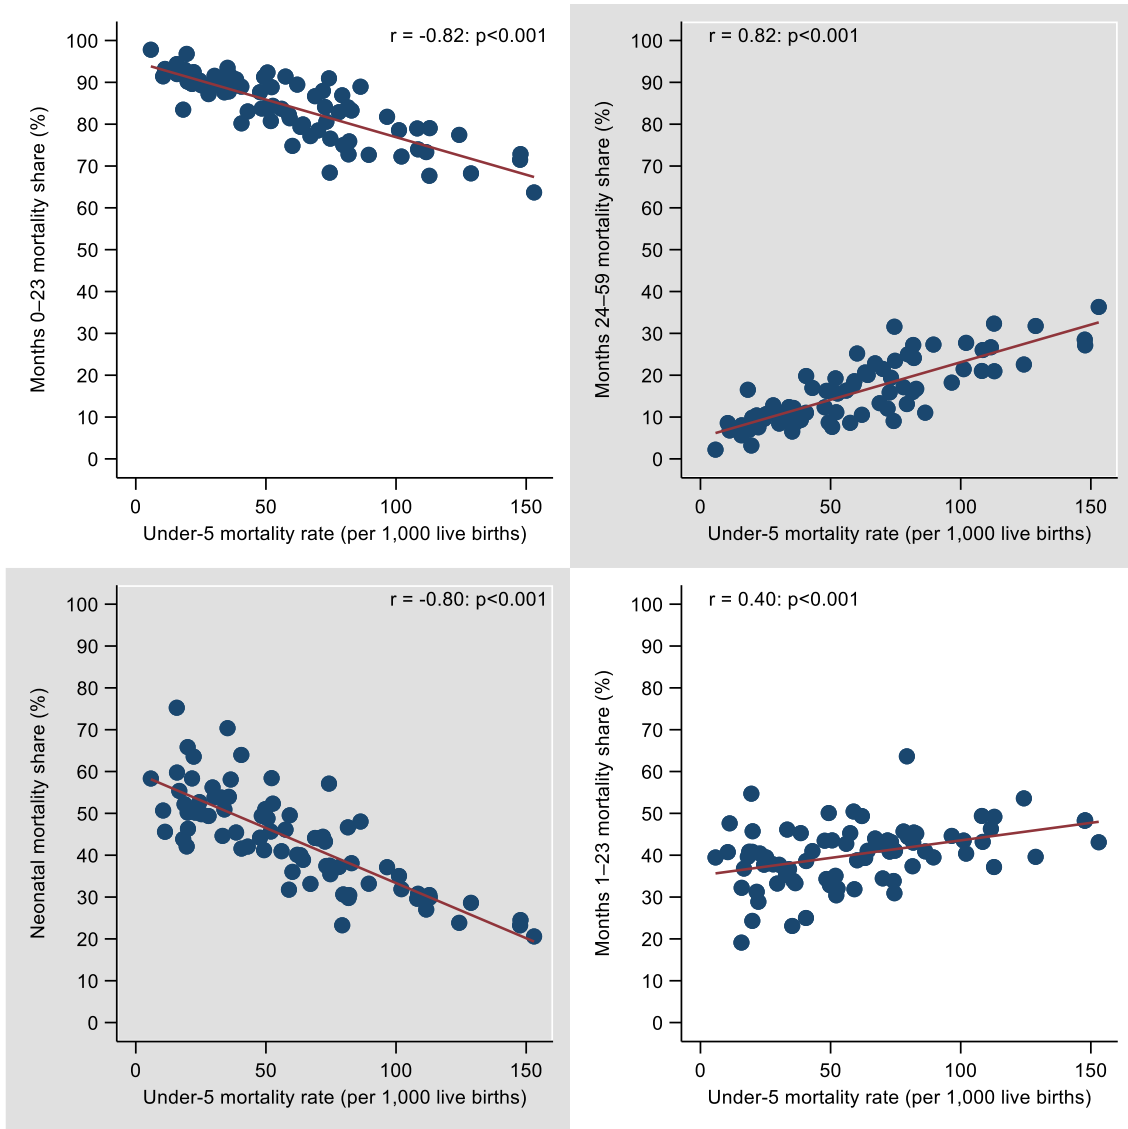

Notes: See eTable 3 in the Supplement for tabulated estimates and confidence intervals.

eFigure 6. Country-Level Association Between Mortality Rate Among Children Younger Than 5 Years and Share of These Deaths Occurring at Different Ages

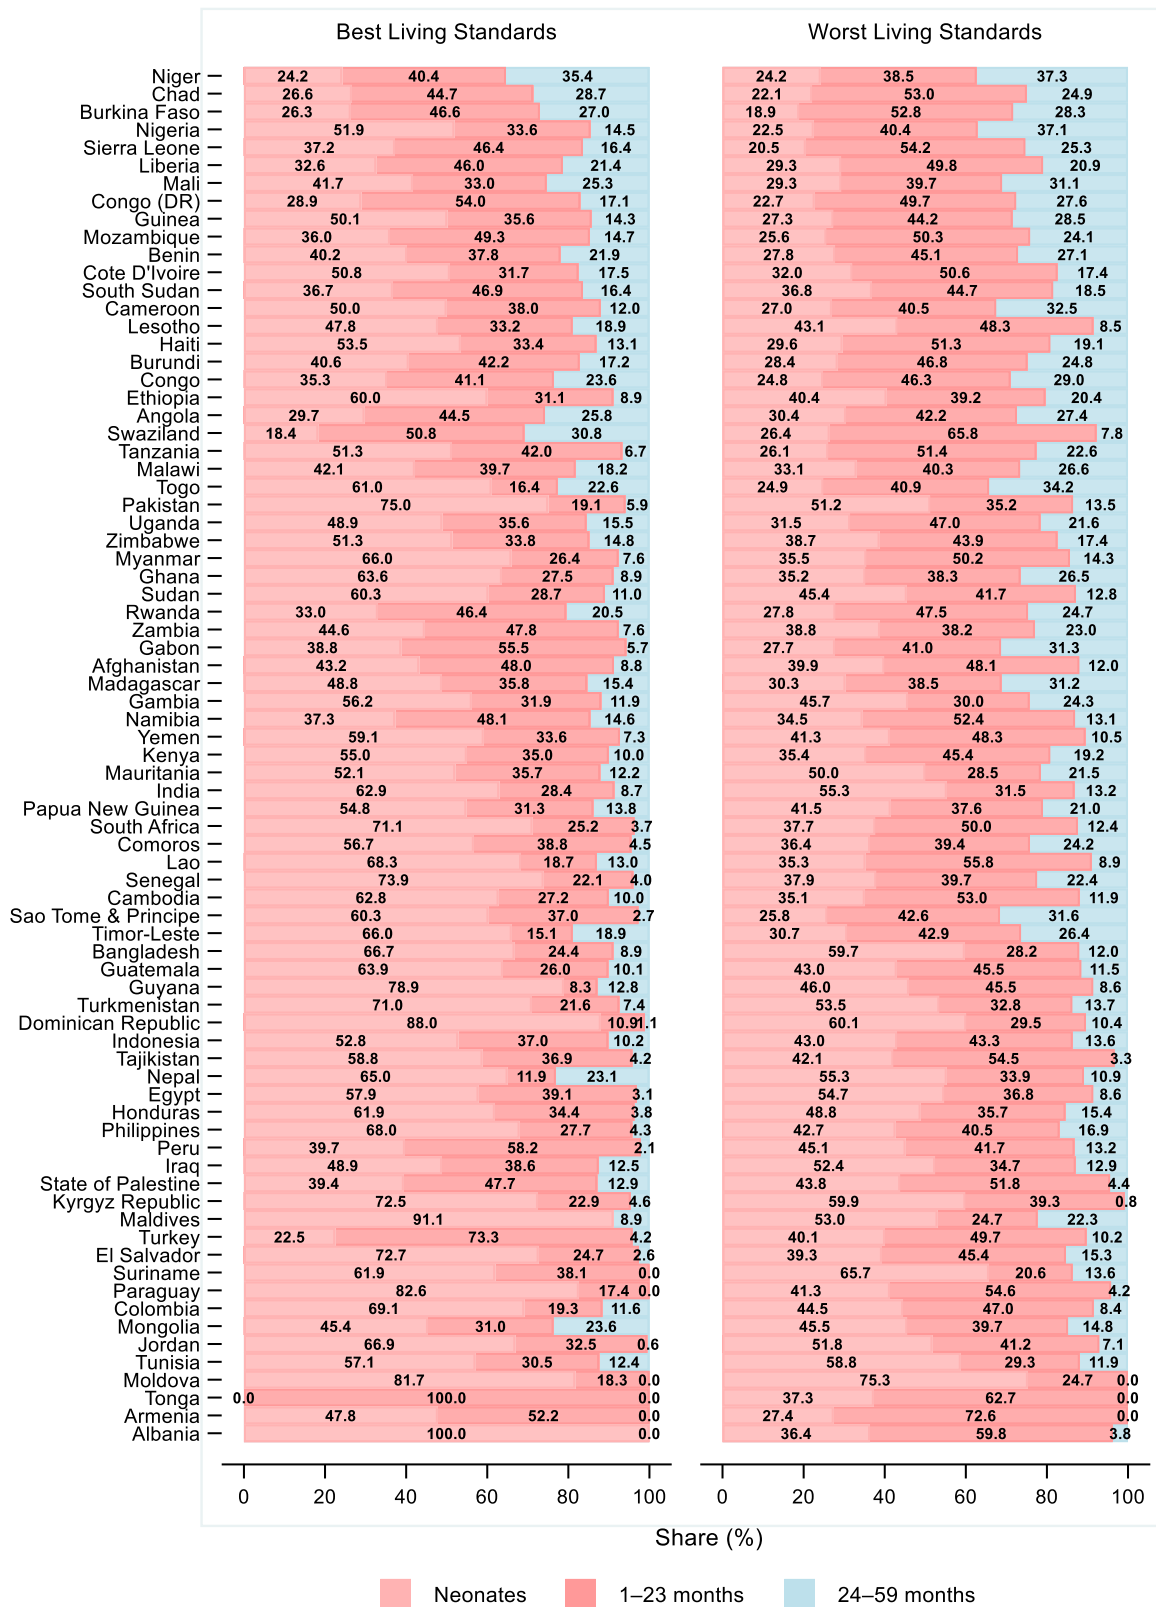

Notes: Pearson's correlation coefficients (r) are shown.

eFigure 7. Share of Deaths Among Children Younger Than 5 Years Occurring at Different Ages Using Detailed Age Intervals by Countries

Notes: See eTable 6 in the Supplement for tabulated estimates and confidence intervals.

eFigure 8. Share of Deaths Among Children Younger Than 5 Years Occurring at Different Ages: Countries by Living Standards

Notes: See eTable 8 in the Supplement for tabulated estimates and confidence intervals. 'Worst' refers to children in the 20% of households with the worst living standards and 'Best' refers to children in the 20% of households with the best living standards, within each country.

eFigure 9. Share of Deaths Among Children Younger Than 5 Years Occurring at Different Ages: Countries by Sex

Notes: See eTable 10 in the Supplement for tabulated estimates and confidence intervals.
